Starting from turn #16, the father adopts a true defensive strategy, using a defensive argument first, and then a second, more generic one, showing a specific concept of education that differs from that of the school. This is the moment in which the clash between school and family culture first becomes evident. At turn #18, the father also refers to

intergenerational differences (“and this is let’s say a problem with I think 99% of young people today”). The father, by using specific and detailed arguments, *contrasts* his way of educating his son (based on trust and respect for his autonomy) with the aims of the school. This is a good example of what we intend as *opposition*.

## Excerpt 2: Meeting #1

### English translation:

16. FATHER: >I if I must< (.) express a global opinion=we=at=home=do follow him we have (1.0) the difficulties I think all parents have (.) these days (.) because this is nor[mal]

17. TEACHER: [yes]

18. FATHER: >the thing that< (3.0) as a parent I must say the truth not that I justify my son’s attitude on the contrary I am very critical when he doesn’t apply himself< **and this is let’s say a problem with I think 99% of young people today** (.) with whom we have contact (.) **I told him that in my opinion to be complete one must find the time to do everything (.) he must find the time to study (.) time to have fun (.) because if not if a boy were focused only on one thing (.) I mean studying (.) he would also have limits (.) I think he has also [some potential]**

19. TEACHER: [potential yes]

20. FATHER: speaking as a parent I’ll tell you this (.) in my opinion if I notice (1.0) well (.) >maybe sometimes today as school doesn’t exist anymore< (.) that is when we used to go to school school was something positive (.) back then either you did it or you did it and that was it (.) **today I think everybody has great potential (.) but >we must have the ability to let them express it<**

21. TEACHER: **this is another reason why there have to be time limits too (.) the time he has (.) that he spends at home (.) if he [only spends it playing football]**

22. FATHER: [I’ll tell you something]

23. TEACHER: there is a time for football (.) but it can’t be football all day so that the thing also continues::: into the next day the match they’ve played they talk about it again the following day and then it’s basically all about the match (.) that once it’s started it goes on and on:::

### Italian original:

16. PADRE: >io se devo< (.) esprimere un giudizio globale=noi=in=casa=lo seguiamo abbiamo (1.0) le difficoltà che secondo me hanno tutti i genitori (.) nel tempo moderno (.) perché è un fatto nor[male]

17. DOCENTE: [sì]

18. PADRE: >quello che< (3.0) io come genitore devo dire la verità non è che giustifico l’atteggiamento di mio figlio anzi sono estremamente critico nel momento in cui lui non si applica< **e questo diciamo che è un difetto penso del 99% dei ragazzi di oggi** (.) con i quali noi abbiamo contatti (.) **io a lui gli ho detto che secondo me una persona per essere completa deve trovare tempo per fare tutto (.) deve trovare tempo per studiare (.) tempo per il divertimento (.) perché altrimenti se un ragazzo fosse solo monotematico (.) cioè verso lo studio (.) avrebbe anche dei limiti (.) io credo che lui abbia anche [delle potenz]**

19. DOCENTE: [potenzialità sì]

20. PADRE: detto da genitore vi dico questo (.) secondo me se io noto (1.0) ecco (.) >forse delle volte oggi siccome non esiste più la scuola< (.) cioè quando noi andavamo a scuola c’era una scuola in positivo (.) allora tu o lo facevi o lo facevi basta (.) oggi secondo me **hanno tutti delle grosse potenzialità (.) però >noi dobbiamo avere la capacità di farglielo esprimere<**

21. DOCENTE: **per ciò ci vorranno anche dei tempi (.) lui il tempo che ha (.) che spende a casa (.) se lo [spende solamente per il calcio]**

22. PADRE: [io vi dico una cosa]

23. DOCENTE: si dà uno spazio per il calcio (.) ma non deve essere calcio tutta la giornata che poi la cosa continua anche::: il giorno dopo la partita che hanno fatto la raccontano anche il giorno dopo e praticamente diventa tutta una partita (.) che comincia e si va avanti così:::

At turn #29, the teacher once again tries to return to his theory that the boy is “too busy” with his after-school activities. Once again, the father opposes his specific view of the problem, referring to his condition as a worker in the private sector,

where “you must always be active and operative.” At turn #30, he identifies a possible solution in the democratization of the teacher-pupil relationship, on which the “pleasure of studying” should depend.

### Excerpt 3: Meeting #1

#### English translation:

29. TEACHER: also because they are busy with so many other activities in the afternoon

30. FATHER: no Sir=not on this (.) I can assure you that I also said something else to him (.) you were talking about time management (.) I'm 46 now and when I am out working (1.0) for my company (.) they teach time management I mean they tell me there is time to do everything because I work in the private sector =they=make us=work=twenty=hours=a day (1.0) and they want us to be always (1.0) active and operative (.) the basic problem here in my opinion is exchange (1.0) I mean you must have a more democratic exchange with the students meaning that basically the students must learn the pleasure of studying (.) this is the crucial thing

#### Italian original:

29. DOCENTE: anche perché sono presi da tante altre attività pomeridiane

30. PADRE: professore no=no su questo (.) vi posso assicurare che io a lui ho detto anche un'altra cosa (.) lei diceva la gestione del tempo (.) io oggi ho 46 anni e quando vado a fare lavori (1.0) per la mia azienda a me (.) insegnano la gestione del tempo cioè a me dicono c'è tempo per fare tutto perché io lavoro nel privato=ci=fanno=lavorare=venti=ore=al giorno (1.0) e vogliono che noi siamo sempre (1.0) attivi e operativi (.) il problema di base che c'è secondo me il confronto (1.0) cioè voi dovete avere un confronto un po' più democratico coi ragazzi nel senso che praticamente i ragazzi devono capire il piacere di studiare (.) questa è la cosa fondamentale

From turn #37, the teacher's words betray his personal view of the aims of the school. In his opinion, parents' requests for sports and music activities would represent a real problem (“and where is

the school in all this, I wonder”). This educational vision, reminiscing about a sort of “withdrawal into tradition,” highlights another element of variability in the school-family relationship.

### Excerpt 4: Meeting #1

#### English translation:

37. TEACHER: it may not be your case but some parents::: come to tell us that afterwards they have to go to the gym because they have scoliosis

38. FATHER: no=no, absolutely no way:::

39. TEACHER: they must study music because they like music and where is the school in all this I wonder and they leave it to the school to deal with the problem

#### Italian original:

37. DOCENTE: non sarà il caso vostro però alcuni genitori::: vengono a dire che poi deve andare in palestra perché ha la scoliosi

38. PADRE: no=no, assolutamente non esiste:::

39. DOCENTE: deve fare musica perché piace la musica e la scuola dico io quando viene e lasciano il problema esclusivamente alla scuola

### ALLIANCE Meeting #9

Participants: Teacher (female), student (female), Father, Mother.

The participants are the teacher, the 11-year-old female student attending the first year of middle

school, her father, a 40-year-old bus driver, and her mother, a 37-year-old hairdresser. The student's family is composed of the father, the mother, the student, a younger sister (age 9 years) and a younger brother (age 8 years). During the meeting, the teacher starts the discussion by presenting the new

report card, introduced by a recent school reform, to the parents. In a second phase, the teacher deals with the positive assessment of the student's performance and her participation in class. The core of the conversation (reported in the transcript

below) seems to focus on the "transition" from primary school to the first year of middle school and its effects on the pupil's school experience. The school-family alliance appears to be another core element of the conversation.

#### Excerpt 4: Meeting #9

##### English translation:

47. TEACHER: then:: let's say she attended (.) she applied herself (.) she understood that (.) the situations (were) (.) well she realized quite quickly that things were different (.) that:: the approach was different (.) that behavior was different (.) maybe because she has a family behind her (.) quite simply. (.) that is I assume that are kids aged ten=eleven years and (.) if they have a choice between (.) playing and working (.) they prefer to play so when>they don't have (.) some constraints< that is the family on one side and the school on the other side to guide them (.) it's clear that they can easily [lose::]

48. FATHER:[it's she had this passage]

49. TEACHER: if we could (.) but how (.) if we could (.) have a walk (.) there's the sense of responsibility ok

50. MOTHER: but at this [age]

51. TEACHER: [there is not]

52. MOTHER: [unfortunately there's not]

53. TEACHER:[there's not] that's why you need family and school (.) that is two entities leading them and guiding them

54. MOTHER: definitely

55. TEACHER: then they realize they can't move just within such [constraints]

56. MOTHER: [definitely]

57. TEACHER: so when there's a cooperation between school and family things (.) generally go

58. MOTHER: go better

59. TEACHER: go better (.) maybe let's say go better in the sense that to some extent: some problems are overcome: and it is also clear that when they improve they can improve even more ((laughs)) well I mean ((laughs)) and in this case she has done just that: demonstrated this situation (.) she applied herself (.) at the beginning she was quite uncertain (.) now she starts to chime in a bit too much raising her little finger (.) but anyway

##### Italian original:

47. DOCENTE: quindi:: diciamo che lei ha seguito (.) si è impegnata (.) ha capito che (.) le situazioni (erano) (.) ecco quello che ha capito abbastanza rapidamente che le situazioni erano diverse (.) che:: l'approccio era diverso (.) che il comportamento era diverso (.) forse perché ha la famiglia alle spalle (.) detto molto francamente. (.) cioè io parto dal presupposto che questi sono ragazzi comunque di dieci=undici anni (.) e che fra (.) il gioco e il lavoro (.) preferiscono il gioco per cui nel momento in cui >non hanno (.) dei paletti< cioè la famiglia da una parte e la scuola dall'altra che l'indirizzi (.) è chiaro che possono tranquillamente [perdere::]

48. PADRE: °[ci sta' che ha avuto questo passaggio]°

49. DOCENTE: se potessimo (.) ma come (.) se potessimo (.) andare a fare una passeggiata (.) là c'è il senso di responsabilità e va beh

50. MADRE: ma a questa [età]

51. DOCENTE: [là non esiste]

52. MADRE: [purtroppo non esiste]

53. DOCENTE:[non esiste] ecco perché ci vuole la famiglia e la scuola (.) cioè due entità che li guidano e li indirizzano

54. MADRE: sicuramente

55. DOCENTE: per cui loro si rendono conto che loro non possono muoversi se non all'interno di quei [paletti]

56. MADRE: [sicuramente]

57. DOCENTE: e quindi allora quando c'è questa sinergia tra scuola e famiglia le cose (.) in genere vanno

58. MADRE: vanno meglio

59. DOCENTE: vanno bene (.) forse diciamo che vanno meglio nel senso che a un certo punto: certi problemi si superano: e poi è chiaro che quando vanno meglio poi possono andare anche meglio ((ride)) cioè voglio dire ((ride)) e in questo caso lei ha dimostrato questa situazione (.) si è impegnata (.) i primi tempi era abbastanza incerta (.) adesso comincia a intervenire un poco po' troppo con quel ditino alzato (.) ma comunque tutto sommato

## ACQUIESCENCE

### Meeting #16

Participants: Teacher (female), Student (female), Mother

The participants are the teacher, the 12-year-old student attending the second year of middle school and her 40-year-old mother, who is unemployed.

The student's family also includes a 45-year-old father, a blue-collar worker, and an older brother (age 16 years). The teacher presents the assessment of the student whose marks are poor in a number of subjects. The mother never replies to the presentation of the report card and the meeting ends in just a few turns.

### Excerpt 5: Meeting #16

#### English translation:

1. **TEACHER:** well well >we already talked with you madam< so you already know the situation (.). eh::: (.). let's give the marks in detail::: (.). let's say::: in short (.). in Italian she got a pass (.). the same for history and geography however in the (.). other::: subjects foreign language that is English she has a °fail° (.). eh::: maths and science >science and maths< >chemistry=physics=natural sciences< fail (.). technology fail (.). art pass (.). music good (.). physical education good (.). religion pass >well these are the marks or rather< she started to improve a little bit well I::: let's say I gave her (.). a pass in humanities but she did the same as with the others <she didn't study enough> she did with me (.). that is **she must pay more attention (.). and she must study more (.).** so eh::: let's take a look at her behavior (.), she's behaves well but she chats °too much° eh=eh

5. **DOCENTE:**cosi:::

## What is Actually at Stake in School-Family Meetings?

At wider level of analysis, the delivery of the report cards represents a real “ritual,” as it has all the main features of this type of social interaction. The school-family meeting takes place, as we have seen, in an institutional place (the school) and at a specific time (for example every 4 months), and the participants are individuals having specific roles (the teacher, the parents, the pupil/child), each assigning, though within the same framework, a particular symbolic meaning to the event. In such encounters the actors stage all the complexity of interpersonal dynamics in an institutional context. These are also meetings of different voices that tell different points of view, modulated by specific sets of beliefs, stemming from the experiences lived by the actors. In many cases the child’s success or failure ends up representing the “stakes” in a confrontation between the family’s and the school’s differing educational views. Taking a particular perspective, inspired by economic dimensions, it is possible to depict an intriguing economically oriented picture of school-family meetings as a real space of negotiation between parents and teachers. At this point the main research question could be: What is actually at stake in school-family meetings? First, the stake is the different representation of “education” and “school” held by parents and teachers. This difference can lead to a two types of opposition. One is between school culture and family culture, even if not necessarily in the form of conflict (multi-dimensional *versus* mono-dimensional vision of the educational process). The second one is within the families’ educational

orientation (instrumental *versus* holistic-orienting vision of school).

With respect to the first opposition, the clash between school and family cultures becomes evident when the parents refer to a multi-dimensional educational vision in accordance with the idea that to be well-balanced, a person must do several experiences (see the Excerpt 1: Meeting #1, turn #18). This wide concept of education differs from the mono-dimensional educational vision presented in several teachers’ talks (as in the Excerpt 4: Meeting #1, turn #39) and circumscribed almost exclusively to the school engagements.

The second type of opposition is between *instrumental versus holistic-orienting vision of school* held by parents.

### THE FUNCTIONAL DIMENSION OF THE SCHOOL

One of the key points around which parents organize their representations of school is what could be called the functional dimension, relating to the different purposes that families think the educational experience should have. In this dimension, it is possible to identify a first basic type of argumentation among those (and these are primarily families with a lower socio-economic status) who consider school a relevant factor for social mobility (see Excerpt 6, below).

Participants: Father, Mother, Daughter, Researcher

The participants are the researcher, the 12 years old female student attending the II year of middle school, the father, 41 years old hydraulic, and the mother, 37 years old housewife.

#### Excerpt 6: Interview #16

##### English translation:

54. FATHER: well:: (.) but:: (.) I think:: (.) ((laughs)) school is definitely everything (.) nowadays: (.) to be educated in something (.) I think:: (.) it’s must (.) so:: better one (.) has more quality:: (.) on (.) a field (.) the more it goes:: (.) and the future (.) really:: (.) it’s absolutely positive really [...]

57. MOTHER: in fact without school (.) without anything (.) ((laughs)) we can’t do:: anything ((laughs))

##### Italian original:

54. PADRE: va bè:: (.) ma:: (.) io penso che:: (.) ((ride)) la scuola è tutto in effetti (.) oggi: (.) essere istruiti in qualche cosa (.) secondo me:: (.) è di obbligo (.) quindi::anzi uno (.) più ha qualità:: (.) su (.) un settore (.) più va avanti:: (.) e il futuro (.) in effetti:: (.) è del tutto positivo in effetti [...]

57. MADRE: in effetti senza scuola (.) senza niente (.) ((ride)) non possiamo fa:: niente proprio ((ride))

These parents adopt an instrumental vision of school; they believe that obtaining a degree will make it easier to find a suitable job. They also believe that education differentiates people and helps to position a person socially. The voice of those parents who see school as essential to supporting their children's growth is completely different. They seem to refer to a holistic-orienting representation of school (*see* Excerpt 7, below), where educating means accompanying pupils through a

comprehensive and progressive discovery of their Self and adapting to the sociocultural context, by means of an empathetic element that is distinctive of the teacher-student relationship.

Participants: Father, Mother, Daughter, Researcher

The participants are the researcher, the 11 years old female student attending the I year of middle school, the father, 52 years old doctor, and the mother, 49 years old housewife.

### Excerpt 7: Interview #2

#### English translation:

**43. MOTHER:** surely it's different from the school we went to (.) before they were (.) so strict (.) that we were afraid of teachers (.) of the head teacher (.) when we went to school (.) if we studied it was because (1.5) there was this (.) **now they're more::: open (.) available (.) towards the children (.) to understand them and also their problems if there are any** (1.5) different from the school of the past (.) I can't tell you if the old school (1.5) was better we should see it in time to see the results (.) now they seem to want to do MANY things (1.5) too many things forgetting (1.5) one's point of view (*(smiles)*)

#### Italian original:

**43. MADRE:** sicuramente è diversa dalle scuole che abbiamo frequentato noi (.) prima c'era (.) una rigidità (.) tale per cui c'era il timore del professore (.) del preside (.) quando si andava a scuola (.) se si studiava era perché (1.5) c'era questo (.) **adesso c'è una maggiore::: apertura (.) disponibilità (.) nei riguardi dei ragazzi (.) a comprenderli anche verso i loro problemi se ci sono** (1.5). diversa dalla scuola precedente (.) non le so dire se era migliore (1.5) quella precedente dovremmo vedere nel tempo ai fini dei risultati (.) adesso sembra che si vogliono fare tante TANTE cose (1.5) troppe cose perdendo (1.5) il punto di vista (*(sorride)*)

This holistic-orienting model of school may be easily related to the notion of the "parental function" as "taking charge" of one's child as a whole and following every aspect of his/her growth. This perception of school is similar in many ways to a family group, and its functions are comparable with the educational functions of a family.

Those opposite views of the school's function are part of the same perception shared by the common sense. According to this, the school is a relevant factor in promoting the development of each individual even when moving from a low socio-economic and sociocultural level.

But the stake in school-family meetings is also the adults' perception of the child. In this case it is possible to talk of an attributional bias (Ross, 1977; Nisbett & Ross, 1980; Ross & Nisbett, 1991) (*see* Excerpt 8) and an opposition between the adult's culture and the youth's culture (as in Excerpt 9). During the report card delivery event, the adult's culture keeps its distance from the youth's culture,

by attributing school results to the child's dispositional aspects rather than contextual ones.

Participants: Teacher, Father, (boy) Pupil

In Excerpt 8 (turn #7), the adult shows a clear attributional bias. In fact, parents and teachers seem to overestimate the "internal" origin of school results (referring to personal characteristics and his effort in his studying), underestimating situational factors (like for example the school system's organization, the curricula, the teaching methodology adopted, the family's supporting role). Even in case of opposition between family and school, adults converge anyway, and form a strategic *peace treaty* by stressing the dispositional and internal dimensions of the pupil.

In Excerpt 9 (turns #48 and #49) and Excerpt 10 (turns #5 and #6), it is possible to see such convergence between teachers and parents.

Participants: Teacher, Father, (boy) Pupil

Participants: Teacher, Pupil (female), Father

The meetings between families and school are an adjustment of the social positions at stake. In the

## Excerpt 8: Meeting #1

### English translation:

48. DOCENTE:[è sensibile]

49. PADRE: [è sensibile] io non lo mai visto (.) che con superficialità gli è passata=la=cosa=addosso lui quando gli hanno mosso (.) una critica è sempre stato con con::: sensibilmente colpito

opening part of each meeting there can be a more or less explicit conflict between the two “educational cultures” or, conversely, an alliance. If the family accepts the school's evaluation (which is very frequent, obviously, in the case of positive evaluations), this does not produce dynamic conversations: a conflict, of any form, contributes to clarifying the sophisticated

processes of attribution of meaning operated by the participants. The constant articulation between individual points of view (sets of beliefs expressed by single individuals) and representations emerging during the conversational interactions is particularly interesting. The need to defend one's position encourages the participants to seek “shared” arguments.

## Excerpt 10: Meeting #8

### English translation:

1. TEACHER: so then (.) ((reads the school report card)) in Italian (.) pass mark (.) in history and civics pass mark (.) in geography good (.) foreign language good (.) science maths pass mark (.) chemistry physics pass mark (.) technics pass mark (.) arts good (.) physical education good (.) music good (.) religion very good (.) >we talked about the girl at the beginning had a phase

2. FATHER: [she got some]

3. TEACHER: [now she's recovering instead] (.) we hope that (.) that's the evaluation global

4. FATHER: global

5. TEACHER: first the evaluation of behavior (.) she behaves correctly (.) collaborates with mates (.) even if she's a little bit **reserved**

3. DOCENTE: [adesso invece si sta riprendendo] (.) noi questo ci auguriamo (.) questo è il giudizio globale

4. PADRE: globale

5. DOCENTE: prima il giudizio sul comportamento (.) un comportamento corretto (.) collabora con i compagni (.) anche se **lei è riservata**

6. PADRE: **sì=sì chiusa**

### SCHOOL-FAMILY MEETINGS AS A NEGOTIATION SPACE

It's worth underlying that adults' culture (parents and teachers) opposes youths' culture fundamentally, with:

a) the denial of child's role as partner in the social interaction. In fact the meetings made the presence of the participating pupils insignificant. When "the family goes to school" to learn about its children's evaluation, the situation becomes, in almost all cases, an "adult affair." To the children, who should actually be at the center of what is happening, a minimum conversational space is given. During the meeting with families, the predominant need is the comparison between two educational cultures; and

b) the shirking of adults' responsibilities through the overvaluation of pupil's dispositional elements, and the undervaluation of the elements of the educational context, both within school and outside school (family).

It is quite evident that the stake in school-family meetings is the pupil's value. How much is it worth? In the case of the opposition between the multi-dimensional and the mono-dimensional vision of education, the child's value depends on his more

or less complying with the model proposed by the family or by the school.

But the object rising or decreasing in value is also the school itself. For some parents, the school rises in value if it trains the child for a job, and it decreases in value if it does not provide the child with technical competencies. Therefore, it is evidently an instrumental vision of the school. For some other parents, the school rises in value when it forms the human being. It instead decreases in value when it becomes instrumental, and provides superficial factual knowledge, without a general framework of meaning.

In the opposition between adults' and youths' cultures we noted that adults manipulate the dispositional element and de-value the context. They emphasize the attributional bias to defend their identity of adults interacting with children. Magnifying the attribution bias could be, from the psycho-social point of view, a sort of defense, probably to protect their self-representation and the image of the family's and school's good functioning as constructed by the parents and teachers. School evaluation ends up coinciding more with what child *is* rather than with what child *knows*.

The analysis of the school-family meetings shows that the individual psychological dimension is of

value in explaining school success and failure. The knowledge of folk-psychological aspects, that is the child's individual dimension, is manipulated, becoming a commodity, a stake. This causes a devaluation of contextual aspects, such as the school organization, the curricula, the teaching methodology, the family's supporting role, the students' socio-economic level and standard of living, the presence of risk factors within the context, or, in Lewin's (1951) words, the "force field" operating when a given behavior takes place. The dimensions taken into account outlined an intriguing economically oriented picture of "school-family" meetings as a real negotiation space, underlining that what really happens on the border of these two educational micro-systems, even if only on a relatively small balcony, is much more complicated than it seems.

Of the many encounters between parents and teachers that take place in a short space of time, the school report event, as we have seen, constitutes a true boundary zone (Tuomi-Gröhn & Engeström, 2003) between the territory of the school and that of the family. In this contact situation, that could, in some ways be defined "cultural" (Iannaccone & Marsico, 2007), a number of fundamental elements of the symbolic-representative dimension generated by the encounter between parents and teachers emerged. Along this boundary, a series of psycho-social processes take place that are the product of the encounter and discursive exchange between parents and teachers. These processes would seem to be unpredictable a priori as they are connected to the attribution of sense of the players involved in the encounter. They appear to be interwoven with contextual factors (the type of school, the condition of success/failure, the disciplinary areas on which "critical" evaluations insist, etc.). In our research, as in other works (Valsiner, 2007b), the boundaries, by acting as "membranes," modulate and determine the relationship between the parts of the system. They make certain elements dynamic, inhibiting others. From this standpoint, school-family meetings take on different configurations that led to the emergence of many of the psycho-social and contextual dimensions involved.

### **Behind the Balcony: What Happens in the School?**

The next step in our attempt to look at inside and outside school from the special location chosen calls for a glance behind the balcony. Many things take place in the school with respect to the learning

of specific knowledge and skills, but we are more interested in how the work of schooling contributes to the definition of the Self. Adopting a binocular vision from the balcony on which we are, it is easy to observe that the Self is formed through a variety of experiences both inside and outside school. Suffice it to consider the interrelationships and the constant transitions among different social settings in which each person is engaged (for example, family, peers, school, etc.). At same time, it is thus not exaggeration to say that the history of educational experiences, as a part of life's wider trajectory, plays a crucial role in the construction of the Self (Bruner, 1996). Every educational institution is the expression of a given culture and will tend to transmit, reproduce, and cultivate knowledge, beliefs, norms of behavior, and even emotions on the basis of which students interpret the natural and social world. Even the idea of Self, with its limits and characteristics, is typical of a given culture. School therefore contributes to the formation of the student's Self in such a way as to fit with the cultural requirements: for example, the emphasis on the values of individuality rather than affiliation, the role of agency and individual effort rather than cooperation, etc. (Bruner, 1996). This is the starting point of the reflection that led to the idea of Educational Self considered as a specific dimension of the Self, a regulatory process emerging from the experiencing of the I-Other relationship (Bakhtin, 1979/1986) in the educational context (Iannaccone & Marsico, 2007).

### **Defining Educational Self: Two Sides of the Same Coin**

The idea of Educational Self involves two related aspects: the construction of the Self during the school age in the adults' discourse and the emergence of the Self when an adult interacts within an educational context (*see* Fig. 40.1).

The construction of the Educational Self (*see* Fig. 40.1a) is basically a dialogical process, taking place during the school age and involving multiple voices expressing different points of view, modulated by specific sets of beliefs and actors' experiences (Markova, 2006). Young people interact with adults, experiencing a dialogical and contractual space where the adults' and peers' voices provide different "as-if" possibilities, contributing to define what a person could be in present and in future time. The student's Self, somehow unclear, comes into contact with adult "voices" and is asked to negotiate, reject, or accept the different possible definition provided

**Figure 40.1** The two aspects of the Educational Self

(Simao & Valsiner, 2007). Through the processes of active internalization and symbolic mediation described above, the child will construct his own Educational Self and will activate it every time he subsequently acts in an educational context.

This is the second characteristic of the Educational Self, that is to become salient every time that the person is involved in an educational activity (*see* Fig. 40.1b), for example during significant turning points and life transitions such as higher education or professional training activities. The school experiences then emerge, providing values, models of behavior, norms, symbolic repertoires, emotional experiences, knowledge and practices that are internalized in the form of “voices” that will constitute a capital of symbolic resources on which the individual will draw (Zittoun, 2006).

This theoretical idea could help to understand how individuals learn to manage the cognitive, emotional, and social dimensions with respect to the identity and the different Self positions when involved in educational activities (Hermans, 1996). Even an elderly person would experience an implication of the Educational Self when enrolling for a university of the third-age course (Leibing, 2005). In other words, the Educational Self can be conceived as a process of sense making on the move, referring to the past but, at the same time, shedding light on the future development of Self (Linell, 2009). The voices of the educational context define the individual’s identity: what he/she is, is not, should be and should not be, would be and would not be (Valsiner, 2007a).

A good example of the significant role played by the Educational Self is provided just by the school-family meeting. In this encounter, as we argued above, parents and teachers have to attribute meaning to their child’s success or failure at school, provide explanations, negotiate their viewpoint with the other, adjust their vision of the child with that provided by the school report card. This social sense-making process, that takes place in a conversational space, is based on the educational perspective (i.e., the representation of schooling

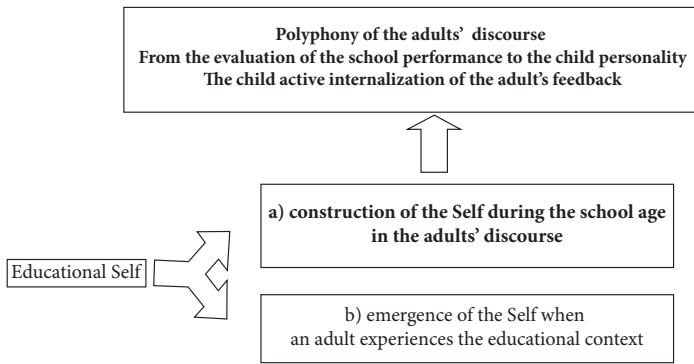

or of childhood) held by the actors (parents and teachers) and on the Educational Self as formed through one’s own educational history. Teachers, for instance, reinterpret the educational models, teaching styles, representations, and formal and informal norms, that they internalized in a continuous dialogue between the voices populating their educational and professional Self (Iannaccone et al., 2008; Ligorio & Tateo, 2008). In other words, past experiences as a student become a lens suitable for reading and interpreting all the present complexity of dynamics in the institutional context and also for modulating the discourse, identity positioning, and social behavior. Suffice it, for instance, to consider how parents feel during the school report card delivery event.

The first dimension of the Educational Self pertains to the adults’ discourse about the child’s Self (*see* Fig. 40.2a). In the excerpts presented below, it is possible to observe the role played by the definitions of the pupil’s Self provided by the parents and teachers, the discourses about the scholastic assessment and the explications of the academic success/failure stressed by adults and pupils and, finally, the process of “active internalization” of the adults’ feedback in the definition of the Educational Self.

Afterward, we’ll discuss the second aspect of the Educational Self, pertaining to the reactivation of this dimension of the Self when the adult enters the educational context. Some arguments evoked by participants during home-school encounters and interviews with parents realized after the report card’s delivery, explain how the Educational Self is reactivated and used to make sense of what happens to the pupil at school through the polyphony of the voices of the Self related to the educational experiences in the adults’ discourse.

### ***Polyphonic Configurations: From Opposition to Juxtaposition of Voices***

School-family meetings are highly meaningful events that involve perceptions, sense making and personal evaluations affecting the construction of Self (Berger, 1995; Dazzani & Faria, 2009;

**Figure 40.2** The construction of the child's Educational Self in the adult's discourse

Huntsinger & Jose, 2009). The meetings are the place where the teacher and parents' representations of the student are defined, made explicit, and modulated at a micro-genetic level (Marsico, Komatsu, & Iannaccone, in press). During the meetings, the student's Self—somewhat unclear and ill-defined—must come into contact with adults' voices negotiating, rejecting, or accepting the different positions. This results in a very dynamic situation stressing the fluid and dialogical nature of the Self-definition's process.

The following excerpts of the family-school meetings concern three types of dialogical events in which the voices of parents and teachers produce different polyphonic configurations: *Opposition of voices* (Excerpt 11), *Different intonation of the voice* (Excerpt 13), and *Juxtaposition of voices* (Excerpt 14). Moreover, Excerpt 12 (*The voice of youth*) is, on the other hand, an example of an interview with a family that shows some relevant dimensions affecting the definition of the Self.

#### OPPOSITION OF VOICES

In Excerpt 11 we can observe an “opposition of voices” emerging during a meeting between teacher, student (a 13-year-old) and his father (a 46-year-old).

The school and the family voice different perceptions of the child. For the school, the boy is shallow and not very constructive. He should be kept an eye on because he is not yet independent and responsible. He is still immature and needs the control and guidance of adults (turn #11). For the family, the boy is fairly independent. He can accomplish his assignments and can evaluate both himself and the teachers. He is certainly mature and able to establish relationships based on trust rather than control (turns #24 and #42).

#### THE VOICE OF YOUTH

The Excerpt 12 refers to the same family as Excerpt 11. The discursive interaction between father and son during the interview focuses on the dimension of evaluation embedded in the process of identity definition.

The boy positively evaluates his less-than-excellent school results, showing that his self-esteem is not attached to the academic assessment (turn #10). The father's statement (turn #15) produces a conversational shift that determines a discursive overlap between the assessment of his son's academic performance and that of the person (“you're worth so much?”).

In this case, the Self is directly involved with the value that the boy attaches to himself. The process of identity definition is ongoing, this clearly makes it difficult for the boy to answer (turn #16: “I don't know how much I'm worth”). During the meeting, he must face the institutional voice of the school that defines his competence and his psychosocial characteristics through the artifact, the school report card. He must also face two other voices as equally meaningful on a psychological level (parent and teacher). They straightway express in the presence of the child the opposite perceptions of his Self (*mature* versus *immature*) as shown in Excerpt 11. In this polyphony, the boy must mediate between what he thinks about himself and what the significant others think about him. In this case, it is possible to talk about a polyphony of voices that define a dynamic and dialogical system of the Self under construction.

#### DIFFERENT INTONATION OF THE VOICE

Excerpt 13 shows the “different intonation of the voice” by the school and the family, attaching different connotations to some behaviors and psychological characteristics of the child's Self. The meeting

6. **MADRE:** [no=no]

7. **DOCENTE:** per carità (.) anzi è un ragazzino::

8. **MADRE:** però: e un po': (.) u:n (.) non in senso cattivo (.) però:: **diciamo che ha le sue:: [idee]**

9. **DOCENTE:** [idee] (.) per cui: (.) si dice:: (.) meglio solo che mal accompagnato (.) però (.) secondo me:: (.) **dovrebbe cominciare ad abituarsi a stare anche un po' con ((*ride*)) i vari tipi (.) chi non è come lui ((*ride*)) (.) magari nel senso (.) taciturno=silenzioso (.) anche per gestirsi per**

10. **MADRE:** no (.) io non credo sia (.) di essere taciturno o meno (.) perché in realtà lui si trova bene con G. ((*cita un compagno*)) che (.) °quando attacca a parlare non la finisce più° (.) si conoscono tantissimo

11. **DOCENTE:** ()

12. **MADRE:** però:: **gli danno fastidio:: (.) gli invadenti**

13. **DOCENTE:** eh! (.) purtroppo ci sono in classe (.) eh:: ed è anche giusto che lui li sappia affrontare

involved the teacher, the 11-year-old student, and his 42-year-old mother, a housewife.

According to the teacher, the boy is introverted and tends to avoid social relationships (turns #1 and #3). This closure could be a potential sign of an asocial personality. He should instead open up to social interaction in order to learn how to tune his behavior and how to manage social relationships (turn #9). In accordance with the school's voice, the boy has difficulties in social integration. From the family's point of view, the boy chooses to spend time alone because of specific preferences (turn #8: "he's got his own

[ideas]"). In the opinion of the family, the boy has clear ideas about the type of interactions and persons he looks for (turn #12). In short, the family reinterprets the boy's taciturn and loner aspects in positive terms, emphasizing his need for autonomy.

#### JUXTAPOSITION OF VOICES

Excerpt 14 presents a "juxtaposition of voices" between family and school during the meeting involving the teacher, 13-year-old student, his 50-year-old father, a doctor, and his 40-year-old mother, a teacher.

### Excerpt 14: Meeting #13

#### English translation:

11. **TEACHER:** although are only in the first 4-months term (.) let's say that the important thing is::: **that overall he seems a mature boy** (.) I must tell you the truth

[...]

23. **TEACHER:** for the deepness of thinking

24. **MOTHER:** yes

25. **TEACHER:** yes but at other times, on the other hand

26. **MOTHER:** yes that's true

27. **TEACHER:** he seems a child to me

28. **MOTHER:** yes that's true=that's true

[...]

36. **TEACHER:** ok he's always like that! ok well he's only 10!

37. **TEACHER:** let's say >he's in this phase of growth < so he shows alternate phases

38. **MOTHER:** [()]

39. **TEACHER:** [yes=yes yes=yes]

40. **FATHER:** he needs to leave childhood behind

41. **TEACHER:** eh! eh! he made a poster in classroom on adolescence and I asked him I said why have you drawn a shrimp?

[...]

50. **TEACHER:** that is what he said later on (.) actually

51. **MOTHER:** ()

52. **TEACHER:** let's say when he wants and::: he's one hundred percent mature and at other times

53. **FATHER:** he is like that at home too

54. **MOTHER:** at home he's like that

#### Italian original:

11. **DOCENTE:** siamo anche al primo quadrimestre (.) diciamo che l'importante che::: **il più delle volte appare come un ragazzo maturo** (.) vi devo dire la verità

[...]

23. **DOCENTE:** per la profondità proprio di pensiero

24. **MADRE:** si

25. **DOCENTE:** si poi in altri momenti invece

26. **MADRE:** si è vero

27. **DOCENTE:** mi sembra un bambino

28. **MADRE:** si è vero =è vero

[...]

36. **MADRE:** va beh è sempre così! va beh che c'ha dieci anni!

37. **DOCENTE:** si diciamo >che è in questa fase di crescita< per cui mostra queste fasi alterne

38. **MADRE:** [()]

39. **DOCENTE:** [si=si si=si]

40. **PADRE:** si dovrebbe lasciare alle spalle un poco di infanzia

41. **DOCENTE:** eh! eh! ha fatto un cartellone in classe sull'adolescenza e io gli ho chiesto dico ma perché rappresenta un gambero?

[...]

50. **DOCENTE:** poi me l'ha raccontato così (.) effettivamente

51. **MADRE:** ()

52. **DOCENTE:** diciamo quando vuole e::: è maturo al cento per cento altre volte poi

53. **PADRE:** lo fa anche a casa

54. **MADRE:** pure a casa è così

The voices of the family and the school seem to converge toward a common perception of the child's Self (turns #11, #25, #26, #27, #28). For both teacher and parents the boy shows a sort of inconsistency, switching from mature behaviors to childish ones (turns #52, #53, #54). The voice of the child is evoked by the teacher through a semiotic mediation device. In fact, the teacher reports (turn #41) that during a classroom activity, the pupil, when asked to create a poster, decided to portray adolescence as a "shrimp," showing the presence of a self-reflexive process with respect to the fluctuations in the definition of his own identity. The boy

himself therefore seems to be aware of the instability typical of the pre-adolescent phase. This uncertainty echoes the mother's discourse (turn #36) accounting for the son's apparent immaturity by attributing him a "lower" age ("ok well he's only 10!"), when he is actually 13 years old.

#### POLIPHONY, SYMBOLIC RESOURCES AND TEMPORALITY

The main purpose, formally established, of the school-family meeting is to communicate to the parents the results of the child's scholastic development. What actually emerges is more complex

and interesting from a dialogical viewpoint. First, the communication of the academic results is situated within a ritualistic and structured context of activity in which many other elements are at stake. The excerpts presented show that during the school-family meetings, the child is provided with a set of symbolic resources in the form of the voices that the adults use to talk about his Self. The pupil then draws on these resources and on the different definitions of the Self given by the significant adults (parents and teachers). A space of negotiation is thus opened in which the pupil can decide to accept, reject, or remodulate the possible definitions of the Self. The outcomes cannot be predicted, but what matters here is the interactive and dialogical nature of this process. It is a fluid and problematic process for the child because these voices can be either consonant, dissonant, or opposite to one another. At the same time, they can partially agree with the child's self-perception or else they can totally disagree with it. This process takes place within the constraints of power relationships and the framework of the specific culturally situated activity. The power relationships limit the range of possible Selves that the child can construct because the polyphony of voices is however a "selection" emerging within given cultural parameters (Bruner, 1996). They define the different identity "possibilities," for instance what a "good" or "bad" pupil is, or what a growing child should or should not become. Besides, the school-family meetings and their voices are contextualized within a time perspective (see Fig. 40.3).

Thus, there is a time "before" the meeting, concerning the whole experience of the pupil in the educational context. This experience contributes to defining his Self and can be partially documented through the academic assessment. There is a "present" time of the meeting and, finally, there is a time "after," concerning the development of the Self in the future. This development can be only imagined within the range of some culturally defined identity options. The adults' voices then contribute to

defining what the child is, what he is not, what he should and should not be, what he could and could not be.

### An Easy Shift

In the previous pages we have underlined how the process of definition of a child's identity is closely connected with his/her scholastic experience. In this perspective, academic success or failure acquires value in relation to a positive or negative definition of the Self (as seen in the Excerpt 2). Besides, school assessments are also frequently used not only to define the features of a "good" or "bad" student, but also to connote the child/pupil's identity.

Scholastic assessment ends up coinciding with what the child *is* rather than with what the child *knows* (as in Excerpt 8, turn #7: the teachers says, "let's say it all defines his character").

Excerpt 15, on the other hand, concerns an interview with a family made up of an 11-year-old pupil, her 52-year-old father, a doctor, and her 49-year-old mother, a housewife. The pupil's academic performance, according to her teachers, is very good.

The excerpt shows that for both the teachers and parents the school results tell what kind of person the child is. In this excerpt, the adults account for school success or failure by attributing academic performance to the child's dispositional and internal aspects (Excerpt #15 turn #21: the father says, "she's responsible"). Thus, results define the pupil but they are the outcome of her personal characteristics in return, like a sort of identity definition feedback loop. It is evident how scholastic assessment can take on meanings that are more closely related to the definition of identity and "self-value," showing how assessing performance can easily become assessing the person. This has a particularly meaningful connotation on a psycho-social level, especially considering the very delicate transitional phase pre-adolescents and adolescent students are going through, in which they face the fundamental task of constructing their Selves.

**Figure 40.3** Polyphony and time perspective. Adapted from Valsiner (2007) with permission.

## Excerpt 15: Interview #2

### English translation:

**18. RESEARCHER:** why (.) do you think your daughter got these very good results? What do you put it down to?

**19. FATHER:** because she is certainly (1.5) in the humanities (.) we know she's more talented (.) she likes reading writing she writes quite well because indeed at home she's been encouraged to read

**20. MOTHER:** >part from the fact< that she's a very conscientious girl (.) she has a conscience (.) she does everything what has to be done

**21. FATHER:** [she's responsible]

**22. MOTHER:** [she's very responsible] she isn't a superficial girl (.) that leaves things she's responsible and conscientious

### Italian original:

**18. RICERCATRICE:** perché (.), secondo voi, vostra figlia ha ricevuto questi risultati che sono sicuramente ottimi? a cosa lo attribuite?

**19. PADRE:** perché sicuramente lei (1.5) nelle materie umanistiche (.) sappiamo è più portata (.) le piace leggere scrive abbastanza bene proprio perché a casa è stata abituata alla lettura

**20. MADRE:**>a parte il fatto< che è una bambina molto coscienziosa (.) lei ha una coscienza (.) fa tutto quello che deve essere fatto

**21. PADRE:** [è responsabile]

**22. MADRE:** [è molto responsabile] non è una bambina superficiale (.) che lascia le cose è responsabile e coscienziosa

In short, on a broader conceptual level, scholastic assessment seems to acquire symbolic meanings and to become: (1) a modulator of the identity-building process; (2) an element that can confirm or destabilize the emerging idea of Self; (3) a negotiational space with respect to the way pupil is perceived by both parents and teachers.

### *The Child's Active Internalization of the Adults' Voices*

The legacy of "evaluations about the person" is the object of the active internalization process that is, the raw material for the definition of the Self. The following excerpt shows how the child reformulates and elaborates the judgements on the Self, emerging during the dialogical interaction with the adults, and uses them to talk about himself. Actually, it is not a passive echoing of adult voices, but a personal and active redefinition of the identity options provided by the adults' discourse. These options dialogically define what the child is but at the same time imply the exclusion of what he is not. In other words, the child appropriates of the "adult voices" that talk about the Self, performing that process that goes from the externalization of the semiotic forms to their internalization as tools for defining and regulating the Self.

The dialogical definition of the child's Self is shown in Excerpt 16, also taken from Interview #1, in which the researcher, the father (a 46-year-old)

and the son (a 13-year-old student) are discussing the child's school results.

During the first phase of the interaction (turns #19 to #26), the father and the son start an exchange in which the parent asks the son to answer for his level of diligence in his studies (turn #19: the father says, "but you believe that you study the subjects thoroughly in the right way all the subjects?"), repositing at turns #21 and #23 his personal viewpoint on the method of study. In a first phase of the dialogue, the son seems to assume an acquiescent position (turns #20, #24 and #28). When the researcher asks him straight out to express his own opinion on why his academic performance is not brilliant, the child appears to be uncertain and confused (turn #28: "don't know!"). The uncertainty seems to disappear at turn #30 when the child chooses to account for his performance by evoking his "superficial" attitude to his studies. Actually, in this turn it would appear that the child chooses to talk about himself with the same connotations as his father's discourse. Nevertheless, he mediates—this could be understood as a son's active internalization—between the adult's voice—that defines him as "superficial"—and the self-perception he is constructing of a person that, despite the recognition of this lack of diligence, does not judge himself in totally negative terms (turn #30 "even in things I like a pass is okay"). This represents a clear example

## Excerpt 16: Interview #1

### English translation:

19. FATHER: >but you believe that you study the subjects thoroughly< (.) >in the right way all the subjects<?

20. SON: °no° ((*lowers his eyes*))

21. FATHER: >and what did your father always tell you< (.) >Italian language, history e geography you can't get pass mark<

22. SON: °not pass mark°

23. FATHER: no (.) I said pass mark >is scant because pass mark:::< means that you actually gave a quick look at the pages (.), am I wrong?

24. SON: °yes°

25. FATHER: >that's what I always say to you?<

26. SON: eh! ((*nod*))

27. RESEARCHER: why do you think you got these results?

28. SON: °don't know!°

29. RESEARCHER: according to dad it's clear, what about you?

30. SON: maybe because I am superficial (1.0) well I don't go into enough::: even in things I like a pass is okay ((*smiles and lower his eyes*))

### Italian original:

19. PADRE: >ma credi che tu approfondisci giusto nelle materie< (.), >in un modo corretto a tutte le materie<?

20. FIGLIO: °no° ((*abbassa gli occhi*))

21. PADRE: >e che ti ha detto sempre tuo padre< (.), >italiano, storia e geografia non si può prendere sufficiente<

22. FIGLIO: °non sufficiente°

23. PADRE: no (.) ho detto che sufficiente >è poco perché sufficiente::: vuol dire che praticamente hai fatto una girata dei fogli (.), o mi sbaglio?

27. RICERCATRICE: perché secondo te, hai avuto questi risultati?

28. FIGLIO: °bo!°

29. RICERCATRICE: secondo papà è abbastanza chiaro, secondo te?

30. FIGLIO: perché sono superficiale forse (1.0), cioè non approfondisco::: pure quello che mi piace lo stesso sulla sufficienza va bene ((*sorride e abbassa lo sguardo*))

of the modulation and negotiation between the adult's voice and the child's vision of his own Self.

In Excerpt 17 the researcher is interviewing a family composed of two sons, 12 and 13 years old, attending two different classes at the same school, the father, a 45-year-old nurse, and the mother, a 41-year-old housewife. Again in this case, the participants are discussing the school results.

In this excerpt, the parents introduce a wider time perspective in the evaluation of their sons' scholastic results (turns #39 to #41). The parents suggest that the results at school are related to life expectations and the commitment required to study is the same quality that should serve to face the forthcoming challenges of life. The topic at stake is commitment, which goes beyond the boundaries of the school results (turn #41). It is something "acquired" through education but necessary for life. In this case, the two sons had good marks, so their capability is not questioned and commitment is "already" part of the definition of Self provided by the adults (teacher and parents).

Son #1, when asked by the researcher, seems to accept this viewpoint (turn #43), but he immediately proposes a complementary explanation (I did what I had to do) in terms of compliance to the school's requirements. Son #2 seems to agree with his brother's explanation (turn #45). In this case, the children's definition of Self seems to agree with the adults', and it doesn't require a significant negotiation between different or opposite viewpoints as in Excerpt 16. The children seem to comply with the expectations of both the family—commitment to grow up—and the school—a "good" pupil fulfills his assignments. Nevertheless, the two pupils in Excerpt 17 do not disagree with the adult position but play a different type of active appropriation and negotiation between voices. In this case they "attune" their definition of the Self by appropriating and internalizing the categories of the adults' discourse. Then they use these categories as self-regulatory instances in order to orient their semiotic behavior, their self-presentation, and sense-making of school experiences.

### Excerpt 17: Interview #3

#### English translation:

39. MOTHER: because there's a question underlying all this there's a question of (.) preparing the future (.) the society (.) as we know (.) is (.) so it's important (.) the=crafts=doesn't=exist=anymore (.) the=manual=labor (.) so with three sons we try to make them understand the importance

40. FATHER: we talk with them above all about these problems

41. MOTHER: commit yourself for your future (.) now we've done our job ((gesticulates)) (.) do your best for your future (1.5) and that's the only way by nowadays (.) and so it's good to commit oneself (1.5) to have a better future

42. RESEARCHER: why do you think you got these marks? (names SON #1) why?

43. SON #1: ((smiles)) during the school year (.) I applied myself (.) I did what I had to do

44. RESEARCHER: so perseverance rewarded you (.) and what about you (names SON #2)?

45. SON #2: eh:: (2.0) let's say the same thing

46. RESEARCHER: you applied yourself?

47. SON #2: yes

#### Italian original:

39. MADRE: perché poi comunque dietro c'è tutto un discorso (.), per la preparazione del futuro (.) La società, sappiamo, è ormai (.), quindi è importante (.) non=esiste=più=il=mestiere, il lavoro=manuale=artigianale. Quindi con tre maschi cerchiamo di fargli capire l'importanza

40. PADRE: ci si parla con loro soprattutto di questi problemi

41. MADRE: impegnatevi per il vostro futuro (.), ormai il nostro lo abbiamo fatto ((gesticola)), per il vostro futuro impegnatevi (1.5) ed è l'unico modo al momento (.) e quindi è bene impegnarsi (1.5) per avere il futuro più facile

42. RICERCATRICE: secondo voi perché avuto questi voti? Corrado perché?

43. FIGLIO 1: ((sorride)) nel corso dell'anno scolastico (.) mi sono impegnato, ho fatto quello che dovevo fare

44. RICERCATRICE: quindi la costanza ti ha premiato (.) E tu Adriano, perché?

45. FIGLIO 2: eh:: (2.0) diciamo per la stessa cosa

46. RICERCATRICE: ti sei impegnato?

47. FIGLIO 2: sì

In more general terms, Excerpts 16 and 17 are examples of the symbolic process of active appropriation that leads to the construction of the Self. What happens is that the children are provided with images of the Self, norms, values, and explanations of their behavior. They elaborate the signs adults use to talk about them but at the same time they elaborate these signs to produce their own view, which is partially coinciding and partially not.

### The Other Side of the Coin: The Educational Self in the Adult's Life

The second characteristic of the Educational Self (see Fig. 40.4b) is the fact that it emerges and becomes salient every time the person participates in an activity within an educational context<sup>5</sup>. The legacy of symbolic resources (systems of activity, emotional experience, etc.) attached to the school experience, is used by the adults to regulate and

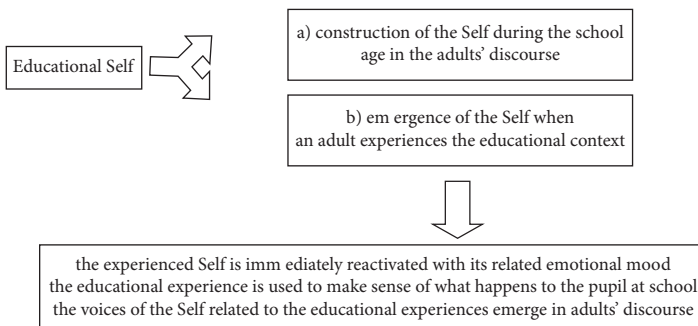

Figure 40.4 The emergence of the adult's Educational Self

modulate the interaction and to make sense of what happens in this type of situation. This process emerges in our data under three different forms:

- 1) the experienced Self is immediately reactivated with its related emotional mood;
- 2) the traces of the educational experience are used to make sense of what happens to the pupil at school; and
- 3) points 1 and 2 emerge in the adult's discourse through the voices of the Self related to the educational experiences.

The first form is presented in Excerpt 18, where we can see how the experienced Self of the parents is immediately reactivated by the school-family meeting. The researcher interviews a family just after the school-family meeting. The family is composed by the father, a 41-year-old craftsman, the mother, a 40-year-old waitress, and the son, age 12 years. First, the researcher asks the parents to evaluate their son's school. The mother starts to talk about the headmaster, who was incidentally her teacher when she left the school before finishing (turns #24,

#26). Then the researcher asks for the father's opinion (turns #27, #30).

Both the mother and the father left school after obtaining their middle school diploma and went out to work. In turn #24, the mother immediately refers to the important turning point in her life ("instead I decided to get a job"). She juxtaposes a present and a past situation linked by the person of her teacher. She was a good student, she loved the school, but she decided to leave despite her teacher's advice. When she comes back to school as a mother, she meets again the same person, who has become in the meantime the headmaster, and she reports his discourse in the third person ("when he saw me he told me 'don't do to your son what you did to yourself'") to argue in favor of her present belief as a parent of a school-age son ("going to school is better than going to work"). The narrative of the mother's biography (turns #24, #29 and #31) seems to be attached to an immediate activation of an emotional and "nostalgic" mood ("If I could go back yes"). On the other hand, when the father is asked to evaluate the school (turn #30) he immediately presents not only the same "nostalgic" mood ("we

### Excerpt 18: Interview #8

#### English translation:

24. MOTHER: yes he's a smart person (.) when he saw me I took my son to middle school for the first time (.) because I didn't finish the school (.) I just finished the middle school and didn't want to go on (.) even if I got good notes (.) when he saw me he told me don't do to your son what you did to yourself (.) he came home to tell me I must go on (.) instead I decided to get a job

25. RESEARCHER: in general (.) what is your idea about the school?

26. MOTHER: it's a good thing (.) beyond literacy (.) going to school is better than going to work

27. RESEARCHER: does daddy think so too?

28. FATHER: yes=yes

29. MOTHER: If we could go back yes

30. FATHER: that's what I said earlier to the teacher (.) I sat down at the little school desk (.) I would go back to school again

31. MOTHER: it's very nice (.) I loved going to school (.) a lot

#### Italian original:

24. MADRE: sì una persona in gamba (.) quando mi vide la prima volta che portai mio figlio in prima media (.) perché io non ho continuato (.) ho fatto la terza media e non ho voluto continuare (.) anche se andavo moto bene a scuola (.) come mi vide disse non far fare a tuo figlio quello che hai fatto tu venne fino a casa che io dovevo continuare mi misi in testa che dovevo andare a lavorare

25. RICERCATRICE: e in generale (.) rispetto alla scuola che idea avete?

26. MADRE: è una cosa buona (.) a parte una cultura generale (.) è meglio andare a scuola che lavorare!

27. RICERCATRICE: anche il papà pensa così?

28. PADRE: sì=sì

29. MADRE: se tornavamo indietro sì

30. PADRE: l'ho detto prima alla professoressa (.) mi sono seduto nel banchetto (.) io ritornerei un'altra volta a scuola

31. MADRE: è molto bello (.) a me piaceva andare a scuola (.) tanto

would go back to school again”), but he accounts for the activation of a specific “educational” behavior (I sat down at the little school desk). Excerpt 18 shows how the adults, while getting in contact with the educational context, immediately activate a repertoire of voices, norms, emotions, and behaviors that are part of the Educational Self, and use it to make sense of their life trajectory as individuals, students, and parents. The parents “know” how to behave and self-regulate at school, even if they are actually there as parents, because they immediately grasp their previous experience. At the same time, the internalized teacher’s voice, once addressed to them as *students*, is now used to account for their choices as *parents*.

The second characteristic of the adult’s Educational Self is that the educational experience is used to make sense of what’s happening at school. The parents provide some evaluations of the school with respect to their past experience and account for a change, which is not easy to elaborate.

As shown in Excerpt 7 (turn #43) the mother immediately compares the present situation of

her daughter’s school with her own experience as a student. It should be noted that she evokes the emotional condition (“we were afraid”) and the relationship with the adults (“the teacher, the principal”) rather than other dimensions such as learning. In the same way, the difference between “her” school and that of her daughter is described in terms of “open-mindedness” and attention to the student’s “problems” rather than subjects or methods.

Excerpt 19, on the other hand, is taken from Interview #3 involving two sons, (12 and 13 years old), the father, and the mother.

In this excerpt, the focus of both parents (turns #40, #41 and #48) is on the change that has taken place in terms of methods, subjects, and programs. As in Excerpt 7, the parents immediately refer to their own school experience to make comparisons. These are two examples of the different way adults refer to their school experience to make sense of their children’s situation. Although, the parents’ evaluations focus on different dimensions, the emotional experience and the relationship *versus* the learning and the method, both the excerpts show a

### Excerpt 19: Interview #3

#### English translation:

39. RESEARCHER: and in general (.) what do you parents think about the school?

40. MOTHER: it has made great strides from time to time (1.5) maybe too many [many:::]

41. FATHER: [many] (.) we remember our school once upon a time (.) a school with (.) a teacher (.) schematic (.) mechanical (.) school isn’t like that any more (.) the programs (.) the subjects (.) are different (.) they do (1.5) not have to study like (.) we used to but like::: (3.0) how can I say

42. RESEARCHER: maybe not the [content]

43. FATHER: [the content]

44. RESEARCHER: [a method?]

45. FATHER: [yes a method]

46. RESEARCHER: school in general has changed like:::

47. FATHER: hasty

48. MOTHER: we don’t have the time to (.) get to grips with one phase and (.) they’ve suddenly moved on to the next one (.) I don’t know (.) maybe that’s good (.) I can’t really say

#### Italian original:

39. RICERCATRICE: e in generale (.) voi genitori che pensate della scuola?

40. MADRE: si sono fatti passi da gigante da un momento all’altro (1.5) troppi forse [troppi:::]

41. PADRE: [troppi] (.) noi ci ricordiamo la scuola di un tempo (.) di una scuola con (.) un insegnante (.) schematica (.) meccanica (.) invece la scuola di adesso no (.) sui programmi (.) sulle materie (.) è diverso (.) devono (1.5) più studiare non in modo (.) come facevamo noi una volta ma come::: (3.0) come posso dire

42. RICERCATRICE: forse non tanto i[contenuti]

43. PADRE:[i contenuti]

44. RICERCATRICE: [un metodo?]

45. PADRE: [sì un metodo]

46. RICERCATRICE: la scuola in generale ha fatto tanti cambiamenti un po’:::

47. PADRE: affrettati

48. MADRE: non abbiamo avuto il tempo di (.) regolarci in una fase che subito (.) sono subito passati alla successiva (.) non so (.) può darsi che sia buono (.) non so analizzare la cosa

certain difficulty in making sense of the change with respect to their own school experience (Excerpt 7, turn #43; Excerpt 19, turns #47 and #48), which is attached to an emotional vividness. Once the school was rigid but reassuring, schematic but stable, it is not only the student's Self that must adapt to the "hasty" change but also the Selves of the parents as former students.

The last aspect of the adult Educational Self is the polyphony related to the educational experiences emerging from the adults' discourse. An example of such polyphony is presented in Excerpt 20, which is taken from an interview with a family composed of a 12-year-old son, the father and the mother, both 45-year-old teachers. The sense of the school experience is expressed in the dialogue between the different voices of the Self, in this case the I-teacher and the I-father (Ligorio & Tateo, 2008).

When the father is asked to evaluate his son's school, the answer is expressed through an alliance of the I-positions of "father" and "teacher" (turn #31). Nevertheless, this evaluation calls into the picture the father's self-evaluation as a good teacher ("doing it with passion") and the whole set of knowledge derived from the personal school experiences in different moments of his lifetime ("pupils are different than in the past").

In short, the function of the Educational Self emerging from the excerpts is that of regulating and making sense of the adult's encounter with the school, through the activation of the specific symbolic repertoires related to the experience of having-been or

willing-to-be a successful or unsuccessful student (Excerpts 7, 18, and 19), parent (Excerpts 7 and 18), teacher or worker (Excerpt 20) with the related emotional and relational implications. The Educational Self is also used to make sense and to regulate some types of power relationships (Bruner, 1996), providing a framework to account for the teacher-student relationship (Excerpts 7, 18, and 19) and for the social value of the education (Excerpt 18). The Educational Self is a legacy of symbolic resources made of the set of knowledge, beliefs, narratives, and affective states established during the personal educational life. We can draw on it when participating as adults in an educational activity, playing different roles and functions, such as in school-family meetings.

The adult would thus activate the Educational Self—that is what has been defined here as the self-regulatory instance of the Self formed during the dialogical interaction in educational contexts—to make sense of the school experience of the child as a pupil but also of their own experience as parents or teachers.

The idea of Educational Self results from a dynamic, situated and dialogical process as underlined by the excerpts discussed. The definition of Educational Self has to do with the formation of Self during a critical stage in life. More in general, this is not a static entity but follows the same complex and fluid process of elaboration of the identity throughout the personal trajectory, in which "*what is*" is connected with "*what was*," "*what is not yet, but is about to come*" (Valsiner, 2009, p. 18). The analysis of school-family meetings provided some initial hints about how the polyphony

### Excerpt 20: Interview #4

#### English translation:

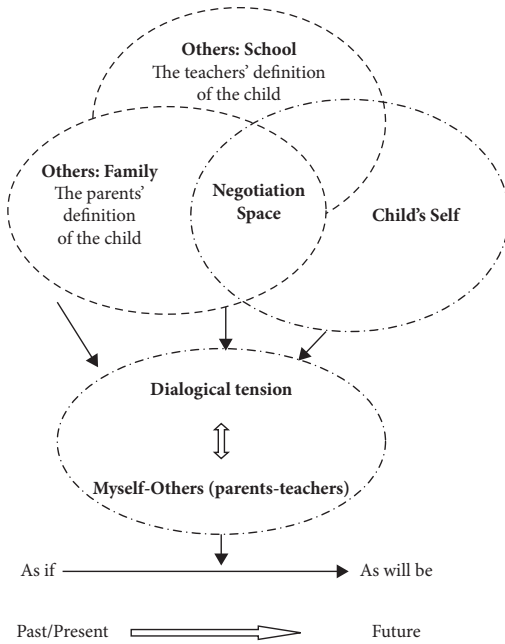

30. RESEARCHER: what do you think about your children's school?

31. FATHER: **the school (1.5) for me as a teacher** and I have seen many schools (.) this school really works (.) I don't know all the teaching staff because the school works (.) if the teachers (.) understand the pupils(.) >believing in their own job< (.) **doing it with passion** (.) which is not always the case (.) in the school=world=like (.) elsewhere in our life and so (.) it depends on the teacher (.) **today the relationships with the pupils are different than in the past**

#### Italian original:

30. RICERCATRICE: cosa pensate della scuola che stanno frequentando i vostri figli?

31. PADRE: **la scuola (1.5) per me che sono un insegnante** e che ho visto parecchie scuole (.) questa è una scuola che realmente funziona (.) non conosco tutti gli insegnanti perché la scuola funziona (.) se ci sono gli insegnanti (.) che capiscono i ragazzi (.) >che credono nel loro lavoro< (.) **che lo fanno con passione** (.) il ché non è sempre riscontrabile (.) nel mondo=scolastico=come (.) in tutti i settori della nostra vita e quindi (.) dipende dall'insegnante (.) **oggi i rapporti con i ragazzi sono diversi rispetto al passato**

**Figure 40.5** Negotiation space and dialogical tension.

of Educational Self would emerge from the process of active internalization and semiotic mediation of the significant adult voices that enter into contact with the child's idea of Self, in course of elaboration or as elaborated so far (see Figure 40.5).

The school-family meetings open a dialogical space where the different voices determine a dynamic system open to different “as-if” possibilities, contributing to defining what a person could be in future time. It is a space of dialogical tension characterized by ambivalence and uncertainty whose borders are permeable rather than rigid. It is a polyphonic space where the confrontation with significant others (myself-others) such as, for instance, parents and teachers activates a process of definition-redefinition-remodulation of the child's Self (Simao & Valsiner, 2007). It stimulates a dialogue and a process of definition and specification, stressed by both “what I think about Me” and by “what others think about Me.”

### Conclusion: Still Standing on the Balcony

Why not to do a little exercise now? You just try to rewind the tape of the visual and virtual tour of the school. What do you see at this moment? The building, the entrance-hall, then the corridors and classrooms. Can you visualize the balcony? The metaphorical balcony on which we have been and where we explored the work of schooling was a

position neither comfortable nor usual, but now we can start again from here. Having a quick glance and using a renewed attention, we would probably realize that the walls of the school, first rigid, now seem more porous, plastic, and permeable. As the contours of cell membranes they let through some elements from sociocultural world. We would, then, recognize that the limited space of the balcony is a very dynamic open-ended system. It's a boundary, which, just as every liminal threshold, is a meeting place. From the balcony we can, finally assume a different angle to see what occurs inside the school. In this way, we would become aware that the work of schooling is constantly interwoven with several elements related to what there is on the outside of the balcony (in society), what happens beyond the balcony (in the school) and what happened or is happening on the balcony itself.

It's always refreshing to summarize, at the end of a long discussion, the main issues stressed.

Using the metaphor of a balcony we pointed out how the school is a *place in between*, a border always interfaced with both internal aspects (practices, discourses, and different actors) and a wider sociocultural climate. The school balcony, as a border zone, is an area of contact with other relevant educational settings. In order to grasp the dynamic and fluidity of this interconnection we need to look at boundary phenomena. A binocular vision focused on inside and outside school allows us to take in consideration the many processes implied in the work of schooling, moving from the role played by the socio-economic and cultural dimensions, passing through the analysis of intersectional points with others educational contexts (such as family-school meetings), arriving at the definition of identity in the school (the suggested notion of the Educational Self).

Looking across the balcony, for example, we highlighted which elements reach school, becoming fundamental factors in constructing school's everyday life. We outlined that the first element to be taken into account is the socio-economic dimension of cultural context in which school acts. We also stressed the relevant effects of families' social and cultural capital on children's school experience.

Paying attention to what happens on the balcony means, primarily, takes into account the intercontextual connection between school and other life contexts as in the case of home-school interactions. Such boundary encounters make evident the intricacy of the interpersonal dynamics in an institutional setting.

The school-family meetings take place in a particular time and space (just on the metaphorical school balcony) within specific “formal/informal” and “open/closed” parameters established by the school. Along these lines, three main modalities of interactional activities (Opposition, Alliance, and Acquiescence) emerge during the parents-teacher meetings that are strictly connected to the family’s socio-economic status and child’s school results.

We have also suggested an economically oriented view of the school-family meeting to stress what is actually at stake in this crossing boundary phenomenon. The different representations of education (multi-dimensionality versus mono-dimensionality) and school (instrumental versus holistic vision) evoked by parents and teachers and the child’s value (in terms of how much he is worth as a person and not only as a student) are the objects of negotiation or, more roughly, the indexes of stock exchange quotations becoming, to a certain extent, commodities.

As we have underlined, the meetings look really heuristically interesting also because it is possible to observe the twofold articulation of the Educational Self. On one hand, the teachers’ and parents’ discourses on school evaluation make explicit several definitions of the pupils’ Self. Such definitions provide a range of identity options that the child should negotiate and cope with during the critical process of constructing his/her Self. On the other hand, during school-family meetings, adults are asked to manage different activities, which is very meaningful from a psycho-social point of view. They have to make sense of the child’s school experience, account for his performance, negotiate between the family and school culture, etc. These activities require the recourse to the symbolic system of autobiographical and social knowledge related to their personal educational experience. Through the balcony metaphor we can look with a new lens at current work of schooling, at its complexity and at its unavoidable interconnections with the broader cultural paradigms of a given society. Studying these extremely complex systems of relationships between inside and outside the school require the researchers to stand exactly on the balcony in spite of the rain or the heat.

### Future Directions

It seems to us that a common trace can be identified throughout our discussion. In this chapter, in fact, we have made an attempt to go beyond a

static vision of schooling, stressing concepts such as “boundary process,” “psychological membranes,” “intercontextual dynamics,” and “intersection points.” In a way, we have pointed out the movement and the openness rather than the static nature and the closure. It’s precisely this “being in between” that should be further explored. By standing on the border and by facing constantly the tension among different parts of the system, new intriguing research questions come forward:

1) How to develop theoretically the *balcony metaphor* and its implication in studying boundary conditions? In order to expand the Border Zone concept with respect to the home-school interaction, which other crossing boundary phenomena should one consider? There are many other different intersection points between school and family that could be empirically explored. One of these occurs when the parents accompany their child to the school. What happens during this daily entrance in the school’s territory? What kind of social processes take place on the liminal threshold constituted by the entrance-hall? Which are the institutional rules ordering this scholastic daily routine and under which conditions are they violated? What is admitted, what is rejected, or just tolerated on this border? In other words, what passes through the balcony and what does not?

2) Which types of experiences make the emergence of the Educational Self possible? The reciprocity of the relationships in motion (Past-Present-Future) and the dialogical nature of each “I” position in motion (the ambivalence between to-be and to-become) must be explored with respect to the formation of student’s Educational Self. Besides, how can we grasp the “polyphony of voices” affecting the definition of Self in others’ educational activities and experiences inside and outside the school?

3) How can one explore the regulatory function of the Educational Self at the level of social roles and power relationships? It represents, indeed, the framework both for the selection of the possible Selves to be constructed by the child within certain cultural parameters and for the regulation of social relationships and social valorization of the education within a given society.

4) Which is the role played by the Educational Self in the adulthood? How does it “work”? To understand the idea of adult Educational Self could be useful to study its reactivation when the person

is involved in an educational activity, for example, during significant turning points and transitions in life, such as higher education or professional training activities.

5) How to reveal the ambiguity of the measurement system used by the school in the evaluation report card? Are those measures (such as the marks) an instrument to commoditize the education? How does this translation of the complex educational process occur? What could be lost or added? Is the translation system clear or is it only outwardly evident? And to whom?

6) Which communicative strategies the school could be improved to make the meeting with the family more effective? Could they be constituted by “interaction protocols,” helpful in reformulating both conflict and acquiescence interactions?

### Appendix: Transcription Conventions

The transcription of school-family meetings and interviews is in line with the conventions of Jefferson’s (1985) Conversational Analysis.

### Acknowledgments

We wish to thank Jaan Valsiner for his constant support, for his generosity, for our insightful meetings that were essential for the development of the ideas presented in this chapter. We also want to thank Luca Tateo for his helpful feedback on an earlier version of the manuscript and the K-seminar’s participants for their numerous interesting suggestions.

### Notes

1. The chapter is the result of a shared reflection of the authors. However, Antonio Iannaccone wrote the paragraphs entitled “Homeostatic functions of the school,” “Maintaining status-quo of society,” “Some practical implications,” “Types of interactions, family’s socio-economic status, and school results.” Giuseppina Marsico wrote the introduction, the other paragraphs, conclusion, and future research’s directions.

2. In architectural terms the balcony is a part of the building that protrudes outward. It’s an element added to the body of the building, a sort of platform beyond the outer wall boundary. Therefore, the balcony enables the relations with adjacent surroundings. For this reason we can define the balcony as a real social space, a place to meet and exchange where many social events occur. As an example, one of the authors (Marsico) reports some “snapshots” of life during her childhood. Many times she has seen her mother calling their neighbor across the balcony to borrow, for example, eggs for a cake and then give her a piece once the cake was prepared by passing the tray from one balcony to another. Many other times she has seen her mother on the balcony chatting with a neighbor of micro-events that had occurred in the little world of the neighborhood. In a sense, the balcony was a venue for exchanging gossip that performs the function of maintenance of the social order. She herself repeatedly has observed from the balcony the neighbor across, accessing daily to a series of actions and to life that flowed in the opposite house.

3. The research was realized in a middle school in the South of Italy.

4. Year 8 in the Italian educational system, which requires assessment in years 5, 8, and 13.

5. The authors are grateful to Luca Tateo for his participation in defining the emergence of adult’s Educational Self and in commenting on the related excerpts discussed in the chapters.

## Collaboration and Helping as Cultural Practices

Angélica López, Behnosh Najafi, Barbara Rogoff, and Rebeca Mejía-Arauz

### Abstract

This chapter examines children's collaboration and helping from the perspective that understanding prosocial development requires attention to the cultural practices and values in which children and adults participate. Children's ways of engaging with each other and with adults are based on practices of their families and the current and historical practices of their communities. We examine cultural values related to the helpfulness and propensity to collaborate that are common among Mexican, Latino/a, and Indigenous-heritage U.S. and Canadian children, as compared with European-American middle-class children. Central to this cultural difference are community values and practices regarding the relation of individuals with their communities—values that can be seen in the organization of children's families and communities.

**Keywords:** Helping, collaboration, prosocial development, initiative, observation, cultural practices, history, schooling, Indigenous, Mexico

This chapter focuses on cultural and historical bases of collaboration and helping. We draw attention to children's development of helpfulness and collaboration in the context of the value placed on these ways of interaction in families and communities, for adults as well as for children.

Child development research often treats children's prosocial development as individual maturational stages of accomplishment, as children learn to help others and collaborate. Helping or altruistic behavior is characterized as developing through nine stages through adolescence, originating in simple prosocial behavior such as responding positively to others and reacting to others' distress in infancy; as children grow older they become more able to detect subtle cues if someone needs help (Eisenberg & Fabes, 1998).

However, in communities that emphasize community-mindedness, helpfulness, and collaboration, children may be more prepared to detect such cues indicating that others need help and to initiate

helping. Children show more prosocial behavior in contexts where such behavior is encouraged and required or expected (Kartner, Keller, & Chaudhary, 2010; Nsamenang, 1992). In communities where collaboration and helping with initiative are the norm, children may be encouraged to develop these aspects of prosocial skill.

Our cultural/historical analysis brings together community values and practices that help to make sense of population differences in Mexico and the United States in children's collaboration and helping. A number of studies indicate that children from Indigenous and Indigenous-heritage communities of Mexico are especially helpful and collaborative in research settings as well as in school and in work with their families and communities. We suggest that their helpfulness and orientation to collaborate are related to community practices, values, and organization that appear to be widespread in Indigenous communities of the Americas.

## Indigenous and Indigenous-Heritage Practices of the Americas, and Schooling

Our cultural/historical focus is on experience with cultural practices and values, which are distinct from people's ancestry and place of residence. We examine historical roots of cultural practices surrounding collaboration and helping, in examining the traces of Indigenous practices among two related populations: (1) Mexican children who live in families or communities that identify themselves as Indigenous, and (2) children whose families are likely to have ancestral ties to Mexican Indigenous communities but who do not live in Indigenous communities nor even necessarily recognize Indigenous roots. We suggest that both are likely to have experience with Indigenous communities' practices, and examine research investigating the extent to which this is the case.

About 12% of the current population of Mexico is identified as Indigenous (CONAPO, 2005; Corona, 2001), and a large proportion of immigrants to the United States are from Indigenous communities. For example, in 2003–2004, 16–20% of California farmworkers were of Indigenous origins (Aguirre, Intl., 2005; CONAPO, 2005.) In addition, the majority of families emigrating from Mexico to the United States come from *campesino* (rural) areas in states such as Michoacán, Guanajuato, Oaxaca, Jalisco, and Zacatecas (National Population Council of Mexico, 2000) where many populations have Indigenous histories (López, Correa-Chávez, Rogoff, & Gutiérrez, 2010; Lorente Fernández, 2006).

However, because of national attempts to erase such an identity in Mexico, many *campesinos* in Mexico prefer not to identify as Indigenous-heritage as it is an identity that is often subordinate politically, economically, and socially (Fox, 2006; Lorente Fernández, 2010). In the early 1900s in Mexico, there was a strong nationwide agenda to “modernize” the nation by cutting ties with Indigenous traditions and language (Bonfil Batalla, 1987, 1988; Stavenhagen, 1988). In some rural *pueblos* (towns), people still consider themselves to be Indigenous, but in others they make reference to previously being Indians, with a dynamic view of Indianness that focuses on changing social status and cultural practices (Lorente Fernández, 2010; Urrieta, 2003). In the early 1900s, many Indigenous towns were transformed into *campesino* towns, but they often retained recognizably Indigenous practices (Frye, 1996; Lorente Fernández, 2010; Urrieta, 2003; Vigil, 1998).

Hence many Mexican families, in Mexico and immigrating to the United States, have involvement in communities that were historically Indigenous. However, most Mexican immigrants in the United States do not live in communities that recognize themselves or are recognized as Indigenous-heritage (Urrieta, 2003), and participation in Indigenous practices among U.S. Mexican-heritage families is often not recognized.

Limited maternal schooling may often serve as an index of familiarity with Indigenous practices among recent Mexican immigrants to the United States and among many *Mestizo* people (of mixed Indigenous and European heritage) from rural Mexico (Correa-Chávez & Rogoff, 2009; López et al., 2010; Silva, Correa-Chávez, & Rogoff, 2010). Because of power dynamics and unequal distribution of resources, rural and Indigenous towns in Mexico have historically had little access to Western schooling—a European and U.S.-origin institution (Meyer, Ramirez, & Soysal, 1992; Najafi, Mejía-Arauz, & Rogoff, 2008; Reese, 2002). Although Mexican communities with limited schooling are not always ethnically Indigenous, Mexican communities where schooling is limited are often marginalized rural communities that have connections with Indigenous practices stemming from community history and/or from contact among neighboring communities, with exchange of ideas and practices.

Families coming from *pueblos* that once considered themselves Indigenous are more likely to maintain some Indigenous practices and have limited schooling than families that have migrated to cities and have more access to formal schooling (Frye, 1996; López et al., 2010; Vigil, 1998). In a town that was considered Indigenous a generation ago, families have little involvement in Western schooling and engage in several longstanding Indigenous practices, whereas in nearby Guadalajara, people with extensive schooling in the last generation engage in these Indigenous practices in an attenuated form, and professional families with generations of schooling do not report engaging in these practices (Najafi, Mejía-Arauz, & Rogoff, 2008).

We speculate that the notable helpfulness and collaboration among Mexican and Mexican-heritage children fits with a valued cultural practice that may stem in part from the organization of family and group work in Indigenous communities of the Americas. This practice—being *acomedido/a*—basically involves being alert to surrounding events and ready to

spontaneously contribute to the direction of the group. Being *acomedido/a* fits with a cultural tradition in support of learning that appears to be widespread in Indigenous communities of the Americas—intent community participation.

### A Valued Learning Tradition of Indigenous America: Intent Community Participation

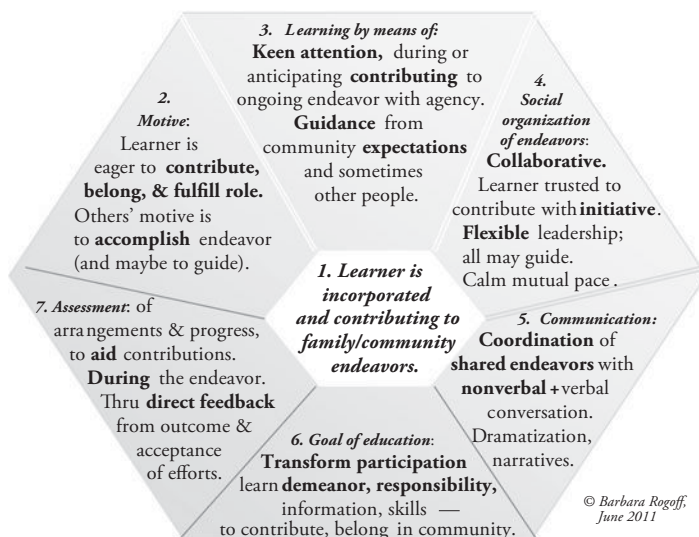

The distinctive approach to helping and working with others demonstrated by children from families with Indigenous Mexican histories is in keeping with a cultural tradition in support of learning that Rogoff and colleagues have dubbed *learning through intent community participation* (Rogoff, Paradise, Mejía-Arauz, Correa-Chávez, & Angelillo, 2003; Rogoff, Moore, Najafi, Dexter, Correa-Chávez, & Solís, 2007). In this approach, children are included in the wide range of activities of the community, and they are encouraged and expected to learn by observing and pitching in to ongoing collaborative activities (Chamoux, 1992; Corona & Pérez, 2005; de Haan, 1999; de León, 2000; Rogoff, 2003). Collaboration and helping (along with learning through observation) are key aspects of learning through intent community participation.

Learning through intent community participation is a part of all children’s lives but is limited in communities that restrict children’s access to observing and participating in the range of everyday activities of their community. In middle-class communities where high levels of schooling are prevalent, children are seldom included in a wide

range of community activities and therefore have less opportunities to learn through intent community participation (de León, 2000; Gaskins, 2000; Morelli, Rogoff, & Angelillo, 2003; Rogoff, 2003). In communities where young children are regularly included in the wide range of social and productive activities, they are often in a position to observe and listen to ongoing events, and they are expected to pay attention and contribute to them. In turn, such inclusion seems also to encourage children’s active interest in knowing what is going on and in contributing to it with initiative.

The defining features of learning through intent community participation are articulated in a prism with seven integrated facets, which together describe this cultural tradition for organizing learning. Here we present an updated version of the prism (Rogoff, 2011), which continues to be under revision as we learn more about how to characterize this cultural tradition for organizing learning. Reading from the upper left-hand facet on Figure 41.1, learning through intent community participation has these seven interrelated characteristics:

1. Learners are *incorporated* in the range of ongoing endeavors of their families and communities, with expectations and opportunities to *contribute*.
2. Learners are *eager to contribute, belong, and fulfill roles* that are valued in their families and communities. Other people present are involved in *accomplishing* the activity at hand, and may provide guidance.

© Barbara Rogoff,  
June 2011

**Figure 41.1** The multifaceted prism articulating the features of learning through intent community participation.

3. Learning involves *keen attention*, during or in anticipation of *contributing*, guided by community-wide *expectations* of responsible contribution and sometimes by other people.

4. Social organization involves *collaborative engagement* in family and community endeavors, with *flexible leadership* and trust in learners to take initiative, along with others who also participate at a calm mutual pace.

5. Communication occurs through coordination of shared endeavors through *articulate nonverbal conversation and parsimonious verbal means*, as well as through narratives and dramatization that contextualize information and ideas.

6. The goal of education is *transformation of participation*, which involves *learning to collaborate, with appropriate consideration and responsibility*, as well as learning information and skills to be responsible contributors belonging in the community.

7. Assessment includes evaluation of the success of the *arrangements* as well as the learner's *progress, in support* of learners' contributions, *during the endeavor. Feedback is direct*, from the outcome of learners' efforts and the acceptance (or not) by others of the efforts as productive contributions. (Rogoff, 2011)

This chapter focuses on the first three facets in examining research on children's collaboration and helping with initiative and keen attention to ongoing events. In addition, our suggestion that the cultural value of being *acomedido/a* helps understand Mexican-heritage children's collaboration and helping with initiative highlights an aspect of the fifth facet.

After reviewing research on cultural differences in helping and collaboration, we argue that the cultural value of being *acomedido/a* contributes to the explanation of cultural differences in studies of helpfulness and collaboration, and we draw attention to cultural differences in keen observation and listening, which are an important part of knowing when to pitch in and help. We also relate cultural differences in collaboration and helping to historical changes in the circumstances of and assumptions about childhood in the United States and Mexico. We argue that children's prosocial development is based not only on the growth of individual children but also deeply reflects the social organization and valued practices of their communities.

## Collaboration among Mexican and Indigenous-Heritage Children of the Americas

### *Cultural Differences in Children's Extent and Means of Collaboration*

To our knowledge, all of the available investigations comparing cultural backgrounds find more, or at least as much, collaboration among Indigenous and Indigenous-heritage and Mexican children as compared with those with less experience with Indigenous practices, including European-American children. Several of the studies have uncovered different ways of coordinating among children from different backgrounds.

Mexican-heritage children have shown a more cooperative orientation than European-heritage children in game situations (Kagan & Madsen, 1971, 1972; Knight & Kagan, 1977; Nelson, Kagan, & Gumbiner, 1982). Also, Mexican-heritage children from regions of Mexico with Indigenous history more often attempted to become collaboratively involved in their sibling's toy-building instruction than did Mexican-heritage children whose parents had extensive experience with Western schooling (Silva et al., 2010).

A study of sibling collaboration found widespread collaboration but with different ways of coordinating among the three siblings (Angelillo & Rogoff, 2005). Sibling triads, aged 5 years to 15 years, spent almost all their time collaborating as a threesome or at least touching base with each other in exploring a miniature museum exhibit, in both European-heritage and Mexican-heritage children from the United States (with mothers averaging 17 grades and 8 grades of schooling, respectively). In an average of only 7% of the time segments for both backgrounds were any of the three siblings not coordinating with or monitoring the others.

However, the ways that the children coordinated with each other varied in the two backgrounds (Angelillo & Rogoff, 2005). The European-heritage U.S. siblings usually coordinated with each other by dividing up access to the exhibit by explicitly negotiating whose turn it would be (in 62% of the 30-second time intervals). They often interrupted each other's exploration agendas and discussed how to manage turn-taking, whose turn it was, and how long turns would be; their turn-taking negotiations sometimes included friction: "But you've had a lot of turns. We haven't even gotten to touch that thing." Among the Mexican-heritage U.S. sibling groups, turn-taking occurred half as often (in 31%

of the time intervals in which the siblings were coordinating with each other), and when turn-taking occurred, it generally was smooth and undisputed, with few interruptions of each other's turns. The Mexican-heritage U.S. siblings' intervals of coordination without dividing up turns often seemed to involve coordination by fluidly blending their agendas together, combining their interests.

Turn-taking may be a strategy, like division of labor, for subdividing an activity or access to resources, contrasting with engagement together with a common agenda. European-American children relied on turn-taking more than Navajo children when pairs of 9-year-olds were asked to teach a 7-year-old to play a game (Ellis & Gauvain, 1992). When asked to work on group projects, Warm Springs Indian students in Oregon worked together effectively without intervention from the teacher, whereas Anglo students often disputed over turns, who would lead, and how to carry out the tasks, requiring teacher intervention (Philips, 1983).

Similarly, European-American middle-class mothers commonly regulated their toddlers' and young children's access to desired objects through turn-taking, and they reported enforcing turn-taking to manage disputes between their young children; these strategies were almost never used or reported by Guatemalan Mayan mothers (Mosier & Rogoff, 2003). The Mayan 3- to 5-year-olds often got access to a desired object by blending agendas with the toddler, such as by helping the toddler with the object or enhancing the toddler's efforts with the object, rather than trying to get it away from the toddler, unlike the European-American middle-class 3- to 5-year-olds. The Mayan siblings' collaboration with the toddler involved little intervention from their mothers.

Fifth- and sixth-graders in a Mazahua Indigenous community (in central Mexico) worked in small groups with smooth and flexible roles, in figuring out how to install panes of glass into window frames in a school construction project:

Each decided what to do and when to do it by coordinating his or her activities with the others of the group... At no time was there any sign of tension or of one member of the group disputing when another took over the more active role. Neither were there signs of children in any way asking or signaling when they were about to 'take over,' or that it was their 'turn.' On the contrary, there was no way to foretell when the role switching between performer and observer-supporter would take place. It was

smoothly done and, apparently at least, with no disagreements or negotiating.

(Paradise & de Haan, 2009, pp. 192–193)

### ***Cultural Differences in Staying Engaged When Not Directly Interacting***

There also appear to be cultural differences in remaining engaged when another child has a more active role. When their partner took a more leading role in instructing a younger child how to play a game, pairs of Navajo children remained more engaged than European-heritage children. The European-heritage children more often became sidetracked and inattentive or made statements that repeated or were unrelated to their peer's previous statements, whereas the Navajo children were more likely to extend or support information given by their peer to instruct the younger child (Ellis & Gauvain, 1992).

In a study of collaboration among U.S. Mexican- or European-heritage 7- to 9-year-old children constructing a three-dimensional wooden honeybee puzzle according to a model, Najafi and Rogoff (2007) also found differences in the children's collaboration and their staying on track when another child took the lead (*see* Fig. 41.2). The children's communities differed in Indigenous histories and experience in Western schooling across generations. The 13 European-American triads were from families with extensive schooling—their mothers averaged 14 grades of schooling and most of their grandparents had completed at least 12 grades of school, as is common among European-American populations (Bronfenbrenner, 1992). The 16 triads of children whose families had immigrated to the United States from Indigenous-heritage regions of Mexico had mothers with an average of 7 grades of schooling; their grandparents had usually completed less than 6 grades. (Most of the children were born in the United States; most of their parents were born in Mexico.) The children of both backgrounds had similar amounts of experience making 3D puzzles and model toys.

The Mexican-heritage children from a community with Indigenous history usually worked with at least one other child either in dyads or as a coordinated ensemble with all three children pitching in together and staying in touch, in 72% of the 30-second time segments, compared with 57% of the segments for European-heritage U.S. children whose families had generations of extensive experience with Western schooling (and related traditions). In turn, the triads of European-heritage U.S. children

**Figure 41.2** Three Mexican-heritage children work together to assemble a honeybee puzzle according to a completed model, in the foreground.

from families with extensive Western schooling had a higher proportion of segments in which they did not work with others in their triad (Najafi & Rogoff, 2007; *see also* Correa-Chávez, 2010), and they more often went off task. Occasions when one or two of the children were off-task for more than half of the 30-second segment were twice as frequent among the European-heritage U.S. triads than among the triads of Mexican-heritage U.S. children from a community with Indigenous history (23% of the segments versus 11%).

Thus, the comparative findings indicate that children from communities with Indigenous-American histories are more, or at least as, likely to collaborate than children from families with extensive Western schooling (and related) experience. The collaboration among children from communities with Indigenous American histories seems to be more fluid and less likely to involve turn-taking to divide the activity, and the children appear to be more engaged when not directly involved.

Children's collaborative strategies are likely to be related to familiarity with distinct formats for interaction, as they develop repertoires of cultural practice based on their experiences in the surrounding social and societal organization (Gutiérrez & Rogoff, 2003). This calls attention to the organization of the institutions and communities in which children and their families participate.

### ***The Organization of Collaboration within Families and Communities of the Americas***

Collaboration in family and community work from early ages is common in Indigenous and Indigenous-heritage communities of the Americas, including many Mexican rural communities (Cazden

& John, 1971; Deyhle, 1991; Lipka, 1991; Romney & Romney, 1963). Children often take on helpful roles where they are responsible for family work and caring for young siblings and for animals, contributing to celebrations and festivals, and serving as language brokers for their parents (Alcalá, Rogoff, Mejía-Arauz, Coppens, & Roberts, 2011; Delgado-Gaitán, 1987; Gaskins, 2000; González, Moll, & Amantí, 2005; Lorente Fernández, 2010; Maynard, 2002; Nájera-Ramírez, 1997; Orellana, 2001; Orellana, Dorner, & Pulido, 2003; Tharp, Estrada, Dalton, & Yamauchi, 2000; Urrieta, 2010; Weisner & Gallimore, 1977). Children's involvement in such activities is often more common in Mexican and Indigenous-heritage communities than in European-American middle-class communities (Farver, 1993; Telzer & Fuligni, 2009; Whiting & Edwards, 1988; Whiting & Whiting, 1975; Zukow, 1989).

The children's contributions often fit with the organization of family and community endeavors, which ethnographic work in various Indigenous-history communities characterizes as involving wide-ranging multi-way horizontal collaborations with respect for individual autonomy (Lamphere, 1977; Paradise, 1987, 1996; Paradise & de Haan, 2009; Sindell, 1997). For example, Pelletier (1970) described a form of horizontal collaboration in an Indigenous community in Canada where everyone contributed as they were needed, "observing and feeling" the process of life and work (p. 21). The collaboration was community-wide, exemplified by the smooth, horizontal organization of community events such as banquets and funerals. When outsiders tried to impose a hierarchical organization on such events, the organization of community events became much less effective.

The horizontal organization noted in a variety of Indigenous communities of the Americas resembles the teamwork described by Senge (1990) in very successful teams. Such teams show *alignment*, which is when a group of people function as a whole, complementing each other's efforts with common direction and harmonizing individual energies. "Individuals do not sacrifice their personal interests to the larger team vision; rather, the shared vision becomes an extension of their personal visions" (pp. 234–235). Senge illustrated these points with the alignment within leading sports teams and jazz ensembles that are "in the groove." The process includes spontaneity, innovations, and coordinated action, "where each team member remains conscious of other team members and can be counted on to act in ways that complement each others' actions" (p. 236).

### ***Solo Work Related to Western Schooling, in Contrast with Collaboration***

Solo involvement is common in Western schooling (Au & Mason, 1981; McCollum, 1989; Mehan, 1979; Philips, 1983). In classroom settings, biases sometimes occur against groups with cooperative social orientations, and competitive or solo-performance orientations are often favored (Widaman & Kagan, 1987). Common practices of Western schooling—such as enforcement of turn-taking, individual work assignments, individual rewards, and punishment of students who aid each other—may often discourage students from helping each other (Graves & Graves, 1983; Kagan, 1984; McClintock, 1974; Ramírez & Castañeda, 1974; Whiting & Whiting, 1975).

A contrast between cooperative adult-child and teacher-directed approaches is clear in a study asking Mexican Mazahua parents and non-Mazahua teachers to put together a market stall with a Mazahua child. The parents treated the children as part of the endeavor throughout, welcoming their contributions and suggestions as responsible and active collaborators (de Haan, 1999, 2001). In contrast, local teachers took charge, assigning and dividing parts and evaluating how well the task had been carried out. In general, the teachers did not engage with the children in the task and did not welcome their suggestions.

Family involvement in Western schooling (and related practices) may compete with experience with Indigenous community practices. Among families with extensive Western schooling, children's individual solo efforts may be encouraged in division of family labor and individual rewards. When students

become parents, their interactions with their children may reflect the practices related to schooling that they have experienced (Chavajay, 2006; LeVine et al., 1991; Mejía-Arauz, Rogoff, & Paradise, 2005; Richman, Miller, & LeVine, 1992; Rogoff, Mistry, Göncü, & Mosier, 1993).

For example, when Guatemalan Mayan mothers with extensive Western schooling constructed a puzzle with three related children, they took on a role resembling the managerial, hierarchical approach common among school teachers, often dividing the group into solo or dyadic teams (Chavajay & Rogoff, 2002; parallel results were found among other Mayan families interacting with fathers, *see* Chavajay, 2008). Mayan mothers from the same town whose families engaged in relatively traditional Mayan practices were more likely to interact with the three children in multi-way collaboration, with all of the participants working together in a coordinated manner where everyone contributed to the task.

Similarly, European-American and Mexican-heritage U.S. children whose mothers had extensive experience with Western schooling more often worked as dyads or alone in the presence of two other children, during an origami paper-folding demonstration (Mejía-Arauz, Rogoff, Dexter, & Najafi, 2007). U.S. Mexican-heritage children from communities with Indigenous histories more often collaborated as an ensemble with the two other members of the triad.

In a follow-up study, U.S. children of both European and Mexican heritage showed less collaboration as a whole group than children from three Mexican backgrounds. However, no differences appeared in extent of collaboration among children residing in communities in Mexico that varied in Indigenous histories and in experience with Western schooling (Mejía-Arauz, Roberts, & Rogoff, 2008). The authors suggested that the social organization of the children's schooling might have canceled out the expected differences in the social organization that might occur in their families. The Mexican children whose mothers had extensive Western schooling attended a school that encouraged collaboration, whereas the Mexican children from a historically Indigenous town (and whose mothers had only basic schooling) attended a school that emphasized solo work. It makes sense that children's modes of working together are related not only to their families' practices but also to their experience in school (Matusov, Bell, & Rogoff, 2002). Children's collaboration and helping develop with experience

with their communities' practices and institutions, which may vary in values regarding collaboration and helping.

In addition to their experience with the practices of schooling, families with extensive schooling are likely to have experience with a whole constellation of related practices that are often characteristic of middle-class cultural traditions. Beyond providing experience with a distinctive form of social organization where helping others is often discouraged and children's work is often solo, extensive Western schooling connects with a set of related practices. These include bureaucratic occupations, cosmopolitan living arrangements, small nuclear families, age segregation, and limited contributions by children to child care and family work, as well as less likelihood of being involved with traditional Indigenous practices (Rogoff & Angelillo, 2002; Rogoff, Correa-Chávez, & Navichoc Cotuc, 2005).

In the next section, we offer the idea that the collaborative orientation of children and their families in Indigenous and Indigenous-history communities may be understood in the context of a cultural value system that emphasizes helping with initiative, that is, being *acomedido/a*.

### **A Cultural Value Promoting Helping with Initiative: Being *Acomedido/a***

The cultural value of being *acomedido/a* may relate to the extent of collaboration and helping among Mexican-heritage children. According to interviews by López (in preparation), many Mexicans define being *acomedido/a* as helping not because one has been asked to but because one acts on an opportunity to pitch in. Such coordinated and collaborative interactions are characterized by ready helping.

The cultural value of being *acomedido/a* has rarely been the topic of academic discourse. We have only found the work of González (2001, 2006), who described being *acomedido/a* as being able to accommodate to the surroundings and make oneself useful. González described this as a common teaching among Mexican parents, to teach children to be *acomedido/a(s)* to fit in wherever they may find themselves by being able to empathize with others' needs in order to work collectively. She described the mothers' narratives in her study as teaching their children to be aware of their surroundings and interpret sometimes hidden meanings to what is said.

We speculate that the value system of being *acomedido/a* may stem in part from an Indigenous emphasis on collaboration, collective action, and horizontal social relations where everybody helps out. The concept of *tequio* (derived from the Nahuatl word *cuatequitl* meaning communal work) is a way that work is organized to benefit the collective. This is a practice that has been prevalent in Indigenous communities of Mexico, apparently since pre-Hispanic times. It involves service or work for a community project such as constructing roads, other public service projects or the introduction of new services such as formal schooling, potable water, and clinics. *Tequio* has been essential for marginal communities as one of the most vigorous institutions for perseverance and solidarity of the community; it is sustained with egalitarian discourse (Warman, 2003). The practice of community contributions has also been adapted to reflect modern day realities. Many Mexican immigrants in the United States routinely send money to build infrastructure and prepare fiestas for towns in which they no longer physically live.

The concept of being *acomedido/a* fits with ethnographic research that indicates that collaboration and helping is expected and often voluntarily offered among Indigenous-heritage and Mexican-heritage children (de Haan, 2001; Delgado-Gaitán, 1987; Lamphere, 1977; Paradise, 1996; Tharp, Estrada, Dalton, & Yamauchi, 2000; Valenzuela, 1999; Weisner, Gallimore, & Jordan, 1988). In many Indigenous Mexican-heritage and Mexican-American communities, children readily contribute to ongoing activities in responsible helping relations, especially in caring for younger children and in multi-age teams responsible for family work (Delgado-Gaitán, 1994; Maynard, 2002; Orellana, 2001; Ramírez & Castañeda, 1974).

For example, all 3- to 17-year-old children in a formerly Nahuatl town near Mexico City helped in their families' household, farm, and forestry activities from 3 to 7 hours daily and reported that their activities were satisfying (Ramírez Sánchez, 2007). In another Indigenous-heritage town in central México, children spontaneously join their elders in a complex organization of collective voluntary work (*cuatequitl*). "In the absence of any coercive attitude or pressure in order for them to do their work, children are enabled to find the jobs they like best, always in coordination with others" (Corona & Pérez, 2005, p. 8). Older children in Mexican heritage families in the United States and in Mexico

often help and guide younger children in how to do things like braid hair, tie shoes, carry out chores, and do homework (Azmitia, Cooper, García, & Dunbar, 1996; Valdés, 1996).

In cultural contexts where prosocial behavior and social responsiveness are important values, a reciprocal orientation is expected. Childhood is a system of reciprocity and exchange among the Nahuas of Tlaxcala, Mexico, where everyone helps members of their family, especially those in the same household (Ramírez Sánchez, 2007). The Nahua children in Tlaxcala claim not to be working even when heavily involved in family work. They describe their involvement as just “helping” as a matter of being part of the family, and regard “working” as paid work outside the family.

### ***The Centrality of Initiative in Helping***

In helping others without being asked, children act with initiative and also with a sense of interdependence with others (Kartner et al., 2010; Paradise & de Haan, 2009). Among the Mazahua of Mexico, “children learn to behave in ways that produce a high degree of apparently unplanned coordination, cooperation, and integration, yet [with] each individual child [following] his or her own path without being ‘organized’ by anybody else” (Paradise, 1987, p. 206).

Comparative studies indicate that Indigenous-heritage Mexican children more often pitch in to help with family activities with initiative, simply as members of the household, compared to Mexican-heritage children whose families have less connection with Indigenous practices and more experience in Western schooling (Alcalá et al., 2011). Mexican Indigenous-heritage children often underplayed their extensive contributions to household work and spoke of their work in collective terms, whereas Mexican children whose families had extensive schooling played up their more limited contributions in individual terms (Coppens, Alcalá, Mejía-Arauz, & Rogoff, 2011). However, Mexican children of both backgrounds claimed that children should help their families by pitching in to help with household work, simply to be responsible, like anyone else in the family.

Such helping with initiative has also been found in classroom settings with Indigenous and Mexican-heritage children. Inuit (Canadian) children have been found to share information in order to help their peers (Eriks-Brophy & Crago, 2003). Inuit children often walked around the room to

observe and directly interact with their peers; this was described by Inuit teachers as “students helping each other” (Eriks-Brophy & Crago, 2003). Though such behavior is often penalized, this method may be a primary form of classroom interaction for some students (Delgado-Gaitán & Trueba, 1985; Mercado, 2001; Paradise & de Haan, 2009; Trueba & Delgado-Gaitán, 1985). It may reflect the value placed on helping with initiative, in the concept of being *acomedido/a*.

### ***A Study of Children Helping with Initiative***

During an origami paper-folding demonstration, cultural differences appeared in the extent to which children helped each other with initiative or in response to other children’s requests for help (such as when another child asked “Can you show me how to do that?” or “How did you do that?” or slid the paper figure toward the child with an imploring expression; Najafi, Mejía-Arauz, & Rogoff, 2005). Triads of 6- to 10-year-old children were from one of three cultural backgrounds in a California town that has a high proportion of immigrants from rural regions of Michoacán and Jalisco, Mexico: 10 triads of U.S. Mexican-heritage children from backgrounds likely to include experience with Indigenous practices (with mothers who had completed an average of 7 grades), 10 triads of U.S. European heritage middle-class children whose mothers had completed an average of 15 grades, and 11 triads of U.S. Mexican heritage children whose mothers had completed an average of 13 grades.

A research assistant showed the children how to fold their origami figures, following a script that encouraged them to help each other as each child folded a paper figure. Most of the help given by the children was in the form of a demonstration, across all three backgrounds; there were also small amounts of fixing another child’s figure, monitoring and verifying another’s folding, and explanation (see Fig. 41.3).

The U.S. Mexican-heritage triads composed of children whose families are likely to be familiar with Indigenous practices (whose mothers had only basic schooling) often spontaneously offered to help other children, without being requested to help. They did so more often than triads of European-American and U.S. Mexican-heritage children whose mothers had extensive Western schooling (averaging 2.0 times versus 1.2 and 0.7 times, respectively). There were not significant differences between the backgrounds in the extent of

**Figure 41.3** A triad folds their origami figures; the Origami Lady is seated to the right, facing the children, just off camera.

help in response to another child's request for help. (However, children from the Mexican-heritage backgrounds with basic or extensive maternal schooling helped in response to 70% and 85% of other children's requests for help, respectively, compared with European-heritage children responding to 51% of other children's requests for help; Najafi, Mejia-Arauz, & Rogoff, 2005.)

Helping with initiative may support smooth coordination among members of a group. Thus a child who notices another child's error in folding could quickly reach over and offer help that is readily accepted. The pace of the activity would not be interrupted as it would if the child had to ask for help and then wait for it.

### ***Mexican Adults Explain "Being Acomedido/a"***

To examine the concept of "being *acomedido/a*," López informally interviewed 17 adults in Guadalajara, México regarding how they define and use the term. All 17 adults were familiar with the term and did not have trouble describing it. They reported that being *acomedido/a* connotes having human quality, humility, and *educación* in which one helps spontaneously, without being asked and without thinking of getting anything in return. It differs from simply helping in that helping can imply doing something from a feeling of obligation or having been asked, but in being *acomedido/a* the desire to help comes from within.

Many of the adults stressed that being *acomedido/a* has to do with the values that are inculcated early in childhood. One participant explained,

*Mi madre me enseñó a saber ayudar. Eso fue el primer conocimiento que yo tuve. Me dió responsabilidad desde temprana edad.*

[My mother taught me to know when to pitch in. That was one of the first things I learned. She gave me responsibilities at a young age.]

(54-year-old male taxi driver)

Participants were also asked if they felt there was a difference in the prevalence of the cultural value of being *acomedido/a* in different regions of Mexico, for example, in a small town or in a metropolitan city like Guadalajara or Mexico City. Of the 15 respondents who responded to the question, 14 (93%) said that people in small towns were more *acomeditos/as*. For example,

*Definitivamente sí, hay diferencias increíbles porque en el rancho se nota la diferencia y gente es como, y no quiero decir que es gente pobre porque también hay gente con lana pero sí, gente más sencilla, entonces hay gente con más de esa actitud.*

[Definitely, there's incredible differences because in the hamlets, you can see the difference and people are like, and I don't want to say poor people because there's also people with money but yes the people are simpler, there's people with more of that attitude.]

(29-year-old female research assistant)

Another respondent explained,

*Pienso que en la ciudad se da menos, como la gente anda tan a la carrera y tiene miles de actividades y como que ya no se da tan espontáneamente eso. A diferencia de las poblaciones más pequeñas, yo creo que sí se da más.*

[I think there's less of it in the city, because people are in such a hurry and have thousands of activities and it's like that isn't done as spontaneously. In contrast with smaller towns, I think it's seen more.]

(52-year-old female professor)

A 29-year-old research assistant explained that to be *acomedido/a*, one has to be aware of the surroundings, be attentive, and be ready to pitch in when necessary, knowing when and how to contribute. When asked about what it means to be *acomedido/a*, she responded:

*Yo creo que ser acomedido es tener sobre todo la iniciativa, o sea, como no esperar a que te lo pidan, sino tener esa iniciativa para hacerlo, pero también tener la visión y la sensibilidad de saber cuando es el momento para hacer las cosas. Y además, sí, tienes que a veces tener conocimiento de la situación porque si yo quiero ser acomedida en algo pero no sé de que se trata, pues a veces estorbas más de lo que ayudas.*

[I think that being *acomedido* is to have above all initiative, that is to say, not waiting to be asked, but having the initiative to do it, but also having the vision and the sensitivity to know when is the moment to do things. And also, yes, you do have to sometimes have knowledge of the situation because if I want to be *acomedida* in something but I don't even know what it's about, well sometimes you would disturb more than you help.]

A common proverb echoes this respondent's explanation that one does not want to be a nuisance when helping because of not knowing what is going on, but rather useful by being alert and ready to help: "*El acomedido siempre queda mal* [the *acomedido* person always winds up looking bad]." This proverb highlights the importance of keenly observing ongoing activities and knowing when and how to pitch in. People are sometimes criticized for being too *acomedido/a(s)* if their actions are interpreted as being in others' business. Thus, the concept of being *acomedido/a* involves being attentive, keenly observing surrounding events, to be able to appropriately pitch in with initiative.

### ***Keen Attention as a Basis for Taking Initiative in Being Acomedido/a***

Keen attention to surrounding events is essential to being *acomedido/a*, to know when and in what way to pitch in. Comparative studies indicate that children from communities with Indigenous American histories more often attended keenly to an interaction not directed toward them, compared

with children with less connection with Indigenous practices and more family experience in Western schooling (Correa-Chávez & Rogoff, 2009; López, Correa-Chávez, Rogoff, & Gutiérrez, 2010; Silva, Correa-Chávez, & Rogoff, 2010; Silva, Shimpi, & Rogoff, 2009).

Traditionally, in Indigenous communities of the Americas, observation has been a prevalent method of learning that includes children's active engagement in the range of their community's work and social activities, as they learn through intent community participation (Chamoux, 1992; Corona & Pérez, 2005; de Haan, 1999; de Leon, 2000; Rogoff, 2003; Rogoff et al., 2003, 2007). For example, adults in a Mazahua community in Mexico describe observation as a more crucial and direct way of conveying knowledge and learning than actually giving directions during work situations, especially when dealing with more complex skills and knowledge (de Haan, 1999). Because young children are regularly included in a wide range of social and productive activities of their community, they are often in a position to observe and listen to ongoing events, and they are expected to pay attention to be able to contribute to them. In turn, such inclusion seems also to encourage children's active interest in knowing what is going on and in contributing to it (Paradise & Rogoff, 2009).

### **Distinct Conceptions of Childhood**

Historically, several distinct conceptions of childhood met up and are interwoven in the lives of families with roots in Indigenous communities of Mexico: those stemming from Indigenous practices and values and those that came with Spanish, British, French, and U.S. formal schooling and colonization. In communities where learning through intent community participation is prevalent, children are often included as participants in the community along with everyone else and are encouraged to pitch in helpfully (with or without use of the term *acomedido/a*). They are treated as people whose contribution and initiative are valuable to the group.

In contrast, in modern Western societies childhood is often treated as a period of continuous dependency in which children are considered not to be able to act independently (Strathern, 1988). In this sense, children are consumers of care and are seen as inadequate to meet their needs of being clothed and fed through production activities (Hecht, 1998; Ramírez Sánchez, 2007).

In Mexico, current childrearing practices of the middle class, such as child-focused activities and age segregation, were highly influenced by discourse regarding childhood at *los Congresos Panamericanos del Niño* [Panamerican Congress on Children], which began in 1916 (Corona Caraveo, 2003). During 1916 to 1935, discussions on childhood revolved around “improving the race,” focusing on the majority of children who were impoverished children of Indigenous communities, mestizos, *negros* (of African descent) and *criollos* (of European descent) whom the state tried to “purify” racially. The goal was to make them more like children of the upper and middle classes, whose childhood was populated with toys, children’s literature, and child-focused educational methods. The middle-class household was considered a private domain and children’s education was considered a tool to open doors for individuality in life, without collective goals. This concept differed radically from childhood in rural and farmworking communities where members defined themselves in terms of collective work and solidarity. According to authors of this time (1916–1935), there was no clear differentiation between adult and child work, in contrast with the upper and middle classes (Corona Caraveo, 2003).

Social welfare programs have had heavy influence on how childhood has been viewed in Mexico. Compulsory schooling took effect in Mexico in 1917 for grades 1–6 and in 1993 for grades 7–9, although many children continued to drop out before completing 9th grade (*Ley General de Educación*, art. 4). The *Oportunidades* program (which began in 2002, but formerly operated as *Progresá* since 1997) provides cash payments to low-income families in exchange for regular school attendance as well as family participation in talks aimed at changes in parenting, producing social and cultural transformations (Escobar Latapí, 2009). These programs have segregated children from the range of activities of their communities and discouraged children’s contributions to the ongoing work of their families and communities.

However, views on childhood in Indigenous and Indigenous-heritage communities can still be contrasted with those of Western societies. For example, children in a Tlaxcala Nahua community are still considered contributors to the family’s economy, although now they attend school. “Work plays a key role in that period of life rather than being a problem that undermines and harms children” (Ramírez

Sánchez, 2007, p. 90). The definition of a good child in this community includes “being a child that helps out,” which is similar to ideas related to being *acomedido/a*. As one participant in this research explained, people do not want to be labeled or want their children to be labeled as *desacomedido/a* (unacomedido/a). Ramírez Sánchez (2007) describes work and *icnoliz* (the Nahuatl word for respect) as going hand in hand, where the reward of work is to give respect as well, and mutual respect is instilled to maintain good relationships. In this Nahua community, the child is seen as a complete social actor from the moment of birth, contrasting with ideas in Western societies where childhood is conceptualized as dependence on adults and a child must go through several stages to learn to be a contributing member of their community.

### **The Importance of Individual and Cultural Processes in Research on Human Development**

Throughout the twentieth century, psychological research on childhood was oriented around controlled research situations that produced a tendency to examine developmental processes and mental functions of childhood without consideration of cultural or historical processes (Cole, 1996). During the second half of that century and since then, the role of culture and social arrangements in children’s development has become clear, thanks to the work of many scholars, especially the Whittings, Bronfenbrenner, Bruner, Cole, and Scribner, and the influence of Vygotsky.

In order to understand helpfulness and collaboration in Mexican-heritage children, the family and community practices in which children participate need to be examined, moving away from focusing solely on individuals as they mature or assuming that their environments match those in which the researchers grew up. Childhood and family functions are tied to the histories of communities and nations, including their education policy, nationalism, and colonization.

In particular, the cultural value of being *acomedido/a* appears to be related to Mexican national and Indigenous communities’ interrelations. The Indigenous practices of inclusion of children in nearly full community functioning may be a source for the cultural value of being *acomedido/a*, even in the face of industrial and colonial pressures to individualize. Indigenous practices may even have spread to the colonizing populations, yielding

cultural values that persist for many Mexican and Mexican-immigrant populations beyond particular Indigenous communities. This may help to explain the widespread findings of collaboration and keen attention among these populations.

We have tried to move beyond the view of helpfulness and extent of collaboration as solely individual characteristics and have suggested that a view of community dynamics is necessary to understand such practices. The cultural value of being *acomodado/a* sheds light on research on helpfulness and collaboration among Mexican-heritage and Indigenous-heritage communities of the Americas.

Likewise, analyses of cultural values and practices can illuminate the extent and means of collaboration and helping among children who have experience with other cultural practices, including those of Western schooling. Historical analyses are indispensable to understanding the origin of such values and practices in the context of the roles of children in a community. Historical analyses are key to understanding the dispersal and transformations of cultural practices with changes across generations and with contact and mobility of communities. The study of childhood needs to take into account worldwide changes and conditions in which children are developing, contexts that may be distant from the conditions that inspired psychological theories based on recent Western cultural traditions.

## Acknowledgments

We are grateful for the participation of the children and the assistance of the teachers and principals of Starlight, Valencia, Loyola Village, El Dorado, and Sierra Vista Elementary Schools in the research reported here. We especially thank Eileen Fuller, Noni Reis, Maureen Callanan, Catherine Cooper, and Nameera Akhtar. The research was carried out with support from CONACYT (Mexico), a traineeship from the National Institute of Health (1 T32-MH20025), a grant from the National Science Foundation (Grant No. 0837898), a UC Santa Cruz Presidential Dissertation Award, and the University of California Santa Cruz Foundation endowed chair held by Barbara Rogoff. Author Mejía-Arauz is now affiliated with the ITESO University in Guadalajara, Mexico.

## A Cultural-Historical Approach to University/Community Collaborative Interventions

Deborah Downing-Wilson, Robert Lecusay, Ivan Rosero, and Michael Cole

### Abstract

In this paper we explore approaches to intervention research viewed from a broadly conceived cultural-psychological perspective. Although scholars who adopt this perspective share a belief in the centrality of culture in human development, they may differ in how they conceive of culture and how it enters into and participates in human thought and action. We examine two cultural-psychological strategies for developing and sustaining innovative educational environments: design experimentation and mutual appropriation. *Design experimentation* is an approach in which researchers and practitioners collaborate to simultaneously engineer innovative learning environments and understand salient aspects of human cognition and learning. They do so by developing and implementing, in a specific educational setting, a version of a learning design and iteratively revising this design in light of results from each implementation. *Mutual appropriation* refers to interventions in which the nature of the intervention is not prespecified, but negotiated among participants over time. We examine these approaches by introducing two examples of university-community research and educational collaborations. The first collaboration, The Beach Boys & Girls Club, is an example of an intervention based on the principles of design experimentation, while the second, the Town and Country Learning Center, illustrates the mutual appropriation approach. Through this comparative examination of the two intervention perspectives, we endeavor to show that a mutual appropriation approach can help the field create interventions that are themselves developmental in their fundamental methodology.

**Keywords:** Cultural Historical Activity Theory, Design Experiment, Intervention Research, Learning Ecology, Mutual Appropriation.

In this chapter we posit two strategies for designing, implementing, and seeking to sustain collaborative intervention programs located in community settings during the after-school hours. Both systems involve cooperation between university groups (undergraduate and graduate students as well as professors) and community organizations (children and their adult caretakers). Both are intended to create new forms of activity, the motive of which is to promote the development and well-being of the participants and the organizations from which they come. Both instantiate a variety of principles of learning, development, and instruction derived from the work of Vygotsky

and his followers working in the tradition of Cultural-Historical Activity Theory (CHAT).

Our discussion centers on the ways in which the two strategies differ with respect to how the relationships are established, how they are structured, and how the activities are organized in response to the needs of the respective communities, the participants involved, and the resources available. The first strategy adheres most closely to what has come to be called "*design experimentation*." The second strategy follows a logic that we refer to as "*mutual appropriation*." We argue that both approaches have their merits and their challenges. Through the creation of functional

systems of interactions appropriate to their historical/sociocultural/ecological circumstances (local and global) they require us to focus on culturally organized activities in their institutional settings as units of analysis. Both provide useful ways to bridge the gap between standard, laboratory-style experimentation and situations-of-use, which include the broader sociocultural environment beyond the immediate circumstances under investigation.

## Design Experimentation

In the early 1980s, Ann Brown and her colleagues embarked on a series of classroom-based studies focused on guided instruction and assessment in social contexts. These studies challenged mainstream psychology and education research, creating what Brown and Campione called "... a sea of change in theories of learning... an awakening to the fact that real-life learning is intrinsically entangled with situations" (Brown & Campione, 1998, p. 154). Brown (1992) and her colleague, Allan Collins (1992), referred to this new methodology as "design experimentation." They viewed design experiments as a serious alternative to, or supplement to, randomized, tightly controlled research paradigms. In recent years the idea of design experimentation has been taken up by a number of researchers interested in advancing theories of learning and development (see the special issues on this topic in the *Educational Researcher*, 2003; and *Journal of Learning Sciences*, 2004). Despite differences among them, proponents of design-based research are likely to agree with three principles that will be central to our discussion:

1. "The metaphor of ecology is used to emphasize that designed contexts are conceptualized as interacting systems rather than a collection of activities or a list of separate factors that influence learning. Ideally design experiments offer a greater understanding of a learning ecology by designing its elements and observing how these elements work together to support learning. Components of a learning ecology typically include the learning activities or achievement goals that are set for the students, the types of discourse and ways of participating that are encouraged, the material artifacts provided, and the practical means through which relations among these elements can be orchestrated." (Cobb et al., 2003, p. 9)

2. For design experiments to achieve its goals, it is necessary to conduct iterative embodiments of the designed pedagogical activity. Collins and his

colleagues (2004, p. 18) summarized this aspect of the approach as follows:

"Design experiments were developed as a way to carry out formative research to test and refine educational designs based on theoretical principles derived from prior research. This approach of progressive refinement in design involves putting a first version of a design into the world to see how it works. Then, the design is constantly revised based on experience, until all the bugs are worked out."

3. Those who adopt design experimentation as a method also argue that it is important to study a wide variety of "authentic" (DBRC, 2003) or "natural" settings or "contexts" (Barab & Squire, 2004; Cobb et al., 2003).

The first line of research we discuss was carried out very much in the spirit of design experimentation as characterized above, although, with a somewhat different orientation both toward the relationship between tasks and their settings and with respect to the expectation that all the "bugs" would be, could be, or should be worked out.

## Intervention through Mutual Appropriation

In a follow-up paper on design interventions, Brown and Campione (1998), having by this time had several more years of experience implementing their idea of "communities of learners," introduce the idea that not only do design experiments *seed* the environment with ideas and concepts that *take root* in the community, *migrating* and *persisting* over time, but participants *appropriate* these ideas and concepts, reshaping and deploying them in unpredictable ways through personal interpretation and experience. They used the term, "*mutual appropriation*" (a term they attribute to Newman, Griffin, & Cole, 1989) to describe this transformation of the original design experimentation concept. In using the term "mutual appropriation" as an explicit alternative to the idea of design experimentation, we should note that we are applying the idea at a different level of analysis than that deployed by Newman et al., who were seeking to describe the bidirectional quality of participant learning in a zone of proximal development (Newman, Griffin, & Cole, 1989). In the present context, "mutual appropriation" is used to characterize the interactions between organizations representing those who are doing the intervening and the partner organization in which, in the spirit of Long's (2001) work on "developmental sociology," both university and community participants

attend to each others' attempts to "appropriate, manipulate, subvert or dismember" (p. 233) particular new initiatives introduced by their partners in the process of their ongoing joint activity. However, contrary to the usual negative implications of such terms as "subvert" and "dismember," our experience, following our own version of a mutual appropriation approach, sees these features of the intervention process as perfectly normal and healthy. They are required for reciprocity, in which the both sides of the interaction (organizationally speaking) are doing their best to achieve the common goals that anchor their continued interactions, while staying focused on their individual activities, which may or may not mesh perfectly with those of the other participants.

### **Resisting Dichotomizing: Some Common Principles of Our Two Interventions**

Up to this point we have been focused on drawing a distinction between the two strategies of intervention research for purposes of setting up a useful comparison. But it would be foolish, in our view, to draw too clear a distinction between the two approaches as we have experienced them. The distinctions matter, but the two interventions, despite important differences (perhaps unsurprisingly because they were carried out by the same research group) share certain theoretical assumptions concerning the nature of desirable environments for promoting development of children and undergraduates as a result of collaborations, under either of the two contrasting interventionist banners. Consequently, before digging more deeply into the differences between the two intervention strategies as we have practiced them, we stop to consider the assumptions common to both lines of research. These assumptions played out differently in the two research projects, but as ideals to be sought for, they are shared presuppositions on our parts, even though they were differentially shared with our community partners, who have their own ideas on the subject.

1. The intervention strategies reported on here are both joint undertakings between a university and a community institution. In both strategies the university brings theoretically guided experience and expertise at building activities and artifacts that promote learning and development, as well as supervised undergraduates to the community institution as labor. The community

institution furnishes local experience, children, space, equipment, and supervision of the activities to provide the undergraduates with a valuable research experience.

2. The programs are mixtures of "leading activities" (as proposed by cultural-historical activity theorists, e.g., Elkonin, 1999) including affiliation, play, learning, peer interaction, and work. The physical location can be crucial to shaping how play, learning, and other leading activities are combined. For example, rules of decorum in a school or library encourage quiet attentiveness but discourage play. Rules of decorum at a Boys and Girls Club or a HUD Learning Center may afford a great range of possibilities for engagement, play being one prominent possibility, but also offer constant invitations to become distracted from the task at hand.

3. Whenever possible, participant structures are designed to minimize power differentials between the participants, particularly between the undergraduates and the children with whom they work. The issue of participation structures and power differentials is also greatly affected by the combination of sponsoring institutions and the concrete activities that are the focus of the collaboration. In both of the cases we examine, formal education in the form of homework was considered mandatory by the local community participants, and the rules for "homework time" were different than those for "enrichment time." Parents from different ethnic backgrounds may demand from their children higher levels of deference to adults and educators than we are accustomed to. In addition, the age of the children involved interacts with both the nature of the institution and the parental cultural expectations to shape authority relations.

4. Heavy emphasis is placed upon the value of communication in a variety of media including computers, conversation, and writing, in the service of solving goals that are provided within the activity setting. Not only is "the thought completed in the word" but in other forms of externalization that enable the transformation of sense into meaning (Vygotsky, 1987). Consequently, the principle of forefronting the use of a variety of communication means is one of the central principles governing our pedagogical intervention research. The ways in which this principle is embodied in the activities varies enormously, depending on the institutional venue, the availability of computers and other digital technology resources, the age of children involved,

and the expertise of the participants, both local and from the university.

5. Participation by the children is voluntary. Children are free to leave at any time. Consequently, the games and other activities that participants engage in must adhere to goals that the children find compelling. In practice, the principle that children should not be forced to engage in the activities is routinely breached at times when homework is mandated by the local adults representing the community organization. Nonetheless, this norm is maintained in as many activities as possible and routinely produces strong affective bonds among the participants after as few as 9 weeks.

### ***The Design Experiment Intervention: The Fifth Dimension***

The Fifth Dimension (5th D) is an after-school activity system designed for elementary-school-aged children. University students enrolled in a course that focuses on fieldwork in a community setting visit these after-school sites to play, work, and learn as the children's partners. A detailed account of the history, design, and implementation of the 5th D model can be found in Cole and the Distributed Literacy Consortium (2006).

The activities at these sites are designed to instantiate the principles summarized above. This is done using a variety of artifacts including educational computer games, written instructions for playing these games in a goal-oriented, collaborative manner, artifacts for distributing the children's and the university students' use of the games, and imaginary figures (instantiated via letters, email, or electronic chat) that interact with the participants to encourage them to externalize their thinking and critically reflect upon their joint activities.

### ***Evaluating the Fifth Dimension Interventions***

A variety of analytical methods have been specially designed to evaluate the usefulness and shortcomings of the 5th D principles and the resulting activities and programs (Blanton et al., 1997; Cole & the Distributed Literacy Consortium, 2006; Mayer, Schustack, & Blanton, 1999). The specific data sources used by different implementers of a 5th D (approximately 40 different research groups from different parts of the world) depend heavily upon the expectations of their local communities, the professional criteria of the academic disciplines they answer to, the specific interests of the

investigator, the social ecology of the activity, and the resources available to them. Evaluations have included videotaped records of 5th D participant interactions, data mining of student fieldnotes, questionnaires, on-site observations by third-party spectators, and indices of the monetary support provided by both the university and community institutions.

Looking first to the 5th D activity systems as an ensemble, perhaps the most striking result is that both the particular combination of activities and the form of the individual activities that evolve from the initial design are highly sensitive to local constraints and resources. No two 5th Ds, even when implemented by the same researcher with the same group of undergraduates in two community organizations of the same kind in highly similar communities, behave like replicas of each other. Within a period of months, if not weeks, each system takes on its own characteristics, a blend of values, norms, and practices characteristic of the local institution (its staffing, architectural structure, its location in the community, etc.) and its university partners (who may be from backgrounds in a variety of social science disciplines, sophomores or seniors, predominantly of one ethnic group or several, etc.).

Tracing implementations in widely disparate conditions quickly reveals that some 5th Ds have failed to survive initial meetings between universities and potential community sponsors. Others have been implemented and run successfully, only to cease operation after less than a year as a result of inability to satisfy institutional imperatives that went undetected in the startup phase. Some 5th Ds have continued to a point where the two collaborating institutions discover that they do not really share a common vision of a good developmental environment for children. Some have been forced to close when the level of continuity in staffing (on either the university or community side) is inadequate, degrading the quality of the ensuing activity. Still others have continued for several years, but coincidence of several "risk factors" (decreased funding, loss of key personnel in two or more parts of the system) have led to their demise despite their recognized value. Finally, many implementations prosper and increase in scope, sometimes "giving birth" to new generations of 5th Ds. At the time of this writing, 30 years after the experiment began, dozens of 5th Ds and their associated university-community superstructures are in operation.

Evaluated in terms of a study of sustainability, the form of design experiment represented by the 5th D can be summarized as follows: (1) Provide a “starter tool kit” consisting of artifacts, rules, and standard roles as resources for creating the joint activity system; (2) begin with a central structure and core activities and watch them change over time in relation to the local setting; (3) seek to sustain the activity system as long as possible, focusing on the factors that threaten sustainability and the measures that are successful in extending the life of the ever-changing experimental design; (4) identify the factors precipitating the death of the program.

From this summary, it is clear that the 5th D is a kind of “upside-down” form of design experimentation. Instead of seeking to fine-tune a single design until the experimenter has “gotten it right,” the interest is in how a system of activities that has been shown to “get it right” when faithfully implemented, is pulled apart, rearranged, and melded with its social ecology (or expelled) in the course of joint activity between the partner institutions over a long period of time.

### ***The Beach Boys and Girls Club: A Concrete Example***

In the spring of 2006, the partnership between the Laboratory for Comparative Human Cognition (LCHC) at the University of California, San Diego UCSD and the Beach Boys and Girls Club (BGC) was the oldest in the UCLinks program and served as the prototype upon which a number of subsequent 5th D programs were modeled (*see* Cole & the Distributed Literacy Consortium, 2006 for details). At the time this project began (mid-1980s), the research team was determining to what extent new communication technologies could provide effective tools and legitimate motives for children to engage in reading, writing, and problem solving, and whether such technologies could also unite researchers with each other, universities to their communities, and different communities with each other. The team was also concerned with working out a means of *in situ* evaluation that would justify the amount of resources necessary to maintain such a program.

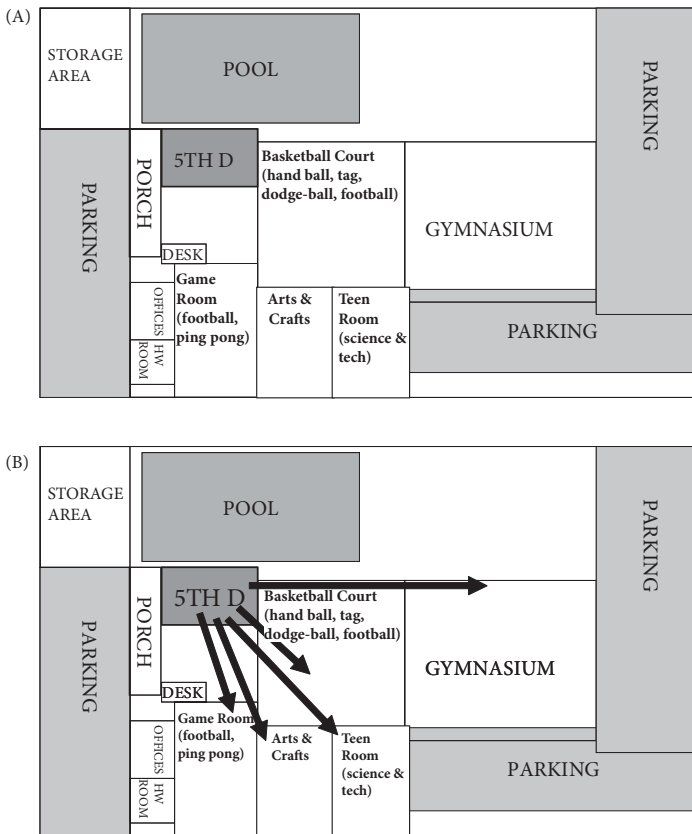

The BGC was located in a relatively affluent San Diego suburb. It sat next to a public middle school and across the street from a public elementary school. However, while the neighborhood’s population was mostly middle-class Anglo-American, there was a

sizable working-class Mexican-American minority. Among the school-age children, the Mexican-American population was considerably higher than it was among the adults, and many of these children attended the after-school program at the club. The BGC charged a nominal fee for participation, but children from families who could not afford the fee were given scholarships.

Figure 42.1 presents a schematic overview of the local ecology provided by the building in which the 5th D was housed. The 5th D was separated from the entrance-hall “control center” of the club by a large window wall, making the 5th D activities visible from most everywhere in the building. The opposite wall of the 5th D room had big windows that looked out on a large swimming pool, which was in constant use. The doors of the 5th D were always kept open, so children could come and go at will, as was true in the rest of the club. At any given time most of the areas of the club were populated by children engaged in a wide range of activities. Club policies changed slightly in keeping with the priorities of the current directors. At times the large central area would be blaring with rock music and children playing hopscotch, while at other times the current director would see that the children were engaged in one of the specialized activity rooms and the central area was quieter.

The 5th D program operated Monday through Thursday afternoons, competing on a “come as you choose” basis with other BGC activities. On any given day, five to eight undergraduates<sup>1</sup> and one or two graduate students, plus a “5th D coordinator” were present to interact with the children. Daily attendance at the BGC fluctuated between 30 and 40 elementary- and middle-school children. Typically 10 to 20 of these children participated in the 5th D program at some point in their afternoon stay.

In the early 1990s the partnership was structured so that the BGC provided the space and the administrative support associated with the running of the club, while the LCHC paid for most of the 5th D activities by employing a site coordinator, sharing in the cost of computers and software, and generally providing and maintaining the supplies necessary for the day-to-day running of the 5th D program. Unfortunately, the BGC experienced chronic staffing problems and the high turnover of BGC employees became an ongoing challenge for the 5th D program. In the fall of 1996, by prior agreement, the BGC hired and paid a site

**Figure 42.1** (A) Schematic overview of the Beach Boys and Girls Club. (B) Overview showing direction of influence in the instigation of change.

coordinator to run the 5th D, but the funding was insufficient to support a permanent employee. At times, former university students who had participated in the practicum served as coordinators for a school term, or a school year after graduating, but more often the club hired someone new, who was then trained on the job by 5th D staff.

### *Tracking Changes in the 5th D as a Learning Ecology*

BGC events showcased the friendly and relatively stable relationship between UCSD and the BGC. For example, children from the 5th D were recognized publicly on awards nights at the club, and at the end of each quarter a sort of going-away party was held as a ritual way of thanking the undergraduates and easing the pain of separation for both the undergraduates and the children, who often had formed strong bonds of affection. In addition, the BGC regularly advertised the presence of the 5th D in its publications. The relationship was also reflected in the BGC budget, which showed an increase over the years in the number of hours and the salary for the site coordinator, who also served

as the computer room staff member when the 5th D was not in session. On the university side of the partnership, the changing organizational arrangements for the practicum course provided opportunities to study issues of sustainability that few had anticipated in the beginning.

During the years of its operation, the 5th D morphed well beyond its initial design, although the “core of the activities” remained relatively unchanged: undergraduates and children played an ever-changing variety of computer games together, children advanced through the individual games on their way to the role of “Young Wizard’s Assistant,” and various unobtrusive ways of assessing children’s academic progress were studied. After many years of instability, the university had built hiring of temporary teaching staff into its budgetary and curricular regime, while the BGC had hired an extremely effective 5th D site coordinator, and the undergraduate students flocked to participate.

The inclusion of a variety of BGC activities, including arts and crafts, board games, and outdoor sports achievements within the 5th D’s regime of interaction, served to infuse the 5th D program into

virtually all of the BGC activities (see Fig. 42.1B). As a result, the 5th D program became the best-attended part of the programming offered by the BGC. However, in the summer of 2006, the BGC closed for renovation for a period of 2 years and the 5th D program ceased operation. An attempt was made to open a 5th D in a nearby BGC, but at that institution the program was not welcomed by staff who had worked out their own regime of activities. Unlike the Beach BGC, the children at the new club did not qualify as an underserved population, making efforts to sustain the partnership difficult to justify from the perspective of the university. When the Beach BGC did reopen 2 years later, the 5th D program was not reinstated. So, while 5th Ds continue to exist and prosper in many locations, this particular design, effective by many criteria, could not be sustained.

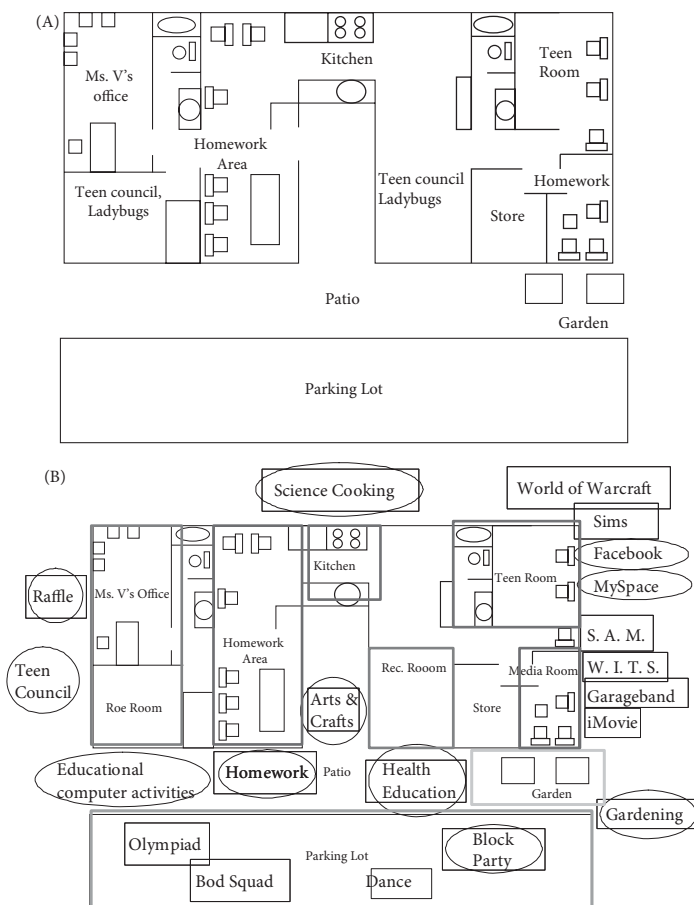

### Using the Mutual Appropriation Strategy: Town and Country Learning Center

In early 2007 the Director of Education of the San Diego Supercomputer Center (SDSC)

approached members of LCHC about establishing a Fifth-Dimension-style, university-community partnership in a local after-school community center. The site chosen, Town and Country Learning Center (T&CLC), is housed in a federally subsidized, 144-unit apartment complex called Town and Country Village. The complex is located in a neighborhood of South-Central San Diego, where the majority of the residents are African-American. Two adjacent apartments inside the complex have been converted to serve as a community/learning center for the exclusive use of the residents.

From the beginning it was clear that applying the 5th D model at T&CLC would be difficult, if not impossible. Neither the geography of the local center (see Fig. 42.2) nor the federally mandated expectation that adults as well as children could use the limited computer facilities, afforded a child-centered, relatively closed space that could serve as the hub of 5th D activities.

An added consideration was the program of structured educational and enrichment activities already

**Figure 42.2** (A) Schematic overview of the Town and Country Village Learning Center. (B) Schematic overview of the Town and Country Village Learning Center showing concentrations of influence. Key: Circle = T&CLC original activity, Rectangle = LCHC activity, Circle & Rectangle = hybrid activity.

in place for the resident youth. These activities were primarily organized by the site coordinator, Ms. V., and were geared toward helping the youth negotiate their personal as well as academic lives (e.g., book clubs, teen service projects (Teen Council), elementary-school-girl etiquette club (The Ladybugs), food sales). Responding to health concerns of some of the resident women, Ms. V. would also on occasion organize nutrition and exercise activities at the center. In the process of familiarizing ourselves with the circumstances on the ground, we simply joined in and tried to help Ms. V. with whatever it was she was already doing. When help was needed with homework, we helped with homework. When the computer network was unstable, one of our team members with a computer-science background helped stabilize the network.

During this time we kept in mind the possibility that individual activities that had proven successful in the 5th D system might be adapted for use in the T&CLC program. Of equal importance, we hoped that lessons from our past university-community partnerships could be applied in developing our relationship with Ms. V. and the youth at T&CLC, as well as with the broader community of residents in the apartment complex. It was out of these circumstances that the approach we are referring to here as “mutual appropriation” was born and is evolving.

What is emerging is a reflexive way of collaborating on the design of activities at the T&CLC that privileges and builds upon the already-established practices at the site. For purposes of exposition (since all of the resulting changes were linked in various ways to each other, not only in our activities at the site but in the way we organized the corresponding course at UCSD), we can crudely distinguish three parts to the mutual appropriation strategy that have so far emerged (*see also* Fig. 42.2):

1. Pre-existing activities that underwent changes because of the addition of 10 to 12 UCSD undergraduate students to the daily program.
2. Hybrid activities that arose from discussions among LHC participants, Ms. V., and the children/youth at the site.
3. New activities introduced by LHC that could fit into the ongoing structure of T&CLC but which depend critically on the presence of LHC and the special resources it brings to the site in the form of technology and expertise.

It is this more or less horizontal mixing of approaches, where leadership is exercised by both

sides of the partnership, that motivates our use of the term “mutual appropriation.” We have some history with the phrase, as discussed earlier in the paper, but here we’ve begun to think about mutual appropriation in new and specific ways. Not only do the partners in this project *mutually appropriate* the activities and the activity system in ways that further their own goals and the overarching goals of the program (in this case, to promote the development and well-being of all those involved) but the participants also strive to act in ways that are *mutually appropriate*, support, or at very least do not subvert, the efforts of the other players. Through mutual appropriation, so conceived, a yours-mine-ours activity system is able to spawn hybrid activities that neither of the original players could have conceived nor implemented on their own.

### ***Tracking Changes in the T&CLC Mutual Appropriation Model***

Before we began our collaboration with the T&CLC community, Ms. V., as the sole site coordinator, had the difficult task of organizing activities for a group of 20 to 40 participants who varied widely in age, interests, and consistency of attendance. She had to be strategic about the kinds of activities she developed because it was impossible for her to supervise all of these activities at the same time. In order to monitor the flow of youth in and out of the center, she locked all entrances except the one door that was in her line of sight as she sat at her desk. She distributed activities throughout the center according to age and proximity to her office, placing the younger children engaging in schoolwork in the areas closest to her, while the presumably more mature, self-reliant teenagers were allowed to work independently at the far side of the center.

That was our starting point. Over time, the structure and content of the activities changed depending upon who initiated the new, joint activities and the source of ideas for the innovation.

### ***Pre-Existing Activities***

As noted earlier, we began our partnership by helping out with the programs that were in place when we arrived. We started with homework—something we knew a lot about, but soon found that we would need to make some fairly substantial adjustments in our approach.

Ms. V. could not, as a practical matter, offer a great deal of individualized homework assistance, so her routine was to insist that the children com-

pleted assignments to the best of their ability before asking for help. Once undergraduates were present, the routines at homework time changed. Our desire to get the kids through their homework and leave time for enrichment activities that were the heart of our interests meant that we had to relax some of our power-leveling preferences and ask the undergraduates to take on more of a tutoring role than we normally like. Ms. V.'s request to do the tutoring quietly put further constraints on what in our view could have been time productively spent by the children and undergraduates delving deeply into the content of the homework. Asking the kids to finish their homework first and then get quiet help from the undergraduates created an atmosphere where "checking" homework was preferable to discussing it. Over time, however, we found compromises. Ms. V. eased her requirement that the children do their homework within eyesight of her office, and allowed some children to work with undergraduates in other areas of the learning center. When the weather was pleasant, tables would be moved outside and tutoring could take place without concern for making too much noise. These adaptations not only addressed the problem of a distracting homework environment, but allowed the undergraduates to tutor the children in deeper and more focused ways.

Another change that occurred, owing to our presence and the resulting increase in manpower, was that a concerted effort could be made to collect report cards and progress reports for each of the children. LCHC needed such information to document the effectiveness of its program and Ms. V. needed it for her own accounting purposes, but it was a time-consuming task that had routinely been pushed aside by more pressing demands. An unintended consequence of actually tracking children's progress in school was to bring to the fore severe deficiencies in the academic achievement of many of the children. This information led to discussions about how best to support the children in their current school assignments while simultaneously providing enrichment experiences that would fill in sometimes gaping holes in their knowledge that made independent completion of homework assignments impossible for many.

### **Hybrid Activities**

Over time, activities began to emerge that are best described as hybrids of ideas from the two sides of the partnership (see Fig. 42.2B). One illustrative

example concerns after-school snacks. A number of issues compromise the ability of T&CLC families to provide nutritious foods for their children. Not only are funds extremely limited for virtually all of the resident families at T&C, but local options for buying fresh food are virtually nonexistent and fast-food chains are ubiquitous.

As mentioned earlier, when we first started to work with Ms. V. and the residents at T&CLC, food sales were a regular practice designed for raising funds for basic materials at the center. Items for sale consisted primarily of prepackaged sugary or salty snacks, or easy-to-prepare items, such as nachos. The children were purchasers as well as purveyors of these snacks. The unhealthy quality of all these foods raised concerns for us. Ms. V. was well-aware of the health issues, but she was balancing the need to raise money and the kids' enthusiasm for consuming these familiar snacks against her concerns about health.

Early in our work at T&CLC we began to work out an arrangement in which we supplemented her monies for providing snacks. Of equal importance, we began to introduce new ways of engaging in the preparation of snacks, including the development of the Science Cooking Club. The club was initiated by a number of undergraduates who organized collaborative cooking sessions for the kids, complete with nutrition lessons that entailed Internet research to find nutritional information and recipes for food that were both healthy and agreeable to the kids. For example, fruit and vegetable smoothies were a big hit. These cooking activities sparked a number of new projects that included making a video documentary about preparing healthy and tasty smoothies and producing a smoothie recipe book. The video and recipe book were in turn digitized and posted to the T&CLC website, not only to showcase the collaborative work between the kids and the undergraduates, but to allow succeeding generations of undergraduates and local youth to build upon these achievements.

In order to ensure that the kids could reasonably apply their new knowledge of nutrition at home, Ms. V. asked that whenever possible, the cooking activities used only ingredients that could be obtained locally. The sad fact that the only place within walking distance to buy fresh produce (in a very limited selection) was a local "99¢ Store" complicated the food project and exponentially increased the educational value of the enterprise for the university students.

The center had a struggling vegetable garden. Taking advantage of this situation, we organized for a routine where, as some of the kids and undergraduate buddies worked in the kitchen, others labored in the garden, breaking soil, building raised garden plots, and doing online research about vegetables and their optimal growing conditions. The results included salads and sautéed greens, which in turn led to new recipes, salad dressing taste tests, new documentary films about gardening, and a garden recipe book.

The kitchen-garden connection turned out to be a cross-cultural connection as well. Collard greens, beloved in the African-American community, were unfamiliar to the undergraduates. In their research, the kids and buddies found that the traditional ways of cooking the greens were not all that healthy. With the assistance of a local parent (who for the first time began to participate in the activities at the center), a compromise recipe was worked out that made everyone happy.

As these examples show, the new, hybrid activities were beneficial not just in terms of providing material, educational, and social resources, but also in terms of motivating the creation of additional new activities. The new recipes, the new garden, the multiple video and textual documents of these activities, and their representation on the T&CLC website helped create a network of interrelated artifacts and practices that the undergraduates and youth could draw upon as they redesigned existing activities and developed new ones. These documentary and representational practices also fit perfectly, both with UCSD's ethos of encouraging reflection and communication about site activities and with Ms. V.'s custom of staging quarterly block parties for the youth and local residents. We grasped the opportunity provided by these parties to present the products of the children's work to their community. As others have shown (i.e., McLaughlin & Brice-Heath, 1993) such public presentations can be a source of motivation for new joint projects.

### ***New Activities Introduced by the University Partners***

With Ms. V.'s approval, LCHC has also introduced a number of activities geared toward developing the T&CLC kids' interests in, access to, and knowledge of science, technology, engineering, the arts, and math (what we have learned to call a "STEAM curriculum"). Typically, these activities also serve as research foci for graduate students

because they have relatively defined goals, can be carried out in separate areas of the center to ward off intrusions from other activities, and thereby make professionally acceptable levels of documentation and orderly data collection possible (see Fig. 42.2B).

One such activity involved building a virtual world, called "Worlds of Internet Technology and Science" (WITS). Similar in look and feel to "Second Life," WITS uses a kid-friendly computer programming language for easily incorporating flash animations and digital photos and videos. These arrangements make it possible to build a variety of environments, fill them with objects collected from various media, and display them in an attractive fashion to others. The builders of WITS were interested in learning if this kind of facility would be useful in after-school science education.

When it was first introduced, WITS attracted a number of the elementary- and middle-school children who built rooms, filled them with pictures, and explored the potentials of this world-building program. But after a few sessions, they lost interest. Obligated to "push the envelope" of WITS's potential, Ivan Rosero, a graduate researcher in our lab, sought to redesign the way in which WITS was implemented to determine how it could be made useful in our after-school setting in a manner that would be motivating for the youth. With the support of a local oceanographic institute interested in extending its public education program, Ivan developed a project he called the Ocean World Activity (OWA) in which a group of elementary-school girls explored topics in marine science. He used a partially designed WITS undersea world as one component of a multi-modal activity that included a visit to the local aquarium, use of plush toys representing various ocean creatures, and artwork to be placed in the WITS virtual ocean.

This new form of activity generated excitement not only among the children, but among the oceanographers who were struggling to figure out new ways to engage the general public, and especially under-represented groups, in oceanographic concerns. Because the multi-modal WITS activity involved many new forms of mediation and representational practices, communication technologies, and challenges for social organization, it served as perfect site for Ivan's thesis work.

Over time, several such UCSD-initiated projects have been implemented at T&CLC. Some have involved encouraging physical exercise including

one activity called the “Bod Squad.” Developed by a UCSD triathlete and graduate student researcher Tamara Powell, the Bod Squad introduced pedometers into races around the apartment complex’s circular drive and expanded existing activities such as jump rope and freeze tag to include academic elements. New UCSD initiatives are a continual source of new activities that are seen as valuable by the community, fun by the children, and objects of research for the UCSD partners.

### **Contrasting the Two Strategies**

Our goal, as stated at the outset, was to contrast two strategies for university-community collaborative interventions in local after-school programs. It is to that topic that we now return.

Both of the research/intervention strategies discussed above are versions of an iterative, action research program. Both allow us test and improve upon our theoretical understanding of how to use CHAT to chart the development of joint activities within the collaborating organizations. Both are longitudinal studies anchored by our desire to understand the process of sustaining the activities as long as possible; our data allow us, albeit imperfectly, to trace development at three different time scales: microgenetic interactions in structured activities, ontogenetic changes in the children over months and years, and cultural-historical time, represented by the interactions among the participants as representatives of their institution that do or do not result in sustainability. Both approaches provide insight into the changing relationships between the designed activity and its ecology over time.

However, they also differ in important respects. A 5th D had already been shown incapable of existing in a HUD housing center in prior years, and it failed, despite a great deal of effort and mutual goodwill. Neither partner could adjust sufficiently to meet the legitimate, local requirements of the other. But a system employing the principles that were a part of the theory that is still growing out of the 5th D intervention could be implemented in such an environment. This could be done if the basic system of joint activity at the institutional level could provide the coordinated resources to ensure that the activity occurs at the face-to-face level of kids, undergraduates, and researchers (who we refer to as “observant participants”).

Two leading design principles are at the heart of the implementation of the T&CLC project.

First, LCHC did not initiate the project. It was originated in discussions that came to us “second-hand.” As a consequence of this mediated initiation, each side of the institutional partnership could feel as if the other were initiating the suggestion to interact. The equal power sharing embodied in that beginning was quickly fused into a variety of ritual joint, communicative gatherings, most prominently, Ms. V.’s participation via conference call in weekly class discussions with the UCSD students. This gave voice to both Ms. V. and the students’ interests and concerns, while the researcher/teachers could step back and allow everyone to speak and be heard. During the afternoons at T&CLC, Ms. V. ruled. There was never a question of UCSD overpowering her. She has done her utmost to make sure that the students’ experience is academically valuable to them, but at the same time that she wants them to adhere to the organization she suggests; lots of discussion goes on informally in the midst of the activity itself.

Second, the two projects differ in the relationship of the joint activity center to the ecology of the children’s lives, their “contexts.” The BGC exists as a safe and healthy place for kids to go after school *separate* from their homes. Although they vary in size, every BGC we know of has a building of its own, often a large, multi-purpose public space. It is a place where kids go until their parents come to get them, or until a specified hour when they are to go home. They are often escorted in groups. It is a group activity in a place set apart. T&CLC, on the other hand, is located near the geographic center of an apartment-house complex. Parents sometimes send their children to the center to get help with their homework or simply to get them out of their hair. The children come and go freely, but the center is virtually never empty from the time it opens at 3:00 p.m. until it closes at 7:00 p.m. It came to be called “The Learning Lounge” when UCSD students were there. But it was, and remains, a crossroads and source of varied support for many of the families in the community.

This combination of a genuine sharing of power and responsibility and the particular location of T&CLC within its community where a large number of the community’s concerns become a part of the joint activity, gave rise to an entirely new set of challenges. Over time, swamped by special needs, the activity system, T&CLC “learning lounge” expanded. It became a *runaway object*.

## *T&CLC as a runaway object*

*Runaway object* is a term coined by Yrjö Engeström, who explains the meaning of the term as follows:

Objects are concerns, they are generators and foci of attention, motivation, effort and meaning. Through their activities people constantly change and create new objects. [Runaway] objects are often not intentional products of a single activity but unintended consequences of multiple activities. [Runaway objects] have the potential to escalate and expand up to a global scale of influence. They are objects that are poorly under anybody's control and have far-reaching, unexpected effects. (Engeström, 2009, p. 304)

The 5th D remained a familiar object of analysis because of its socio-ecological position between the school and the home and the relative affluence of the community. The social circumstances of the children and their families were rarely a focus of concern in organizing the 5th D activities. The routines were sufficiently flexible to permit the inclusion of children dubbed "special needs," which included in our case a child with Asperger's syndrome and mentally challenged children, as well as myriad children who were deemed difficult in some way.

As time progressed, we discovered that at T&CLC the special needs of the children extended well beyond anything we had been confronted with before. We were not dealing with a few special-needs children. At T&CLC we were dealing with a special-needs *community*. Health problems appeared in the form of widespread obesity and diabetes, among the children's caretakers as well as the children. Unemployment was so bad that families were constantly moving out because they could no longer afford subsidized housing. Healthy food was not locally available, and affordable healthy food amounted to an oxymoron.

Initially we tried to incorporate the required new activities into the center. We contacted colleagues in the medical school for help in organizing educational activities for parents. We began to collaborate with our colleagues in CALIT2, the local UC technology center that takes an interest in new uses of technology for health and education. We contacted people in the Urban Community Gardens movement. We searched for, and found help from, a UCSD extension in identifying ways to increase the availability of local and affordable workforce training programs.

At first it seemed that the addition of new activities, and bringing in different constituencies of local residents would fit well within our mutual appropriation approach, but we soon discovered that there can be too much of a good thing. At total capacity, we found it an effort just to maintain the Learning Lounge and a few activities that could be made attractive to the kids. Before long we were spending so much of our time coordinating with all of the new organizations whose expertise we were calling on that we no longer had any time for analysis of what we were doing, and we could no longer even specify our object of analysis!

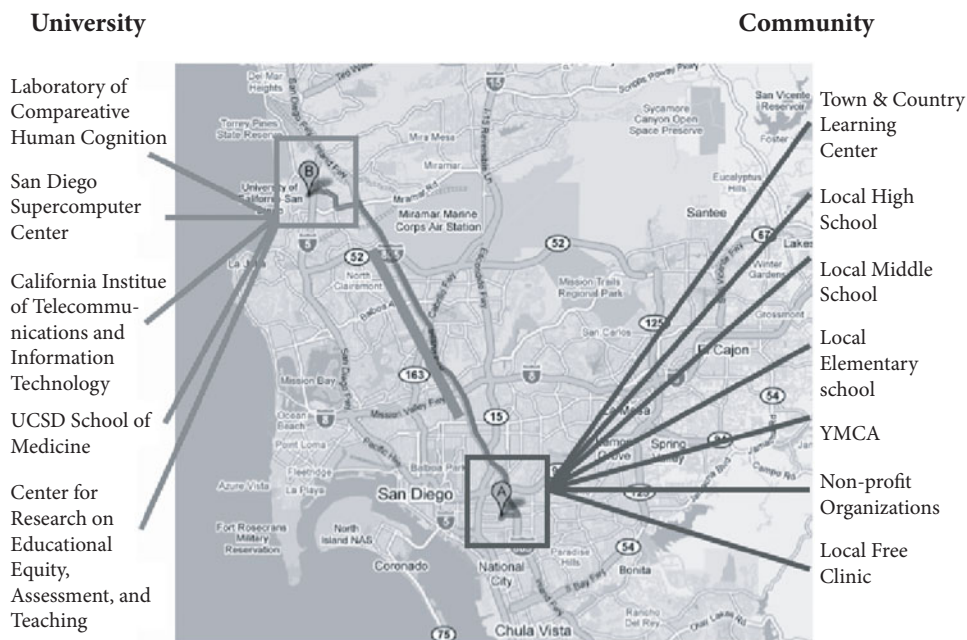

## THE CENTER FOR COMMUNITY WELL-BEING

As might be expected, the strains that we were experiencing were also being experienced, in their own way, by all of the parties we had involved at T&CLC. As a consequence, while we have continued to develop the Learning Center Learning Lounge activities, we have banded together with colleagues from the university as well as the larger community that is home to the T&C Apartment complex to create the Center for Community Well-Being (CCW; [www.ccw.org](http://www.ccw.org); See Figure 42.3).

To the CCW has fallen the task of engaging the runaway object that emerged at T&CLC. It coordinates the activities of an interdisciplinary group of UC San Diego faculty and staff with partner organizations in the Southeastern San Diego community to develop integrated projects aimed at improving education, health, economic development, neighborhood safety, and community services.

## Final Comments

Both of the strategies we describe here were developed under the constraints of the specific local ecologies in which they were embedded. The encapsulated nature of the BGC partnership is typical of Fifth Dimension projects, but not universal. Members of the LHC research group, for example, have maintained an in-school and after-school program for more than a decade at a local elementary school where numerous 5th D activities have become part of the daily practices of the classroom teachers. This can be seen as evidence that some 5th D programs can and do morph into arrangements that come to resemble the mutual appropriation model. The vast majority of its specific routines and local cultural features evolve into hybrids of those of the contributing institutions.

**Figure 42.3** Schematic showing the relationships between the university and community participants in the Center for Community Well-Being.

The project at T&CLC is also specific to its historical/social/cultural time and space. Whether initiated by the university or the local community, the specific activities that, as an ensemble, came to occupy T&CLC evolved into a hybrid new form of after-school educational activity. The explosive expansion of the institutional arrangements that were required to implement and sustain the various new objectives—health, employment, nutrition, etc.—seemed naturally to evolve into the CCW with its broader mandate and greater institutional and geographic reach. As a result we are witnessing at present the objectives of our original program extended into areas and in ways we could not have imagined.

The two research strategies, involving two kinds of cooperative social arrangements, clearly have important precedents in their general impulse. The connections to the work of Dewey’s laboratory school and general philosophy are obvious in each. They also have some well-established precedents in Jane Addams’ work at Hull House, where she put “enrichment” programs like poetry reading on hold until some very practical services like temporary housing, daycare, education, medical and legal services could take root. Addams insisted that the value of the neighborhood program rests in its “...flexibility, its power of quick adaptation, its readiness

to change its methods as its environment may demand.” (p. 126) She described the Hull House as a place where information was interpreted, rather than as an agent for social leveling. In her eyes, Hull House was first and foremost a meeting place where a cross-section of Chicago residents united around common social problems (Addams, 1893/2002b).

Addams’ sentiments are echoed in more recent works of Lave and Wenger (1991) and Matusov, St. Julien, Lacasa, and Candela (2007). For Lave and Wenger (1991) the business of a community is the ongoing activity that shapes and sustains the community itself. Learning is a byproduct of the processes of negotiation and renegotiation of one’s participation in community life. Matusov et al. (2007), who, like us, make undergraduate education a key element in their approach, note that learning and development are integral parts of the process of transcending one’s life circumstances, and as such require a certain amount of directionality. They ask, “Who defines that directionality? How is it defined? Who talks on behalf of the “transcending” (p. 36)?

It is precisely these complicated issues of agency, both personal and institutional, that continue to vex and inspire the development of the design experiment and mutual appropriation strategies. As we continue to explore these programs we hope to bring them into conversation with others

sharing common theoretical grounding, such as Yrjö Engeström's Developmental Work Research approach (Engeström, 2010) and allied approaches in the participatory action research tradition (Schensul, 2010). Although it seems clear to us that these alternative strategies have much in common, they are developing in very different social, economic, and cultural ecologies, and so are certain to diverge in unpredictable and interesting ways. We look forward to fruitful discussions among the various approaches.

## Acknowledgments

The authors acknowledge the support of our collaborators at the University of Colorado, Boulder's Physics Education Research group and Tufts' Center for Engineering Education and Outreach as well as the research group at Cornell University who supported our learning of, and use of Worlds for Internet Technology and Science (WITS). Robert Lecusay acknowledges support from the National Science Foundation Graduate Research Fellowship and the American Educational Research Association's Minority Dissertation Fellowship Program in Education Research. Support from a grant to the Laboratory of Comparative Human Cognition from the UCLinks Program from the Office of the President of the University of California is also gratefully acknowledged.

## Affective Networks: The Social Terrain of a Complex Culture<sup>1</sup>

Nandita Chaudhary

### Abstract

Affective networks of relationships frame every social encounter that a person has in life. Mainstream psychological research has, however, failed to take adequate consideration of these dynamics in the writing about and exploration of human conduct across cultures. In every step of research, we espouse elements of our habitual cultural dynamics. When we consider a context unfamiliar for us, we tend to superimpose our familiar ways of living onto the other culture, the other person. Also, there is a preference for quantifiable, observable elements of human conduct, which has contributed to much knowledge about human phenomena in specific settings but everyday lives of ordinary people all over the world remain largely ignored by psychological research. This occurs on account of the tedium involved in searching the streets for processes that defy simple labeling and categorization. The greater the distance between the socio-economic, cultural, and geographic conditions of a researcher and the researched, the more arduous the journey of intersubjectivity, the agreement between partners in research. This makes our judgments more prone to incorrect exploration. Indian community life is characterized by complex, confounding and contradictory manifestations of ways of living owing to internal and external factors. This makes it all the more critical to inform ourselves about ambient social reality and personal proclivity in order to understand people and their conduct. This chapter discusses some of these features of social life in India that impinge upon interpersonal encounters, and thereby need to be attended to in research.

**Keywords:** culture, person, environment, ecology, social cognition, cultural differences, Indian family life

As a term, culture has continued to defy simple elucidation. Scholars persist in searching for ways of defining culture with reference to nature, communication, meaning, material, or activity. It is essential to reflect on academic discourse related to the term precisely because there has been an inadvertent marginalization of non-Western, minority, subaltern societies based on the definition of culture in scholarly discourse, especially in the field of psychology. Thus the definition of culture and its application has become recognized as a political issue over the years. In theories, methods, and interpretation—in fact, in every step of our research—we espouse elements of the explicit and implicit relations among people and between people and their worlds. The

intersubjectivity of any encounter and the interobjectivity of the social group determine the ways in which a people are going to be constructed, whether as objects to be guided into making sense of their own lives, or as participants, capable of defining their own reality. Whereas intersubjectivity refers to the agreement in perspectives between individuals; interobjectivity is relevant because there are culturally shared variations regarding the world around us (Moghaddam, 2003). Moghaddam contends (2011) this is an essential consideration in academic discourse; otherwise we will continue to have increasingly isolated dialogues within the social reality of our own cultural or academic affiliations. Human relations “rely on the non-conscious engagement

in practices that occur within a social field” outside of the subjects, and not primarily on intersubjective relations (Sammut, Daanen & Sartawi, 2010, p. 452). Priming intersubjectivity over and above interobjectivity creates a bias toward individualism and reductionism emerging out of Western individualistic traditions and suffers from what Moghaddam (2010) labels as the “embryonic fallacy” (p. 465). This tendency to assume that psychological experiences are initiated at birth has resulted in intersubjectivity becoming a “problem” to understand since it becomes difficult (if not impossible) to explain HOW we comprehend others’ perspectives IF we are the source of our own understanding? The solution to this is contained in the cultural resources that surround us.

This chapter focuses on the study of social relationships among Indians from within, primarily to inform the academic audience about the unique ways of understanding the world that characterize Indian communities. If an “outsider” position on Indian culture and tradition is adopted, interpretations are not likely to fit the phenomena very well, precisely because of the different emphases that are placed on cultural activity. And yet, in this world of created contrasts, compare we must. In order to advance reasonable comparisons and constructions about people, we need to better understand their realities by adopting favorable approaches. In this manner, culture is not seen simply as a disturbance for the elegance of a research design. Cultural activity and ascribed meanings are so “dense” that if these are not considered from an indigenous perspective, the basic agenda of the (re)search could be obfuscated.

### **Inclusive Separation and the Person-Environment Interface**

A meta-conceptual paradigm for dualisms constructs the person and environment as distinct from each other. Duality is a favored format precisely because it facilitates simple heuristic advancement in the study of any phenomenon. However, when we are dealing with human social phenomena, metallurgical precision is not a precondition, and the ways of presenting social processes has to fit. For instance, the person in any given social setting is at the same time influenced by, and influencing the context. The complete separation of the two processes will have to be an artificial one. The interaction between person and environment in such a system is visualized as a transfer of information

between two separate elements of reality, in independent existence. Reality is constructed with logically separate processes of individuals on the one hand, and their environments on the other. This formulation is neat, but somewhat inadequate when it comes to explaining the human condition. Another way of considering the person-environment interface is *inclusive separation*, where a person is viewed as distinct, but without being independent of, but in constant interaction with the environment (Valsiner, 1998). This approach has several important consequences on the way in which theory and research is advanced.

### **Conversational Structures**

In cultural psychology, attempts are made to understand culture at the individual level as it is guided by collective culture, while simultaneously creating it (Valsiner, 2001). The study of culture as social interactions between individuals and small groups was identified as critical by Simmel (1971) when he distinguished between “subjective” and “objective” culture. By analyzing individual action, Simmel studied how social institutions are influenced. He advanced an idea that structure of a social setting (whether it is dyadic and triadic) is fundamental; interactions between two people, and those between three or more, would be very different in nature, to the extent that the increase in size of group would result in greater “individual freedom.” The “inner unity of a group loosens as a group becomes larger” (Farganis, 1993, p. 40) on account of multiple mutual relationships. Rather than going into size of group and beyond, I am going to select the distinction between the dyad and triad that Simmel makes in order that we can understand the fact that the structure of social interaction can have deep impact upon the dynamics of discourse through the examples provided in this chapter. This demonstrates that cultural reality operates not only at an individual level, but also at the group level—in this instance implying that the size of a group can impact social dynamics. I will pick up this point for discussion a bit later.

To return to inclusive separation and the interface between a person and the environment, we can visualize the intersection of person and the surrounding context (read culture here) in Figure 43.1.

If we visualize a person as object A in the below Figure 43.1, and the environment as not-A, or B; using Valsiner’s notion of inclusive separation (2004, p. 18), we can assume a point X on the surface

**Figure 43.1** Person-environment interface

where a person and the context meet. There are two ways of understanding this interface. One that argues for what Valsiner calls *exclusive separation*, the point where non-A starts and A ends; and the other where this is seen as the meeting point between A and non-A, and thus the interface of BOTH A (the person) and non-A (the context), resulting in a dialogical interface between these two features that is at the same time, both A and B. This dialogically (as distinct from a dialectically) constructed view of the *person-in-context* allows for us to argue for a space where we can include both processes. Dialogicality between phenomena (Bakhtin, 1981), whether these are perspectives or persons, permits us to consider different processes not in opposition (A versus not-A) but as relational (A or not-A); focusing on the interface between the two positions. After all the formation of not-A in itself originates the moment that one considers A, and is thus foundational for this. If we apply the dialogical principle to the relationship between a person and her environment, there is an inevitable dynamic re-description of the world. We can therefore construct such a relationship with the following elements that are not distinct from each other, but in constant dynamic exchange with each other. Culture can be visualized as the activity that belongs *in between* the person and the environment rather than the person belonging to culture, or the culture belonging to a person (Valsiner, 2007). This interface, the semipermeable membrane allows messages to travel both ways; from the person to the environment, and from the environment to the person.

### Supplement, Surplus and Excess: The Process of Abducting Meaning

In the dialogue between nature and culture, the person and her context, there emerge several processes that require explication. When a person enters

a culture, whether as a child or an outsider, we are confronted by a context that is “*overexplained, overdetermined by meaning*” (Valsiner, 2001, p. 117, emphasis original). How do these meanings become manifested? Valsiner continues with a statement that human minds have the proclivity for jumping to conclusions in any encounter. When symbolic forms are created in collective culture, where multiple motives contribute toward polysemy, or multiple meanings, the mind rushes to make sense of these experiences (Obeyesekere, 1990, p. 56). We are it seems, primed for telling stories (Turner, 1996):

The constant yet unnoticed ‘power of story’ as a mental activity like vision, for instance, is really the quality of the mind that makes everyday life possible in the human sense. Here we mean story not in the sense of entertainment, but as a thread that we are capable of weaving. Much as these networks bind us, they also create complex webs of activity, identity, reality and family.

(p. 13)

The teleological function of the capacity of humans for storytelling was really to save our worlds from collapsing into chaos, dealing with the overwhelming uncertainty that confronts us at every moment of our lives. Toward this end, we take everyday experiences and color them with our own (socially guided) meanings and connections, and manufacture our stories about experiences, people, ourselves. We are able to see patterns in phenomena, come to conclusions, or adduce reasoning. However, there is another process in operation that we use with amazing alacrity: abduction. *Abduction* is the tendency of the human mind to pick out a possible solution (Peirce, 1955). Somewhat like a hunch where we have an intuition that there is some connection, even sufficient similarity can be the criterion for problem solving when we use abduction. In scientific research, for instance, the initial idea of a study is obtained through the process of abduction. It is after that initial identification that we move toward inductive and deductive processes for logical analysis. In social encounters, this abduction of meaning is formative for the ways in which collective sense is constructed and applied, as we will see later in the chapter.

There are some other processes in cultural encounters that have relevance for this discussion. Here I would like to introduce the notion of *supplement* (Derrida, 1974/1997) that is described as that activity exterior to original, natural element, that

attempts to replace it in any given situation, like child-rearing practices that realize the completion of the deficient natural system (Gillespie, 2003). Interestingly, it is both the accretion as well as substitution functions of any supplement that characterize the idea of a supplement according to Derrida (1974/1997). When human beings interact, the emergence of one idea leads to the simultaneous production of its alternative, and we have to understand the open, dialogical relations between social phenomena. In dialogical relations, for instance, it is the relational rather than the logical, dichotomous categorization of phenomena that are considered. Perhaps cultural activity can be assumed to be accumulated “supplementarity,” both adding to and substituting for natural processes and perhaps in many domains, even overtaking these. Of course taking a dialogical approach to the interaction between nature and culture (and not dialectics) make it quite impossible (and rather futile) to disentangle the points of departure from nature and the entry of culture in most instances. Linked with the notion of the supplement in human activity is the process of communication that becomes essential for any cultural process to sustain. Meaning already exists when a person enters social interchanges and is not something that each individual person manufactures afresh on his or her own. In the communication, social groups set up individuals for certain confrontations over and above others through conversations, rituals, myths, and several other cultural processes. This predetermination of individual reality is clearly intended by the social group, and then actively reconstructed through everyday interactions during which a person both “gives” and “gives off” certain messages (Goffman, 1959) what Bakhtin (1990) terms as “excess,” thus making the “other” a very larger than life element in the reality of humans (Mead, 1934). This perhaps reflects almost an opposite orientation from that of the bias of individualism where intrapsychic phenomena are privileged. The “surplus,” the enlightened information that our minds are capable of engaging with regarding Self in the world of others (Gillespie, 2003) are central to the dynamic construction of culture.

### ***Cultural Dynamics in a Specific Instance: The Indian Mother***

Cultural processes precede and succeed every individual's life, and impact these in long-lasting ways by preparing the setting with prior attention. Thus the culture that we live within can be argued

with, fought against or discussed; but it cannot be ignored. In the co-construction of meaning, individual minds contribute actively to collective meaning by tugging at these in specific ways, constantly renewing the organic reality of cultural meaning systems.

Let me take an example from Indian cultural dynamics and attempt to apply some of the theoretical ideas presented in the preceding paragraphs. Among Indians, we find that there is an impressive and almost exaggerated centrality that is placed on others. One such other is the mother who finds place in the dramatic as well as the everyday (Chaudhary & Bhargava, 2006; Desai, 2010; Kakar & Kakar, 2007; Thomas, 1995). In a more detailed examination of gender relations, we find that the status of the mother is not simply a question of gender relations that places men at a superior place as is often misconstrued on account of the predominant patriarchy of Indian society. The status of women is believed to be lower than men on account of demographic, traditional, and social findings. This makes it quite difficult to understand paradoxical manifestations of attitudes toward women in contemporary Indian society from an outside perspective (Bumiller, 1990).

The woman may be discriminated from birth, seen as a burdensome liability in her youth, be treated unfairly and badly by the husband, actively harassed by her in-laws, but somehow when came to her role as a mother, particularly of a male child, her power and influence knew no bounds. To the Indian imagination, the mother represents the source of all things.

(Desai, 2010, p. 25)

There is a clear worshiping of the idea of motherhood by people; despite the fact that the same person may not be respected within another relationship. As Desai suggests further, that in the sociopolitical context, it is not the person but the position that is marked. It is not surprising therefore, that India has been home to some of the most powerful women in the political arena. Social positioning is another activity that needs mention in order to understand this fully. One of the first features of a person that an Indian will attempt to assess (perhaps as important as gender) is the social status, which would include economic status, ethnic membership, place of origin, caste group, etc. This is not simply to get a picture of a person's circumstances, but to assess what the position is with respect to himself or herself; as

a guide to appropriate conduct after considering whether the person is above or below in social status with reference to the self (Varma, 2005). In interpersonal interactions, similarly, it is the role and relationship rather than demographic descriptors that define conventions for close social encounters. The Indian sense of self is believed to be constantly changing, partly because context is considered to be formative in determining conduct (Menon, 2003). An imposition of an assumption of “ontological individualism” (Bellah et al., 1985) while analyzing social interactions in India would be misplaced. The variability in the ways people can approach a situation will be limited to predetermined categories guided by the ideology of individualism, and would thus fail to be understood appropriately.

To advance the point about “mothers” in India, we find that in the care of children, although the mother is considered pivotal, this emphasis does not preclude the importance of other members within the child’s network. But before going any further I would like to add a cautionary note here. When I speak of Indianness, I do not imply a homogenous, monolithic structure of a consolidated, coherent way of living. If anything, Indian culture provides us with the exact opposite of each of these adjectives. The number of people, the diversity in languages, ethnic practices, stories, and spirituality makes such statements rather impossible to make. Even the past is textured with variety and multiplicity. India “does not have one past, but many pasts” (Ramanujan, 1999, p. 187). To add to the texture of variability is the fact the past always has a constant presence in our present (Anandalakshmy, 2010).

At certain levels there are aspects of cultural traditions in India that can be traced to roots as far back as a few thousand years, but such a continuity must not be confused with stagnation.

(Thapar, 2000, p. xxv)

Thus we find that there is an intricate interweaving of “pasts,” which, along with geographical distance and ecological variation, make it possible that people of one area may not have stepped over into another, and thus “every description of tradition can be as a negation or contradiction of another” (Anandalakshmy, 2010, p. 19). So when we write about any phenomenon, this reality must be kept as an essential clause. Returning to the issue of motherhood in India that I am using as an example of a dramatic domain of activity in India, what are some of the manifestations of this centrality and how does

this weave in with other relationships that the child has to live among?

I have argued, in fact that when a mother is so important, then perhaps there would be wisdom in preparing for unfortunate eventualities, especially where survival rates may be compromised on account of health status. Several scholars (Kurtz, 1992; Trawick, 1990; Tuli & Chaudhary, 2010) have found a corresponding importance that is placed on other people in addition to the importance of the mother that could be characterized by the dialogicality, the inclusive separation of mothers and others (Chaudhary, 2006). The child is believed to be naturally attached to the mother, but very intense and intimate exchanges between mother and child are often private, even within the socially dense context. In the presence of others, the mother is actively encouraged to distance herself and correspondingly promote closeness of the child with others. The dynamic arrangement for corresponding supplementary resources enhances her activity along with creating a substitute for her role in a person’s life. Here we find possible instances for both enhancement of as well as the potential substitution for the mother. Women in the larger family network often compete between each other playfully for the child’s care and attention. Perhaps why this happens is precisely on account of the putative centrality of a mother’s role in a child’s life. This is perhaps an instance of supplementarity in the Derridean sense. This emphasis is also communicated in the kin term *Ma-si* in Hindi that refers to the mother’s sister as “like-mother,” as this term translates. It is also noteworthy that the mother’s sister is also potentially substitutive in several ethnic groups in India; in the event of a woman’s death, the marriage between her husband and her sister is not only permitted, it is also seen as the best possible option (for the children). This theme resonates widely in Indian literature and popular media.

Regarding maternal love, Hindi has a special expression “*Mamta*,” also a popular name for women, which finds an important place in everyday discourse. An investigation of people’s understanding of the term demonstrated that mother’s love had a sort of magnetic quality with regard to meaning. In the interviews, people were eager to discuss meaning, sometimes extending the feelings of (this form of) love to other relationships, debated about the specificity or flexibility of mother’s love, and even chose to say in some instances, that *Mamta* was responsible for making mothers

more vulnerable to manipulation and exploitation by uncaring children! There seemed to be no doubt about the “natural” quality of Mamta, although it could transcend the specific mother and her biological child and manifest itself in other affiliations as well (Chaudhary & Bhargava, 2006). I will deal with this in greater detail in a later section.

### Social Setting and Situated Discourse

Everyday conversation has a fluid and flexible quality that makes it rather elusive to consider for academic study. However, in order to approach people in context, it is essential to explore ordinary experiences of unexceptional members of any given society. Rommetveit (1992) discusses the essential components of a dialogically based sociocognitive approach to the study of human beings. Proposing basic distinguishing features of this approach, he places importance on context-situated discourse:

What distinguishes a socio-cognitive and dialogical paradigm from orthodox ecological psychology is an acknowledgement and superordinate concern with cultural invariance and variance, with social construction of shared realities, and with issues of ‘intersubjectivity’ encountered in our encounters with ‘Lebenswelt’ (lifeworld) from within. (p. 21)

If this approach is accepted as a basic tenet of human activity, then we have to accept some of the corollaries about the human mind as well. These are extracted from Rommetveit (1992, p. 21–23):

- The human mind is basically social and informs us not only about a person, but also that which is being interacted with
- Ordinary language mediates this activity for known as well as novel experiences
- Shared social reality guides a person’s approach towards any encounter with the ecological-cultural reality
- These predispositions place limits on potential conduct, although not entirely
- On account of these predispositions, activity is always from a ‘particular’ perspective
- ‘Attunement to the attunement of the other’ characterises human activity
- In any situation, the respective meanings are guided by subjective perspectives, and can never be absolute
- Joint attention and dialogue facilitates the ‘attunement to the attunement of the other’

- Any declaration about a particular phenomenon by a person is based on the ‘dialogically established shared social reality at this stage’
- Transcending of specific perspectives is inevitable through assimilation of terminologies into everyday language

Advancing this proposal, we can visualize any construction of potential activity with the self and others as arranged in the following manner. Consider a person who is approaching an event. I propose these four domains of activity as dialogically related (rather than separated from each other). The first category is the self and itself, we carry an elaborate range of predispositions that we have inherited and created for ourselves as people, a strong internal proclivity that constitutes our subjectivity. Another domain is a person’s information and approach toward the outside world that constitutes our objectivity. I define this not simply as the “unbiased, impartial” attitude as defined, but the belief in an impartial, unbiased element of our collective reality! Then there is the real or imagined “other person(s)” in any encounter. The individual under discussion here will have an element of intersubjectivity, the belief about the beliefs of the other. This is taken as a stance which the person operates from, an assumed objectivity about the world. Once the intersubjective capacity is developed ontogenetically, we conduct ourselves with this basic element of our reality. Then the last element is the putative knowledge of collective and social reality, tradition and convention. This presentation can be seen as one possible way of understanding the constituents of a person’s perspectives in any given encounter.

### Methods of Approaching the Study of Human Beings, Intersubjectivity and the “Psychologist’s Fallacy”

Every cultural community creates over the years a range of shared understandings of social reality. These “collaboratively constructed objectifications of the world” that are shared within and between cultures is what Moghaddam (2003, p. 222) refers to as *interobjectivity*. If we search ancient Hindu texts for defining human activity, the delineation of *sravana* (hearing about or experiencing), *manana* (thinking about, cognition) and *nidhidhyasana* (meditation), make the three important methods for study of reality, what can be argued as first-person, second-person and third-person methodology (Rao, 2008). The focus is placed on transactional AND transcendental reality, and consciousness receives a central

place in such a construction. The complex and confounding construct of consciousness has driven its study outside of mainstream psychology, focusing largely on measureable domains of activity. In the study of the self, the primary search has been for the consolidation of literature about a notion of self that is based in the ideology of individualism. More recently, we have encountered several approaches to research and theory that have attempted to contrast the development of self in other cultures where there is a departure from the ontology of individualism that characterizes most theorizing about the self (Menon, 2003, Misra, 2010).

### *Ambiguity in Cultural Dynamics*

It has been my experience that most industrial projects in our discipline have tended to suffer from a syndrome that could be characterized as an “avoidance of ambiguity.” We search for means and standard deviations in the troubling conditions of the central tendency that is (often unquestioningly) assumed. To speak of “*a* culture, this culture, as a consensus on fundamentals—shared conceptions, shared feelings, shared values—seems hardly viable in the face of so much dispersion and disassembly; it is the faults and fissures that seem to mark out the landscape of collective selfhood” (Geertz, 2000, p. 250).

Psychology’s stories could be argued as being told largely from the stance of an informed academic discussing a naive subject both within any culture and cross-culturally. James (1884) remarked that psychologists become confused about what is in their minds and what exists in the minds of their subjects, what he calls the “psychologist’s fallacy.” Consequently, psychologists tend to attribute and impose ideas that they have in their minds onto others, initiating the debate about assumed positions, privileged perspectives and putative objectivity in research and other academic activity. The mutual recognition of consciousness is an essential ingredient in the methodology for investigating human experience. If we use Table 43.1 as a template, it

is possible to see this phenomenon as confusion between subjectivity and intersubjectivity, a capability for social cognition that children are believed to develop around the age of 4 years of age! Several other overlaps can also be visualized: that between interobjectivity and objectivity, where social reality is assumed as being a universal principle; or between subjectivity and objectivity, a common mistake that our version of the truth is the final word.

Moscovici (1976) stated that societies are constructed largely around their own survival. As far as human conduct and social processes is concerned, ambiguity and ambivalence prevail over exactness and clarity. Depending upon the situation, society “inhibits what it stimulates” (p. 149) with the simultaneous excitement and inhibition of particular tendencies like aggression, sex, or hunger. The chances for satisfaction of these is either inhibited or enhanced depending upon the situation, and within cultural dynamics lie the prohibitions as well as strategies for transgression. Thus when we speak about meaning and culture, it is possible to see how meanings are complex, multiple, and even contradictory. Everyday talk is authored by human beings but it is constantly attributed to society (Valsiner, 2007) since the distinctive quality of social processes is that they seamlessly enter personal positions and vice versa.

The study of linguistic terms has been a very important introduction in unraveling cultural reality (Wierzbicka, 1997) and providing a local framework within which culture is manifested in the minds of its members. There are other symbolic modes like ritual, icons, art, and music, which provide valuable insights into the meaning systems of any culture. Through decades of the dance of meaning and symbolism, collective culture becomes focused on some elements of created ideas more than on others. Through this sifting of symbols, the unique collection of ideas that emerge at any given time is the substance of culture. To return to the domain of motherhood in India, we find it is greatly “overdetermined” by meaning (Obeyesekere, 1990) such that it is believed to be at the center of existence of every woman within herself and for every man in his association with his mother, as was discussed in the earlier section. If we look at the vocabulary for a mother’s love, there is an interesting dynamic arrangement of ideas that emerges. Like any culturally valued symbol, motherhood in Hindi is labeled by a special term that is at the surface simple and straightforward to understand.

**Table 43.1 An orthogonal arrangement of self-other understanding**

Person Level	Individual	Group
Self	Subjective	Objective
Other	Intersubjective	Interobjective

With this objective we (Chaudhary & Bhargava, 2006) proposed a study to investigate people's beliefs about the meaning of the Hindi word Mamta, which is commonly believed to be the "natural" love of a mother for her child. Although there were several dictionary meanings available in addition to "mother's love," through the interviews it emerged that both collectively and individually, the meaning seemed to have first become quite reduced at a collective level, and then was found to again expand in the individual meaning. At the collective level, the several dictionary meanings had actually become simply reconfigured into a single meaning, "mother's love" characterized as deeply selfless and devotional. A mother's life is constructed as revolving around her children and vice versa. This dictionary meanings of Mamta which originally carried meanings like *Yeh mera hai, is prakar ka bhav* (this is mine, this kind of feeling), *mamatva, apnapan* (self-feeling), *lobh* (greed), *moh* (love), *abhimaan* (pride), *garv* (pride), *sneh* and *prem* (both meaning love); and lastly we find *mata ka apni santan ke prati sneh* (a mother's love for her child) (Pathak 1995, p. 612). The Sanskrit root word from which Mamta derives is *mamatva*, meaning "love for the self" and pride. So the idea starts with love for the self, or selfish love, expands to reach pride, love, ownership, and greed. Additionally, Mamta is also a popular name for a woman in India. Over the centuries, the dictionary meanings have become rather obscured as "society" has adopted (or abducted) the last meaning, that of mother's love toward her child, as the single accessible meaning for ordinary users of Hindi. We find that social history made up of contributions by individual people and collective movement

gradually transforms the meaning of words that become over-laden with a singular meaning. But the story does not end there. Actually the story never ends. In our conversations with individual people, we found that although the starting point becomes the well-known meaning, people's arguments take the meaning in other directions, like the possibility that the meaning could also include father's love, love for a pet, feelings toward a friend in need, quite easily. However, none of these meanings return even remotely to selfishness, pride, and greed. The meaning is unequivocally positive, despite the fact that it could have harmful outcomes (like the spoiling of a child with unconditional love could make him or her dismissive toward the parent).

In Figure 43.2, there are two points in time at which meaning is being transformed, or at least changing in emphasis. Firstly, we have the collective shift over the centuries of a term originally created with a certain range of meanings (Point A in Fig. 43.2). Guided by cultural priorities, one meaning takes precedence over all others and remains dominant in the initial reaction of all respondents without exception. Soon after this declaration is made, and people actually say they may not know about this since they are not "experts" or experienced in the matter (some men and unmarried women said this), the participants in the study went comfortably into a detailed description of their views on the matter. This is characterized by point B in the diagram (see Fig. 43.2). This is the moment in the interview where people were actually constructing their views on the matter. It is proposed that in every social encounter, this is precisely what happens. People's views on matters are not something

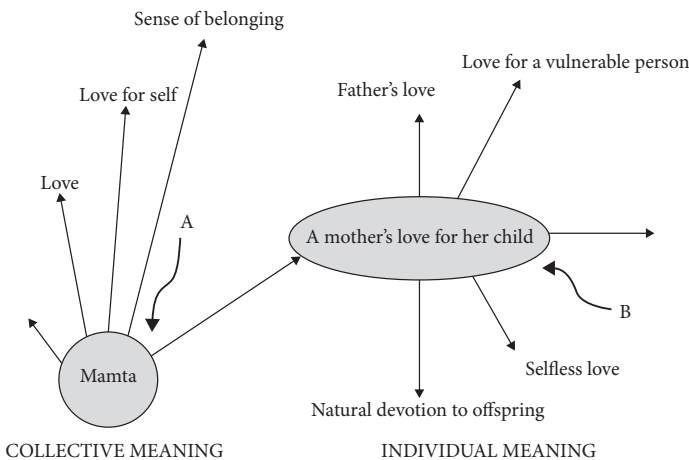

Figure 43.2 Schematic diagram of instances of "abduction" in the meaning of "Mamta"

they always carry around in their heads a priori; these meanings are actually constructed and re-constructed in the actual encounters of everyday life. The interview is simply a social opportunity, albeit with its own particular formalities and this is precisely why the active, flexible interview method becomes critical as a technique for data collection (*for an excellent illustration, see Bernheimer & Weisner, 2007*).

If we return to Table 43.1, we can conjecture that there is an obscuring of the distinction between two sets of processes, one between interobjectivity and objectivity: that people believe the cultural meaning to be a natural endowment. Menon (2003) supports this interpretation in her declaration that Indians do not distinguish between convention and natural law. The other mixing is between the collective meaning as being personal. The latter connection is typical of cultural activity where collective beliefs are articulated AS IF they are personal. This is a process at the individual level that strengthens and sustains society and culture. What we experienced during the interviews was an enthusiastic defense of a culturally valued notion. People defended the presence and need for this love in order for society to survive and prosper through the careful nurturing of individual children. This unequivocal acceptance of an idea is a demonstration of the power of cultural activity and its active recreation through individual voices. Also, the confusions that we have between what we believe as individual agents and collectively shared ideas, prepares us for supplication.

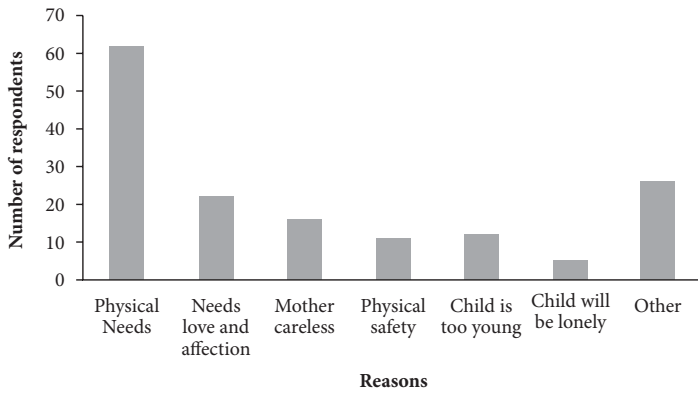

### **Justifying Cultural Practices: Sleeping Arrangements in the Home**

Advancing the reason/randomness debate related to cultural practice, another important feature of any cultural practice is that although it may be arbitrary and/or adaptive, in its justifications provided by members of culture, it is argued as strategic and meaningful. We find that people actively justify actions and invest much emotion in the choices that they putatively “make” in ways of living. At the risk of sounding dismissive, there is some evidence for a sort of exaggerated ownership that is communicated while discussing personal choices that may simply have been a matter of adopting prevailing practices. The commitments that we are primed toward from a very early age become the glue that binds people to their culture. Gradually, these ties may become loosened as we travel through our lives and encounter other ways of living.

Let us take another example of cultural beliefs and practices from a recent study. A total of 46 female university students in New Delhi, India were asked about the sleeping arrangements at home (Chaudhary & Gilsdorf, 2010). It was reported that at the age of 5 years, all of them were sleeping in the same bed with another person: parents, grandparents, siblings, or another family member; and currently, 23 of them still continued to sleep in the same bed/room as their parents. Although these patterns may have persisted on account of several factors, especially the space available and number of members in a home, the electricity costs of using extra power and therefore extra expense; these sleeping arrangements were argued mostly on the basis of emotion, security, love, and care. It was found that the young women justified co-sleeping with reasons like: the young child needs physical contact for love and security (at age 5 years) and predominantly “fun” and affection at their current age. Those who had moved into an independent room reported that they often returned to their parents’ room whenever the mother was alone at home, as in the afternoon or when the father was away; something that they found very pleasurable. It is important to note that these were all young women, and responses of men would have been different. Inspired by Shweder’s work (Shweder, Mahapatra, & Miller, 1988), a second phase was added to the study related to gathering opinions about a specific hypothetical situation: A young mother who shifts her 5-month-old baby out of her bed to a cot in another room. This question was asked of 51 college-going female students and 103 parents and other family members in the students’ homes (51 men and 52 women). The findings showed that with the exception of one respondent (a student’s mother) who argued that the mother must have had her reasons, there was an unequivocal objection to the action of separating the child. “How could she do something so ‘cruel?’” “When the child grows up she will also not care about her parents since she was rejected by them at this tender age?” “It is very *inconvenient* for the mother to run up and down to another room at night?” “How will there be love and attachment?” “A ‘*real*’ mother would never do such a cruel thing!” (Emphasis original).

In another study of mothers and their young infants and choices for sleep arrangements through observations and interviews of mothers and other caregivers (Kaur, 2010), there was a similar finding related to opinions about proximity during sleep.

**Figure 43.3** Opinions of respondents about independent sleeping of a 5-month-old baby (N=154)

Although it was considered essential for the mother and child to be close together, it was also possible to substitute the mother for any other person, like a grandmother. This was done as much to release the mother for household work and other children as for the baby; and also sometimes to make the older person feel involved in the home. This resonates well with the earlier discussion about the coexisting importance of the mother and others presented earlier in the chapter. In response to the query about proximity during a baby’s sleep, 11 (out of 27) participants shared a legend as a justification not only for sleeping close to the baby, but actually always remaining “facing the baby” during sleep, preferably with your hand on the child in order to protect the child and facilitate a sleep “free of fear.” Regarding facing the child during sleep, however, all of them asserted its importance, to the extent that if the mother got tired of sleeping on one side, she would flip over lengthwise rather than face away from the child. Consolidating the responses of the different people who had different versions and lengths of the story, a close approximation of the legend would be:

This story is about the Hindu god Shiva and his wife goddess Parvati. As the legend goes, one day Parvati was taking her bath and wanted to have a person guarding her bathing area. For this purpose, she created a ‘son’ from the dirt of her body. Shiva was not aware of who this person was when he returned home. This was his own son, Ganesha whom Parvati had created for her own safety. Ganesha also did not know who this man was at the entrance to the home, and thus prevented Shiva from entering his own home. Deeply angered by being prevented from entering his own home, Shiva severed Ganesha’s head. Upon seeing this, Parvati turned upon Shiva

indicating the enormity of what he had done and pleaded him to return her boy to life as he was innocent. She threatened to leave Shiva if he was unable to do this. Shiva then asked his guards to search the world to find a mother who was sleeping with her back towards the baby and bring the head of the baby to him so he could replace the son that he had killed. The guards searched everywhere until they discovered an elephant mother and her baby where she was turned away from the baby. They took away the head of the baby elephant and Ganesha was recreated. This legend carries a strong and resounding message: Mothers who turn away from their babies in sleep run the risk of losing their child to the forces of danger.

(Kaur, 2010, p. 34–35)

Here we find the instance of a *phantasm* (Boesch, 1991; Valsiner, 2001), a personal reconstruction of a myth in order to make it available and applicable to an individual person. Whereas myths are collective stories that guide cultural reality, the phantasm makes these myths adaptively available for individual consumption. In most instances, we are unable as individual minds, to grasp the reasons for the bind that these collective realities place on us, whether it is attachments to the homeland, the people in our lives, or the things that we cherish (Boesch, 2002, p. 134). We find again that similar to the instance of the meaning of Mamta that derived from older meanings, one of these meanings seemed to be abducted for personal use. Similarly, in the retelling of this story, the women of different ages were using the myth in a very personal manner since the question was not about myths they know about divine mothers and children; but when they were asked how they sleep and why! As indicated in the review of research on morality referenced above,

Hindus do not make a systematic differentiation between convention and morality in everyday conduct. I argue here, that a similar confounding exists between mythical reality as constructed in daily discourse and everyday conduct, what Pattanaik (2009) calls the tendency to understand the world according to principles of “Mythos” rather than “Logos,” which he describes as a propensity for the subjective, discursive and descriptive rather than being bound by logical argumentation. But this does not also imply an absence of logical thought among Indians, it simply indicates preferences and propensity in the ways in which the world is understood.

There seems therefore, no confusion in combining scientific reasoning with spiritual discourse, no difficulty in blending traditional and modern beliefs, using adaptive strategies that Tuli labels as “elective interdependence” (Tuli, & Chaudhary, 2010). Ambiguity, according to Trawick (1990) is an overarching principle of social life among the Indian community. It is true that it remains hard if not impossible to characterize a billion people with one overarching feature, but this term is one that certainly has appeared as a descriptive label for Indians often enough.

### ***Culture, Context, Relationships and Social Cognition: Another Example***

In the preceding arguments, I have tried to reference examples that display the critical importance of context in understanding findings, although much of psychological research persists in adopting the opposite view: that context-free, “pure experimentation” is the best method of studying people. Certainly, the engagement in relationships that occurs in a particular setting gives us critical information about intersubjectivity and interobjectivity that are needed to understand conduct. Unless we notice and explore affective networks in a cultural setting, we are unable to advance toward a comprehensive analysis of events, whether these are within or outside of scientific research.

In another study that was conducted in two distinct subcultural conditions to explore precisely how the social setting will influence children’s conduct and adult interactions with and about children, Bhargava (2010) examined 3-year-old children’s social cognition in urban Mumbai (a large metropolis) and rural Rajasthan. The village selected for the study was small (population of 2,904, primarily agricultural, and typically rural). Mumbai has been the commercial capital of the country for centuries

and is characterized by dense, plural communities from all over India, with an estimated population of 13,662,885. For the families that participated in this study, most young couples were living as nuclear units (average family size was 3), all with only one child at the time of the study. Although the mothers were not working outside the home, they were all educated and fathers of the young children were employed in salaried jobs in the private sector. There was a characteristic enthusiasm for education among the urban residents and a great deal of effort is placed on children’s preschool education and future school selection at this age. The homes were equipped with toys, books, and other materials that children played with regularly, and mothers typically were engaged very closely with the actions of the children, deeply curious about the study and what the researcher was doing with the children and how this would be interpreted. The participants in the study were eager about the study, primarily on account of the fact that they considered such a participation to be “good for the child.” In contrast, the rural families were usually large, with several couples and children living in co-residence with their relatives. Apart from this, the movement between families within the community was characterized by fluidity and flexibility. Children were relatively free to roam the streets at this age, usually in the company of other children who were older. Very few of the children attended the one government-run preschool program, and although education was valued, the educational future of the children did not emerge as an important concern at this age. It is important to note that the economic and religious profile of the groups was quite similar, although very difficult to compare on the basis of the different ecological and economic characteristics of the urban (read corporate) and rural (agricultural) economy. The rural and urban families had a similar relative socio-economic position *within* their community. They were neither from among the very rich nor the very poor in their respective regions; and in that sense were assumed to be comparable. That is the differences between the two groups could be attributed mostly to the ecological differences, that is rural urban differences in family life. The study was focused on children’s sociocognitive abilities, to map the ways in which the ecological setting, epistemological orientations, and social interactions framed children’s expressions of self and other persons. While using multiple methods, the study focused on using standardized methods (false-belief task), language assessment

(receptive and expressive language based on picture descriptions), a play task (using similar materials) developed especially for the study, and a storytelling task where an ancient Indian story was used for gathering adult input to the child. The presentation of play materials required the family to put away all toys belonging to the child so that there was some similarity in the conditions for the activity. There was a tremendous contrast observed here, since only one rural home had some toys for the children that were within the child's reach.

The findings indicated that although 3-year-old children fail the false-belief task as is expected of their age, the reasons for their responses within the task could be attributed to their handling of dolls/puppets, and the discourse features of their community. Both these findings also demonstrated marginal advantages for urban children over the rural children. Let me elaborate this point. In the play with objects, there was a distinct "fear" of the dolls as could be seen from the videos of several rural children. Additionally, even those who were not fearful found them to be unfamiliar, despite the fact that these dolls were custom-made to "look" familiar in terms of hair, clothing, and appearance. Urban children on the other hand went speedily to play with dolls, often making sounds while simulating quarrels or other actions. It is not that this sort of play was not found among rural children, but its frequency and arrangements were appreciably different. During the play task, the researcher asked children to attribute feelings and activities to the dolls since that is a requirement for the false-belief task and she wanted to investigate whether the assumption and expectation of projecting thinking and feeling capacities to dolls was actually on an equal footing for all children. An activity that emerged with frequent manifestation (although the dolls looked nothing like babies) was rocking and breastfeeding the baby by giving it to the mother's breast! The dolls were also used for placing other materials on (e.g., a purse, spectacles, etc.) In urban homes, children were much more exposed to play materials that were clearly absent in rural homes, and the play with dolls was far more intense and complex, there was NO evidence of fear or hesitation. The children named the dolls with ease, and assigned roles, gender, and names. It is also possible to find support for this finding from Edwards (2005) where she found that doll play is more frequently observed among cultures that do not permit children to play with babies.

These two groups belong within one nationality and certainly also one cultural group if we take the popular meaning of culture. However, we can see that in many ways the social context forms an essential part, not only of the child's social cognition, but also of the shared understanding of the world, the objectivity and interobjectivity. To act as if the experience of playing with a kitchen set with a mother doll and a baby doll is "free" of context, and can be expected to manifest in all children at around the same maturational stage is another addition that we can safely add to the list of common fallacies with which psychologists can be afflicted. As a consequence, if a dyadic, "context-free" experimentation with objects is considered in a multi-party social context, then the child will certainly be reacting more to the transformation in the social setting rather than the task at hand. There were other very engaging differences that emerged in discourse strategies. This time, it was the number of interacting adults rather than rural and urban differences that emerged. For example, when dyadic homes (with mother and child) were separated from multi-party homes (the child with several adults, including the mother, grandparents, others), irrespective of location, the differences in discourse strategies (amount of talk by adults to child, for example) were significant, rather than by the rural-urban division. It is thus immediate context and the larger ecological setting *both* that need to be considered along with several other factors. This certainly loops back to the importance of the structure of the social setting discussed earlier (Derrida, p. 167, in the sense that children in rural areas did appear to have greater "freedom" from adult supervision. This was also reflected in the ways the people talked with each other. Far more conversation was directed to "everyone in general and no one in particular" (Chaudhary, in press) in rural areas than in urban, where there was more focused, dyadic conversation observed.

### **Conclusions: Affective Networks and Effective Strategies**

If the workings of culture are contingent upon social history and ecological and immediate setting, then affective networks in any encounter become integral to its study. Social interactions are not only a domain of study, they are also the context within which things are happening. Taking any example from developmental psychology, it is possible to explain the point raised here. We assume that a

trait like compliance, for instance, is something that a preschool child has *inside* her mind as a trait by which she is likely to agree or not agree to do something. We link the findings of such a trait to children's capacities to listen to others OR to follow their own minds, which are a priori assumed to be opposite behaviors. Then, if a researcher is considerate to the context, she may chose to link the children's said attitude to what is vaguely referred to as cultural context or goals. That is, whether the cultural group under study is inclined toward reinforcing children to be compliant or independent (as if there were only two options the child has). In such instances it becomes a requirement of meaningful research to search the layers of reality surrounding the child a little bit further. As an example of such a probe, a student of mine (Tomar, 2009) selected different tasks to investigate compliance in children: throwing an attractive-looking chocolate piece out of the window, placing a toy scoop (used in the sand pit of the school) on the head and placing his or her own shoes on the table between the researcher and the child. Although we expected the child to be least willing to throw the chocolate out of the window, the findings of the study showed the exact opposite. The preschool children in the study had NO hesitation in throwing the treat out of the window, and quickly justified it by saying it must have become dirty or spoiled, many did not even give a reason. But the (socially unacceptable) task of placing the shoes on the table received the least compliance. In between was the placing of what was assumed to be an unclean toy (it was not dirty) on the head. What Tomar (2009) concluded from the children's conduct is that taking any one or two tasks without first checking out some of the collectively shared beliefs about objects, would probably lead to superficial and even erroneous interpretations of children as autonomous or compliant! Here, the simple task of lacing one's shoes on the table is in complete violation of social conventions since any table is seen as a base for revered activity like placing books or food. Such a violation would be internalized very early by a child. This example demonstrates the existence of layers within layers of human conduct that are prepared for at a very early age, and the child's compliance may not simply be linked with her agreement with an adult, but to WHAT the agreement requires her to do. The loading of affect onto such tasks may go unnoticed by a person who approaches the phenomenon from the outside. It is thus necessary to pry open these layers

of affect that surround any given social encounter even if it is a research study.

It is possible to use self-other and individual and group dynamics (see Table 43.1) to assist in unraveling the complexity and in providing a framework for its study. In the example of compliance above, the young children's understandings of the world around them overtook the desire to comply with a friendly and engaging adult. Intersubjectivity seemed at this moment to have surpassed intersubjectivity, even at such a young age, since the act of throwing away the chocolate must have been rather difficult for the children.

Regarding reason and randomness, is it possible that there is a randomness to the reason in the sense that what may seem reasonable in one socio-historic setting, gathering meanings over the years, is not seen as such in another, such that collective meanings and attributions to nature, convention or individual agency may be different in different situations, individuals, and cultural settings. In order to understand these phenomena, it is critical to disentangle the distinct arrangements between an individual and the other in such a way that we are able to identify the levels of activity in a culturally relevant fashion. Meanings derive significance only within a particular worldview and despite the fact that the human situation (of sex differences, power, authority, politics, relationships, conflict) may seem to manifest universally, their dynamic reconstruction and meaning attribution is contingent upon local reality. Is it possible that reason is simply a post-hoc justification for what may simply be gut reactions of people in lived circumstances, driven by motives that range from greed to empathy as has been recently argued for the rather contentious domain of morality and human history (Bloom, 2010)? We have, Bloom argues, given far less importance to the forces of deliberation and persuasion in our research of choices that people make. Language is a critical process in this regard, as the author argues:

Stories emerge because people arrive at certain views and strive to convey them to others. It is this generative capacity that contemporary psychologists have typically ignored. Moral psychology in particular focuses nearly exclusively on studies in which volunteers are exposed to artificial moral dilemmas that have been thought up by other people, such as situations in which one must choose.

(Bloom, 2010, p. 490)

Perhaps reason and randomness coexist in locally meaningful ways and thus it may not be productive to actually see this in opposition as much as a layering of reality by local communities in making sense of their lives and the lives of others. This opposition that has been created between the arbitrariness of culture and its reason has in fact been an important reason for truncating the progress of dialogue between different theories about culture and human dynamics. It is, perhaps, time that we move beyond debate and into dialogue between different perspectives, and treat each theory as having some justification *within* the defined framework. After all, the historic and situational setting within which an idea is promoted, whether it is Skinner's "Beyond freedom and dignity" or Goffman's "Presentation of self in everyday life" or Geertz's "Available Light," each inspiration has a certain logic of its own that is best placed within the social reality of that particular intersection of time and place. It is during active recursion and application in a different world that we find ourselves and our minds having moved from the local significance of an idea to its global evaluation. Culture, Geertz (2000) argues, is set of "control mechanism" plans, recipes, instructions, rules, and other advice, that are superimposed on the genetic predispositions that we inherit.

Human evolutionary theory thus rests on the concept of a 'dual inheritance,' in which genes and cultures both are powerful determinants and each co-evolves with the other. We can distinguish cultural change from genetic change and can see how cultural change can follow an independent path from genetic change, but no great or eternal chasm separates them. Over time, genes and cultures interact repeatedly, constraining or reinforcing each other, forming the dual inheritance that shapes the life ways of the human organism. The human mind is remarkable for finding multiple pathways through the natural world, but those paths are always contingent on what came before and what is happening now to the planet. Historians need to acknowledge the importance of the environment and to embrace the theory and worldview of evolution for the dazzling light it sheds on the origins, development, and fate of humanity. (Worster, 2010, n.p.)

It is only by productive collaborations between different disciplines that a reasonable advancement of the scientific study of human conduct can be advanced. It is by focusing on social networks and interpersonal interactions among people that we

can make reasonable advances in understanding human conduct *in situ*. We need to find our ways back onto "rough ground" as Geertz suggested (2000, p. xii) in order that the friction thus created by using unfocused and unformulated ideas, that can take us from our smooth (and slippery) practices of understanding ways of living to more realistic ones.

### Future Directions

Several critical arguments emerge from this chapter that have potential contribution for future directions in research and theory. Firstly, psychological theory has to incorporate both personal and collective reality, since separating them is confounding and artificial. Secondly, any investigation of social-psychological processes must employ multiple methods in order that the complexity of phenomena may be attended. Further, quantification of human phenomena must be considered as and when there is a meaningful application of and sufficient grounds for assigning numbers to the processes under study. Also, the creative collaboration between disciplines: anthropology, sociology, literature, and psychology will go a long way toward developing a meaningful scientific study of people. The ideas that we develop for research and scholarly discussion must remain grounded in everyday reality, rather than only those pulled out from secondary and tertiary abstractions manufactured in university departments. Ordinary conditions of everyday lives *must* become the main focus of our study so that we can make reasonable interpretations of and contributions to the scientific understanding of the human condition. In my understanding, the loyalty and commitment must be toward the phenomenon, and not toward one or another way of looking at it. When ideas become industries, we (unwittingly) become constrained to think in particular directions, with specific meaning attributions. The discursive, open, and creative approach of cultural psychology allows us that freedom for exploring ideas within the context as well as from above.

### Note

1. I would like to acknowledge my doctoral students Pooja Bhargava and Punya Pillai for their assistance.

Xiaowen Li

**Abstract**

The topic of peer relations is a hotspot in contemporary developmental psychology. However the specific foci of research in that area vary under different viewpoints over development. Here we look at peer relations from the perspective of potential development and with the purpose of guiding self-development. Thus, the researcher is not merely concerned the relationship between peer interaction and self-development, but also emphasizes its significant value in analyzing individuals' developmental status. As an individual usually externalizes his/her inner world in peer interaction, peer relations provide a principle way to study the development of self-identity through analysis of the changes in peer interaction. Our investigations in Chinese primary and middle schools also revealed that the organized peer relations (which are called *Jiti* in China) was imbued with driving force for self transcendence. The activities carried out in *Jiti* provided students with creative opportunities to develop their potential, based on which the school cultural ecology was constructed.

**Keywords:** peer relations, potential development, organization, school cultural ecology

The essay mainly comes from the author's research findings under the background of Chinese educational reform program—New Basic Education (NBE)<sup>1</sup>—which forms the study position of guiding children's active development as well as an intrinsic perspective on peer relations. The essay involves the following subjects: The methodological standpoint of research on peer relations from the position of development; the self-developing dynamic from peer-relations organization in school context; the function of subliming; growing potential within school cultural activity; how to research the developmental stage features of students' self-identity from the aspect of peer-relations performance; constructing school cultural ecology by organizing students' peer-relations and developing their potential.

**The Development Perspective**

The topic of peer relations could be discussed in multiple psychological subdisciplines, because it is a phenomenon that exists universally in human beings. Peer- relation functions in various forms and influences individuals of all ages in diverse ways. Nevertheless, in the field of psychological research, it is particularly emphasized in children's development. Therefore, the discussion of this article is based on the perspective of developmental psychological research and the author's practice of a series of field researches aimed at promoting school students' development in the program NBE.

Theorists from different fields tend to choose different focal points when discussing the same topic. It is not only affected by investigators' research interests, but also influenced by their values orientations.

It is no longer believed that science should be of neutral value. In fact, the practical value and effectiveness of a research has become an important criterion both in project approval and assessment of findings. In terms of psychological research, especially in those applied branches, the practical significance seems to be especially important. With regard to developmental psychology, I think its value lies in guiding children's development through investigating the underlying mechanism.

### ***Intrinsic and Extrinsic Relationships***

There are various angles from which to study peer relations. As for a "relationship," it could be studied in the following two ways: (1) *intrinsic relationship*, which describes relations within the individuals, and (2) *extrinsic relationship*, which focuses on the outside relations between individuals.

The studies of extrinsic relationship tend to compare an individual's state or characteristic in peer interaction and to investigate pertinent influencing factors. Measurement is widely used in extrinsic relationship studies. I should say that the accessibility of measurement tools makes comparative studies very popular in peer-relation researches. Through comparative research and correlation analysis, researchers attempt to find out the characteristics that popular children possess, or to investigate the relation between peer-relation quality and well-being. However, the majority of the findings seem just to certificate people's common knowledge. For example, the popular children are more amicable and animated. Science should go beyond the immediate accessible information (Valsiner, 2000), while how to define "beyond" still remains questionable in psychological research. It may be believed by some that to prove the existence of daily phenomena with psychological experiments could be considered as kind of transcendence of ordinary experience. In other words, whether observed phenomena or human experience are widely existing facts are not sure until they are fully demonstrated by data. But, is it really necessary or indispensable? Objectively speaking, it is a psychological research's conundrum because everybody is so involved with the topics studied in this field. Nevertheless, it should be clear that the value of psychological research lies in adding knowledge by providing interpretation of the well-known experience and exploring the yet unrevealed psychological facts.

In contrast, the perspective of intrinsic relationship focuses on the relationship between peer

interaction and individual development, which emphasizes the interaction between the two counterparts. For example, friendship participation can operate as moderator in conflict solving (Lansford et al., 2007). Also, intervention with peer relation was of developmental and contextual sensitivity (Dishion, Dodge, & Lansford, 2006). In fact, the typical intrinsic relationship perspective can be seen in some famous theories (for example, Piaget's cognitive development theory, Kohlberg's moral development research, Selman's research on self-consciousness development, and Kegan's theory in self-development). Peer relation as an important organic component of a child's relation system, plays a significant role in promoting his or her development. On the one hand, peer interaction shapes children's development. And on the other hand, peer relations can be viewed as externalization of children's psychological states, through which children's inner worlds can be observed. Thus, the intrinsic perspective seems fit for research of developmental psychology.

In the field of psychological research, it is emphasized to select representative samples to make sure that the results could be inferred to the whole population. However, it is not executable in operation. In fact, we can only conduct research in a particular context with a small group of people. Nevertheless, deductive inference is still feasible when the research is conducted in a dynamic and systematic perspective. The intrinsic perspective possesses this advantage. It puts the features of peer relation and its changes in a developing dynamic relational system, thus it can generate insights of the characteristics of the Self developing process, which are not limited to the specific peer relation observed.

As mentioned before, comparative studies are common in the extrinsic approach, which is undoubtedly useful in some cases. However, when we only simply compare complex features, it is probable that we can only obtain limited fragmentary information. This limitation is especially distinct when the research is conducted in large samples, such as cross-cultural studies, for example individualism vs. collectivism. It is because that: (1) there are so many factors functioning together in a complex phenomenon that any single feature extracted from it could not fully explain it; (2) the larger the population is, the more complicated the situation will be, which makes sampling more difficult to be well-representative. Thus, comparative studies in this case usually are oversimplified, the researchers would be

like a blind man who feels an elephant—by taking a part for the whole

Let's take the cross-cultural studies on children's emotion expression as an example. It is believed that children from collectivist culture are more inclined to conceal anger in contrast to those from individualistic culture (*see* Eisenberg et al., 2006). Chinese children are often chosen as representative of collectivist culture. The explanation of the phenomenon described above is that individuals in collectivist culture usually regard open emotion expression, especially negative emotions, as a threat to close ties, therefore they choose to suppress emotion expression, even unconsciously (Kleinman, 1980).

Comparative studies like this only discussed the cultural attribution of emotion expression, but it still left subjects' psychological meaning embodied in emotion unknown. I could say it may be cultural anthropologists' task to reveal principles and rules included in culture convention, while the field of psychological research need only be concerned with the activities in individuals' psychological sphere. And actually, the emotion expression of Chinese children is various. Even if a researcher take hundreds of children as subjects, it only occupies one-millionth of the total 300 million Chinese children. Furthermore, if we fail to analyze the data by exploring the subjective meaning in certain context, it will not make much sense for children's psychology and cultural recognition, even though we have 100 million children for comparative study.

Recently, some longitudinal studies about friendship attempted to investigate the psychological meaning of emotion expression (Corsaro, 1994, 2006; Winterhoff, 1997). Findings suggest that African American, Italian and Latin children usually forge and develop friendship by arguing or teasing with each other. By contrast, children from Caucasian American middle-class families are more anxious about conflict because they sensitively regard conflict as an adverse factor to friendship. Thus, they tend to ask for help from teachers when there is an argument or collision. The researchers suggest that children's attitude toward conflict is intensely related to adults'. If teachers are sensitive to the threatening influence of conflict, they are more likely to intervene when the children are involved in conflict.

The longitudinal studies mentioned above walked into children's daily lives and studied their behavior in certain contexts. It is only when the behavior is analyzed in specific situations that we can see

the psychological meaning behind it. Then we can understand the individual sense or his/her mind theory (Li, 2009b). According to the sensitive reaction of the children and teacher to conflict, we can infer that both of them may consider conflict behavior as rudeness and it will jeopardize friendship. The close connection of conflict and friendship may bring different understanding toward conflict-related emotions such as anger. Thus children may tolerate them. Interestingly, these findings from process-focused research seem quite incompatible from the assumption provided by the cultural attribution mentioned above.

In fact, the culture in any country is a multivariate system that evolves over time. In China, for example, the understandings of anger expression are quite different in different social classes. In the eyes of traditional high-level cultured class, it is considered to be indecorum for a man to lose his temper. But to the roughscuff, things are totally different. There's an old saying: "no discord, no concord." It means that in many cases people get to know each other through a quarrel or fight. As the society of China undergoes a tremendous change, the diverse manners of anger expression that used to be a typical feature of social classes, in current times become personal action; even within a family, the anger expression manner may be totally different.

The progress-focused approach may be more proper to investigate dynamic topics such as conflict and emotion expression. For example, Corsaro (2006, p. 105) discovered in his longitudinal study that the children were more cooperative in friendly competition with each other. Meanwhile, the researchers from Taiwan (Huang, 2008; Li & Chen, 2002) studied conflict using depth interview and longitudinal tracing skills. They indicated that conflicts could be described in different types and may develop and transform.

### ***Gained and Potential Development***

How to define development in research of peer relations from developmental standpoint? There are multiple definitions about development. At present, it is mainly believed that development is the collection of those already gained features in each stage. The underlying hypothesis of gained development is that the rules of development are settled. Hence, pertinent methodology of research requires that the samples should be selected to be well-representative of the population, and to make sure that the

outcomes are verifiable. However, the development by no means keep to predetermined rule, but is realized through interactions among multiple factors. For unconscious beings, occasionality and variety in life can only be explained as doomed, but for human beings it is the arena to act out subjective activeness.

It is expected to create Hartmann's saying "an average expectable environment" to the new born generations (Erikson, 1998, p. 212). That is why developmental researches could not only focus on already gained features, but also to explore potential capacity and make it possible. As Vygotsky emphasized, teaching should go ahead of development. It is worth noting that well-adapted development is not spontaneous outcomes but the result of guidance with advancers. Thus, psychological development could be viewed as an active constructing process based on individual's potential capacity. The potential development perspective provides a more productive way to study development that contributes to direct practical activities.

The idea of potential developing was formed through research on students in primary and middle school, in Chinese NBE program (Li, 2009a). It is observed that students of each stage (mainly characterized by grade) develop certain self-identity tendencies that could be viewed as a value orientation of self-positioning. The tendencies could be expressed in adaptable or unadaptable ways, or could just be suppressed. Problems may come out in the latter two situations. Thus, cultural activities that are in accord with students' self-tendencies and created by peer cooperation provide a chance not only to adjust problematic states, but also to urge on active development.

In my opinion, development could be realized both in vertical and horizontal ways. The former means individual enters a higher stage, which is already emphasized in developmental studies so far. And the latter means expanding or enriching one's capacity in every stage. It may be parallel to the concept of fulfilled personality that Abraham Maslow mentioned. Vertical development takes place with the growth of age and is to a great extent based on and constrained by physical maturation, while horizontal development takes place by full potential expanding and culture creating in peer relations. Children could gain those two types of development and achieve a fulfilled personality if they are guided under school culture, which also improves their quality of life.

### ***Teachers' Double Roles in Children's Potential Development***

In the point of potential development to research, the focus is developmental tendencies of different grades, which are manifested in the self-identity orientation. It is a tough question because the orientation inside is not easily observed by others or perceived and reported by themselves, as Kegan (1982) indicated in his Self-evolving theory. He said that the Self develops through a continuing process of immersing into a certain state and then transcending it. When the individual was immersed in certain state, he/she could not yet take the psychological state of himself/herself in this stage as a regulatory object, thus it is impossible to initiated active self-regulation. Conscious self-regulation usually emerges later than the unconscious self-regulating behavior (Li, 1990).

Because the individual's self-consciousness of a certain state develops later, we can get little information through direct interviews or questionnaires. However, the orientation of self-identity is embodied in the peer interaction. It is because the self in essence is the organization of relationships and the individual's experience. Especially for the developing children, peer relationship is of vital importance.

Because direct observation would produce little effect, multifarious equipment and tools are invented as an extension of human sense organs to expand observation in scientific research. Psychologists also invent pertinent tools, such as measuring scales and experimental equipment. Unlike tools like the telescope, periscope, or microscope, psychological scales usually don't measure the psychological phenomena in a straightforward way. However, sometimes we can only get a superficial understanding from designed scales as they could only provide insufficient and fragmentary information of ordinary experience. Just like a person who has myopia but wears a pair of presbyopic glasses, it would probably lead to even worse visual images. It is necessary to explore other suitable ways to enhance the insight of psychological research. In terms of psychological observation, the human beings may be most efficient resources, especially the two types below: the ones who are close to the one observed and the subject themselves.

The teachers are the uppermost important resources in children's research conducted in school because, as teachers, it is part of their responsibility to concern and observe the students as they work with them. They always evaluate the students

in a relative perspective under certain context, for example, comparing to other grades. In this way, the teachers can most possibly notice the changes that have happened in the students. It is worth noting that through our educational reformatory experiments, student's developmental stages seem more obvious, and the teachers are more sensitive about the changes happening in children.

In China, there is an appointed teacher in charge of a class called the class advisor. They usually not only have to supervise the whole class all-sidedly, but also have to teach one of the subjects. In a sense, the information provided by a class advisor is equal to a large sample with even higher ecological validity. It is obvious in my experience that talking to class advisors is more efficient than to students, especially when students are in the lower grades. The original information provided by class advisors that are close to students' daily lives will be the materials for further investigation.

The teachers also have the principle roles in guiding children's development, which could not be realized outside school. Thus, the cultural ecological approach needs to be introduced into developmental research, rather than abandoned or rejected. Kohlberg used to transplant his psychological model of moral development into school education, but failed at last. He considered it a psychologist's fallacy because the research applied in school education should come from those school education practices (Kohlberg, 1983c, 1985a). The question of how to construct an active school life for students deserves more attention in the developmental field.

### **Construction of Peer Relations and Developmental Dynamics**

As we know, the individual develops during the process of interaction with his or her environment. However, the interaction is carried out by medium activities, in which development realizes. The medium of development exists in relationship, which contains special meaning and the developing motive power.

### ***The Medium of Personality Development: Jiti and Cultural Activities***

George Herbert Mead (1934) has early discriminated the difference between object and stimulus and suggested that the stimulus could be considered as objective while objects were subjectively constructed. Individuals construct their personal meanings of the stimuli presented during activities that

are social in essence. Lev Vygotsky proposed two kinds of mediums: psychological tools and social others. The intermediate others endue meanings to related symbols during activities, thereby to make them function as psychological tools (Kozulin, 1997). Leontiev also emphasized that "activities should be associated with the concept of motivation," and an activity "contains underlying motivation in both subjective and objective ways" (Leontiev 1980, p. 68).

Vygotsky explored the micro-mechanism of cognition development in his research. He suggested that cognitive function developed through the organizing process of symbolic tools, while the social others were significant in forming those tools. Leontiev's theory of activity also has its own contribution to personality development. He emphasized that individual internal need also functions as a potential motivation force.

School provides abundant mediums to guide development. Not only individual teachers or classmates, but also the organized student peer relations called "Jiti" serves as an important medium. The symbolic tools that are beneficial for enriching personality development could not only be obtained from classroom learning experience, but also from the cultural activities. In other words, the cultural activities created by Jiti are the main medium for personality development.

Collectivity can be translated into Chinese as two words, "Qunti" and "Jiti." *Qunti* means crowd, *Jiti* are groups with organization. In Chinese school, we say that the class "forms Jiti" meaning, it is a growing force that unites the classmates and draws them closer to one another. If we say that a class "fails to form Jiti"—that means that the organization of this class is slack and inactive.

### ***Developing Motivation in Jiti***

Environmental factors can stimulate or impede development, depending on whether they can arouse an individual's inner motivation or not. Jiti and related cultural activities can function as mediums to help children to achieve self-transcendence just because they are satisfied with the individual's need.

### **BASIC ASSUMPTION AND THE ORGANIZED TEAM ACTIVITIES**

For one thing, Jiti activities provide places for peer interaction. It is human being's instinctive demand to live in a group, especially during adolescence. However, the influence of peer communication

might be positive, or not. The *basic assumption* was suggested by Bion (1961); he said “the individual must assume in order to be a part of a group.” It is particularly obvious in the school context.

The organized activities are not only aimed at providing a place for peer interaction, but also at helping young adolescents to put their energy into creative exercise. It really was an challenging work. The children in experimental classes participated with great interest in the activities of team constructing. They negotiated with other team members to give their team a lovely and meaningful name; for example, the Bees, which represent hardworking, the Ants, which means team spirit, Ultraman, which indicates great power, and Ikkyusan (a Japanese cartoon character), which means bright and intelligent. Even the naming process gave the team members a chance to learn how to negotiate to achieve a consensus.

A class meeting was followed to pronounce the establishment of the teams. Each team prepared elaborately to attract other’s attention. Some drew a painting to illuminate the team’s name or composed a children’s song to declare the slogan. They did the preparation work after school so they could ask their parents for help. In the class meeting, all the children presented themselves, team by team. All the team members wore a badge with the team name on it. They were so proud of it that when a little boy lost his badge, he burst into tears.

It was observed that in some nonexperimental classes, some energetic boys usually crowded spontaneously and ran after each other after class. They kept on running in the corridor and fought as a group with another group. This example showed that children need appropriate ways to release extra energies. That is also a specific demonstration of the basic assumption proposed by Bion (1961).

#### **A DEVELOPMENTAL CIRCLE: COMPETITION—COOPERATION—SELF-TRANSCENDENCE**

The findings of cross-cultural studies showed that Chinese children tend to cooperate more but compete less. However, cooperation and competition are in fact two inseparable concepts in the organization of peer relations. We designed activities that require competition between classes to form each Jiti, which spontaneously promotes cooperation within the class. Only when the whole group runs for a common purpose, all the members are driven to work together.

However, cooperation and competition are not of the same level in the psychological development state, as competition functions more instinctively while cooperation doesn’t. Although people need to be socially connected, they are not born to collaborate with each other. In contrast, the human being has an innate motivating force striving for perfection (Adler, 1932), or self-enhancement. Cooperation requires individual to be capable enough to assume a shared goal and to realize it.

Competitive situations are set to activate students’ cooperation within groups as well as competition between groups. But the competitive task could easily end with contests among outstanding students of each group, then the others couldn’t participate. Therefore, it is of prime importance to emphasize that all members’ active participation is the foremost evaluation criterion. And, it is also the reason why cooperation needs direction and training.

Our ultimate aim is to achieve individual development through collective cooperation, which in fact serves as an essential and effective pathway. Groups can generate a strong driving force to its members. But sometimes it results in problem behaviors. For example, the phenomenon of conformity revealed in Solomon Asch’s experiment might be a principle reason in gang fighting or anti-Semitism in World War II. Therefore, it requires proper design to make sure the group driving force functions positively, which is also one of the primary rules for Jiti organization. Once the groups are motivated to win by cooperation within the groups, each member will try hard not to be a drag on his/her group. Jiti can provide individuals, especially those less independent or capable, with courage to challenge themselves with tasks beyond their own present ability, as the risk of failure is shared by all members and the tasks carry some playful color with peer context. In this way, the sense of honor of Jiti becomes a strong motivation for self-transcendence.

#### ***Peer Relation within the Mechanism of Ideal Self-Regulation***

In my doctoral dissertation research, I found significant discriminating features between adaptable and unadaptable students, which existed in their peer relation. The well-developed individuals could form and modulate their own goals during interaction with peer(s), while the problem students tended to avoid or reject peer communication (Li, 1991). Following are two examples.

Chen used to be a shy and timid boy. He always talked in a quiet voice and never spoke aloud in public. But when he entered fourth grade, he changed a lot. By then, he was so active to express himself to the whole class with a clear and sonorous voice. Following is the interview with him about his change.

Li (L): Why are you not timid anymore?

Chen (C): It doesn't feel good to be timid. But it feels great to be valiant.

L: Is there any advantage to be[ing] valiant?

C: Yes. Now I have more friends.

L: Do you think your classmates prefer valiant ones?

C: Yes, I think so. Some of my classmates are quite lively and active. My dad asked me to learn from them.

L: How did you learn then?

C: In the winter vacation, I try to seek chances to talk to strangers in the park.

L: Didn't you feel embarrassed?

C: Yes, I was very embarrassed at the beginning. But I encouraged myself that 'it's not a big deal, just practice.'

L: I can notice that you're quite courageous now in class. You dare to speak and often try to be the first one to speak.

C: I said to myself, 'the sooner I finished the presentation the better, because the pressure is released after that.'

Another student Xu WC, who was also in fourth grade, was excellent in self-reflection and self-regulation. He was good at self-analysis by comparing himself to other students.

Xu (X): I am not satisfied with my performance this term. I only got 91 or 92 in Chinese examinations and in math the scores are seldom above 95.

L: What's the reason do you think?

X: I did quite well in basic knowledge and composition. But I lost many scores in reading.

L: Why does it happen?

X: I think the main reason is I hadn't made clear the questions before I answered.

L: Do you have any plan to improve it?

X: I have to read more.

L: Do you have any reading material after school?

X: I prepared some by myself. I usually visit the bookstores every several months and buy myself some books.

L: Are these ideas from your parents?

X: No, they are my own ideas.

L: Why?

X: Because my academic performance was not satisfying last term. And I was not so active in class.

L: Why do you think so?

X: Comparing to some of my good friends in class.

Individuals usually become aware of their own disadvantages by interpersonal comparison. However the awareness of self-deficit doesn't necessarily lead to developmental self-regulation. It is difficult to protect the self-esteem for both sides compared (Baumeister et al., 1996). But the situation is not the same when the comparison takes place between close friends. The affection involved in friendship would eliminate the threat to self-esteem caused by comparison. This psychological mechanism provides the basis for the function of self-development: (1) The children who have established friendship with peers tend to make objective self-assessments through peer comparison; (2) the children then build up the goal for self-improvement; (3) the sense of belonging and acceptance by others drives the individuals to produce positive self-regulation.

#### RE-ESTABLISHMENT OF PEER RELATION: APPROACH OF IMPROVING SELF-IDENTITY

During my doctoral program, a student who used to be unadaptable made marked improvement, which attracted my attention. In the interviewing analysis, I found there were two main reasons for his progress. First, he joined in a team and was accepted by others in the team. The members of the team were enthusiastic and willing to help him when he was in trouble. Second, some of the members were quite outstanding in class. He was happy to have the opportunity to be teammates with them. The student who used to be a scrappy defendant tried his best to control and regulate himself in order to make the team work harmoniously.

I realized that it may be a feasible approach to intervene by helping unadaptable students with establishing good peer relations. In my doctoral program, I chose four cases to follow, three of which were quite successful (Li, 2001). Here are the records about two of them; one is successful and the other unsuccessful.

Zhang and Xu were both fourth-grade students, both moderately intelligent. Zhang lived in a middle-class family. His parents took very good care of him. And Xu's parents were less educated. His mother took charge of a little café and his father spent much time playing cards outside. Neither of them returned home until midnight, so Xu always had to stay home alone after school.

Zhang was a vivacious boy, and had been diagnosed as Attention-Deficit Hyperactivity Disorder (ADHD). He had accepted treatment in a hospital for over half a year but it didn't help much. Zhang was in a boarding school; he couldn't accomplish his homework every day and could not get along with others well. He even kept a diary, which recorded every conflict with his classmates as a plan to get revenge one day. His deskmate Duan, who was a girl, and the boy behind them, Wang, who was also a roommate (classmate) of Zhang, were both excellent students. They were chosen to establish peer relations with Zhang.

After 2 weeks, I found Zhang didn't improve much because Duan and Wang hadn't changed their relation with Zhang. Then I required them to do something to show they were friendly to Zhang.

After that, Duan and Wang came to Zhang and showed their willingness to make friends with him. Moreover, all the roommates were involved in discussing useful strategies to help Zhang. Wang also played the record of the roommates' meeting they shared ideas to help Zhang to Zhang. Zhang was quite moved. Below is our conversation after that.

**Zhang (Z):** Duan and Wang told me that they wanted to make friends with me and would not treat me as before anymore. If I did something wrong, they just reminded me to correct it instead of reporting to the teachers. Previously, they always told the teachers, but now they don't do it anymore.

**L:** What do you think about the roommates' meeting?

**Z:** I will not fail them.

(Several weeks later)

**L:** Do you find that you're more popular now?

**Z:** (thinks for awhile) Yes. At the very beginning, only Duan and Wang showed kindness to me. But now more and more classmates would like to be friends with me (and he gave many examples).

**L:** And they are happy for your good performance. Do you feel that?

**Z:** Yes, when I got 83 in math, or when I finished my homework before 5 o'clock, they even applauded to me.

**Wang (W):** One of our classmates said, 'We were so happy to see Zhang finished his homework, even happier than when I finished mine.'

**Z:** I feel so good about myself, ever since Grade 2. But there were less and less classmates who were willing to play with me, because I quarreled with them quite often and never apologized. Therefore, my friends were quite few.

**L:** How do you feel about that?

**Z:** It was fine when nothing went wrong. But when I was in trouble, for example, when my pencils were used up, they wouldn't lend me any. They might say, 'I treat you the way just as you did to me before.' As a result, I grew to dislike them.

**L:** But now you expect them to like you, right?

**Z:** Yes.

**L:** What have you done to make yourself more popular?

**Z:** Just in some respects. For example, I used to be reluctant to accept their advice, so I always would like to say, 'Why don't you make better of yourself first?'

**L:** But now you know that it isn't a good reaction, right?

**Z:** Yes, actually it is quite offensive.

By then, Zhang had behaved much better than before. Duan and Wang were excited about that, and discussed what to do next.

**Duan (D):** I find that Zhang gets along with us quite well now. He would like to talk to us or even help us when we are short of stationery or something else. Sometimes he answers back when I remind him something. But a few minutes later he may come back and tell me a joke to amuse me as apology. He is quite different now. And our classmates are nice to him. I think what we are going to do next is help him to pass the tests. He failed two mid-term examinations. If he still can't pass in the finals, the situation will be tougher.

**L:** Do you have any plan?

**D:** First of all, I can help him to make his homework better. Now he behaves quite well in class, listening very carefully.

**L:** Does he have any trouble in homework?

**D:** He will ask me for help if he has problems.

**L:** Do make sure that he really understands and improves the quality of his homework. Do you think the improvement of his relationship with classmates also has benefited in his academic performance?

**D:** I think so. People would not be so willing to help him if he is in bad with others. But now if Zhang had any problems, we are happy to help him.

**L:** How does Zhang feel about it?

**Z:** I think he knows it is good for all of them. Our teacher also praised him because he can finish his homework on time recently, and carefully.

Zhang also told me that Duan and Wang tried their best to find out ways to improve Zhang's relationship with others. For example, when someone is looking for a ruler, they may give their own ruler

to Zhang and ask Zhang to lend it to the student actively. Along with the improving of peer relation, Zhang gradually stepped into self-monitoring and self-regulating of his studies.

But things didn't go smoothly as we imagined. Sometime later, Zhang resumed his former manner. It was known that Zhang was participating in a drama play representing the school at that time, so he didn't have enough time for his homework. In that case, Duan's reminding might sound like a threat to his self-esteem. Also Duan was upset and complained a lot to me. After mediation, Duan decided to forgive Zhang. Meanwhile Zhang also realized that if he didn't accomplish his homework as required he might fail the exams. Then they became reconciled.

It is quite normal to have twists and turns during the development process. Individuals tend to detach from the Self-Object relations (the term of Kohut's self psychology, the Self is formed from the Self-Object relations), which may be a prelude before being independent as they gain inside growth and seem to undergo a retrogression. Therefore, it is also a great challenge for the helpers. They should not only provide assistance appropriately, but also handle the target's retrogression, or even attack behaviors. Thus, it is necessary for teachers to get involved to intercede.

Since then, Zhang stepped into a steady progressive period. At the end of that semester, Zhang actively invited Wang to have a conversation with me together. Following is a selection.

Z: I set a schedule for myself.

L: For preparing the final exams?

Z: (nods his head) Yes, I've made the plan. I found that there were 15 days left. So I planned to revise the new learned characters, one lesson a day. Until now I've finished ten lessons. And there are five left.

L: Is it an assignment required by your teacher?

Z: No, I do it by myself, in a notebook.

W: (to me) Zhang is very self-disciplined now. Just the other night, Zhang's handwriting practice wasn't going smoothly. I set an example for him, he was glad, and promised to do better next time.

L: How did it happen?

Z: I desire to get better.

L: Why?

Z: I find that my brain doesn't work when I reject accepting their advice. But when I really think over their suggestion, things go through.

The improvement in his relationships with others enables Zhang to consider his classmates' suggestions

in a less aggressive way that contributes to his growth, as it eliminates the threat to his self-esteem. In his final exams, Zhang made remarkable progress. His class advisor told me that Zhang's parents also noticed Zhang's change at home. He could finish his homework during summer vacation all by himself. In the following semester, although Zhang's<sup>2</sup> academic performance was still not good enough, he could manage himself in class and in homework.

Another case, Xu, was not successful. Xu was 12 years old and he behaved more childish than his age. He also couldn't accomplish his homework every day and could not get along with others well. The interventional tracks of Zhang and Xu were almost opposite. Zhang moved slowly at the very beginning but progressed quickly later on, while Xu changed immediately when intervention was involved. But the happy days did not last long. Antagonism appeared between Xu and his teammates. The intervention program was termination. Xu then acted in his original manner again.

Because there were no students of great capabilities like Duan and Wang in Xu's class, I tried to involve the natural team to which Xu belonged as a base for intervention. Xu immediately raised an objection because there was no captain in his team. But some students on the team to which the captain belonged were incompatible with Xu. On balance, Xu accepted his natural team.

At the very beginning, Xu was excited that the teammates invited him to be their friends. And he didn't feel lonely anymore, because his teammates called him in turns after school to remind him to finish his homework or answer his questions. During the first several weeks, I often heard that there had been a noticeable improvement in Xu's behavior and academic performance.

However, as Xu improved, especially when he did better than his teammates in some aspects, the relationships within the team changed. Xu began to show his discontent with his teammates again, and complained to me that there was no captain on his team. Moreover, he began to criticize his teammates for their reading or examinations. As Xu kept on censuring and attacking others in the team, the just-established relationship between them ruptured. Thereby, the intervention came to an end.

Throughout this process, we can observe the need for object relation in Xu (Kohut, 1985). He cared so much about the status of his teammates in class, because it was related to his self-esteem satisfaction. It reflected his attempt to look for Ideal Self-Object

(one of the Self-Object relations found by Kohut which offers value attached) in his peer relations. When he made an improvement, he began to depreciate others to magnify himself, in which the others functioned as a Mirroring Self-Object (another kind of Self-Object relation which pays close attention to and appreciate the Self). However his team failed to provide him appropriate sources to satisfy Xu's wants. It can be seen that the Jiti atmosphere is quite important for peer intervention. In Zhang's case, his change was largely contributed to the social support provided by the peers of whole class.

### **School Cultural Activities and the Sublimation of Developmental Potential**

The incompleteness in evolution drives human beings to pursue self-actualization as a distinctive force. However it could only be achieved in jointly creative activities. The school culture constructed by students with peer-cooperation provides a platform for students' potential development. The creative cultural activities not only conform to the growth needs of children and adolescents, but also create chances to realize their self-transcendence.

### ***Developmental Problems as Expression of Potential***

Many problems can be viewed as normal phenomena in growth, because it is ordinary that individuals may experience maladjustment during transition. As a Chinese adage says that children usually gain prominent growth after sickness, the crisis as Erik Erikson (1968) described could turn out to be an opportunity for further development, although frustration or rapid change often brings uncomfortable stress. Problematic behavior may emerge if it isn't appropriately expressed. Aggressive behavior doesn't necessarily result from aggressive motivation. It is possibly driven by other needs. One of our researches (2001) demonstrated that sometimes an individual may attempt to fulfill his/her self-esteem by attacking others. In my interview, a well-known assaulter in school told me, "I have no chance to be the best, so I choose to be the worst. Anyway, I am still one of the most powerful students in school."

In junior middle school, young boys usually manifest their masculinity by fighting with each other. A student of that age said they probably fight with close friends as a solution of conflict and the fight might be stirred by a skirmish. But they usually didn't deal with strangers in this manner.

Because close friends wouldn't consider it too seriously as they know each other well. When he was asked why he'd like to choose this way, he said, "it's okay for boys." It means that fighting equals masculinity for boys (Guan, 2008). The teachers also found that they might fight heavier when they were surrounded and watched, especially when there were some girls around.

Another researcher Honggang Sun (2005) compared the fight and quarrel behavior in third- to ninth-grade students in Dezhou (it is a more traditional small town in Shangdong province) and Shanghai. He found the fights and quarrels that happened between the sexes were related to puberty, because it increased in the fourth grade when most girls' puberty begins. Sun also found that as the fighting and quarreling between sexes increased, it decreased within sexes. But the situation in middle-school students was a little different between the two cultures. In Dezhou, quarreling and fighting within the sexes raised while it decreased between the sexes in middle-school students. But in Shanghai, the contrary was the case. We can see from the findings that fighting and quarreling could possibly be viewed as an approach adolescents taken to release their energetic drive.

The drive boosts with hormone increasing during puberty, which easily transforms to skirmish or similar behavior. Ma (2009) found that in the third-grade students in China, girls and boys tended to interact with each other in a "hit and hit back" manner. While in fifth grade, they would like to run after each other or quarrel. Gossip emerged in sixth grade and prevailed in junior middle school, and would not confine within the class.

In fact, it is ubiquitous that drive is expressed in transformed ways, especially in rapidly growing adolescents. Drive should be released, but it is not good enough. The drive also is potential, it should be expressed in a sublimation way as Freud described. Creative school culture activities can serve as an effective approach to guide to sublimation. At present in most schools counseling and other interventional ways are a principle approach adopted in the school's psychological health program. Such a working model tends to prevent unhealthy activities but does not necessarily promote health. We can borrow ideas from Higgins' (1987) theory of self-discrepancy, the former approach works to prevent "ought-not-to-be," but not moves to the "ideal" state. The activities aiming to guide sublimation not only provide the opportunity to express children's

growth needs, but also direct them to approach the ideal self.

### ***Positive Intervention Realized in Creative Culture Activities***

When the activities are designed in accord with children's developmental potential, they can initiate the creativity of children. As school cultural activities are carried out in the form of play, which are full of challenge but without any risk of failure. Thus those culture activities aiming at developing children's potential can produce positive psychological intervention, which also works on some special children. The following cases will demonstrate this.

Case 1: There was going to be a dance contest held in a fifth-grade class. They competed by team. All the students gathered together by team after class to discuss what to dance and practiced it again and again. The dance contest was wonderful, everybody improved, including several problem children. One boy whose parents were addicted to drugs and gambling had been impaired in social interaction. He changed to be positive and genial. Another boy who suffered inborn movement disorder even had problems in walking. His father worried that he was not competent to participate in the dance and tried to ask him to quit. But the teacher and all the team members encouraged him not to give up. He enjoyed so much in the performance and became self-confident.

Case 2: A sixth-grade girl was well-known in her school because she once escaped home at night and committed suicide. It seemed no one can touch her heart. She was good at drawing, so she joined the publicity team and took charge of writing articles to report news in class. Once, she wrote a piece of news on the blackboard to praise a student in class whose ability was poor but studied hard. The student hence received warm concern from classmates and really gained improvement from then on. The class advisor asked the girl to write a poem about the whole story, and her team performed the poem at class meeting. It was too difficult to name which factor contributed to her improvement. Whatever the reason, it was a great encouragement to the girl. She has been much more positive since then and also improved a lot in her academic performance.

Case 3: A less intelligent eighth-grade girl used to have trouble with social avoidance. After joining the activity held in her class, she became much more outgoing and confident. All the students were organized in groups to interview the graduate-school

fellows to find out their working experience and use it as materials to create a story, poem, or short play to share with other classmates in the class meeting. Later on, there was a basketball-shooting contest in school. The boys were much more enthusiastic but a few girls were interested. Surprisingly, the girl mentioned above stood out and won two shots for the class. The once self-abased girl told her class advisor, "I am not good enough in academic record, but I'm happy for my good performance in other respects."

It could be noticed that different activities were organized in different grades, because only when the activity can satisfy students' developmental potential, can it inspire children's initiation and creation to the utmost extent. Moreover, it also benefits students' self-efficacy. We can see from many cases that, the positive effect gained in Jiti activities can transfer to other aspects of children's lives. They will not only be more enthusiastic in Jiti life, but also acquire academic improvement.

### **Developmental Studies in School Context**

The construction of school cultural ecology is based on the understanding of student's developmental features at each stage. The researches in this perspective need to focus on development of the whole personality rather than specific areas. Also, it should be emphasized that the researches need to be conducted in the school context. So, we focus on children's self-identity development in school. As we mentioned before, we selected peer relation as a main focal point.

### ***The Cultural Ecological Approach of Developmental Research***

There are two approaches to explore the characteristics of each developmental stage. The first one is interview based on observation in the school context. As we discussed above, the teachers are the main target for interview, because they can provide us rich information about the children's changes through their daily observations. We also can get information from the research conducted by researchers in the university on the topic of self-development, such as relational representation, the development of self-disclosure, self-presentation, emotion regulation and gender identity, etc. The information collected from the two approaches are different, as the teachers in primary or middle school can tell us more information about the students' behavioral changes that happened in school while the latter can reveal more information about their inner world.

It is worth mentioning that the observations under the school context can not only provide information about students' daily lives, but also can serve as an examination of the intervention implemented. As it was stressed above, only when the cultural activities adapt to students' self-development trends, is it possible to involve them to participate with great enthusiasm, and generate positive outcomes. Conversely, the after-effect of activities works as an important evaluating indicator to judge whether the designs are reasonable or not. It could be called *cultural ecological validity* (Li, 2008).

From the two ways described above, we can get omnifarious information about students' development in school. It leaves another question to the researchers that they need to discriminate the proper information that could be used to describe stage characteristics. Although quantitative analysis is much more common used in psychological research, in my sense, it is not suitable here.

For one thing, the stage characteristic of students is embedded in the school context in which they live. It is determined by school culture to a certain extent. Secondly, as in our research, the phenomena that contain useful information usually are obtained by observation or teacher's report, which are difficult to be transformed to quantified variables directly. It is because the phenomena observed by teachers usually still remain unconscious to the students themselves. Still, sometimes some typical phenomena only appear in a few students in a certain stage. Although they are not prevalently presented among all students, they provide a breakthrough point to the researcher to analyze the change that happened in different grades. If so, extensive measurement would probably obliterate valuable information. Considering the reasons described above, I think a qualitative method is more applicable to analyze the data obtained by the methods discussed above and to thus conclude stage characteristics.

However, the findings generalized from everyday phenomena are not bound to get essential understanding beyond daily knowledge. Only if we make clear the evolving mechanism underlying the characteristics of different stages, the stage characteristics generalized could afford the process of reasoning. So we need further analysis based on inferential explanation. In fact, it is not only a further step of study but also a step of verification. Inferential explanation is also an approach of verification, it is common in some other disciplines, such as history or uranography. Because in these areas it is not easy to

get sufficient empirical evidence, the reasonableness of inference of theory thus functions as an important approach for verification. In our research, it is only when the underlying mechanism that explains the logic of change happening in different stages is clear, the stage characteristics demonstrated could be viewed as universal law, which then could be extended to different school cultural contexts. The more important thing is it makes the construction of school cultural ecology possible.

### ***The Generalization of Stage Characteristics***

At the beginning of our research, we found that similar phenomena emerged in the same grade, although maybe in different classes or different schools. We also found that the developmental characteristics were related to school experience. For example in China, in some places 5-year primary school is standard while in other places there is 6-year primary school, thus the junior middle school starts sixth grade in some places but at seventh grade in the others. The students entering sixth or seventh grade as the initial period of middle school behave similarly. They tend to be more positive so as to leave a good impression on others at the beginning (Peng, 2004; Xu, 2004). The similarity of school experience for students in the same grade may be a significant factor to shape the developmental characteristics in the certain stage, especially when guidance is intervened (Magnusson, 1999). This exactly manifests that development is historical.

After 4 years of research accompanied with educational reform in schools, the stage characteristics from first to ninth grade became clarified. On the whole, each grade could be distinguished from others by its special features, especially in the transition period: third or fourth grade in primary school and seventh or eighth grade in junior middle school. In the transition period, the individual develops with identity change as well as peer relation evolvement (Jiang, 2006; Chen, 2008; Hu, 2009; Li, 2010). Following is the generalization of the characteristics in the two transition periods.

The following phenomena are common in second-grade students. They are eager to be praised by teachers, so they try hard to project themselves to attract teachers' attention. And, they may be unhappy when they see others getting praise but they don't. It is different from students of first grade for they will be happy no matter who in the class is praised by teachers. There's an unusual phenomenon

that the straight-“A” students may falsify their papers in order to get the highest score. Also, in this stage, parents are more impactful than peers to impel the children to study harder (Li & Shen, 2007). The common characteristic in this stage is that children are obedient to teachers and parents, as they follow the teachers’ rules and behave conformably to get positive evaluations.

While in third grade, students would like to show their cleverness. But unfortunately they usually make silly mistakes because they are unable to attend to everything at one time. They may conflict with each other because both of them would like to take an active part in the activities without noticing that they may interfere with each other. They seem to be undisciplined and disobedient to the class leader. In third grade, students tend to play with peers of the same gender. The interesting thing is the children may depart from their normal behavior to capture others’ attention. For example, the good students may break the discipline in class and the backward students may take any chance to assert themselves (Wang, 2007). What’s more, when asking them to imagine what will happen if they fail in the exams, their own imagined feeling and reaction in that situation seems the most driving force to make themselves work harder (Li & Shen, 2007). We can see from these phenomena that the individual in third grade has developed intense self-consciousness, they desire to present themselves but without corresponding planning and regulating ability.

Students in fourth grade become quiet and sophisticated. They begin to develop a circle of friends, and keep touch with each other after school by phone or others ways. Those used-to-be-helpful students seem insensitive to other’s difficulties anymore. Those who are not smart or beautiful may be desolated by others. The girls begin to pay attention to their appearance and the interaction with the opposite sex becomes sensitive (Ma, 2009; Liu, 2009). In addition, more private topics emerge in self-disclosure talks (Zou, 2007). Also, they become more independent of teachers and parents. These phenomena reflect that the personality of students in this stage has gained structural development. The selective peer relation becomes dominant in their evaluating system instead of teachers or parents.

Students in seventh grade form their own peer groups quickly after they become familiar with each other. Individuals of this age are interested in popular culture. They star-chase celebrities and follow the

fashion, and share the popular information within their groups. The students in seventh grade are also most vigorous and active; they like to participate in all kinds of activities such as sports games with great enthusiasm. They also enjoy wandering around the campus and easily conflict with others. The students in seventh grade are the ones who are zealous in peer interaction and school activities. Moreover, they begin to build up their own culture through peer interaction.

Compared to students in seventh grade, those in eighth grade tend to be more sedated. They are more rational in celebrity chasing but act more passively and sophisticated in daily school life (Li, 2001; Qian, 2007). They would like to help friends to conceal their mistakes. Also, they try not to embarrass others by judging or assessing their disadvantages. However, they are can be honest with close friends and the mildness of their expression is inversely proportional to the closeness of their relationship, which is opposite in lower-grade students (Jiang, 2006; Chen, 2008). Compared to other grades, they are least willing to confide their troubles or worries to others (Zou, 2007). Furthermore, they express their emotion in accordance with the cultural custom. For example, they don’t express intense emotions in public. It is also found that the individuals of this age express the emotion with the intensity parallel to the way they experience it when confronted with minor emotional affairs. However, when they are facing big issues, the degree of expression is much lower than feeling (Li & Li, 2007). It seems in eighth grade, another structural transformation of personality happens. The social custom plays an important role in regulating the individual’s behavior.

### ***Analysis of the Evolutive Mechanism of Self-Identity***

As we discussed above, we need to analyze the internal relation of the observed phenomena from the perspective of self-development tendency and explain the change trajectory in a historical view. In fact, the generalization of stage characteristics and the analysis of the developmental mechanism are two processes closely interacted, which could be called *double cyclical research* as Tania Zittoun suggested (Zittoun, 2006, p. 88). We can’t understand the development tendency or the possible problems until we can provide a full explanation of the evolutive mechanism between various grades.

The developmental trajectory of students from first to ninth grade could be described in terms of self-identity development in line with the evaluation system, which determines the developing individual's value orientation and thus influences their feelings and behaviors. In general, individuals transcend their previous state and immerse into a new one as they move to the next stage. In each transition, individuals integrate the evaluating rules of certain significant others and move to new relationships. In each step, tendencies of both development and problems are engendered. The trajectory of development from first to ninth grade is briefly described below.

The children who enter the primary school in the first year are still unfamiliar with the school conduct norms. As most of them find it difficult to take goal-oriented activities, they can only focus on the present task. After 1 year of school life, individuals are able to transcend the previous state and become sensitive to the evaluation from others, especially the teachers. Thus, they strive to get praise and avoid criticism by others, which functions as a driving force to self-regulation.

The school life shapes individuals original sense of themselves as historical beings. They begin to step over the state of pursuing exterior evaluation and begin forming his/her own sense of evaluation. They begin to concern their own abilities, and being brilliant becomes the dominant desire. The original sense of historical perspective is still strongly self-centered with narrow consciousness. Thus, the students in third grade usually have difficulty completing things comprehensively, although they are quite active to make themselves prominent. It is worth noting that the self-presentation behavior impels peer interaction, which encourages individuals to turn to positive negotiation of self-identity construction.

Individuals can reach a holistic understanding of themselves and others through frequent interactions. The peer interaction spurts in fourth grade, through which individuals realize self-positioning. But in this stage, individuals selectively build up relationships with peers, who actually function as an externalization of his/her self-concept. In addition, as the girls at this age begin puberty growth, peer interaction also provides a place for them to share private topics. On one hand, the selectivity of peer interaction at this stage is beneficial for children to pick and develop ideal characteristics. On the other hand, it may cause alienation and rejection

between peers, especially in a class exhibiting weak cohesion.

The interaction experience in fourth grade provides an opportunity for students to integrate various types of relations. Students in fifth grade gradually tune in to other people's needs and their internal experiences. They also internalize the school norms and teachers' requirements as school experience increases and the thinking develops. Thus, "generalized other" (Mead, 1934) is formed to regulate individuals' behavior initially and reasonably (Li, 1993a, 1993b, 2010).

The children are eager to project themselves once again in order to take a favorable advantage in the new environment when they attend junior middle school. Based on the experience in primary school, they soon get over the evaluation rules provided by school and enter the stage of individualization. So they also enter selective communicative activities. But now they don't select friends for self-positioning, only with the purpose of making friends. Also, children in puberty tend to identify ideal gender roles and develop romantic relationships. The peer relations mainly based on common interest construct the specific cultural circle for the adolescent, thus subcultural evaluating rules come into being, whose influence on adolescents may go beyond that of school norms.

The personality structure of students in eighth grade tends to be multidimension. Most obviously, they become identified with the mundane culture, which is embodied in their interactional style and social values. They would like to behave sophisticatedly at that time. Such a phenomenon indicates a transitional period in personality development.

We can observe the spiral developmental trajectory of self-identity from primary school to junior middle school. Each step is achieved by forming evaluating rules in certain relationships, which guide the individual to construct self-identity. Students in lower grades tend to adopt teachers' assessments as rules. Peer interactions get strengthened in the intermediate grades but the influence of teachers is still dominating. When students enter in junior middle school, peer relations prevails and the culture constructed through peer interaction is of great influence. The spiral trajectory reveals that when the child has mastered the rules in his/her present stage, he/she would turn to the process of individualization to transcend the present state of relationship. Once the individual achieves a relatively stable state, he/she has the ability to become involved in

new relations and construct new evaluation rules. We can see a similar description of track in the theory of Loevinger (1976) in the development of rules guiding self-regulation, and also in the theory of Kegan (1982) on immersing and transcending within relations.

### **Peer Relations and School Cultural Ecology**

The main target of schooling is to guide development. Because the constructing process is implemented by people, it is possible to bring unsuitable coerciveness, which will cause a negative effect on developing children's capacities. The activities that are in accord with children's potential development would guide children to be involved in the self-transcendence, and produce positive outcomes as well as the process itself. Thus, the organization of a supportive peer relations network, which is based on the potential of students in each grade, becomes fundamentally important to the construction of school culture.

### ***Borrow Ideas from Cultural and Ecological System Study***

How to construct the school culture? We can borrow some ideas from the law of cultural development and the ecological system. As Valsiner suggested, "in the sense of semiotic mediation of the relation of the person with the external world, culture operates on the basis of functional opposition" (Valsiner, 2000, p. 53). It is a very interesting topic, as the phenomenon of culture operates on the basis of functional oppositions mainly exists in the forming process of culture. The culture usually originates from human being's predicament, which is similar with the individual's development as the individual tends to realize self-transcendence by overcoming all kinds of problems when he/she is growing up. Furthermore, during the process of culture development, the emergence and prevalence of a new culture is for the purpose of meliorating the deficiency of the previous culture. When the new culture matures, it will encounter unprecedented problems again. Through the process of continuously discovering and resolving new problems, the culture thus evolves.

The ecology develops in a systematic way. Each part of the system plays a certain role as the system works as a whole. The wholeness of the system derives from its multiple hierarchical nested structures, which make the system operate in a dynamic

way. The structures open to each other and make the interaction between different levels possible. The system gains vitality through energy exchanges within and between systems, in which each part participates in production as well as consumption. The interaction within and between systems would bring changes to the structural hierarchy and also the boundary between systems, thus modifying the relationship between the system and its surroundings.

### ***The School Cultural Ecology System***

The energy of cultural ecology is spiritual in essence. The developmental potential serves as the fundamental energy resource for school culture construction. In the school cultural ecology system, each participant produces as well as consumes the spiritual source. When the students of various grades are involved in expanding their potential, it would probably create a richer school experience.

The process of production and consumption of energy of school culture is realized in peer interaction. The resource of development comes from various ways, including individuals' inner potential, the societal history and culture, and also the relationships between individuals of different grades or capacities. The peer-relation organizing was the foundation for school cultural ecology construction. The ecosystem of school culture is constructed by inter-related organizations, which are based on the characteristics of each grade.

The peer relations organized in different structures can be viewed as Jiti of different levels, as the subsystems of the whole school culture ecosystem. Jiti organizes the activities for the students, which consist of two major parts: (1) the students' self-management of their daily school lives, and (2) creative cultural activities. The former is similar to social customs for adults and the latter is equivalent to festivities or celebrations. These activities are designed according to the orientations of self-identity and potential, and are aiming to prevent probable problems. The activities guide and encourage self-transcendence.

### **Cultural Activities According to Developmental Tendency**

The organized activities construct the hierarchical structure of school cultural ecology, and constitute the students' developmental lives. It is because the activities are provided with a dual function: to construct Jiti and to guide self-transcendence. That

means, Jiti is formed through activities and meanwhile the cultural activities organized by Jiti, during which students' self-development is realized.

Because students are in different grades, they have different abilities in understanding and assimilating the culture resources and also they differ in emotional experience and expression. For example, students in lower grades are more imaginative, so they're especially interested in activities related to fairy tales or myths. The children in puberty become more sensitive and they are easily emotionally aroused. Students of higher grades in primary school are well-developed in thinking, thus the intellectual challenge might be more attractive to them. The cultural activities in accordance with children's developmental potential are easier to gain resonance among them, thus resulting in a better cultural ecological vitality.

The activity design also needs to consider the stage characteristics of self-identity because it reflects individuals' developmental orientation. When the evaluation system has not internalized yet, then children operate only with external evaluation rules, therefore it is important to strengthen the intrinsic value of the rules. The activities assume the responsibility to internalize the rules, which are embedded in the designs. Sometimes, an individual overemphasizes the external evaluation rules just because he/she is provided with too simple and arbitrary rules. So it needs to adopt a multivariant evaluation system into the activities, which is beneficial to broaden his/her horizon of value orientation. As in the transitional period, individuals' positioning of relationships change, the activities also serve as a medium to help the individuals to develop new relationships. For example, helping students of lower grades, or conducting social investigations and sharing them with classmates in the form of art. These activities can bring a new visual field for the students and help them to establish new relationships, and the students can obtain a sense of self-value never experienced before.

Although children in the individualization period show more activeness in exploration, they usually can't attend to everything at the same time. Thus it is necessary to direct them to behave reasonably and efficiently as well as gain independence in an acceptable way. For example, students in third grade are eager to show their abilities, therefore, the idea of "being bright and smart" is most encouraging for them (Lu, 2008). The pertinent activities around this topic also show great cultural ecological

validity. We have practiced a series of activities around the theme of how to cleverly study, cleverly communicate, and cleverly manage their lives.

### ***Autonomous Management and Culture Creation in Peer Organization***

Students with different potential have different demands in peer relations. Some need to be supported by accompaniment, some need to be inspired in cooperation, and some need to be encouraged to self-transcendence through helping others. The Jitis and pertinent activities are supposed to provide a dynamic network to fulfill the internal need and realize potential development.

It is important to encourage students to manage the school life for themselves, as it is helpful to build up and maintain the Jiti. There are many things in school daily life, for example, cleaning the classrooms, arranging the desks and chairs, handing in and out homework, producing the publicity column, being librarians of class, taking care of potted flowers in classroom or managing the campus order, and so on. Some of the things are requisite while some are dispensable. But it is necessary to pick up these dispensable trivial things and turn them to all kinds of jobs, which provides many opportunities for students to participate in daily management, especially for the students in lower grades. Most of them are excited and honored to take a job in class at the beginning. However, it is not surprising that they will lose interest soon. Then it provides another opportunity to guide the students to construct meanings in their ordinary work. It is crucial to emphasize the importance of cooperation and creation as well as autonomy in the daily work. As they are a member of Jiti, they are responsible to protect its honor. It is observed that children are easily motivated once the trivial things are endued with significant meanings.

Jiti as the organization of peer relations not only provides the place for activities but also generates the driving force to initiate development. The leading structure of peer organization varies between grades, from job groups, teams, class committees, to associations across the grades. The structure grows larger and more complex in higher grades. But it also contains the structure of the lower level, thus the structure of peer relations in higher grades is multilevelly organized.

The individual's relationship network develops as the organization grows. More and more, physical and psychological spheres are available

to be involved in activities. Students mainly work within the class when they organized by team. And the class committee can carry out activities across classes or grades, or take the responsibility to manage the campus; for example, third-grade students are suitable to perform guard duty on campus as it is too difficult for lower grades but too simple for the higher grades. The fourth-grade students can assume the responsibility to help the students of first grade to adapt to school life. Students of higher grades can establish school-wide associations with the assistance of teachers. The positioning of self-identity develops as the responsibility changes in different peer organizations.

The dynamic of the organized cultural ecological system can exert influence on students of all levels. Take the fourth-grade activity called “hand in hand” for an example. The fourth-grade students become big brothers or sisters to the first-grade students and help them to acclimate to school life. It is especially helpful to the Chinese children, as they seldom have the chance to be brothers or sisters because of the one-child policy. In order to help the litter brothers or sisters, children in fourth grade consciously behave better than they used to. For example, they will finish their homework on time and learn to do the housework at home. They also dare to raise their hands and answer the questions because they want to be a desirable model to follow. During the process of giving and receiving, both students of fourth and first grades gain improvement.

### Concluding Comments

In this chapter, I discussed the research methodology and related work on peer relations and construction of school cultural ecology.

1. Concerning the study on peer relations from a psychological development aspect, the viewpoint of intrinsic relations should be taken, and close attention should be paid to the necessary connection between peer relations and self-development.

2. Organized peer relations basing on growing characteristics is a powerful medium of students’ development.

3. The energy of growing could be transformed, which could lead to trouble or positive creation. School cultural activities may catalyze potential development of children and adolescents. The designing of cultural activities depends on stage characteristics of the self-identity and potential.

4. The research on stage characteristics of students’ development gets help from multiple approaches. The reasonableness of the explanation on the stage-evolutive mechanism and the guiding effect of cultural activities should be taken as the foundation of research validity judgment.

5. The peer relations are organized in the students’ self-management of their daily school lives and creative cultural activities. The structure of peer organization varies between grades, the differences between grades become the condition of interaction. This structure constructs school cultural ecosystem.

### Future Directions

During our work with the children, we noticed that the individual’s development was closely related to peer relations and its organization, which is called “Jiti” in this chapter. In fact, the peer interactions, social identification, and self-development usually happen concurrently, however in the psychological field they are often studied separately. Thus, considering the peer relations, we need to further investigate the following questions: In what ways does peer interaction have an effect on self-development? How do children construct the selves in the Jiti and activities? And, how do the various structured Jitis and activities influence the individual’s personality development?

Generally speaking, children can achieve better flexibility and complexity in their personality structure if they are immersed in multilevel organizations and diversiform activities. However, it is difficult to adopt the mainstream research method in present studies because it is incongruous to the research topics that focus on dynamic process. For this reason, it is necessary to explore a cultural and ecological approach in developmental studies, which is often used in clinical psychology or anthropology.

My research of peer relations shifts from research of self development, the research experience made me ponder this thought: It is common in the psychological field that further research is often carried out by gradually subdividing with same perspective, in a sense, which is similar to the methodology prevalent in atomism era in physical history. However, ceaseless subdivision may not make much progress and even become trivial. To a certain degree, the development of physics benefits by turning into a dynamic and relational perspectives. As in psychological research field, the expansion of horizon should always be better than a narrow and stagnated perspective.

## Acknowledgment

Research of this chapter was funded by support of the Chinese Ministry of Education. The author is grateful to her doctoral student, Shuzhen Hu, for translating this chapter.

## Notes

1. New Basic Education is a famous reformatory educational practice in primary and middle schools that was initiated by Professor Yelan in 1994, who worked in the Education Department in East China Normal University. As the only psychologist in the research team, I mainly focused on the students' development.
2. Now Zhang studies art in Moscow.

Bert van Oers

**Abstract**

Playfulness is a distinctive feature of human behavior across history and cultures. The status of playing in society is still a matter of dispute. In order to understand the phenomenon of play in its relation to culture, two issues deserve further study. First is the development of the social representation of play itself. The other issue consists of studying the possible ways cultural influences get into play. This latter query needs a conception of play that articulates the relationship of play and culture that includes an explanation of the position of adults with respect to play, and an explanation of learning in play. This chapter presents an activity theory approach to play, in which play is seen as a particularly formatted activity. This interpretation of play provides us with an analytic description of play (and its possible consequences) in various cultural practices, and with an outline of play development.

**Keywords:** play, culture, development, activity format, rules, freedom, involvement, learning, adult

**Introduction: Scouting the Field in the Wars on Play**

A considerable number of studies all over the world have revealed that play is probably a universal form of human behavior. In his *Politics* (book VIII, 6, pp. 20–32), Aristotle already wrote about play and, for example, considered the rattle a “capital invention,” because the rattle is a useful toy for young children to play with “in order to amuse them and prevent them from breaking things in the house” (Barnes, 1985, pp. 2126–2127). Toys (like dolls, balls, hoops, wheeled cars, play animals, etc.), as well as game playing were quite common in ancient cultures (Castle, 1961).

Descriptions and pictures of playful activities and toys are well-known from various cultures. Examples have been found from Mayan culture (fourth century) and from many different other cultures all over the world ever since (see for example Roopnarine, Johnson, & Hooper, 1994). Playfulness seems to be a distinctive feature of children’s behavior all over

the world (Serpell, 1994). The belief in the significance of play for human development is widespread and persistent. Not without reason, Smith (2010, p. 28) dubbed it the “the play ethos,” which he circumscribed as “a strong and unqualified assertion of the functional importance of play, namely that it is essential to adequate (human) development.”

Despite the seeming universality of play, the cultural status of play is today still an issue of debate: is it a necessity of immature developmental state (a feature that human beings share with young animals), is it a cultural invention for occupation in leisure time, is it a developmental necessity for the beginnings of early learning in the areas of physical exercise, social relations, creativity, and elementary cognitive skills, or is it a characteristic quality of contexts for real human cultural learning?

In his seminal work on play and cultural history, Huizinga (1938) defended the view that a human being is essentially a playing creature (a *Homo ludens*) that could create culture as a

result of this nature. In his view, culture starts *within play* and develops as play (Huizinga, 1938, pp. 102, 224)—i.e., as an element of playfully accomplished human activities. In his study of the evolution of playing within Western culture since the ancient Greek times, he explains that many modern cultural activities and institutions (like language, religion, law, and art) have their roots in human endeavors with a playful nature. However, Huizinga also pointed out that the cultural-historical process tends toward the expulsion of play from everyday activities, leading to a separation of play and serious work. In the heydays of positivistic science (in the 1930s and 1940s), Huizinga was particularly concerned about science and learning, which seemed to break away from its playful origins as a result of a strong methodification of learning (Huizinga, 1938, p. 263).

### ***Rhetorics about Play***

As Sutton-Smith (1997) already has pointed out, the debate on play in the past century is populated by a number of different rhetoric, representing implicit narratives “wittingly or unwittingly adopted by members of a particular affiliation to persuade others of the veracity and worthwhileness of their beliefs” (Sutton-Smith, 1997, p. 8). He distinguished a number of different rhetorics in the play literature, based on the different claims with regard to potential developmental outcomes of play (e.g., cognitive progress, identity development), or to appreciated behaviors that may emerge in play (like for instance showing autonomy or power, using fantasy and imagination, playing out the Self). Scrutinizing the evidence for each of the claims, Sutton-Smith concluded that there is little ground for substantiating the different rhetorics on the basis of available research outcomes. Finally, he came to the conclusion that play is essentially an opportunity for learning to adapt through dealing with variability (comparable to the variability that the human organism had to deal with in the evolutionary process). “Variability is the key to play” (p. 229). As such, in his view, play is “a facsimilization of the struggle for survival” and “as an exercise in adaptive potentiation [it] is no guarantor of actual progress, apart from becoming a player” (Sutton-Smith, 1997, p. 231). He ends up with a definition of play as “a virtual simulation characterized by staged contingencies of variation, with opportunities to control engendered by either mastery or further chaos” (p. 231).

Obviously, Sutton-Smith does not want to do away with play in education. Education has to stage the contingencies of variation and opportunities for control. However, Sutton-Smith’s analyses of the value of play for development, and his definition remain disappointing as he does not specify the types of contingencies and opportunities that are required for becoming a player in a specific cultural context or life form. Basically, his definition can also apply to a pedagogy of leaving the child on the streets in the wilderness of present day’s life forms. Sutton-Smith’s definition of play seriously suffers from this neglect of the relationship between play and culture, and its pedagogical consequences.

Remarkable in the analyses of both Huizinga and Sutton-Smith is that they accept the idea of play as a special type of activity that can be distinguished from types of disciplined goal-directed activities. Today this evolution of the status of play into an exclusive activity is particularly evident in education and leisure activities. For sure, play in modern societies is still an accepted way of behavior, but it is often dispelled to special places and special moments, where benefit is not a purpose and learning may only be an incidental by-product of spontaneous actions. The consequences of this situation are fiercely debated in education.

One position in this debate maintains the view that play belongs to the nature of young children, who have the right to play out their fantasies, to exercise their newly developed capacities in their own ways, and to develop according to their nature. Play is said to be the work of children, creating opportunities to explore, pretend and practice (*see for example* Edwards, Gandini, & Forman, 1998; Paley, 2004). It is:

... the model for the life-long practice of trying out new ideas. Pretending is the most open-ended of all activities, providing the opportunities to escape the limitations of established rituals. Pretending enables us to ask ‘What if?’  
(Paley, 2004, p. 92)

Proponents of this point of view often refer to Piaget as a theoretical foundation. Their maxim for children until at least 6 years of age could be summarized as follows: *Let them play, engage them in rich situations, and give them socio-emotional support, and then they will learn (provide minimal guidance only when it is needed)!*

The opposite position maintains that the purpose of education is to help children with developing the

necessary abilities for participation in their cultural community. The nature of the acceptable participation for each of the individual members is a matter of dispute in society, but whatever the choice, the outcome is assumed to depend on the nature of the developmental tasks that children from an early age learn to accomplish at home and in institutions like school. The development of children primarily depends on teacher-directed activities especially designed for them (i.e., cultural development results from their work at learning tasks). Play, according to this view, is different from work, as it is mainly a moment of free activity, leisure, and relaxation for children. The basic maxim here is: *Let them work at developmentally-appropriate tasks for their future welfare. Let them play freely after work, and they will more effectively learn on later tasks!* Playing and working are seen as different and strictly separated activities. Playing is conceived of as more or less free play, with minimal interference of an adult and with main outcomes in the area of self-regulation, social competence, and emotional development. Work is generally seen as a teacher-led activity with primarily cognitive outcomes. In a literature review, Hart et al. (1998) demonstrated that young children's enrollment in direct instructions was associated with higher levels of stress. Combining work with relaxation in free play in a classroom might be seen as a way of reducing stress and keeping young children at ease. This "work-and-play-approach" is popular in standard-driven early childhood education (*see for example* van Hughes, 1999, pp. 3–5; Hyson, 2008; Jacobs & Crowley, 2007; Leseman, Rollenberg, & Rispen, 2001; Maxwell, Ritchie, Bredekamp, & Zimmerman, 2009; [www.pyramidprinciples.com](http://www.pyramidprinciples.com)). As a result of the separation between play and work and their respective functions, there is a tendency in modern Western culture to capitalize on cognitive-task work in schools and marginalize play under the pressure of preparing children for cognitive achievements (e.g., Moyles, 1989; Michnick Golinkoff, Hirsh-Pasek, & Singer, 2006).

More recently, the insight is growing that educating young children is not purely a matter of alternating didactic instruction and work with free play periods (Nicolopoulou, Barbosa de Sá, Ilgaz, & Brockmeyer, 2010). New approaches have emerged that try to go a middle-way and look for possibilities of adult participation in children's play that do not impair the quality of playing, but still contribute to children's learning. The basic idea of these approaches is that adults try to get children

involved in culturally meaningful activities and collaboratively assist children in acquiring the abilities for improving their participation in these cultural activities. Evaluation studies have demonstrated that this is a viable way to go, and that play can indeed be used as a context for cognitive learning (Hirsh-Pasek, Michnick Golinkoff, Berk, & Singer, 2009; Barnett, Jung, Yarosz, Thomas, Hornbeck, Stechuk, & Burns, 2008; van Oers, 2010a, 2010b). The basic maxim of this approach is: *Let children playfully participate in cultural activities and assist them in appropriating the necessary tools for improving their participation.*

### **Pressing Problems for a Theory of Play**

Though different from Sutton-Smith, the three approaches described above can also be seen as rhetoric about play, often based on implicit conceptions and beliefs. As a consequence, the debate among these rhetorics is seriously hampered by a lack of clear definitions of what play is and how it relates to culture. In modern literature on play following one of these rhetorics, at least three interrelated problems can be identified that need to be solved, in order to advance understanding of play, its cultural value, and applicability for educational purposes:

- **Definition of play:** In many studies on play, no clear and explicit definition of play is given. Play is assumed to be self-evident, and often characterized as "immature," or "juvenile" behavior. A large variety of definitions are available from the literature (*see* Pellegrini & Smith, 2003, pp. 277–278). Most of the time some criteria are mentioned that characterize the activities of children as self-chosen, spontaneous, and purposeless activity, based on imagination and fantasy, no interference from adults. The problem with these loose operationalizations is that they do not give a positive description of what play actually is: "no interference from adults," for example, only indicates the absence of a specific condition, but does not positively articulate what play actually is. A frequently cited quality that play does not seem to serve any immediate purpose, is also problematic as a definition of play, as many forms of role-play and games have some quite specific goal within the ongoing activity for children. Similar doubts can be expressed with many other attempts at defining play: adult-free activity, for example, is not by definition play. Moreover, some qualities or dispositions (like self-chosen activity) may not exclude activities that are

not acknowledged as play, like practicing a newly learned ability. Furthermore, much of the literature is limited to specific types of play, like symbolic play, role-play, constructive play, manipulative play, outdoor play, rough-and-tumble play, etc. It remains unclear what these different types of playing have in common. Piaget's (1951) definition of play as a form of adaptive child behavior in which assimilation dominates accommodation also suffers from serious flaws as the mechanisms involved (assimilation, accommodation) haven't been easy to operationalize, independently from observed behavior already identified as play, which leads to hopeless circularity in the definition. Vygotsky (1966/1978, pp. 92–104), finally, tried to define (role)play more directly by characterizing children's play activity through referring to the rule-governed and relatively free nature of activities in an imaginary situation, which satisfies the child's desires to be like the adult. In his view, a preschool child in play emulates adult roles on the basis of generalized affections he has assigned to these roles in the course of his development (Vygotsky, 1966, p. 64). In the enactment of these roles the child creates an imaginative situation that adds a predominantly affect-based interpretation to a situation (i.e., sense or *smysl*), which opens the possibilities for the child to act on the basis of fantasy, emotions and affect, rather than being determined by perceptions of the situation and conventional meaning (*značenie*)<sup>2</sup>. As a sense-based activity, the child has considerable freedom in imagining the situation and its action affordances, but this is a limited freedom, according to Vygotsky, as actions are also determined by the rules dictated by the meanings of objects. In Vygotsky's words:

In his play a child is free, i.e. he determines his deeds on the basis of his own 'I.' However, this is an illusory freedom: he subordinates his actions to a certain sense, and acts on the basis of the meaning of the objects.

(Vygotsky, 1966, p. 76)

However, Vygotsky's definition is also too wide, as, for example, a mathematician's thinking when studying the peculiarities of inflection points on cubic curves also fits this definition. Although there is no theoretical reason why we should exclude this type of activities from the category of "play," it is unlikely to believe that this is what Vygotsky had in mind when he tried to clarify the notion of play.

All in all, there is still much work to be done for a clear definition of what may be counted as play. After summing up the evidence that substantiates a mandate for playful learning, Hirsch-Pasek et al., (2009, p. 53) stipulate that a more specific and consistent definition of play and learning is needed in order to advance the dispute on the relevance and usefulness of play in education. However, Wittgenstein's (1953) revelation of the difficulties in defining play may seem to apply here. Wittgenstein's analysis, however, was linguistic (about the meaning of words), rather than psychological, and the core of his argument was that we don't need a definition in order to use the word "play" correctly in a specific situation (*see* Wittgenstein, 1953, pp. 66–78). The referents of the word "play" are interrelated by a "family resemblance" ("*Familienähnlichkeiten*," *see* Wittgenstein, 1953, p. 67): they belong together within a certain outline without sharing a common element (essence) that a definition of play may refer to. Nevertheless, despite these linguistic-philosophical problems with the definition of play, it still remains possible that people can agree on the use of the word "play" as a qualification of a specific current activity, without being able to define its essence unambiguously. Notwithstanding these linguistic problems, it may be viable from a *psychological* point of view to specify the criteria of the activities that underlie the family resemblance of play, and that people may refer to as "play," despite its diversity in appearances.

- **Position of the adult in relation to play is not conceptualized:** as play is not an isolated phenomenon, it must be clear how it relates to its (cultural) environment. Regardless of its status (natural or cultural), play is still a phenomenon that is part of a cultural environment, so the position of the sociocultural community (particularly the adults as first representatives of that community) toward play must be specified. Part of the debate about play in schools is directly related to this question of the extent to which an adult is permitted to participate in children's play. Basically, the clarification of the position of the adult with respect to play has to be based on a conceptualization of the more abstract relationship between culture and play.

- *In the prevailing approaches to play, no explanation is given of the process of learning in the context of play.* Mostly, learning in play is admitted as a spontaneous and incidental event.

How learning in the context of play can be psychologically explained remains unclear. In concluding their review of research outcomes that give evidence for the relevance of play as a context for learning, Hirsh-Pasek et al., also conclude:

With a clearer definition of playful learning, we could isolate the mechanisms through which play influences children's learning. That is, we know that play fosters academic and social learning. We also know that play is characteristic of developmentally appropriate pedagogy. Yet, many of the studies do not directly examine the pathways through which playful learning relates to child outcomes.

(Hirsh-Pasek et al., 2009, p. 54)

In this chapter I want to address the question of the relation between play and culture from the perspective of cultural-historical activity theory, which answers the problems stated above. In the next section, I will dwell on the different ways that culture and play are related. In the following sections I present some tenets of cultural-historical activity theory, and develop a notion of play as a specific activity format. This format also provides us with a way of describing the development of playing in ontogenesis. A description of this process will be presented including an interpretation of different types of play in terms of the proposed approach. In conclusion I will briefly reveal some urgent queries that need to be solved through future research.

## Culture and Play

### *Conceptualizing Culture*

For an explanation of the relationships between culture and play, and more particularly the role of culture *in* play, we first need to clarify what we mean by culture. Defining culture, however, is a complex and extremely tricky business (see Cohen, 2009; Jahoda, 1993, 2012). The reason for this is the same as the previously described problem with the definition of play. Culture is not a uniform phenomenon that can be characterized by one essential core element. As Cohen (2009) points out: there are many forms of culture, each with their own beliefs, ideas, values, moral rules, symbols, and rituals. Fiske (2002, p. 85) defined culture more or less exhaustively as:

a socially transmitted or socially constructed constellation consisting of such things as practices, competencies, ideas, schemas, symbols, values,

norms, institutions, goals, constitutive rules, artifacts, and modifications of the physical environment.

In all definitions of culture we find references to the notion of shared elements and to the fact that culture is transmitted across time and generations. Culture is represented both in the social world (e.g., as institutions, practices), and in the individual. An important function of a culture is to control diversity within a community in order to maintain identities (at a communal and personal level) in the present and in the future. The components listed by Fiske above can be seen as means for this control of variety. The basic functions identified by Boesch (2012) can also be interpreted as means to control variety within the limits of expectations and desires. Such means help members of the community to figure out what it means to be a part of this community, to make decisions about how to participate in this community and to reflect on acceptable variations. An important function of culture is to retain, to guard, and to negotiate values with members of a community. Therefore, culture is sometimes also defined as a system of meanings (see for example Serpell, 1994). However, as Leont'ev (2003) points out, cultural meanings can only function and contribute to personality development as far as they make sense for the individual members of the community (i.e., insofar as they are personalized *meanings, are related to personal interests, and make personal sense*). According to Leont'ev (2003, pp. 412–418) culture is basically a field of collective senses. To put it in more mundane terms: culture is everything we find is valuable for us.

However, this does not mean that each community only hosts one uniform culture. The historical process of cultural selection of those means and values that have turned out to be effective for the control of variation, depends on different factors (ecological, social, psychological, biological; see Tavory, Jablonka, & Ginsburg, 2012). This very fact may lead to a differentiation of subcultures within a community that may even be partly incompatible.

For the present argument I conceive of culture (in line with the reflections above) as a family of historically developed expectations in the members of a community about acceptable varieties of acting in their community. These expectations are controlled, transmitted, maintained, and changed with the help of the shared cultural tools (see for example the list of Fiske given earlier) within the context of cultural

practices. Culture (i.e., its expectations about what is acceptable or not) is interactively represented in the ways of behaving of agents and most of the time implicit in current practices (Christopher & Bickhard, 2007).

For the study of the value of play and the relationship between culture and play, this is an important starting point. Obviously, in most cultures play is one of the accepted ways of behaving and of participating in the life of a community. However, given the diversity of cultures, it should be taken into account that play may have no or less value in certain (sub)cultures, as historical and cross-cultural studies of education have revealed (Baggerman & Dekker, 2005; Smith, 2010). Play is not always an acceptable type of behavior. Following up on Huizinga's point of view, we can now conclude that culture probably has emerged out of playfully carried out activities, but also has acquired a position that made it possible to control play and make out what is acceptable as play as well as within play. Our question about the relationship between play and culture now turns into an inquiry of culture in play—i.e., into the question of how culture exerts its influence in play.

Starting out from the definition of culture above, we can see two lines of possible influence of culture in play:

(1) along the line of social representation—i.e., the cultural-historical evolution of the concept of play;

(2) through the introduction of cultural elements (artifacts, norms, etc.) into play activities.

Both lines will be examined below, with a special emphasis on the second, as here we can unfold how an activity interpretation of play (as a product of line 1 above) can answer the problems stated at the end of the previous section, concerning the position of the adult and the relation between play and learning.

### ***The Evolving Social Representation of Play: Three Views on Play***

One of the fundamental control devices of culture on play is based on the culturally produced conceptions of play. A conception of play defines what should be counted as play within the community, and consequently what is permitted in a context of play. Culturally shared and sanctioned concepts control the behavior of educators and, consequently, also delimit the actions of the players

themselves. Educators often guide children's play in ways that are consistent with their own culturally transmitted views on play (see Valsiner, 1989, Chap. 7). Institutions like schools perpetuate cultural values and convictions (including their view on play) in explicit and implicit ways through their habits of organizing and valuing educational sessions and outcomes (see Daniels, 2012).

Looking at the history of discourse on play, one can see that the notion of play is an evolving "social representation" (Moscovici, 1988, p. 230), in which a socially shared notion of play is developed that serves as a basis for a social group to communicate about play, consolidate its notions, and through intensive and permanent communication eventually may change this notion over time.

The prevailing social representation of play today has developed over a long period of time and is expressed in different narratives (as can be seen in the previously described approaches to play). For a long time the social representation of play could be labeled as "*Play as a natural kind*," which was based on two assumptions:

(1) Play is a *natural behavioral type*, which is inherent in human nature. Basically, this view is grounded in a naturalistic interpretation of human development that was romanticized in the eighteenth century, for example by Rousseau and his followers. This naturalistic conception attributes the capacity for playing to human nature, which is especially manifested during childhood. The play studies in the nineteenth and early twentieth centuries focusing on comparisons between animal and child behavior (Groos, 1898, 1901; Buytendijk, 1932) are clear examples of this point of view. A basic assumption of this perspective is that free and uncultivated ("wild") fantasy is the origin of play. An interesting and influential elaboration of this point of view was proposed by the German philosopher Friedrich Schiller (1759–1805) (although his contribution is rarely acknowledged in the discourse on play). According to Schiller (Letters 14 and 15, in Schiller, 1980, pp. 394–400) play follows from an urge that originates from the tensions within the human being between being an object (with a need for being sensually stimulated and formed) and a subject (with a need for giving form to the material world). In play the human being has the freedom to solve this tension one way or another. Especially in the arts, according to Schiller, a human being

finds the optimal conditions for practicing the urge to play. In Schiller's view, play is a necessary phase of preparation for the civic and political freedom in later life (Schiller, 1980, letters 14 and 15). In this sense, we have to interpret Schiller's statement: "A human being plays only when he is human in the full sense of the word, and he is only then genuinely human when he plays"<sup>1</sup> (Schiller, 1980, letter 15, p. 399). Play makes a human being complete as it creates the opportunities to be free and to learn to manage this freedom. Schiller's ideas have deeply impregnated thought on play, and may be seen as one of the roots of the widespread associations of freedom, creativity, and expression with the phenomenon of play (as for example in Froebel's approach).

(2) Play is seen as a *special type of activity "sui generis," in distinction to other activities like learning and work*. From this point of view, play is seen as a specific type of activity alongside reading, constructing, fighting, traveling, gardening, shopping, etc. Many theories of play assume a distinction between play and work (e.g., Hughes, 1999, pp. 3–5). Play is often conceived of as a specific activity that prepares one for adulthood, where children can learn and practice important skills for later adult life (work).

As a consequence of these assumptions, the social representation of play as a natural kind is characteristically an ahistorical and individualistic view on children's play.

From the beginning of the twentieth century, a new discourse on play emerged in the wake of Vygotsky's cultural-historical theory of human development, leading to a new social representation of play, which could be dubbed "*Play as a cultural kind*." On the basis of this view, human play became conceived of as one of the cultural means for adjusting the process of enculturation to children's physical and psychological characteristics and capacities. Elaborating Vygotsky's point of view, Leont'ev (1983/1944) explained that children's play is not comparable to playful activities of animals, as the child is surrounded by a world of cultural things and activities. The wish to participate in the social group, make contact with this world, and participate in it leads to the desire to act like an adult (Leont'ev, p. 305). The start of the child's play does not originate from some innate fantasy or an urge for freedom (p. 313), but from his imagination of the ways these cultural activities may be accomplished (p. 310). Fantasy, according to Vygotsky and Leont'ev, is a

product of playing and not the origin. The imagined situation, as taken by Vygotsky, is further specified by Leont'ev as the child's way of imagining a cultural *activity*, and of the role the child may play in it (p. 315). In this role the child plays out its version of the adults' behavior. Precisely in the constraints the social environment puts on role-playing, culture exerts its controlling influence (by articulating necessary rules, tools, objects, and goals).

Following this point of view, El'konin (1978, pp. 39–64, 1989, pp. 67–68) emphasized the historical dimensions in this approach to play, while he pointed out that play depends on the *historical conception* of the position of the child in society, with regard to cultural activities, peers, and adults. The conception of play changes across history and cultures in compliance with specific historical, ideological and economic conditions. From this point of view, we can see play indeed as a cultural invention to give children access to important cultural experiences, in a way that is not risky and gives room to explore new combinations of actions (Bruner, 1972; Karpov, 2005).

Continuing on the Vygotsky-Leont'ev activity-theoretical view on play, Göncü, Tuermer, Jain, and Johnson (1999) summarized the main constraints for the realization of a cultural-historical activity view on play. In a general way this also exemplifies the ways play and culture are related, and how culture controls the concrete embodiments of play in social life. According to Göncü et al., children's play in a particular community at a certain moment in the cultural-historical development is determined by:

- *The economic structure of children's communities*: Depending on the economic structure of a society, special types of cultural practices are available for children during their life in that community. Participation in these practices (or imitation of these practices) opens specific roles for children and creates particular activity-based opportunities for learning.
- *The beliefs of children's communities about play*: The opinions of the members of the communities about what play is, when and where it should be permitted etc., determine to a great extent the occasions for play for children in that community.
- *Children's values about play, conveyed to them by the community*: When children themselves believe that play is frivolous and for the little ones, they will most probably refrain from playing when they grow older.

- *Children's interpretation of the situation that they regard as play opportunity:* This includes the affordances for playing that children notice in a situation, children's perceptions of adult roles that can be adopted for their personal purposes, how they may be transformed, as well as the perceived possibilities of idiosyncratic use of cultural artifacts and rules.

The social representation of play based on cultural-historical activity theory is evidently different from the social representation of play that propagates the idea of play as a natural kind. The conception of play as a cultural kind controls the actions of educators and players by controlling basic constraints as to what is allowed in the context of specific cultural activities, and by co-regulating the course of an activity by providing cultural tools and rules. In the following I employ this perspective for my further analyses of the role of culture in play. In order to do so, I have to elaborate a more specific definition of play within the outlines of a cultural-historical activity theory. A brief account of cultural-historical activity theory will be given first.

### **A Brief Account of Cultural-Historical Activity Theory (CHAT)**

In his theory of activity, Leont'ev (1975) distinguishes a number of fundamental constituents of activities. He characterizes an activity as a cultural-historical category for the analysis of human behavior. Activity originates from a  *motive*  and is directed to a (mental, verbal, or concrete)  *object* . Basically, the motive-object defines the general nature of an activity. An activity where a ball is the object is essentially different from an activity that takes a book or vegetables as an object, because they call for different rules, different instruments, different goals, etc. At specific moments, an activity is always instantiated as a series of goal-oriented actions. To give a simplified example: in the activity of starting a car, different coordinated steps have to be taken. Every step is a particular subgoal-directed action, which has to be realized at the right moment in order to reach the final goal (e.g., drive away). For starting a car, a person has to insert a key (action 1), then (action 2) check if the car is not yet in gear (unless you have an automatic gear change), declutch by putting down the corresponding pedal (action 3), turn the key (action 4), if the engine starts, move into appropriate gear (action 5), etc. Depending on your specific goal, some actions may be different

from the one here described, some may be omitted (e.g. action 5), some may be carried out in parallel. Finally the steps have to follow some definite logic in order to coordinate the actions in an effective way and accomplish the activity. Activity in this conception is a structured way of acting.

Critical appraisals of the theory of Leont'ev have extended this theory in at least two ways. Brušlinskij (1982; Brušlinskij & Polikarpov, 1990) has argued that the strongly morphological character of Leont'ev's theory misleadingly pictures human activity as an unrealistically stable structure, whereas the living human activity also develops  *as*  a structure. That is to say, according to Brušlinskij, that human activities are plastic and most of the time gradually changing while being accomplished. The motive might shift, goals become more detailed and slightly different, tools are replaced sometimes by others, the use of the tools becomes more automatic, the order of goals may change because of experience, some of them may be lost without notice, skipped (on second thought), or be corrupted. This continuous change of the activity constituents over time is what Brušlinskij called the  *process aspect of activities* . In his view this aspect is particularly important for the understanding of thinking and communicating as activities. In my view, this is particularly relevant for the interpretation of play in terms of activity theory.

A significant expansion of activity theory was also proposed by Engeström (e.g., 1987;  *see also*  Sannino, Daniels, & Gutiérrez, 2009; Daniels, 2012) in his argument to link the activity theory of Leont'ev with the institutional dimensions of cultures. Engeström explained that the relationship between an agent and his object is not only regulated by the artifacts that structure the course of actions, but also by the culturally instituted rules of behaving, the agent's position in a community, and the way agents within an activity are assumed to cooperate (division of labor). He transformed activity theory into a theory of activity systems. In his research of the institutional dimension of regulation of activity systems, Engeström has demonstrated that the actual course of activities often depends on the tensions that emerge between the different components of the activity system (rules, division of labor, artifacts, etc.). Activities (and the culturally accepted variety of actions within that activity) are deeply influenced by institutional constraints.

The Leont'ev-Brušlinskij-Engeström approach to human activity is a powerful instrument for

the analysis and understanding of human actions. However, it does not give us the criteria for defining the potential of cultural activities for human development. My theoretical and empirical analyses of cultural activities over the past decade, lead to the claim that the way an activity is carried out (i.e., the activity *format*), may be decisive for its developmental effect (van Oers, 2003, 2008b, 2010b).

In many cases the order of the actions is regulated by cultural rules (in cooking, starting a car, or otherwise). Taking the activity of cooking as an example: if, for example, you want to save energy (for environmental reasons), there is a rule that says: don't switch on the stove before the pan is on it. It is important to notice here that a realization of an activity at a certain moment is always a *rule-governed pattern of actions* that may differ across situations or persons, or even across time (dependent on new cultural insights). Whether the actor is in the position to vary the actions depends on many different (situational, institutional, or personal) factors, like the tools available, (limiting) conventions regarding the ways activities have to be carried out, expertise, moral-ethical point of view, etc.

From the perspective of activity theory, I maintain that activities can be qualified on the basis of three parameters that constitute its format. First, the nature of any activity depends on the *rules* that define the activity and how the object should be treated, as well as the rules that prescribe how a role within that activity is to be accomplished. Secondly, the character of a cultural activity depends on the *degrees of freedom* that an actor is allowed in choosing or changing actions, tools, rules, goals. It is obvious that the process aspect of an activity is to a great extent dependent on this quality of the activity format. The extent to which the community (responsible adults) allows the participants to make their personal versions of actions, rules, tool use, etc. determines the course of the activity. Thirdly, the *level of personal involvement* of the actor in an activity also determines the quality of an activity, particularly its personal value for the actor, and his engagement to abide by the rules, or creatively adjust them, his willingness to endure and to spend efforts.

Summarizing, any activity can be characterized by these three dimensions: the nature of the *rules*, the *degrees of freedom* allowed to the actors, and the *level of involvement* of the actor. These three dimensions can vary, according to the nature of the situation. These three dimensions constitute

the format of activities. The format with the highest developmental potential for human beings is the format that is characterized by explicit rules, some degrees of freedom for the participants in the activity, and high levels of involvement. Leont'ev (1959, pp. 325–327) has argued that the absence of involvement is a result of a complete lack of relation between a person's meanings (as expressed in his actions and goals), and the purpose and products of the activity he is engaged in. According to Leont'ev, this condition leads to alienation in the agent from the cultural activity in which he or she is involved, and has severely negative consequences for identity development.

It is important to note here, that a specifically defined format of activities is a cultural invention depending on cultural conventions (like the social representation of play), theoretical background, image of the child, ideology, etc. For a given activity format, it is the cultural (pedagogical, educational) environment that allows a certain level of freedom to the participants, that takes care of awareness of rules and their acceptable variations in participants, and that organizes an activity in such a way that chances for involvement are optimized.

### ***Activity and Learning***

An important characteristic of cultural activities (or practices) is the function of learning. Participation in an activity always includes the possibility to improve the agents' way of participating in that activity, either as a reaction to contingent conditions (like impediments), or on provocation and guidance by others. The change of the ability to participate is a result of learning. Within the context of activity, the process of learning can be seen as the process of (spontaneous or intentional) change of the actions that constitute the person's accomplishment of an activity. The types of changes can be of various kinds. Sometimes the accomplishments of an activity change through the appropriation of new tools and actions (like the change in the communicative activity as a result of appropriation of the techniques of writing). In other instances, the accomplishment of an activity can also change as a result of learning an action to perfection (automatization). This activity-based learning theory was developed in the 1950s in the Netherlands by van Parreren (1951, 1971) as an elaboration of the action theory of Kurt Lewin (1953), and by Gal'perin in Russia (1964, 1976). For the present argument, there is no need to elaborate this theory at length here (*see* van Oers,

1996a; Haenen, 1996). It suffices to say that each cultural activity includes the possibilities of learning and teaching.

In the next section I will show that play can be conceived of as a specific type of activity format, and how it includes adult participation and learning.

### Play as a Particular Format of Activities

From her sociocultural studies of children's lives Rogoff (2003) concludes: "children's play builds on what they observe, but what they have the opportunity to observe differs greatly depending on whether they are included in the full range of their community's activities or are segregated from many settings that are restricted to adults" (p. 299). In terms of activity theory, she articulates that "play" has no object of itself, and always borrows the object from other cultural activities children in which have been engaged. In fact, this denies the idea of play as an activity *sui generis*. It asks for an explanation of play in terms of cultural activities carried out in a way that people in our culture call playful.

The activity format previously described is a useful means for characterizing activities in the play format. From this point of view, play is an activity that is accomplished in a particular format. The parameters of this play format (rules, degrees of freedom, and involvement) will be discussed below.

- Play is a rule-governed activity: a basic parameter in the play format is the presence of (implicit or explicit) *rules* that guide the players' actions and interactions. These rules may be object-bound or implied by the practice the children are involved in, like in the well-known activity wherein children try to push blocks of different shapes through the differently shaped wholes into a box. Or in role-play, when children play house and take care to follow the rules of the dining table script. The importance of the rules for the children's play is evident in cases where the players rectify each other for complying with these rules. A well-known (often not explicitly stated) rule in children's play is the *as-if rule*. Children can start a role-play with the call "let's do as if we were pilots" and then start playing. When the rules become more explicit and sanctioned, the play becomes a game according to Leont'ev (1959, pp. 498–500) and Piaget (1951, Chapter 5).

- Players have some degrees of freedom in the choice of actions, instruments, goals. The second basic parameter of the play format is the

presence of some *level of freedom for the player*.

This is an essential element for an activity to be playful. Like Vygotsky (1966) already pointed out, absolute freedom is not possible and it would be contradictory with rule-parameter of the play format. The degrees of freedom give the players the right to use their fantasy and make their own (idiosyncratic) version of a sociocultural activity. The universal use of the "as-if rule" is a clear expression of the child's relative freedom in play. The players' freedom is also obvious in the often-observed gradual changes of the rules, goals, or meanings in play. These are expressions of the process character of activities (*see* Brušlinskij's contribution described above) and belong to one of the most remarkable features of play. How much freedom is allowed in a particular situation is largely a matter of cultural acceptance. In a doctor play, for example, one child put the stethoscope on the patient's knee, and ended up eating the medicine he had prescribed (sweets). Most certainly this child has never seen this before in a doctor's practice, but he makes his own version of the activity, and nobody protested against it. On the other hand, cultures sometimes do limit the child's freedom in play, as is the case with versions of the doctor's play that are deemed as sexually unacceptable in most Western cultures. A play would be seriously threatened as being play, when the degrees of freedom were reduced to (next to) zero. Activities with no degrees of freedom (if ever possible) become rigid behavior patterns of sheer mechanical operations that have nothing to do with play.

- Participants in a playful activity are always highly involved in the activity. Play is their own activity. *Personal involvement* is the third parameter of the play format. When personal involvement is low or decreases, an activity will stop being play for the player but will become a compulsory activity. In a play activity, children have the right to voluntarily decide if they participate and when they quit. For children, play activities fulfill basic desires to be like significant others and be part of a social group (Vygotsky, 1966, p. 64). Activities that children want to play contain elements (like roles, tools, peers) that make participation attractive and raise emotional or affective reactions in the participants, which stimulate involvement. Involvement in play can be interpreted in terms of flow in the sense of Csikszentmihalyi (1997). This personal involvement is a result of an intense (emotional)

relation between the player and the moment of his activity in a given situation, called “*pereživanie*” (Vygotsky, 1984, p. 382). Involvement in play activity expresses the harmony between the player’s actions and the intrinsic purpose of the activity. The player at a particular moment is what he acts out and even doesn’t feel his activity at that moment as play, distinct from “normal” behavior. Involvement, according to the Russian stage director Konstantin Stanislavski (a contemporary of Vygotsky), is the basis of authentic play. It is related to an intense experience (“*pereživanie*”) of being the real actor in a particular situation. It is this state of mind that he tried to create in stage players to help them learn to play a role as credibly as possible (see Stanislavski, 1989; see also Luria, 1982, p. 162). Activities in the play format always exhibit this type of involvement.

Play activities can now be defined as activities that are based on (implicit or explicit rules), that allow some degrees of freedom to its participants, who carry out the activity with a high level of involvement. From this view on play, it can be seen that an enormous variety of play is possible depending on the concrete value of the different parameters. It is noteworthy to add here that the often-articulated criterion of play as having no immediate purpose or intended goal is no part of the definition. In the view presented here, play can include activities with and without immediate purpose. The previously discussed distinction between goal-directed work and play can be distinguished precisely as a difference in degrees of freedom of the actor. Basically there is a gradual transition from work to playing. Nevertheless, most of the time (school)work does not allow much freedom for the actors (pupils or teachers) in the choice of goals, tools or actions (nor does it take high levels of involvement as a requirement either).

In some cases, players use their freedom to subordinate themselves to the laws of chance (Callois, 1958), like in games with dice, lotteries, or casinos. These activities can be conceived of as play in which the actor freely chooses for himself the role of problem-solver (as the game challenges the player to invent new solutions or strategies on every surprising turn), or even to let themselves be put in the position of the object to be played with (like in the casino or lotteries). As a last example I can also refer to humor as an example of play with meanings in which the player takes the liberty (and is

permitted to do so!) to combine different meanings of one object (or word) into one plot of a narrative (Koestler, 1964). Humor is often an element of play and is the direct consequence of the freedom of the players in an otherwise rule-governed context.

A consequence of this approach to play is that basically any cultural activity can be formatted as a play, if this is accepted by the cultural environment in a certain situation. Sometimes, children spontaneously transform works they have to do in a school context (like setting the table) into a format that complies with the notion of play, as was apparent from the observations of Hännikäinen (2001). On the other hand, Callois (1958) pointed out that adult activities, like gambling with money on the financial market, can be seen as a culturally accepted play version of trading goods. It is obvious that this activity complies with the play format, as explained here. It is also clear (in the context of the financial crisis of 2008), that the acceptability of the variations in cultural versions of activities (like playing on the financial market) is dependent on cultural ideas and norms.

The variations allowed within activities also cause ambiguity with respect to the meaning of a person’s actions. For this reason, our culture has invented different signs that communicate the meaning of activities, for example by designating special places as “play places,” (like playgrounds, sport fields, casinos). Bateson (1972) and Garvey (1990) have also pointed out on the basis of rich observations, that children themselves also develop different behavioral signals to communicate in the play the status of their participation and their compliance (or not) to certain tacit rules. A smile for example may signal “I am joking,” or a change in verb tense may signal that one steps out of the play momentarily for comments, reflection, and revision of the rules.

### ***The Role of the Adult in Children’s Play***

Having defined play as a particular activity format, we can now from the perspective of activity theory answer the two last questions that were posed at the end of the first section, and clarify the relationship of the adult to children’s play and explain how learning should be conceived of in the context of play.

By analyzing play as a certain type of activity, play is interpreted as a culturally defined quality of activities. Cultural activities are by definition social and historical entities, and by the same token other people (like adults) are always involved, either concretely or

virtually. In a specific situation an adult can decide to stay physically out of a child's (children's) activity. However, in his play the child uses culturally developed objects (including instruments) that somehow canalize children's actions into specific forms, that prevent risks or otherwise unacceptable forms (*see* Valsiner, 1987). In these cases the adult is physically absent, but virtually represented in the objects or the rules of the practice that the child is imitating. On the other hand, adult participation in children's play in no way necessarily violates the playfulness of children's activities. There may be a danger that the adult intrudes into the activity of children in a way that annihilates children's degrees of freedom, or reduces their involvement. In those cases the style of participation seriously threatens the quality of children's play, rather than his/her participation *per se*. The participation of an adult in children's playful activities is the main point of influence of culture on play and children's development (Karpov, 2005). As we have demonstrated in our research, this is the main reason why play can serve as a productive context for meaningful cultural learning (*see* van Oers, 2010a, 2010b, 2010d).

As to the process of learning, activity theory has elaborated a conception of activity-based learning that was explained above. In the context of playful activities, children structurally may change their actions as a result of experiences with objects, instruments, or communications with adults or peers. When these actions turn out to be sustainable over situations and time, we can speak of learning. There is no inherent contradiction between play and explicit learning. There is evidence that children in play strive for improving their actions by learning, as this improves their ability to take part in the activity. That is why they sometimes call for help of an adult in their activities (e.g., Prammling Samuelsson & Johansson, 2009). Notwithstanding the possibilities of learning within the context of play, learning cannot be seen as a defining aspect of play. Learning can take place in play on a spontaneous and incidental basis, learning can be promoted within the context of play by a participating adult or peers (*see* van Oers, 1999), but it can also be absent. It may even be possible that a particular organization of the playful activity prevents learning—e.g., when the child is preoccupied with one aspect of the play situation (like the boy involved in a role-play in a supermarket who wanted to hear the ringing noise of the counter over and over again).

On the basis of the presented interpretation of play as a specific activity format, it is clear that a huge variety in play activities is possible, depending on the nature of the objects or instruments involved, the nature of cultural practices imitated, the type and complexity of the rules to be followed. The types of play that I have discussed so far, were presented from a synchronic perspective, focusing on types of play that may appear in a certain period of life. From a diachronic perspective, however, it is necessary to ask if we can distinguish developmentally different types of play that follow each other and perhaps emerge subsequently. This is a question of the development of playing, or the development of playful activity during ontogenesis. In most developmental theories play is acknowledged as a dominant phenomenon in the early stages of child development (a leading activity, according to Vygotsky, 1966, p. 75). According to most theories, play remains present in the child's life after the age of about 8 years old in the form of games and fulfills no clear developmental function (except as a domain of social learning or leisure and creativity). From that age (school age), according to Vygotsky (1966, p. 76, author's translation):

play becomes a more limited form of activity, predominantly as sport, which fulfills a specific role in the school child's development but lacks the significance of play for the preschooler. (...) At school age play does not die away, but permeates the attitude towards reality. It has its own inner continuation in school instruction and work (compulsory activity based on rules).

Vygotsky seems to suggest that in the course of development a transition takes place from playing to work, whereas the fate of playful activities remains obscure. He continues: "Only a profound internal analysis makes it possible to determine its [i.e., play's, *author's addition*] course of change and its role in development" (p. 76). In the next section I will demonstrate how an activity theory approach to play may be able to answer this question about the ontogenetic evolution of play.

### **Ontogenetic Evolution of Playing** ***General Outline of a Cultural-Historical Developmental Theory***

Several attempts have been made to construct an order in the development of playing (Piaget, 1951; Smilansky, 1968; Vygotsky, 1984; El'konin, 1989). El'konin (1989) criticized Piaget's theory

as too exclusively focused on the development of symbolic function and cognitive progress. The same critique might be leveled against the stage theory of Smilansky (which is actually an elaboration of Piaget's by adding a phase of constructive play between sensorimotor play and sociodramatic play). Rubin, Watson, and Jambor (1978) elaborated these theories by adding a dimension of development in social participation. Close scrutiny of the stage theories of Piaget, Smilansky, Rubin et al. demonstrates that these theories do not cover all types of play and lack a clear definition of what play is and an explanation of how the stages should be ordered (see Pellegrini & Smith, 2003, p. 279, for a brief summary and critique).

El'konin (1989) constructed a stage theory of development, focusing on the mechanisms of development, and elaborating Vygotsky's idea of *leading activities*. Play in this view is a leading activity for young children in our Western industrial society from the age of about 1 to about 8 years old. Play at these ages, is a leading activity because children in this period have a propensity to playing and play yields the greatest developmental benefits for the child at these ages, which moves them into a new stage of development (Karpov, 2005; Leont'ev, 1983, p. 306; Vygotsky, 1966, p. 75).

The mechanism of development and for the transitions from stage to stage is explained by El'konin by the tensions that emerge over time between development in the cognitive-technical domain (the use of cultural instruments) on the one hand, and the development in the social domain (volition, motivational, emotional moral aspects) on the other. Different stages of development can be characterized as leading activities in which one of the two domains of development dominates until the moment that the discrepancy between the two domains of development has passed a certain threshold, and becomes a psychological problem for the child. In some periods the child makes a spurt in

appropriating cultural tools, but the necessary motivational development required for the use of these instruments lags behind. In these periods the focus of activity and learning is on objects and tools. In other periods, the development in the motivational sphere dominates while the instrumental development lags behind. The focus of activities and learning is on social interactions with other people that help in developing the required volitional qualities (motivation, interests, emotions, attitudes, moral stand). Critical points in development, according to El'konin, are based on these discrepancies between the two domains of development, which urge to a transition from one leading activity to the next. For the sake of brevity, El'konin's theory of leading activities can be summarized in Table 45.1.

It needs to be mentioned that previous leading activities and their alternating foci do not completely disappear after transition to later leading activities. They become less dominant, but the faculty of changing from one focus to another (at will) remains. As can be seen in the scheme in Table 45.1, play dominates in the second and third periods. The focus of the dominant activities alternates and will be embodied in the course of development in different types of activities, with different motivations and demands from the social world.

Karpov (2005) gives a valuable overview of El'konin's developmental theory of leading activities and summarizes lots of empirical evidence demonstrating the essential role of the adult in the transitions from one leading activity to the next. His presentation, however, is not systematically based on activity theoretical analyses, and fails to characterize play and the position of the child in each of the leading activities (see van Oers, 2010c). In his presentation, play seems to disappear after stage III and it remains unclear what precisely happens with play after the age of 8 years.

Our own systematic analyses on the basis of conceptual work and empirical research has now

**Table 45.1 Overview of successive leading activities (adapted from El'konin, 1989)**

	I	II	III	IV	V	VI
<i>Leading activity</i>	Looking for contacts	Manipulative play	Role-play	Learning activity	Defining social position in a group	Labor
<i>Focus</i>	World of persons	World of objects	World of persons	World of objects	World of persons	World of objects

produced a developmental course of playing, based on reinterpretations of El'konin's ordering of leading activities from the perspective of activity theory. I will argue that each leading activity can be interpreted in terms of the play format. In this interpretation, play does not necessarily disappear or take a marginal position, but changes in the course of development. Depending on cultural decisions, the play format (particularly allowing degrees of freedom to the children, and the educators' willingness to create conditions for high involvement) will be implemented or not. If a cultural community indeed fully accepts the activity format (rules, degrees of freedom, and high involvement) as "normal practice," then play becomes a continuous characteristic of human cultural development, throughout individual development.

As demonstrated above, the role of culture with regard to play is undeniably present in the concrete manifestations of play. Culture controls the varieties of human actions by defining the constraints of human activities, sanctioning the outcomes, pre-defining the rules and time restrictions, providing tools (sometimes in versions that limit the individual's actions, e.g., for reasons of safety). Schools and families have an important role to play in controlling acceptable behavior. They constitute the royal road of cultural influence on human activities by their defining the acceptable values of the parameters. Despite the importance of cultural institutions for the manifestations of play, I cannot dwell too long on this dimension in the following descriptions of the types of play.

### ***The Development of Playful Activities in Ontogenesis***

Starting out from a reinterpretation and elaboration of El'konin's description of the course of human development in terms of leading activities, it is possible to give the following descriptions of the different types of play that may occur in the course of human development. It should be borne in mind, however, that once emerged, types of playing will never completely disappear or become irrelevant. They may adopt new forms and are still accessible alongside newer forms of play.

According to El'konin, in the first six months of life children are engaged in activities that are motivated by their search for socio-emotional contact. It is evident that these activities fit into a play format. From the very first day of their life children are received in communicative practices that introduce

regularities (answer-response) in children's behavior, and that allow them a high degree of freedom in the choice of responses. Part of the regularity in this stage of activity development is probably based on what Piaget called primary and secondary circular reactions to stimuli in the environment. Highly significant, however, are the cultural forms of regularities introduced in the child's activity by engaging them in interactive practices. Peek-a-boo is one of the universal forms of play at this stage of development that teaches children to be part of a rule-governed (communicative) activity (see Bruner, & Sherwood, 1976). A significant moment in this contact play is when objects (toys) become a part of the interactions. Objects play an important role in directing attention, pointing, building shared attention, and learning to see another person as an intentional agent (Tomasello, 1999, p. 56; 2008, pp. 135–165; Karpov, 2005, p. 106). The focus on objects by shared attention and (proto)communications between child and adult sets the stage for a new form of play in which the social orientation of the contact play changes into an object-oriented activity.

Manipulative play. Characteristic of this type of play (starting in the first year of life) is the repetitive handling of objects available in the environment, like feeling, putting in the mouth, tasting, throwing, hitting, breaking, rolling, etc. The format of this activity also fits in with the previously defined play format. Within certain limits, children are more or less free to choose the exploratory or instrumental actions they want to perform on the cultural objects, and they can continue as long as they are interested (which is an important condition for involvement). A specific type of manipulative play must be mentioned here, as it takes place in most children's life for a longer time: rough-and-tumble. While playing around and play fighting, children manipulate and explore their own and other children's bodies and learn about their own possibilities, but also about social values. In the manipulative activities, explicit cultural constraints are put on the children's actions by providing them with restrictive rules (like in rough-and-tumble) or with toys with specific affordances. On the other hand manipulative play activities like toy play also essentially show the child's relative freedom in handling the toys and even redefining their nature by using them in unexpected ways (Pellegrini & Jones, 1994). The communication with the children largely focuses on object-related language (Lisina, 1987) and opens important ways

for the emergence of symbolic thought (Callahan, 1999; Puchova, 2005; Karpov, 2005, p. 133). By the production of toys, a culture exerts significant influences on the child, through the affordances it raises and the type of communications with adults and peers it elicits. The toy often implies cultural roles, like a car toy implies a driver, or a toy hammer implies a carpenter. Through observation and communication, children often adopt a new form of manipulative play that is imbued with meaning from the child's interpretation of the related role ("playing the chauffeur"). This role-bound manipulative play forms a step toward role-play (thematic play) and imitation of sociocultural activities in which different roles are coordinated.

Role-play. This is probably the most widely studied form of play. Characteristically, role-play is an imitation of a cultural activity in which the play format is optimally worked out. Actually, it even creates the opportunities for the child to participate at all in these types of cultural practices. The status of these activities as play is not disputed. As Vygotsky already pointed out, children are motivated to get involved in adult activities and learn about the rules and tools of this activity. At the same time children also need some freedom in acting out the adult roles in their own ways. According to El'konin (1989), the major motive for the child for this type of thematic role-play is to learn about social relations and about the ways people interact in the contexts of the cultural practices they encounter in their daily lives. It follows from the nature of this type of play that culture has a significant influence on the child's activity, his learning, and identity, through the tools that are provided, the way the use of these tools is regulated by information and social values, the type of interactions that are required and accepted. A bus driver interacting with his passengers has to apply specific abilities, possess specific knowledge, and has to follow certain rules of interaction. The same is true for the cashier in the supermarket, the waitress in the restaurant, the guide in the museum, etc. By participating in these activities in a playful way, children learn about these practices, the roles, instruments, and social rules of interaction. Particularly important in such role-play activities is the expansion of children's communicative abilities. As a result, children start making their own means for communicating with the help of others, and begin constructing signs for communicating new aspects of their play activity to others (see van Oers, 1996b, 2008a). Since the 1990s, research has

demonstrated that the forms of role-play in which adults take part can have a positive effect on children's learning (Wood & Attfield, 1996; Singer et al., 2006; Bodrova & Leong, 2007; Dolya, 2009; Hirsh-Pasek et al., 2009; van Oers, 2003, 2010a, 2010b, 2010c, 2010d). In our own applications of the concept of role-play we have discovered an important (but in literature neglected) type of role-play, which we call *director play*. In regular role-play, children play out the roles in concrete behavioral ways. In director play, children project their ideas about a role onto external objects (e.g., dolls, play animals) and play out a role-play on a table or screen, like in playing with a doll house, or a miniature garage, kitchen, shop, etc. In schools, children are often invited to play out a narrative in a role-play in order to stimulate literacy development (see Christie, 1991). In our own research school, we discovered that playing out a story on a table with little dolls in reconstructed environments (we call these tables "story-tables"), has similar positive effects on language development as role-play wherein children themselves feature (e.g., Nauta, 2010). Director play frees the child from limits of physical reality and might be seen as one way of dealing with cultural restrictions in schools and other educational situations. Director play is a special type of play as it continues in children's lives for a longer time than actually enacted role-play. Director play transforms in our industrialized culture into all kinds of simulation games that children play on their computers (like SimCity, the Sims, World of Warcraft, etc.) from primary school onward. In director play, children organize a virtual world, and play roles in that world without the real dangers, or some of the limitations that are put upon players in the real world. The only limitations are cultural limitations, embodied in special features of the games or in pedagogical conventions of the environment in which the game is played. Much role-play continues in children's cultural development in the form of director play that already starts at the ages of 5 or 6 years old in primary school. In the context of role-play (including director play) children are confronted with tools and their possible applications and expected outcomes. The motive to master such tools (both physical and ideal, like mathematical symbols) in order to improve participation generates a new motive that marks a new form of play, which we dubbed *productive play*.

Productive play. The type of activity that children are engaged in from their middle childhood

onward is mostly not recognized as play, because of its purposeful nature. El'konin refers to it as “learning activity” as the new leading activity, a designation adopted by Davydov (e.g., 1996, 1999) and Karpov (2005) as well. However, there is no logical prohibition to conceive of human productive activities (production of meanings, knowledge, rules, norms, or commodities) as activities in a playful format. Production processes always abide by (implicit or explicit) rules (construction rules, economic rules, ethical rules, etc). However, in our industrial Western society, large differences are found in these activities as to the freedom attributed to the agents, and to the conditions created for keeping agents intrinsically involved in activities. For economical reasons, productive activities in our industrialized society are usually evaluated on the basis of effectiveness. Therefore the organization of these activities tends to be strictly regulated and leave little or no freedom to the worker. Leont'ev (1959) analyzed these types of activities and argued that they tend to minimize the personal sense of the worker's actions, and to obstruct the feeling of connectedness with the activity and its products. According to Leont'ev, this leads to alienation and hampers the development of a broad cultural identity. The latter types of activity occur frequently in industrial societies, both in the production of meanings (like in schools) and in the production of goods (factories). They tend to be the opposite of playful activities. In the following, I will briefly sketch two general types of productive activities that incorporate playfulness.

Productive activities in school have to do with the *production of meaning* and operations in different intellectual domains (such as language, mathematics, science, economics, history, music, etc.). Recent understandings of these types of learning activities emphasize the importance of creativity and personal meaning in these processes (*see for example* Wells, 1999). They conceive of subject-matter learning as a process of guided co-construction of meaning in which the pupils are allowed to explore and critically discuss their own solutions and hypotheses (*see* Kuhn, 2005; Mercer & Littleton, 2007; Darling-Hammond, 2008). Good examples of productive learning activities in a playful form can be found in the movement of Realistic Mathematics Education (RME). The rule-bound nature of mathematical activities is beyond doubt. Within such activities RME tries to support pupils in the production of relevant mathematical meaning by getting them involved in meaningful activities in which they are

challenged to solve problems and to produce their own solutions, compare them with others, discuss them, and improve them with some freedom within the boundaries of the accepted mathematical rules (*see for example* Freudenthal, 1990; Yackel & Cobb, 1996). When schools can accept (and deal with) a relative freedom of pupils in a learning activity, learning can be organized according to the play format, co-regulated by pupils and teachers, and based on engaging problems. Actually, pupils and teacher are emulating an adjusted version of a cultural activity, called science. Obviously, in science the existence of rules, academic freedom, and high levels of involvement are deemed essential features. Davydov (1983) too—following Hegel—has pointed out that science in its optimal form is essentially “free intellectual labor,” producing knowledge by dialogue (direct and critical discourse with participants in an activity) and polylogue (discourse with all other absent experts; *see* van Oers, 2001). Davydov, however, was initially very reluctant to adopt the model of academic inquiry-based learning for educational purposes (*see* Davydov, 1968). From the point of view, presented here, academic learning can be playfully accomplished in primary school, provided a teacher participates in this play and upholds the standards of science by taking account for those elements of the activity the children cannot accomplish yet. It goes without saying that through the dialogues and polylogue, culture has a significant influence on the course and outcomes of this playful learning activity.

Another type of productive activities in a playful format are the activities that purposefully aim at the *production of variations*, in actions, tool use, interpersonal relations, etc. Well-known examples of such activities can be found in games and sports in which variations of actions (or the invention of new or surprising actions) is essential for winning the competition with other players. In educational contexts, playful formats of productive activities can be found in pupils' imitations of adult cultural practices. Elsewhere, I gave an analysis of how 5-year-old children appropriate parts of musical culture by imitating a musical performance practice under adult guidance (*see* van Oers, 2010d). As another more elaborated example, I can refer to a Dutch school where 12-year-old pupils run a Third-World Shop in their school, under guidance of the teacher. The pupils are highly engaged in this practice, do have the freedom to organize it in their own way within the rules of this type of practice, and

within the limits of the law, ethics, and financial constraints of the school. Their way of running the Third-World Shop obviously fits in the play format of this type of cultural activity. Further examples of cultural learning in playfully formatted activities can be found in the use of gaming in secondary (vocational) education (see Shaffer, 2006; Veen & Vrakking, 2006; Gee, 2007a, 2007b), and in the Fifth Dimension settings supporting literacy learning in out-of-school contexts (see for example Brown & Cole, 2002). It would go too far here to analyze productive activities in institutionalized labor from the perspective of the play format. Inherently there is no reason to assume that they couldn't, but for the present argument it suffices to say that particularly labor resists the play format for cultural reasons (economy, finances, international competition). The cultural tendency to view teaching (as one type of cultural labor) as a goal-directed, curriculum-based, and effective type of activity mostly does not allow much degree of freedom to the teacher. It is, however, only one way of formatting this activity. Exactly this view on teaching is incompatible with playful learning of pupils. It is one of the cultural arguments for separating play and learning.

### **Conclusion: Play as a Specially Formatted Activity in Culturally Structured Environments**

Play is an essentially cultural phenomenon. Understanding play requires understanding of the relationship between culture and play. This chapter argues that the influence of culture on play runs via two different routes: on the one hand, via the social representation of play in a cultural community at a certain moment, and on the other, through the ways invented by a community to control variety in play activities in order to maintain cultural coherence, cultural values, and identity.

Analysis of play from the perspective of cultural-historical activity theory leads to a number of significant conclusions and implications.

First of all, the fundamental conclusion that play as such, as a specific entity *sui generis*, does not exist. Play is a qualification of cultural activities, and can be identified as a particular *activity format* that is manifested as highly involved accomplishment of rule-governed activities that allows the participants a significant degree of freedom in the choice of goals, actions, objects, tools, and rules, and in making personalized versions of them. Consequently, the classical ideas of free play owned by the child, and

of the play-work distinction must be abandoned as untenable.

The activity point of view solves at least two of the recurrent problems in play theory: the role of the adult and the problem of learning in play. Viewing play as a cultural activity implies that the participation of other people is by definition acceptable. This is not to say that other people (e.g., adults) must always participate in children's play, but there is no theoretical objection to the participation of adults in children's play as long as this does not destroy the typical play format. If and how an adult should participate in children's play depends on the community's social representation of play and the adults' educational intentions. It is partly an empirical question regarding the efficacy of a specific structured environment for the achievement of educational goals.

The participation of adults in children's play also creates opportunities within the play context to support and guide the playing child in the appropriation of new actions and meanings. As all cultural activities, activities in the play format inherently imply the faculty of learning. The frequently practiced separation of moments for playing and moments for learning has no theoretical ground. Learning as a process of changing actions and meanings is intrinsic to play.

This point of view also further extends the cultural-historical theory of development of El'konin. Considering the fact that meaningful learning consists of the appropriation of cultural contents in ways that make personal sense to the learner, we can still maintain with Vygotsky and El'konin that play is the leading activity for young children—i.e., the activity in which young children's learning contributes optimally to the child's development. But from the activity point of view it is clear now that the play format should not be abandoned when the leading activity changes into new forms (e.g., into productive learning). The child's developmental trajectory as a procession through different leading activities is at the same time a trajectory of learning to participate in these new activities (with new foci), formatted as play. As is argued in this chapter, the activity approach also opens a productive perspective on the question of what happens with play when children grow older.

In ending, it must be noted that the activity theory approach to playing as presented here has various implications that couldn't be addressed here. In passing, I mention only two of them. The

activity approach throws a new light on the issue of *play training*, which can be conceived of in this perspective as assistance of children to participate safely in new activities, with new and more complex rules, while feeling free to employ them in ways that suit them best. Play training begins with creating involvement and feeling safe and free in a cultural context with others. Another eternal problem is the query about the return effect of playing on culture. Of course this is a complex and long-term process, but in general it is comprehensible that children who have been accustomed to their right to modify cultural activities in play, may grow older with a more liberal attitude toward cultural activities as playfully formatted and (consequently) changeable. The innovation of culture depends on the innovation of activities and its including tools and rules for the control of variety in this activity, and on the attitude of future generations to do so. This is probably also what Vygotsky (1966, p. 76) might have meant at the end of his play article when he writes that play evolves into a new relation to reality.

The first signs of the research from this perspective show that playfully formatted cultural activities can be productive as well, and benefit the development of both individuals and their communities. However, like always, more research is needed to substantiate that claim.

## Future Directions

In our department “Theory and Research in Education” (VU University, Amsterdam) we are contributing to a network of schools, innovators, and researchers that works at the implementation of a play-based curriculum in primary schools (Developmental Education for 4- to 12-year-olds). Our research program<sup>3</sup> is continuously gathering evidence for the support of this curriculum. Positive evidence has been provided in recent publications, quoted above.

Independent from our locally inspired efforts, the approach to playing needs further elaboration and empirical support. For the future, the following research themes might be valuable contributions for a deeper understanding of the relationships between culture and play:

1. (Educational) *What are the psychological, cultural, and economical consequences of playfully formatted cultural activities?* Educating children and youngsters in an activity format that gives them much freedom and responsibility for their own

actions and others’, will presumably have positive influences on children’s development as a cultural individual. We may think of deeper understandings of cultural contents, but also of developments at the social and moral-ethical levels. Further studies are needed to explore these effects both at a personal level and at the level of institutions (like schools), communities, and societies. In particular, systematic studies are needed into the possible ways of feeding culture into (children’s) activities without destroying the basic requirements of the play format. However, more problematic consequences might be expected too, because of the revaluation of tradition and authority (see Ziehe, 2008; Arendt, 1961), that may follow from the play format. These too deserve serious study in the near future.

2. (Psychological) *Describe the development of playing as developments of play activities.* According to the presented view of play, the development of playing in ontogenesis should be conceived of as a development of the accomplishment of activities in a play format. Currently I hypothesize that this development is strongly dependent on the use of more complex rules. In manipulative play, the rules are often implicit and embodied in the features of the play objects, in role-bound play the rules are more articulated but still dependent on the person’s imagination of that role, in role-play (both director play and thematic role-play) the rules are related to a player’s narratives about the theme-based play activity. Rules can be seen as one of the points of access of culture into play. Further study of the development of playing in terms of increasingly complex rule employment is urgently needed. Furthermore, formatting cultural activities (like learning, work, institutional behavior) as play can be expected to have prominent effects on the development of attitude, identity, and critical agency. Further psychological study of this process is urgently needed.

3. (Anthropological/cultural) *Studying the dynamics of the social representation of play in different cultural communities.* Play is a cultural phenomenon depending on what a cultural community accepts as variations in the accomplishment of activities. The development of social representations of play in different cultural contexts calls for further study in order to both understand better the existence and value of playing in cultures, and the educational potentials of play activity in a multicultural society.

## Notes

1. "Der Mensch spielt nur, wo er in voller Bedeutung des Worts Mensch ist, und er ist nur da ganz Mensch, wo er spielt." (Italics from Schiller).

2. There is a serious translation problem here. Vygotsky systematically refers to "sense" (*smysl*) when explaining the dynamics of play. Sense refers to the personal and emotionally colored interpretations of reality, and should be distinguished from conventional meaning (*značenie*), as Vygotsky clearly explains in his *Thinking and Speech* (Vygotsky, 1934). Unfortunately, in most translations of Vygotsky's 1966 article on play (in Vygotsky, 1978 and in the translation on <http://www.marxists.org/archive/vygotsky/works/1933/play.htm>) this crucial distinction is lost. From the Russian text it is unambiguously clear that in Vygotsky's view, personal *sense* (rather than conventional meaning) dominates play actions.

3. Research program "Developmental Education in the school context" of the department Theory and Research in Education, Faculty of Psychology and Education, VU University Amsterdam.

### Abstract

The chapter starts with an overview of the ongoing debate between evolutionary and culture-relativistic approaches and their contributions to describing and explaining cultural similarities and differences in emotions. As a theoretical and methodological completion of existing approaches, the chapter highlights the importance of an integrative developmental perspective on the ontogenetic emergence of emotions, in identifying the ontogenetic roots of their cultural similarities and differences. A developmental perspective can also serve as a validation of indigenous approaches, as well as for cross-cultural comparisons of adult emotions. This approach focuses on emotional expressions as a culturally constructed sign system that mediates between the cultural and psychological spheres. The acquisition of expression signs in interpersonal interaction leads to a transformation of biologically determined precursor emotions of neonates into the culturally functional and differentiated emotions of adults. Such an approach facilitates the identification of constitutive components of culturally differentiated emotions and their constitutive sociocultural factors that channel common and culture-specific pathways of emotional development.

**Keywords:** body language, emotional development, emotion regulation, emotions, emotion socialization, nonverbal communication, parent-child communication, sociocultural factors

Emotions are everyday and omnipresent phenomena to which people pay considerable attention and which provide them with many positive, but also sometimes painful experiences. Emotion researchers from different theoretical traditions are relatively unanimous about the function of emotions. They assign an adaptive function to emotions in regulating human activity. Emotions signal significant personal concerns or motives under changing situational circumstances (*see* Frijda, 1986; Mesquita, 2001; Scherer & Wallbott, 1994). Researchers agree that the specific causes of emotions and expressions displayed in given situations yield enormous diversity across cultures (Levenson, Soto, & Pole, 2008; Mesquita & Leu, 2008; Safdar, Friedlmeier, Matsumoto et al., 2009; Shweder, Haidt, Horton, & Joseph, 2008).

This is in sharp contrast with the few and straightforward causes and expressions of animals, which seem equipped with only a few emotions, namely seeking, rage, fear, panic, sexual lust, care, and play as a form of pleasure (Panksepp, 1998).

In contrast, researchers do not agree on the issue of how emotional diversity can be classified and explained. There is a long-standing controversy between exponents of the different theoretical traditions as to which necessary and sufficient criteria indicate an emotion and to what extent individual emotions are biologically prewired or culturally co-constructed.

The origin of the modern universally oriented emotion theories can be traced back to the work of Charles Darwin (1872), and the modern culture-relativistic

emotion theories to the ethnographic observations of Malinowski (1922) and Margaret Mead (1928, 1935). Darwin supposed emotions and their expression to be a product of phylogeny, they are evolutionarily adaptive and could be found in humans, as well as in primates and mammals. He assigned the capacity of each human individual to feel and express emotions in the same manner. Emotion theories in the tradition of Darwin's evolutionary approach have focused on providing evidence of the universality of so-called basic emotions. By contrast, emotion theories in the anthropological and co-constructivist tradition have claimed that emotions are culturally co-constructed. They have focused on describing indigenous concepts of emotions (e.g., Lutz, 1988) and on observing culture-specific modulations of emotion (e.g., Briggs, 1970; Levy, 1973). Research on emotion and culture has so far ranged between these evolutionary and culture-relativistic approaches.

In this chapter, we provide a brief overview of this ongoing debate and present an approach that can mediate between these contrary positions. Our approach takes a developmental perspective on the ontogenetic emergence of emotions. It focuses on emotional expressions as a culturally constructed sign system that mediates between the cultural and psychological sphere (*see* Holodynski & Friedlmeier, 2006). The acquisition of expression signs over the course of interpersonal interactions leads to a transformation of biologically given precursor emotions of neonates into the culturally functional and differentiated emotions of adults. Such an approach enables us to identify constitutive components of culturally differentiated emotions as far as they are developmentally rooted and constitutive sociocultural factors that channel common and culture-specific pathways of emotional development.

### **Paradigms of Cross-Cultural Research on Emotion**

There are many emotion theories that can be assigned to four overarching emotion paradigms (*see* Holodynski & Friedlmeier, 2006). Each paradigm can be defined by a specific standard of equivalence for cross-cultural comparisons in which classes of indicators or components are used to define and classify an emotion (*see* Friedlmeier & Matsumoto, 2007). These standards also contain implicit assumptions about the development of emotions. In the following section, we consider these different

standards associated with each paradigm and discuss their advantages and disadvantages.

#### ***Structuralistic Paradigm: Emotion as an Innate Configuration of Reactions***

By nature, humans are equipped with a set of basic emotions as their phylogenetic heritage, as stated by Darwin (1872). This notion has been developed in subsequent evolutionary theories of emotion, such as the neuro-cultural theory of Ekman (1992, 1994a) and Levenson et al. (2008), as well as its developmental counterpart, the Differential Emotion Theory of Izard (1977, 2009). Common to all these theories is the assumption that each basic emotion can be defined by a prototypical inborn hard-wired configuration of an expression, especially a facial expression, a peripheral-physiological body reaction and a subjective feeling. Facial expression is of particular significance, because its internal feedback serves as basis for the subjective experience of the emotion, called feeling.

What remains controversial is the number of identifiable basic emotions. Ekman (1984, 1992) assumes at least six, namely joy, fear, sadness, anger, disgust and surprise (*but see* Ekman 1994a). Izard (1977) assumes that there are 10, adding shame, contempt, interest, and guilt, because a prototypical facial expression can also be assigned to these four emotions. Tracy and Robins (2008) add pride to basic emotions, because it can be recognized from body expression (erect body, arms up in the air or akimbo) by members of very different cultures. The components that can vary according to the specific culture are the cause of a specific emotion (e.g., fear of cancer or heart attack in Western cultures vs. fear of the curse of their ancestors in tribal cultures) and cultural display rules of expression that prescribe who must display which expression to whom in which situation (Ekman & Friesen, 1972).

In empirical research, the assignment of the prototypical facial expression to the label of the corresponding emotion by members of very different cultures is considered to be the standard of equivalence for defining a basic emotion. Additionally, it is assumed that basic emotions can be observed from birth onward in each culture, while the modification of expression according to display rules occurs only over the course of ontogenesis. Cross-cultural studies that have been conducted along this standard of equivalence have found the following:

1. Prototypical facial expressions were assigned to the corresponding labels of joy, fear, anger, sadness,

disgust, and surprise, beyond chance level in very different cultures, including those that had not had any contact with Western media before the study. This was taken as a proof of the universality of basic emotions (Ekman, 1972, 1992).

2. Evidence of culture-specific display rules (see Matsumoto, 2000, Chap. 11 for an overview; Safdar et al., 2009) and their development (Cole, Bruschi, & Tamang, 2002; Garrett-Peters & Fox, 2007; Saarni, 1984).

The structuralistic paradigm and the associated studies have been criticized for several reasons:

1. The unreflected application of English-language terms for classifying basic emotions (Wierzbicka, 1999) and the forced-choice format for matching facial expressions with terms of emotion might prevent participants from using more culture-specific assignments. A free-choice format for labeling the six prototypical facial expressions revealed significantly more culture-specific assignments (Russell, 1994; *but see* Ekman, 1994b).

2. Emotional expression has, *a priori*, been narrowed down to facial expression. From a methodological perspective, this reduction provides a clearly operationalized criterion for measuring emotions, but it excludes all other channels of expression that are obviously used by people of all cultures such as gestures, posture, tone of voice, etc. (see Collier, 1985). The analysis of expression remains incomplete and possible culture-specific variations in these other channels thus undiscovered.

3. Cross-cultural studies refer mainly to the recognition of emotions via pictures of (mostly) posed prototypical facial expressions (Ekman, 1972; Russell, 1994). The recognition of a prototype, however, is not the same as the observation of emotion expression in daily life. This also applied to situations in which display rules could not serve as an explanation, such as in solitary situations in which people display mainly reduced expressions instead of full-blown expressions (Chovil, 1991; Fridlund, 1994; Holodynski, 2004).

4. Many studies revealed that neonates and young infants did not display the prototypical facial expressions of sadness, anger, fear, and surprise that are categorized as basic emotions. It was not before the second half of the first year of life, that infants started to express these emotions. On the other hand, distress, with its expression of crying, is an expression that can be observed already at birth,

but is not labeled as a basic emotion. From birth onward, only expressions of these basic emotions are observable: interest, pleasure, and disgust (see Camras, 1992; Oster, 2005).

### ***Functionalistic Paradigm: Emotion as a Relationship and Process***

Theories of emotion that are allocated to the functionalistic emotion paradigm define an emotion through its function in regulating individual activities. The definition of emotions by Campos, Barrett, and Campos (1989) is prototypical. Emotions are “processes of establishing, maintaining, or disrupting the relations between the person and the internal or external environment, when such relations are significant to the individual ...” (p. 395). Accordingly, an emotion represents an action readiness, which is triggered through an appraisal of occurrences or facts, with respect to their relevance for motives and personal concerns, and is intended to change the situation in a manner that serves the motives. This action readiness can be displayed as expressions, body-related and experience-related forms (Frijda, 1986).

The appraisal pattern that triggers the emotion and the action readiness are considered as a standard of equivalence for determining an emotion. The latter can be expressed in the full range of differentiation of expressions and bodily reactions, i.e., not only in patterns of facial expressions. Major cross-cultural studies have demonstrated that both appraisals and patterns of action readiness can be universal and culture-specific (e.g., Frijda & Mesquita, 1992; Scherer & Wallbott, 1994; Scherer, Wallbott, & Summerfield, 1986).

The following criticisms were leveled against these approaches and studies:

1. The appraisal and action readiness components were almost exclusively assessed by self-reports of experienced emotional episodes. Thus, the ethno-theories of the participants with respect to the emotions have been assessed rather than real emotional episodes. Real episodes might contain additional features that the participants might not remember anymore.

2. The emotional concepts preselected by the researcher and the classification of both components are generally oriented toward Western emotion theories. An indigenous analysis of appraisal and of patterns of action readiness was not conducted, and

therefore, it was not possible to discover concepts other than the preselected Western ones.

3. Whether appraisal or action readiness patterns for a given emotion are universal or culture-specific depends on the level of abstraction that applies to the categorization of respondent answers. The more abstract the categorization, the more likely is the evidence of universality (Mesquita, Frijda, & Scherer, 1997). Accordingly, all cultures have experience of physical threat—and that of fear in the broadest sense. Likewise, there is experience of losing someone who is close and loved or important, leading to grief. Furthermore, there is an obstruction of motive satisfaction by third parties, and thus anger. In order to avoid hasty generalizations, the suggestion is made that patterns should first be extracted from an indigenous analysis of reports and only then, the cultural comparisons will follow (*see* Shweder et al., 2008).

4. No cross-cultural developmental studies have been conducted, which have investigated the development of these emotion-specific appraisal and action-readiness patterns.

### ***Co-Constructivist, Language-Focused Paradigm: Emotion as a Cultural Concept***

Theories of emotion referring to the language-focused paradigm can be found mainly in the cultural anthropology research. The main goal of these extended field studies was to provide a comprehensive ethnographic analysis of individual cultures including emotions. The work of Lutz (1986, 1988) and Abu-Lughod (1986) are groundbreaking in this context. The methodology entailed detailed and repeated questioning and observations of members of the particular culture, with the aim of capturing the emotional concepts in their culture-specific uniqueness. In these studies, emotions are considered as a combination of an unspecific bodily arousal component with a linguistically coded scheme of interpretation. It is assumed that the scheme prescribes how the stimulation is interpreted and how one is to react (Lynch, 1990). The linguistically coded concepts of emotion for the culture in question, in combination with bodily arousal, constitute the standard of equivalence for determining an emotion. The ethnographic studies have concentrated on reconstructing the concepts of emotion and single emotion qualities that indigenous people hold.

1. Some families of emotions within a given culture have been linguistically overrepresented—there are a large number of similar emotion concepts—whereas other families are underrepresented. The former are characterized as hyper-cognized and the latter as hypo-cognized emotion concepts (Levy, 1984).

2. Some of the emotion concepts of a given culture directly reflect the uniqueness of relationship formation within this culture. The emotion labels assigned to these concepts of emotion cannot be translated into terms of other cultures without a loss of meaning. Accordingly, the indigenous concept of *fago* from the Ifaluk of Micronesia in the Pacific, cannot simply be translated into English. The reason is that it represents a culture-specific mixture of comprehensive care, sadness, and love that can only be understood through cultural practices of the Ifaluk (Lutz, 1988). Analyses of culture-specific emotional concepts and their terms such as the German *Angst* or *Weltschmerz*, are of similar difficulties. In order to resolve this translation problem, Wierzbicka (1999) proposed a Natural Semantic Metalanguage (NSM) for describing emotional concepts in terms that occur in almost all languages. In this manner, the extracted concepts can be translated into all languages and their content and meaning compared.

3. The ethnographic studies cover a series of socialization and upbringing concepts that refer to the socialization of culture-specific emotions (e.g., Briggs, 1990).

With regard to these language-focused theories of indigenous emotion concepts, the following should be noted critically:

1. The bodily components of an emotion are conceived too simplistically, as a nonspecific arousal component, which meaning only becomes specific through integration into emotional concepts. This approach, which is reminiscent of the emotion theory of Schachter and Singer (1962; Schachter, 1964), has proven to be too simple (*see* Reisenzein, 1983). Similarly, the insufficient consideration of the expressive components of an emotion has been criticized and a re-embodiment of ethnology was recommended (Lyon, 1994, 1995).

2. Based on this simplified perspective of expressive and bodily components, it has been assumed inappropriately, that the indigenous emotion concept

describes and determines the real emotional episode completely. Accordingly, it is no longer possible to determine whether there is a difference between a real emotional episode and the corresponding concept of the emotion. This becomes clear with respect to the emotional concept of romantic love, which is mainly a concept in Occidental societies, and does not occur in everyday life in some societies such as the ethnic groups of the Bara in Madagascar or the Makassar in Sulawesi, Indonesia, in which marriages are arranged by the parents. Where this concept does not prevail, neither do the corresponding emotional experiences. However, this is not necessarily the case, because young members of these cultures in particular, do present bodily “symptoms,” which are very similar to those of being in love. However, in the culture in question, these symptoms are regarded as indications of a dysfunctional “love magic” or obsession, and accordingly treated as an illness (Röttger-Rössler, 2002, 2006). It is particularly interesting to consider this complex relationship between emotional concept and emotion as the subject of a comprehensive analysis, which is, however, not possible with an exclusively language-focused approach.

### ***Co-Constructivist Component-Oriented Paradigm: Emotion as a Multi-Component System***

The criticism of a mainly language-focused analysis of emotions has led to a culture-informed analysis of emotions that breaks down an emotion into its components and conducts a detailed culture-informed analysis of these components. Accordingly, emotions are defined as:

... multifaceted, open phenomena that are shaped to be effective in the sociocultural context in which they occur. The primary facets of emotion are emotional experience, which among others, is constituted by the appraisal of the situation and action readiness, expressive behavior, autonomic and central nervous system changes, and behavior.

(Mesquita & Leu, 2007, p. 735)

The focus is placed on a differentiated analysis of the components, to which the linguistically coded emotion concepts also belong, but to which they are not reduced. In their “symbolic approach to emotion,” Shweder et al. (2008) argue similarly, along the lines that each emotion can be broken down into

its components. These components must then be compared between cultures, in order to determine the extent to which they are universally comparable or culture-specific. Here, the equivalent measure is thus formed through the specific components of an emotion (see Shweder et al., 2008; Mesquita & Leu, 2007; Section on the components of an emotion), namely:

1. cause/antecedent events,
2. appraisal,
3. communication and symbolization/  
emotional behavior,
4. self-management/action readiness,
5. physiological reaction patterns,
6. affective experience,
7. normative social appraisals of the emotion  
itself,
8. social management/regulation.

Here it is assumed that each emotion in each culture can be described exhaustively on the basis of these components. Universality and culture-specificity are demonstrated on the basis of congruity or deviation in the configuration of these components. This culturally comparative component analysis of emotions has been extended in two directions. One direction refers to an indigenous analysis of emotions, with the emphasis on a reconstruction of selected emotions on the basis of its components. In this respect, one concentrates on those emotions that are regarded as central for a given culture, such as a re-analysis of the nine “basic emotions” from the Indian Sanskrit text *Rasādhyāya* from the third to fifth century AD (Shweder et al., 2008), which has little in common with the six basic emotions from the neuro-cultural theory of Ekman (1992; see also Horton, 2006, for an analysis of “*Lung Lang*” as a kind of Tibetan anger; Menon & Shweder, 1994; see Shweder, 2003 for an analysis of “*Lajja*” as a kind of shame in India).

The other approach aims to analyze the culture-specificity of the stated components of an emotion. Accordingly, cultural differences could be revealed in the individual emotional components, which correspond with the sociocultural conditions of the particular culture (Mesquita & Leu, 2007). For example, differences in the significance of the feeling component have been revealed. Western cultures assign a personal significance to emotions. They are perceived and interpreted as private and internal

experiences, which is why members view the feeling component as a central feature of an emotion (Mesquita, 2001). Asian cultures, in contrast, perceive and interpret emotions as situation-related indications of relations between persons and their environment. Emotions are therefore conceived more as a function of situations and tend not to be made dependent on the actual subjective feeling of the individual (Mesquita, 2001).

Both approaches focus on the cultural manifestations of the distinguishable components, with their normative embeddings, which lead to the fact that some emotions are more central for one culture than others, such as shame for India or for many Asian cultures, and anger for the U. S. culture. Thus, the conclusion can be drawn that it is possible to understand and recognize the emotions of other cultures, but this does not mean that one is also able to experience them personally. One can easily recognize that a person who kneels down in front of an altar is feeling humility toward God, but may be unable to feel it personally if one is an atheist.

Some critical points can be raised regarding this paradigm:

1. The assumption that every component of an emotion is essentially subject to cultural modeling introduces many degrees of freedom to the theory. As a consequence, a falsification of such descriptions seems barely impossible because the criteria to identify an emotion and delimit it from others become ambiguous.

2. The proposed component analysis does not, so far, contain any indication of how the individual components are mutually related, as is the case, for example, in the neuro-cultural emotion theory, where the feeling component is conceptualized as feedback from the expression component. When the assumption of a feedback loop between the expression and the feeling component is valid, then culturally modified expression signs must also lead to correspondingly changed internal feelings. For example, when culturally constructed expressions of romantic love are used—such as tenderness, love songs, love poems—this emotion will feel different from an experience of pure sexual excitement.

### ***Conclusion: What Do Existing Emotion Accounts Tell Us?***

The discussion of current emotion theories and their culture-related consequences can be summed up as follows: First, the diversity of conceptual and

empirical work has not yet led to consistent results on the extent to which single emotions can be viewed as universal or culture-specific. Up to the present, the most differentiated approach has been presented by recent co-constructive theories that conceptualize an emotion as a multi-component system and propose conducting an indigenous as well as cross-cultural analysis of all components of a single emotion: cause of an emotion, appraisal, action readiness, expression, bodily reaction, feeling, normative evaluation of the emotion, and its regulation.

Second, such procedure could avoid dividing an emotion into a quasi-culture-free, evolutionarily prewired core and a culturally superimposed shell, as proposed by the neuro-cultural approach of basic emotions. By contrast, multi-component approaches suggest to divide even basic emotions into their components, analyzing these components first *within* a specific culture-informative framework and then checking for similarities and differences between these multi-componential emotional constructs across different cultures.

Third, the proposed procedure, however, raises the issue of operationalization. How different must two emotional constructs be, in order to label them as (disjunctive) emotions? The “elegant” solution of the language-based approach, which considers each emotional concept as a separate emotion, has been rejected as incomplete. A multi-component approach also has to deal with the methodological problem of specifying valid criteria for each component that allow a classification of single emotions and a decision as to whether or not two emotional descriptions belonging to different cultures are equal or not.

Fourth, the above-mentioned emotion theories provide an implicit answer to this problem, by referring to the development of an emotion. An emotion can be identified as universal when it can already be observed at birth or when it adopts similar features over the course of ontogeny in almost every culture; an emotion can be identified as culture-specific when it is possible to refer to culture-specific conditions of socialization that evoke substantial and demonstrable modifications in several of its components that transform the entire configuration into a different emotional quality. This developmental reconstruction of an emotional quality within and across selected cultures can be used as an additional method for validating the classification of single emotions as similar or different.

Finally, most studies conducted within the scope of the emotion theories have analyzed the emotions

of adults who are already socialized members of their respective cultures. The use of cross-sectional research designs does not enable testing the effects of culture-specific conditions, because such designs only ascertain a co-variation between features of an emotion and those of cultural conditions. Testing for causal relations requires longitudinal designs, at least a developmental approach that analyzes the developmental pathway of an emotion and its corresponding cultural contexts from birth onward. Some potential and provisional conclusions of such an approach are described in the next section.

### The Advantages of a Developmental Approach to Emotions

Reconstructing the development of single emotions within a culture and comparing their developmental paths between cultures can be used as a valid criterion for determining which emotions can emerge in a given culture over the course of ontogeny. An analogous method was used in evolutionary biology to provide evidence of the descents of species. Within this approach, it is not sufficient to compare recent species and to ascertain similarities. It is necessary to discover and provide evidence of common lines of descent between the species in question. This developmental approach can be adapted to the analysis of human emotions (Griffiths, 1997). The core idea is that the emotional system of an adult is the outcome of a developmental *history*, in which one has to take account of more than the current functionality of the system elements. A number of these system elements are already specified through the phylogenetic and ontogenetic history. These specifications then become the raw material for subsequent phylogenetic and ontogenetic transformation processes. Thus, a developmental approach of emotions does not start without certain preconditions. We use the following methodological considerations as a starting point:

1. For the emergence of universal emotions, two developmental scenarios are theoretically possible: (a) Each component of an emotion is innate; in this case, they have to be observed from birth in all cultures or emerge in the ontogenesis at a similar time period in all infants; (b) Not all of the components of a single emotion are innate, but the cultural conditions of their development are comparable within different cultures, with the result that these comparable conditions evoke a comparable emotional quality.

2. The emergence of culture-specific emotions is only possible when two conditions are met: (a) At least some of the components of an emotion are relatively undifferentiated and changeable at birth, which enables these cultural conditions to modify and adapt their components to culture-specific affordances over the course of ontogeny; (b) Culture-specific conditions can be identified that are responsible for the emergence of different features within the components.

### Ontogenetic Starting Point: A Limited Repertoire of Innate Emotions

An important source of evidence in a developmental analysis is the empirical study of the emotional repertoire of neonates, in contrast to the emotions of older children and adults. Emotions of neonates are less pronounced and more elementary than those of adults. A review of the relevant literature provides evidence of five distinguishable emotions that can be characterized by a distinctive expressive pattern, triggered by a specific cause: distress, disgust, startle reaction, interest, and endogenous pleasure (see Holodynski & Friedlmeier, 2006; Sroufe, 1996). The main purpose of the first three emotions is to signal need-related deficit states or impairments of physical integrity, whereas the last two (interest, endogenous pleasure) serve to build up psychological representations of the external environment and the internal body world (e.g., a feeling of tension and relaxation cycles in adventure games such as rocking, swinging, or jumping; see Sroufe, 1996):

1. *Distress* is expressed particularly through crying preceded by motor restlessness, and this crying signals an urgent need (be it for food, warmth, body contact, or attention) that the caregiver not only has to satisfy but also feels obliged to satisfy (see Boukydis & Burgess, 1982; Oster, 2005).

2. *Disgust* is expressed by screwing up the nose and sticking out the tongue in order to spit out food, signaling unpalatable food (see Rosenstein & Oster, 2005; Soussignan & Schaal, 2005).

3. A *startle reaction* is expressed by wide open eyes and a freezing of the body. It signals a threat of overstimulation that may be triggered by an abrupt and strong irritation (such as losing one's balance or being splashed with water). Here, we refer to a physical reflex, as opposed to the emotion of surprise or fear (see Ekman & Friesen, 1985).

4. *Interest* is expressed by turning toward the source of stimulation, visual focusing, and an inhibition of motor activity. It signals the novelty of an external stimulation (Langsdorf, Izard, Rayias et al., 1983) and serves to detect contingencies in perceptions of the environment.

5. *Endogenous pleasure* is expressed by smiling, which signals the completion of a tension-relaxation cycle triggered initially by subcortical stimulation. Nonetheless, over the first few weeks of life, it is triggered increasingly when the baby recognizes contingencies between stimuli, e.g., repeatedly seeing the face of the caregiver (Sroufe, 1996).

The observation of neonate emotions has been conducted mainly with neonates and young infants from Western cultures. Therefore, a compelling proof of universality has yet to be done. However, the assumption seems reasonable that the emotional repertoire of neonates does not differ fundamentally between cultures. If these results could be corroborated, it would disprove Bridges' (1932) hypothesis that neonates display only two distinct emotional states, a positive and a negative one.

### ***Expression as a Culturally and Biologically Necessary Component***

During the first period of ontogenetic development, children of all cultures are dependent on the care and support of their caregiver, who must notice the current needs and motives of their offspring appropriately and ensure their satisfaction. These initial conditions require a perceivable expression of the children's needs and motives. The expression serves as a signal of the prevailing needs of the child (Holodynski & Friedlmeier, 2006; Sroufe, 1996). Therefore, the expression is a necessary component of an emotion. The expressions of the five emotions of neonates reveal a peculiarity (Sroufe, 1996). They are not yet fully adaptive as the expressions of children and adults that are fine-tuned toward the cause of an emotion. The expressive patterns of neonates do not yet focus on the cause of the emotion triggered and the eyes are often closed or do not focus on the cause (with the exception of interest). Additionally, the expressions are not triggered promptly after the cause appears; they need time to increase and decrease (with the exception of disgust and startle reaction).

Taken together, the causes of neonate emotions are not clearly marked by the expression with respect to

their temporal and spatial features. Because of these features, Sroufe (1996) has labeled these emotions as precursor emotions. This undirected and open feature of neonate expression compels caregivers to infer the specific need of their baby to some degree, by trial and error (Holodynski & Friedlmeier, 2006; Sroufe, 1996). If emotional expressions are primarily undirected, the caregiver can focus the child on specific causes in the course of social interaction. It is obvious that expressions are the primary medium of communication by which emotional messages are signaled and socialized.

Comparing neonate emotions to the so-called basic emotions, it becomes clear that distress is not the same as anger and sadness, endogenous pleasure is not the same as joy, being startled is not the same as being fearful and interest is not the same as surprise (see Oster, 2005). These basic emotions cannot be observed from birth onward. From a functionalistic perspective, this observation seems reasonable because anger, sadness, fear, joy, and surprise require an ascription of meaning, of which young infants are not capable and that manifests itself in expressive patterns that are triggered promptly and focus on the cause.

### ***From Interpersonal to Intrapersonal Regulation of Actions by Emotions***

Most emotion theories proposed in general psychology (e.g., Lazarus, 1991; Scherer, 2001) assume that an emotion regulates the action of the individual experiencing it. The target of the emotion is the individual himself or herself, who then performs an act that serves his or her concerns. Because action regulation is intrapsychological or intrapersonal, it can be described as having an *intrapersonal regulation function*. Generally speaking, this seems to be the case in adults.

Taking a developmental perspective opens up another possibility. For infants, it is obvious that the main function of emotions is to regulate the actions of their caregivers. A cry expressing distress does not lead a baby to engage in any coping actions. Instead, it leads the caregiver to perform the necessary act to satisfy the baby's need. What is so special about this regulation is that it is directed toward influencing the mind of another individual, so that he or she will act to satisfy one's concerns on one's behalf. The target of the emotion is thus another individual. Because action regulation is interpersonal or interpsychological, it can be described as having an *interpersonal regulation function*. This differentiation

into an intra- and an interpersonal function can be applied to any individual emotion quality. For example, anger can lead one to merely threaten another individual, so that he or she will get out of one's way (interpersonal regulation). However, it can also lead to an assault on the other person, so that he or she is *forced* out of the way (intrapersonal regulation). Sadness leads one to seek somebody who can provide consolation. However, it can also lead one to cry alone and console oneself.

From the perspective of developmental psychology, the originally dominant form is the interpersonal regulation function (*see also* Fogel, 1993; Sroufe, 1996; Tronick, 1989).

This developmental mechanism can be viewed as just one example of a more general psychological principle governing the development of higher psychological functions. According to Vygotsky (1931/1997), every higher psychological function starts as a social action—that is, as an interpersonal function—before it subsequently emerges as an individual action—that is, an intrapersonal function:

For us to call a process 'external' means to call it 'social.' Every higher mental function was external because it was social before it became an internal, strictly mental function; it was formerly a social relation of two people. The means of acting on oneself is initially a means of acting on others or a means of action of others on the individual. (Vygotsky, 1931/1997, p. 105)

This mechanism has major consequences for the development of expressive reactions. If emotions essentially possess an interpersonal regulation function at the beginning of ontogenesis, then expressive reactions become the central mediators in the action regulation of (young) children, and they achieve this through their *semiotic* function as signs for others. This shifts the focus of analysis to the quality of the expression signs and the ability of caregivers to heed the expression signs of infants.

### ***Emergence of New Emotions in the Course of Ontogenesis***

A large body of studies in developmental psychology has shown that most of human emotions emerge over the course of ontogenesis. This is especially the case for social emotions, such as various forms of embarrassment, shame, guilt, empathy, pride, or gratitude (Barrett, 2005; Ferguson, Stegge, Miller, & Olsen, 1999; Lagattuta & Thompson, 2007; Stipek, Recchia, & McClintic, 1992). These

social emotions are characterized by appraisals that require social competencies, including the ability to perform joint attention, inferring the intentions of others, distinguishing between self and others, and the acceptance of social norms. Children acquire these abilities demonstrably only in the course of ontogenesis (Denham, 1998; Quinn, 2005; Sroufe, 1996). Two conclusions can be drawn from this. On the one hand, if children from different cultures acquire these social *abilities*, it is likely that they will also acquire such social *emotions*. In this respect, these emotions may have universal features. On the other hand, the acquisition of these social abilities and emotions are embedded in a world of culture-specific ethno-theories and the educational practice of their social interaction partners (Quinn, 2005), which may also introduce culture-specific features in the components of these emotions.

A research challenge for the future is to formulate a timetable indicating the ages at which children of different cultures are confronted with educational practices that lead them to acquire the mentioned social competencies and at which age they display the various social emotions mentioned above. A comparison of the developmental pathways in different cultures can provide knowledge about the emergence of universal or culture-specific features within these types of social emotions.

### ***Windows of Culture-Specific Patterns of Meaning and Interaction in the Acquisition of Emotions***

The incompleteness of neonate emotional expression and cognitive abilities, as described above, opens up potential for shaping these emerging expressions and abilities:

1. Culture-specific educational practices determine the extent to which children are exposed to situational causes of single emotions, e.g., causes that trigger distress or joy.
2. Culture-specific patterns of how caregivers interpret children's expressions determine how caregivers react to them.

This can be illustrated by the development of smiling and pleasure in young infants in cultures relating to different ethno-theories about the significance of smiling and joy. Some cultures, such as the ethnic group of the Nso, who live in North Cameroon, do not interpret a smile of an infant as a social sign of making contact, as is the case in Western cultures (Keller & Otto, 2009). Therefore, Nso

mothers rarely establish situations in which visual contact is possible, namely face-to-face-interactions. Additionally, when their infants smile at them, they do not react contingently to this by smiling back. The opposite applies to German mothers. They frequently establish face-to-face interactions and reinforce their infants' behavior by smiling back. In response to these cultural differences, German infants show an increasing amount of smiling and joy, compared with the Nso infants, even in the first 3 months of life (Wörmann, Holodynski, Kärtner, & Keller, 2010).

Several cross-cultural studies demonstrate how different educational practices lead to different frequencies and features of expression, e.g., European-American children displayed stronger anger reactions than Nepalese children (Cole, Bruschi, & Tamang, 2002), also expressed more negative emotions in achievement situations than Japanese children (Lewis, Takai-Kawakami, Kawakami, & Sullivan, 2010) and Japanese children decreased disappointment reaction compared to German children (Friedlmeier & Trommsdorff, 1999), but they increased distress/empathy reactions compared to German children (Friedlmeier & Trommsdorff, 1999; Trommsdorff & Friedlmeier, 2010).

### ***Conclusions: What Do We Know of Early Ontogenesis of Affect?***

The reconstruction of developmental conditions and pathways of single emotions in different cultures can be used as an additional criterion of validity, in order to identify single emotions and their universal and culture-specific features. State-of-the-art developmental research yields the following general insights:

1. Neonates seem to exhibit a repertoire of five distinguishable emotions that can be labeled as types of distress, endogenous pleasure, interest, disgust, and startle reaction.

2. The primary function of these emotions is to regulate social interactions between child and caregiver. Through expression, the emotion signals an appeal to the caregiver to act on behalf of the child to satisfy the child's motives. Using an emotion to regulate one's own behavior in a motive-serving manner is a secondary result of learning.

3. The initial social medium that mediates social impact is the selection and type of emotionally relevant situations by caregivers, and secondly, within these situations, the interpretations and

reactions of caregivers to the child's emotional expressions.

4. From birth onward, both child and caregivers use expressions to communicate with each other and from birth onward, these expressions are modified by their mutual reactions and interpretations. By contrast, language-based emotion concepts impact on children's emotional reactions only when they start to use language and to acquire these concepts. This is possible only from the age of 2 years onward.

5. The described conditions of the ontogenetic starting point reveal that the number and cultural peculiarity of emotions increase only with increasing age. These emotions emerge initially in social interactions and serve to regulate these interactions. In a secondary developmental step, they can also be used for self-regulation.

6. A developmental analysis of social interactions between child and caregivers of different cultures enables us to assign culture-specific influences to particular age ranges and patterns of social practice. This approach can supplement cross-cultural analysis of adult emotions.

Our developmental analysis of emotions reveals that expression is a primary medium for the communication, regulation, and socialization of emotions and social relations. Therefore, in the next section, we take a closer look at emotional expression, considering how it works as a medium of cultural experience and tradition for the development of emotions.

### **Culture and Emotion-Related Sign Systems**

Expression and language are sign systems. Signs have the peculiarity that, on the one hand, they belong to the material cultural sphere, because expression and speech signs are perceivable for other people and can be used for communication and to influence others. On the other hand, they belong to the psychic sphere of a person, because one can use signs not only for communicating with others, but also with oneself, in order to regulate one's own actions and emotions (Holodynski & Friedlmeier, 2006; Vygotsky, 1934/1987). Therefore, signs are an interface between the mental processes of an individual and his or her cultural environment. Co-constructivist emotion theories have already taken into account the significance of signs in the form of language-based ethno-theories of emotions

and their enculturation. In the following, we argue that even nonverbal expressive reactions can be conceptualized as a culturally constructed sign system, which specializes in mediating and regulating emotional processes. In addition to language signs, expression signs function as a second interface between culture and individual, by which socially constructed experiences are exchanged.

### ***Artifacts as Vehicles of Human Culture***

Using socially created artifacts (in the form of tools and signs) to reshape their naturally given environment within a process of social coordination, and passing on this cultural heritage to the following generations is a species-specific characteristic of human beings. Later generations, in turn, adopt the artifacts and apply them to regulate their activities and to maintain social and cultural life (see Cole, 1996; Vygotsky, 1931/1997). Artifacts are not just human-made objects such as tools, machines, and buildings, but also human-made sign systems and their tangible forms, such as speech or written language (Wartofsky, 1973). We also add the nonverbal language of facial expression, gestures, posture, tone of voice, gaze behavior, and spatial behavior. Artifacts are the vehicles of human culture. Wartofsky (1973) describes them as “objectifications of human needs and intentions already invested with cognitive and affective content” (p. 204). They are simultaneously both something real and something ideal (nonmaterialistic). They are tangible and therefore possess an objectively perceivable form. Artifacts need such a form so that their use can be handed down from person to person.

At the same time, cultural artifacts are also something ideal—that is, they have a signifying form when they are used as signs. This is necessary so that they can serve as a means of psychological regulation. For example, a knife is perceived as a tool for cutting meat or bread and its social existence calls on people to use it in this manner. A second possibility is to use it as a weapon to threaten another person. With this usage, the knife is not used as a tool to affect things (food), but as a sign to modify the intentions of the receiver, who is forced, for example, to hand over his money. The factual choice, however, depends on the motives and intentions of the sender—and its factual impact on the receiver, on his correct interpretation of the indicated appeal and his willingness to comply.

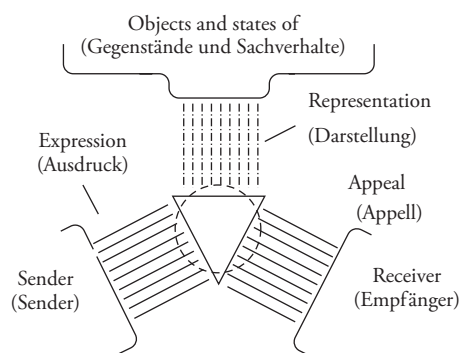

Looking at artifacts in this manner transcends the dualistic controversy that views culture as being

exclusively either something internal, consisting of learned signs and shared systems of meaning, or as something purely external, consisting of handed-down action procedures and material products (see Cole, 1996). Over the course of human history, the creation, generational transfer, and continuous development of the cultural sphere have led to the emergence of a cultural form of acquiring and passing on experience.

Artifacts can be divided into tools and signs, according to their predominant use. As a rule, tools serve to influence and reshape both objects and the nonsocial environment; signs serve to influence the intentions of other people. For the purpose of analyzing emotions, the sphere of signs is relevant. Signs can be used not only for transmitting messages about facts to others; beyond this symbol (or representational) function, signs also make an impact on the interaction partner, as both a symptom and an appeal, as Bühler (1934/1984) noted in his Organon Model of sign usage (see Fig. 46.1; see also Scherer, 1992).

If a sender uses signs to convey a message to a receiver, the message also serves these two purposes:

1. As a *symptom* (expression in Fig. 46.1), the signs used signal the intentions, wishes, and expectations of the sender. At this point, we do not take into account the distinction between genuine (sincere) and deceptive (fraudulent) intentions. When children grow older, they become capable of deceiving their interaction partners about their real intentions (Feldman, Jenkins, & Popoola, 1979; Feldman, Tomasian, & Coats, 1999).
2. As an *appeal*, the signs used simultaneously form an impression on the receiver, indicating that he or she should act in a certain way. At minimum, a sender requires a receiver to pay attention to the

**Figure 46.1** Karl Bühler's Organon Model

signaled message and to demonstrate an attempt to understand it. Usually, the receiver should also do something in conformity with the signaled message, e.g., to help the sender, give him information, stop doing something, etc. Whether the receiver will respond appropriately to the appeal depends on the intentions, wishes, and expectations of the receiver.

Thus, signs serve to regulate social interactions. As mentioned above, two sign systems in particular are relevant for a culture-focused analysis of emotion, language, and expression. In the following, we deal only with the system of expressions, because, in most emotion theories, expressions are not appropriately analyzed through a semiotic perspective and because expressions are the primary sign system that is already in use before children acquire a language.

### ***System of Expression Signs and Emotion Episodes***

In cross-cultural research, expressions have been analyzed especially within the neuro-cultural theory of basic emotions (Ekman, 1972, 1992, 1994b). Within this research tradition, expression has been conceptualized in a reduced form for several reasons:

1. Expression is reduced to an analysis of facial expression.
2. Expression is reduced to its symptom function, meaning that it primarily signals the subjective feeling state of the sender to the receiver.
3. Modifications of expression are mainly conceptualized as intensifying, weakening, neutralizing, or masking an emotional expression (e.g., Matsumoto, Yoo, Fontaine et al., 2008).

These reductions have contributed to the fact that the impact of expression on the construction and enculturation of universal and culture-specific emotions has been generally underestimated. The analysis of expression, however, can be supplemented by the following features and capabilities (see Holodynski & Friedlmeier, 2006).

*Expression signs are coded in all channels of expression.* They contain not only facial expression, but also body posture, gestures, tone of voice, touch, gaze behavior, and spatial behavior (Collier, 1985). Furthermore, symbolic actions can also be used as expression signs, for example the exchange of (wedding) rings as a sign of attachment or love, waving national flags as a sign of national belonging.

*Variety of cultural expression signs termed “emblems.”* Expression signs are also culturally constructed, as illustrated by countless examples of culture-specific emblems, which are used as emotional expressions, such as the victory-sign, giving someone the “finger” (or bird), kneeling down, etc. (see Ekman & Friesen, 1969; Morris, 1994; Posner & Serenari, 2003).

*Expression signs have a symptom function.* They refer to how the sender appraises the situation and also what the sender intends to do next (Holodynski & Friedlmeier, 2006; Scherer, 1992). Thus, expression signs provide the receiver with information about the appraisal and action readiness of the sender. For example, in many cultures, bared teeth signal that the sender feels physically threatened by the receiver and is ready to attack. Wierzbicka (1995, 1999) has analyzed the assigned appraisal and action readiness of many bodily expressions like kissing, hugging, kneeling down, and also of the prototypical facial expressions (see Table 46.1).

*Expression signs have an appeal function.* They appeal to the receiver to follow the signaled message and react in accordance with the appeal. It is because of the appeal function that expression signs are culturally constructed and used by individuals. Expression signs are designed to have an effect on the receiver's intentions to follow the appeal and to signal approval in reciprocating to the sender through complementary expression signs. As a result, a prototypical course of interaction evolves (Goffman, 1967; Posner, 2001). The triggered expression signs of the receiver react on the sender, and the sender's emotion either disappears, if the receiver has followed the appeal or allows the sender to increase or modify his or her signaled appeal if the receiver disregards or even actively rejects the sender's appeal. For example, bared teeth convey the appeal for the opponent to withdraw, or face the possibility of attack. If the opponent withdraws, the sender's rage and bared teeth disappear; if the opponent resists the sender may increase his threat or attack physically.

*Differences between expression signs and language signs.* Besides the above-mentioned common grounds of expression and language signs, some substantial differences have to be taken into account that are important for an analysis of expressions:

1. In comparison to speech signs, expression signs have a limited scope of representation. They refer only to personally significant relations between

**Table 46.1 Assigned Meaning to Facial Expression Signs**

Expression sign	Appraisal of the cause <sup>a</sup>	Action readiness of the sender <sup>a</sup>	Appeal to the receiver <sup>b</sup>
Smile	I feel something good now.	I want to continue the current action or interaction. I want to join you.	Let's continue the current interaction.
Down-turned mouth	I feel something bad now and I know I can't do anything.	I don't want to do anything now.	Look after me. Make everything good again.
Wide open eyes with immobile eyebrows	What I perceive is threatening, but I can't do anything about it.	I want to know more about this, but I can't do anything now.	Don't hurt me, I submit. Help me out of danger (directed toward trusted person)
Raised eyebrows	What I can perceive right now is new or unexpected.	I want to know more about this.	Give me more information.
Eyebrows drawn together	I didn't think this would happen.	I want to do something now. I think I can't do it.	Stop blocking my goals.
Bared teeth	I feel something bad now.	I want to do something bad to someone now.	Hold off! Give way or I'll attack.

<sup>a</sup>Adapted from Wierzbicka (1999, pp. 189–215). <sup>b</sup>Adapted from Fridlund (1994, p. 129).

person and environment, meaning aspects of the situation that are relevant to personal motives.

2. Expression signs have a particular perspective of reference: Basically, it is first-person present-tense (Wierzbicka, 1999). This means that the person who expresses is the one who feels, and the one to whom the expression is addressed is the one who is intended to act. Expression signs refer only to the relationship between sender and receiver (or cause, if the receiver is not the cause of the emotion). Only at an advanced level it is possible to refer to a past or future emotion or to an emotion of another person, and then only through using additional indications or information. Therefore, a complete analysis of expression must include the object or person to whom the expression is addressed (Holodynski & Friedlmeier, 2006). When using pictures of (facial) expressions that are only posed for the camera, as in studies on the recognition of facial expressions (Ekman, 1972; Ekman & Friesen, 1986), substantial information about the context is missing.

3. In contrast to language, it remains questionable whether combinations of expression signs follow syntactical rules. There are some indications of

syntactical rules (Holodynski & Friedlmeier, 2006): (a) The level of exchange seems to matter and may refer to status differences between people; (b) The distance of exchange seems to matter and may refer to the level of intimacy between the interaction partners.

*A (culture-specific) lexicon of expression signs.* Expression signs used in a given culture can be gathered to a culture-specific lexicon similar to a lexicon of words. The meaning of an expression sign can be defined by the particular appraisal and action readiness each sign refers to and by the particular appeal each sign signals to the receiver. For example, a pout is an expression sign. Its meaning can be defined by compiling three facets: (1) the appraisal that the person who expressed it have not got what he wanted to get, (2) the action readiness that he is going to demonstratively show his frustration to the receiver, and (3) the appeal to whom the pout is issued that the receiver ought to console the sender and fulfill his wish. All three facets together reveal the meaning of a pout (Kottonau, 2010; Table 46.1, for additional examples; see, Posner & Serenari, 2003; Wierzbicka, 1995, 1999).

*Ritualization of emotional interactions.* Emotionally loaded patterns of interaction that frequently occur in a given culture usually adopt a ritualized mode. This ritualization provides a predictable frame of interaction for the involved members, such as modes of mutual greetings, excuses and forgiveness, showing dominance and submission, insult and revenge, grief and consolation, etc. (see Goffman, 1967; Posner, 2001). These ritualized modes have been analyzed partially as cultural display rules (Ekman & Friesen, 1986) and cultural feeling rules (Hochschild, 1979), but these concepts focus predominantly on the emotion and expression of the initiating sender and not on the mutual exchange of expressions by both sender and receiver.

*The use of expression signs as display.* Expression signs can be used by a sender only as a display to induce the appellative effect on the receiver, but without a concurrent feeling. In analyzing expressions in the light of their appeal function, display rules can be conceptualized also as prescriptions regarding which appeal a person is allowed or obliged to send to which receiver in which situation. Parallels to Goffman's (1967) analysis of human's face-to-face behavior can be drawn.

*Universality and culture-specificity of expression signs.* The collection of expression signs and their meaning in different cultures is a precondition for answering the question to what extent single expression signs have a universal or culture-specific meaning. As far as we know from cross-cultural studies, some signs seem to be assigned a universally similar meaning across cultures like bared teeth as a sign of rage, kneeling down as a sign of humility, laughter as a sign of amusement. One reason for a universally similar coding may be the iconic mode of coding that is typical for expression signs and that differs from the symbolic mode of coding with respect to language signs. An iconic coding means that a sign is similar to the relationship or circumstances to which it refers (Holodynski & Friedlmeier, 2006). However, the cross-culturally similar interpretations of these iconic expression signs do not mean that a person also uses and shows these signs in his or her own personal expressions. People from Western cultures usually interpret kneeling as a sign of humility, but they probably do not do it themselves because they probably do not feel humility—except if they are highly religious people who feel humility toward God.

*The problem of classification.* A comparison of expression signs across cultures contains a methodological problem in terms of what level of analysis

should be used for classifying signs and rituals as either equivalent or different. The following two episodes can generally be classified as modes of insult and revenge: Imagine the community of “men of honor” in the Prussian city of Berlin in the nineteenth century. A sign of showing contempt to another man of honor was the insulting gesture of slapping the opponent's ears with a glove. This gesture obliged the insulted person to “demand satisfaction,” to restore his honor by challenging the insulting person to a duel (see Frevert, 1998). Compare this ritual of suffering and restoration to an insult by a German adolescent giving a Turkish peer “a finger” in Berlin in the twenty-first century. This gesture might provoke the insulted Turkish peer into a physical attack leading to a fight (Uslucan & Fuhrer, 2003). Although both episodes have a similar relational structure, both insults and reactions are embedded in different cultural frameworks of meaning and action, with different signs and modes of concrete interactions and different long-term consequences. A sound analysis of these modes of emotional interactions should not simply classify them as equal, but first conduct a careful and culture-informed analysis of the existing expressions and rituals in each culture and then compare them cross-culturally, according to the analyzed components of the involved emotions.

Taken together, it seems worthwhile to analyze human expressions within the perspective of a culturally evolved sign system handed down from one generation to the next. This perspective opens up not only an analysis of the existing emotional concept of a given culture, but also a second pathway to the cultural phenomena of emotions.

## **Components of an Emotion and Its Interrelations**

Emotion expression is only one of several components that constitute an emotion. For a complete understanding of the functions and features of individual emotions, it is necessary to take into account the other components. For this purpose, we draw on the cultural psychology approaches of Shweder et al. (2008) and Mesquita and Leu (2007). We focus particularly on the component of action readiness and its relation to the component of subjective feeling and discuss the feedback hypothesis that recently received increasing broad acceptance. Feedback models (Damasio, 1994; Ekman, 1984; Holodynski & Friedlmeier, 2006; Izard, 1977, 2009; Levenson et al., 2007) assume that a subjective feeling consists

of an internal feedback loop of expressive and body reactions that accompany an emotion. However, neither of the above-mentioned multi-component models has addressed these interrelations.

### ***Causes of an Emotion***

This component refers to the culture-specific causes of an emotion. The appraisal of an emotional situation is rooted in what the relevant cause is judged to be (Frijda, 1986). Cultures may differ or be quite similar, in terms of the prototypic causes they provide for eliciting the different types of emotions. These culture-specific contexts and their interpretations by emotional concepts of the given culture define the range of motives, actions, and experiences in which emotions are embedded (see Frijda & Mesquita, 1992; Mesquita & Leu, 2008; Scherer et al., 1986; Scherer & Wallbott, 1994).

### ***Emotion-Specific Appraisal of the Particular Cause***

This component deals with how a person appraises the relationship between a given cause and the actual motives and concerns. Whether appraisal patterns for a given emotion are universal or culture-specific depends on the level of abstraction that applies to the categorization of respondent answers (Mesquita, Frijda, & Scherer, 1997). In order to avoid hasty generalizations, the suggestion is made that patterns should first be extracted from an indigenous analysis of reports and only then, the cultural comparisons will follow (see Shweder et al., 2008).

Furthermore, the emotional appraisal process must be distinguished from a deliberately enacted evaluation of the motive-relevant relationship between an individual and the environment. In the latter, the prior emotional appraisal process is reconstructed *post hoc* with the aid of conceptual knowledge (Fogel, 2009; Lazarus, 1991, p. 144). This reflective evaluation is stored in other neural circuits than that of emotional appraisal (Fogel, 2009, pp. 95–101). Only human beings are capable of performing such reflective evaluation. This ability starts to emerge only during the 3- to 6-year-old age range and requires the acquisition of language-based concepts (Campos, Frankl, & Camras, 2004; Holodyski & Friedlmeier, 2006; Holodyski, Seeger, Hartmann & Wörmann, in press).

### ***Action Readiness of an Emotion***

This component describes how an emotion is used to change the person–environment relationship

in a motive-serving manner. The component contains expressive reactions and actions that establish or enhance, weaken, or break some form of contact with aspects of the environment, or ones that either aim to do this or assist in doing so (see Frijda, 1986, p. 13). Such changes that are relevant to motives can be achieved by two different modes of emotional behavior (see Frijda, 1986, pp. 11–13; Holodyski & Friedlmeier, 2006):

First, expressive reactions directly change the relationship between the individual and the environment, by using instrumental and problem-focused behavior. Frijda (1986, p. 11) gives “disgust” as a prototypical example. This expressive reaction (retching, opening the mouth, pushing out the tongue, wrinkling the nose) reduces contact with distasteful substances and helps to expel them. Other prototypical instrumental behaviors are fleeing or freezing in the case of fear, or attacking in the case of rage. Shweder et al. (2008) subsume such behavior under the label of “self-management.” Many studies on anger and fear, for example, focus on this instrumental mode of action readiness (Stemmler, 2004).

Second, expressive reactions change the person–environment relationship indirectly, by using them as signs in order to influencing the behavior of an interaction partner. The latter should modify this relationship in a way that serves the sender’s motives. For example, when an infant displays an expression of disgust during feeding, this signals to the feeder, that the baby does not want any more food and that feeding can stop. This turns the expression into a sign. We have considered this form in more detail in the previous section. Using expressions as signs works only when both sender and receiver refer to a common pool of expression signs with shared meanings, and when the receiver feels obliged to obey the appeal. Shweder et al. (2008) subsume this aspect under the label of “social management” and “communication and symbolization.”

In most cases, the second alternative of an appellative mode is used. As already mentioned above, each emotion originally has an interpersonal regulatory function because young children cannot act by themselves; they are dependent on the support of others to whom they appeal through expression signs. Such signs, however, can also be used for intrapersonal regulation, in order to regulate one’s own actions in a motive-serving manner (See below section about interpersonal and intrapersonal regulation).

### ***Physiological Reaction Patterns***

Some emotions seem to have a very strong physiological reaction pattern, such as fear in confronting a life-threatening cause or rage in the face of an assault (Levenson, 2003; Stemmler, 2004). In some theories, this component is treated as the only valid indicator that a “hot” emotion and not only a “cold” cognitive evaluation have been triggered (*see* Lazarus, 1991). A second issue of long-lasting debate has dealt with the nature of emotion-specific physiological reactions and whether each emotion can be characterized by a specific response pattern (Ekman, Levenson, & Friesen, 1983; Jänig & Häbler, 2000; Stemmler, 1989).

A way of disentangling the diverse and contradictory arguments and results is to adopt a functional view including the physiologies of emotions (Jänig & Häbler, 2000; Stemmler, 2004). These physiologies combine at least three different components:

1. The non-emotional content of the ongoing activity during which the emotion appears; the specific bodily conditions immediately before a person experiences an emotion, e.g., if he or she is running, “only” sitting and thinking, or even weakened by a cold.

2. The specific physiological adaptations when the emotion is triggered, but before a coping action occurs. Different situational constraints require a different preparedness of the body: A sudden life-threatening cause needs a different bodily preparedness compared to a threat that is not life-threatening and does not appear suddenly.

3. The organismic, behavioral, and mental demands that are necessitated by the executed coping action in the pursuit of an emotion goal, e.g., to flee or to fight, or to signal deference or sympathy.

Because of these dynamic and multi-layered physiological adaptations, it is probably invalid to assign only one characteristic pattern of physiological response to each emotion. On the other hand, if the eliciting cause and the corresponding appraisal and action readiness is specified, e.g., preparation for an escape, in contrast to freezing in reaction to a life-threatening cause, both physiological adaptations are clearly distinguishable, regardless of whether the person perceives both emotional states as similar, namely as fear (Stemmler, 2004). The consequence for studying the physiology of emotions is to differentiate emotion families into subtypes, according to their situational causes, appraisals and available

coping possibilities, e.g., fear of being killed, of being beaten, of being teased, and to compare only similar subtypes cross-culturally.

Only a few cross-cultural studies have been conducted that directly measure physiological reactions in response to well-defined elicitors for specific triggered emotions. These studies used sad, disgusting, and amusing film clips (Roberts & Levenson, 2006; Tsai, Levenson, & Carstensen, 2000) on different ethnic groups (African, Chinese, European, and Mexican-Americans) within the United States and they used the direct facial action task (Levenson, Ekman, Heider, & Friesen, 1992) on European-Americans and Minangkabau of West Sumatra. The studies revealed similar cross-cultural physiological reactions for the elicitors used. These studies, however, cover only a few emotions, especially subtypes of anger, fear, disgust, and joy, and cover only a few cultures. Therefore, the issue of cross-cultural similarity and differences of physiological reactions remains unsolved and controversial (Larsen, Berntson, Poehlmann et al., 1993; Stemmler, 1989).

Furthermore, the functions of several physiological reactions that accompany emotions have not yet been fully explained, e.g., shedding tears or blushing, which can be observed across cultures. Displayed in a social context, they have an appeal function for the interaction partners, but it remains unclear whether they also have an instrumental self-regulating function (*see* Casimir & Schnegg, 2002; Vingerhoets, Cornelius, Van Heck, & Becht, 2000). Damasio (1994) argues that physiological reactions can serve as somatic markers of emotionally important situations. Because physiological reactions can also be perceived internally by interoceptive sensations, they can accentuate both the situational context and cause of the elicited emotion and support its long-lasting storage and subsequent retrieval from memory.

### ***Subjective Feeling of an Emotion***

This component contains the perception of one’s own emotional states from an actor perspective. This component is only indirectly accessible by self-reports. In narrative interviews, people use different descriptions of their subjective feelings (*see* Fogel, 2009; Frijda, 1986; Kövecses, 2008):

1. Descriptors of interoceptive sensations of accompanying physiological reactions (“I’m sweating,” “my heart is beating,” “I feel cold”).

2. Descriptors of proprioceptive sensations of accompanying expressions (“I laughed”), action impulses (“I could have hit you”), or actions (“I ran away”).

3. Descriptors of metaphors that circumscribe the felt sensations (butterflies in the stomach, having a lump in one’s throat).

4. Labels of emotion (“I am happy”).

The use of emotion labels is already an interpretation of subjective feeling, because a felt intero- or proprioceptive sensation is assigned to an emotional concept, which always refers to specific culturally colored interpretations of the emotional episode that can lead to different coping actions. It makes a difference whether a quick-tempered interoceptive sensation is labeled as an unjustified tantrum or a justified indignation.

The answers to the question whether subjective feelings can be conceptualized as a feedback of the person’s elicited action readiness remain controversial. One approach uses interoceptive sensations of ongoing physiological reactions as first assumed by James (1899; *see also* Reisenzein, 1983; Schachter, 1964), and another approach uses proprioceptive sensations of facial expressions as assumed by Izard (1977) and the neuro-cultural emotion theory (Ekman, 1984; Levenson et al., 2008). Recent models (Damasio, 1994; Fogel, 2009; Holodyski & Friedlmeier, 2006; Laird, 2007) conceptualize the feeling component as somatic markers that contain both components of sensations. The supporters of a feedback conception regard the adaptive function of feelings as a feedback of body reactions. The action readiness of an emotion is not only carried out, but it is also internally represented by a feedback loop that enables a continuous fine-tuning of the action readiness, in accordance with the affordances of the unfolding emotion episode. Furthermore, a large body of studies corroborates the feedback hypothesis (*see* Laird, 2007). The cross-cultural studies of Levenson et al. (1992) yielded instructive results. The voluntary manipulation of facial expression by means of the direct facial action task can trigger feelings linked with the particular emotions, in fact, in both analyzed cultures (the Minangkabau of West Sumatra and North Americans). However, the voluntary manipulation of one’s own facial expressions could be performed more effectively by North Americans than by the Minangkabau, but additional information that could explain these differences is missing. A feedback model of feelings yields

three further conclusions that could also be instructive for cross-cultural analysis, but have not yet been studied in detail.

#### **USE OF EXPRESSIVE SENSATIONS FOR INTERPERSONAL AND INTRAPERSONAL REGULATION**

In a feedback concept, the emotional expression signs designed to impress others, such as pouting or crying, are also proprioceptively represented as expressive sensations, in order to fine-tune their expressive appeals to the receiver’s reactions (Fogel, 2009; Holodyski & Friedlmeier, 2006). These sensations can be used just as effectively for *intrapersonal* regulation. The sensation of crying can lead to a search for somebody who can provide consolation. However, it can also lead one to cry alone and console oneself. Accordingly, a person can also interpret the accompanying expressive sensations as internal signals, in order to perform the necessary coping actions for satisfying his motives by himself and not through an interaction partner. Hence, from the actor perspective, the *intrapersonal* regulation of expression falls back on the same subjective feeling signs as *interpersonal* regulation, only the target of the appeal differs. The feedback process gives rise to *expressive* sensations in both cases. This makes it easy to switch between inter- and intrapersonal regulation, without the need for any additional rules governing the transformation between external expression and internal feeling (Holodyski & Friedlmeier, 2006).

The ability to use expressive sensations also for self-regulation must be learned by children. Studies with German children reveal that they become able to shift from inter- to intrapersonal regulation between the ages of 3 to 6 years (Holodyski & Friedlmeier, 2006). Because cultures differ in their degrees of intrapersonal regulation, the ability to become aware of expressive sensations might differ accordingly and may lead to cultural differences of feeling (*see* Friedlmeier, 2010).

#### **EXPRESSIVE SENSATIONS AS SOURCE FOR ENCODING AND DECODING EXPRESSION**

A feedback model can also explain how (facial) mimicry functions. (Facial) mimicry is the (more or less) involuntary imitation of the expressive reactions of another person (Bavelas, Black, Lemery, & Mullett, 1987). Through body feedback, the imitated expression triggers expressive sensations corresponding to the state of feeling of the individual

being imitated. This can trigger a transmission of feeling known as emotional contagion, particularly in infants and young children (Field, Woodson, Greenberg, & Cohen, 1982; Hatfield, Cacioppo, & Rapson, 1994; Saarni, Campos, Camras et al., 2006).

The analysis of the expressive repertoire of a given culture can reveal many culture-specific new creations that are also part of social rituals, starting with greetings and ending with complex religious rituals (Klassen, 2008). As children and adolescents are introduced to these rituals, they watch and carry out the corresponding expression signs and actions by imitation, which again elicits corresponding subjective feelings via the feedback loop. The active imitation of these rituals can be regarded as the mechanism by which a specific mode of feeling can be handed down to the next generation. For example, social rituals that contain expressions signs of humility, such as kneeling down, lowering one's gaze and self-evaluations of being guilty and humble can very effectively also trigger the corresponding subjective feelings of feeling small and guilty in comparison to a mighty God or some powerful person (see Roberts, 2008). These forms of emotional imitation and contagion are also used especially in staged public rituals of collectives, such as religious groups or national gatherings (e.g., a politician commemorating of a famous military victory). These staged rituals are aimed at evoking a particular kind of belonging to the collective, by inducing a jointly felt arousal.

As early as 1912, Durkheim (1912/1995) drew attention to these staged rituals of jointly induced emotional arousal and referred to this as "effervescence" (see Cariton-Ford, 2005; Fox, 2006; Tiryakian, 1995). These collective rituals also contain ritualized forms of expression and action, which those involved have to carry out. The feedback loop also enables the internal sensations of these ritualized expressions and actions, and elicits and enhances the corresponding feelings of strong emotion and belonging to the collective. It is the particular mode of production that makes the difference in eliciting a corresponding feeling. Note, for example, the very different orchestration of a Memorial Day by the Nazi regime, in comparison to a remembrance day for those killed on 9/11. Sociological and historical research have already investigated such complex and clearly culture-specific emotional qualities (e.g., Fox, 2006; Olaveson, 2004), while emotion research has focused mainly on the so-called basic emotions of

anger, fear, sadness, disgust, joy, and social emotions of pride, shame, or guilt.

#### LEVELS OF SUBJECTIVE FEELINGS

Izard and Malatesta (1987) have claimed that the subjective feeling of an emotion would not change during the course of life. This claim seems to be correct, insofar as a proprioceptive sensation of a smile at the age of 2 years may be felt similarly to the proprioceptive sensation of a smile at another age. The point at issue, however, is how the proprioceptive and interoceptive sensations, which are triggered by an emotionally significant cause, are embedded in the broader sphere of subjective feelings over the course of ontogenesis.

There are several approaches that assume different levels of feeling, characterized by different levels of integration and generalization. In accordance with Craig (2008), Fogel (2009) proposed four levels and called the two highest levels *embodied self-awareness* and *conceptual self-awareness*. Valsiner (2005) stated over and above the mentioned levels two additional ones that are characterized by a higher level of generalization. At these two levels, a feeling is not related to a single emotional episode, but to a whole sphere of life, such as a feeling of justice or of depression, a feeling of *amae* in the Japanese culture (Morsbach & Tyler, 1986) or of *naklik* in the Inuit culture (Briggs, 1970) that are both generalized, but culture-specific forms of care and love.

In the following discussion we focus on the common levels of these approaches:

*Sensations without an object.* The basic form of subjective experience consists of a proprio- or interoceptive sensation as such, like a sensation of a frown, palpitation, or a dry throat. This corresponds with the second level of self-awareness in Fogel's (2009) model. Expressive and bodily sensations per se, however, are not *sufficient* to produce a feeling experience, if an orientation toward an external event or thought as the perceived cause of the sensation, is lacking.

*Embodied self-awareness.* It is assumed that, for a fully adaptive emotional reaction, the feedback sensations must be psychologically connected to the perceived cause of the emotion, in order to mark the cause and calibrate the emotional reaction to the particular circumstances and reactions of the interaction partners. As a rule, the cause of an emotion is represented simultaneously in one's sensory perception of the (real or imagined) event. The object from which the threat proceeds is manifest, for example, as the

visual image of a growling dog. This is why Damasio (1994, pp. 173–174) refers to sensations as somatic markers of an emotional cause. Fogel (2009) calls this level embodied self-awareness (*see also* Level 1 of Valsiner's model, 2005) A sensation evolves into a feeling, when it can be assigned to a suitable object to which it is directed and from which it is perceived as being elicited. We hear about the death of a loved one, and simultaneously feel how tears fill our eyes, which impel us to seek social support. These states of feeling are established already in late infancy and toddlerhood, before children learn to describe their emotional feelings with words.

*Conceptual self-awareness.* At the third level, a label and its related emotional concept are assigned to the relationship between sensation and eliciting object. Fogel (2009) refers to this level as conceptual self-awareness. The form of fine-tuning of an ongoing emotional episode that a person selects and performs depends on how this relation is interpreted conceptually. At this level, cultural display rules (Ekman, 1972) and feeling rules (Hochschild, 1979) come into play.

A good example is provided by the conceptual self-awareness of specific body sensations that are triggered especially in adolescents, by seeing a very attractive potential girlfriend or boyfriend. In Western cultures, this is normally conceptualized as falling in love whereas it is conceptualized as a kind of sick spell of love or bewilderment in a culture such as the Makassar, an ethnic group on the Indonesian Island Sulawesi, where marriages are arranged exclusively by parents in line with status and other nonromantic considerations. As the observations of Röttger-Rössler (2002, 2006) revealed, adolescents of the Makassar also reported bodily sensations and displayed expressions that are similar to those reported by Western adolescents who fall in love. The different ethno-theories, however, lead to very different reactions and conceptual self-awareness. In Western cultures, the focus is on the positive aspects of these sensations and people are encouraged to cultivate this emotion, by specific expression signs of shaping and dramatizing the romantic relationship such as kissing, touching, holding hands, exchanging rings, etc. In the culture of the Makassar, however, the focus is on the negative aspects of these sensations and their consequences, and affected individuals are urged to suppress and avoid situations in which they are at risk of becoming overwhelmed by such feelings. As

a consequence, the adolescents of these two cultures may develop two quite different culture-specific emotions associated with love.

*Cultural differences in experiencing levels of feelings.* How these feedback loops are conceptualized and educated is a product of cultural ethno-theories and child-rearing practices. Ethno-theories differ in terms of whether an emotion tends to be viewed as the outcome of a private experience or as a public experience shared with others. Western cultures assign a personal significance to emotions. They are perceived and interpreted as private and internal experiences, which is the reason that members view the feeling component as a central feature of an emotion (*see* Mesquita, 2001). In Asian countries and some other cultures, e.g., Samoa (Gerber, 1989), emotions are rather seen as public experiences, i.e., emotions are perceived and interpreted as cues about relationships between persons and their environment. Emotions are therefore conceived more as a function of situations and tend not to be made dependent on the actual subjective feeling of the individual (*see* Mesquita, 2001).

Taken together, a feedback conception has far-reaching and instructive consequences for a culture-specific coloring of subjective feelings. Research provides evidence that the feedback loop seems to be a universal feature of an emotion. As far as expressions and bodily reactions have culture-specific features, also the subjective feelings are colored in a culture-specific form via the feedback loop. Furthermore, the level of self-awareness on which the feedback is felt, has also a culture-specific coloring, because the way in which a person interprets his or her sensations as a quality of feeling (conceptual self-awareness) depends on the acquired emotional concepts.

### ***Normative Social Appraisals of Emotions and Emotion Regulation***

The components of cause, appraisal, physiological reaction, action readiness, and feeling seem to describe an emotion sufficiently. Such a view, however, can be applied only to the emotions of young children who take only the relationship between their prevailing motives and actual situational conditions into account. For older children and adults, a further condition becomes relevant, namely the social norms that are connected to these emotions and situations.

Human motive satisfaction is not an individual act, but is always embedded in a network of social

relations. For many of the actions required to satisfy their motives, individuals are dependent on coordination with other people and *their* motives. Even just obtaining sufficient food to satisfy one's hunger requires a coordination of actions by numerous human beings. The way in which such social relations are coordinated cannot be varied at random, but is subject to material constraints, as well as cultural norms and rules. They map out how this social coordination of individual motives should proceed and how much scope is available to the individual. Hence, a fully developed activity regulation of an adult requires not only the prevalence of differentiated emotions, but also the ability to coordinate them with cultural norms and demands (*see* Holodynski & Friedlmeier, 2006; Quinn, 2005). As a result, emotions become the target of cultural norms and demands for regulation. Emotional qualities like pride, joy, anger, shame, or sadness, which seem to be universal, may well be evaluated completely differently in a normative sense.

Depending on the specific culture, these emotions may be welcome and appropriate; they may be tolerable; or they may even be unwelcome and inappropriate. For example, feeling of shame is considered problematic in Western cultures but appropriate in Asian cultures, whereas the exact opposite applies to anger (Miyake & Yamazaki, 1995; Stearns & Stearns, 1986).

From the perspective of culture, these normative demands appear as display rules (Ekman, 1972) and feeling rules (Hochschild, 1979). The latter prescribe who should feel which emotion in relation to which cause. Hochschild (1979) reports the example of the working life of American airplane stewardesses, who are trained not only always to express friendliness toward their passengers, but also to feel it. A milder form of such feeling rules relates to the tenets for emotional expression, stipulating which expression should be shown to whom in which situations, termed display rules. The feelings that the person actually experiences in such situations, are irrelevant. A good example is Ekman and Friesen's (1975) study of Japanese and American undergraduate males, each in their own country, who viewed a disgust-inducing film in both a solitary and a social-interview situation. In the social condition, the Japanese college students masked their expression of disgust to a greater extent with a smile than the American college students, whereas neither cultural group masked its expression in the solitary condition (*see*

*also* Fridlund, 1994, for a critique; Safdar et al., 2009).

Display rules contain not only rules that end up increasing, decreasing, or masking an emotion, but also those that prescribe specific expression signs as how to exactly an emotion should be displayed, in order to send the prescribed appeal to the receiver, such as a particular expression of gratitude or humility. The culture-specific shaping of expressions by display rules also influences the accompanying internal sensations and feelings.

From the individual perspective, the developmental task consists of the acquisition of these rules and becoming able to regulate his or her emotions in accordance with them. This aspect deals with how individuals acquire the ability to contain or dam undesirable consequences of their emotions and to regulate them in line with normative display and feeling rules within their culture, but also with regard to (anticipated) motives and future expectations. This means that people are no longer directly at the mercy of their emotions and their action readiness, an ability termed *emotion regulation* (Campos et al., 2004; Cole, Martin, & Dennis, 2004; Thompson, Lewis, & Calkins, 2008).

A complete description of an emotion refers not only to the culture-specific causes, appraisals, action readiness, physiological reactions and feelings of the individual emotions, but also to the emotion-specific display rules and feeling rules of the given culture. In order to obey and follow these normative rules, people must acquire the ability to regulate their emotions in line with these rules. We have now described six components that comprehensively characterize an emotion. Such a differentiated approach enables also a differentiated comparison between emotions within a given culture, but also between cultures. In the next section, we deal with the features of sociocultural contexts and their norms, which contribute to culture-specific facets of the components and the emotional repertoire of members of the culture in question.

### **Conceptualization of Sociocultural Environment for Emotions**

As emotional phenomena evolve through and are modified by cultural contexts, we need to identify relevant characteristics of the cultural contexts that explain similarities and differences across members of different cultures. Several layers of cultural characteristics can be differentiated, from global cultural dimensions to emotion-specific norms regarding

the appropriateness of emotional expression and feeling. We outline some of these cultural characteristics below.

### ***Global Cultural Dimensions***

Cultural dimensions (e.g., individualism, masculinity, power distance) (Hofstede, 2001) or value dimensions (conservatism vs. openness for change) (Schwartz & Bardi, 2001) have often been applied in cross-cultural studies on emotion in order to explain cultural differences. Part of cultural variance could be explained with respect to the recognition of emotions (Matsumoto & Kuppertsbusch, 2000), emotional expression and display rules (Matsumoto, Yoo, Fontaine, et al. 2008), emotional expression and experience (Matsumoto, Consolacion, Yamada et al., 2002), as well as emotion regulation (Matsumoto et al., 2008).

Although cultural variations in emotions can be explained, these cultural dimensions are not sufficient to explain the individual differences of the emotional repertoire within a given culture. These dimensions are too abstract and global to explain how they affect the emotions of an individual person. We need more concrete concepts that bridge the gap between individual and culture in a meaningful way and that can be tested empirically.

The concept of self-construal (Markus & Kitayama, 1991) may be a more appropriate approach. The meaning of cultural context for emotion and emotion regulation consists of the conceptualization of desired goals regarding emotions and their regulation. Emotion regulation is universally motivated by the needs and motives of the individual and the maintenance of relationships (e.g., Gross, 1998; Thompson et al., 2008) and to act and feel consistently with the self (e.g., Thompson & Virmani, 2010). These goals in the context of relationships and the self vary across cultures. Self-construals (independent and interdependent self) can serve as a relevant cultural model for cross-cultural studies in developmental psychology (Greenfield, Keller, Fuligni, & Maynard, 2003). In contrast to norms and values, self-construal refers to a person's identity, which allows the determination and derivation of related socialization contexts, as well as the consequences for behavior, cognitions, motivations, and emotions (Kitayama & Markus, 1994). In Western cultures, self-expression and an open communication of "ego-focused" emotions such as anger, pride, and disgust are tolerated more readily, indicating the inner states of independent individuals, who are

expected to rely on themselves to meet their goals and whose states are not easily understood without emotional expression (Markus & Kitayama, 2001). Cultures with interdependent selves typically prioritize values such as the appropriate demeanor in hierarchical relationships (e.g., respect for elders and loyalty to family), social harmony, and group interests. Ego-focused emotional expressions are viewed as potentially disrupting interpersonal relations and should therefore be strictly controlled (Wang, 2003) and the emphasis is rather on "other-focused" emotions, such as sympathy and guilt.

Even the concept of self-construal may be too general, as it leads mostly to a dichotomous perspective of cultures. Culture not only affects emotion at the individual level, by the general self, but also entails shared expectations regarding the components of an emotion (appraisal, expression, action readiness, regulation). It is plausible that cultures differ in specific norms about emotions that can refer from general perspective of emotion to very specific expectations about appropriateness of feeling, expression, and regulation (*see* Mesquita & Leu, 2007). These emotion-oriented norms do not exist in a vacuum, but are reflected in cultural practices, as well as in the form of ethno-theories (subjective beliefs) of socialization partners. The transmission of cultural knowledge about emotion is provided by participating in cultural practices as well as through socialization. Caregivers shape children's emotional development by regulating their emotional episodes according to expectations and standards that mostly reflect shared cultural norms. As a result, children learn to display emotional reactions that concur with available cultural norms (Mesquita & Albert, 2007). Accordingly, the impact of culture increases the probability of emotional reaction that concur with cultural norms and decreases emotional reactions that are inconsistent with cultural norms. The emotional process is flexibly related with the specific contexts in which they occur. Emotional outputs vary across emotions, people, and cultural contexts.

### ***Cultural Norms of Emotions***

Norms of emotion may refer to *salience*. Similar emotions may occur in different cultures, e.g., pride, joy, shame, but the level of tolerance to displays of these emotions and their appropriateness may vary. Consequently, the same emotions are placed in different contexts and assume different meanings. Emotions like pride and joy are seen positively in cultures with an independent self. Cultural members

are open to such positive emotions, seek such situations and evaluate them more positively. They remain in these situations longer and try to maintain or even strengthen them (see Eid & Diener, 2001). A devaluation of the display can be expected when cultures evaluate emotions as inappropriate. An expression of pride about one's own achievements is acceptable, if this serves the welfare of others, but not merely serving the individual's interests (e.g., Stipek, 1998).

Culture-specific norms refer to the *importance of emotions* for personality development. Cultures with an emphasis on an independent self-evaluation regard emotions as a means of regulating actions, which is important for psychic well-being. Cultures with an emphasis on an interdependent self aim to overcome emotions by regulating them deliberately. For example, Chinese people tend to consider emotions as irrelevant and even dangerous, as they can make the person sick (Potter, 1988; Wu, 1982). Moderation and control of emotions is thus a valuable goal.

Furthermore, the *preference for regulation strategies* varies across cultures. *Problem-focused regulation* aims to change the social and physical environment in a motive-serving manner, whereas *reflexive strategies* like self-soothing, distraction, and reappraisal aim at changing one's own emotional state without changing the social environment. These two forms are specific examples of *primary and secondary control orientation*. As studies have revealed (cf. Rothbaum, Weisz, & Snyder, 1982; Seginer, Trommsdorff, & Essau, 1993) secondary control is preferred in cultures with an interdependent self-orientation, and primary control in those with an independent self-orientation. Finally, *cross-cultural differences in action readiness* can be expected. Lee, Aaker, and Gardner (2000) demonstrated that different self-construals are associated with different regulation strategies (approach and avoidance). People with an independent self are "promotion-focused," seeking for relevant information to achieve their objectives. They prefer positive information about themselves. People with interdependent self-construal are "prevention-focused," seeking information that avoids conflict with social norms and they also emphasize relatively negative information about themselves.

### **Cultural Practices**

Cultural norms about emotions are not written laws, but can rather be inferred through an observation of *cultural practices*, in which emotions are embedded. Furthermore, they can be observed in

socialization practices by caregivers, whose socialization goals and strategies are guided by beliefs that are at least partly culturally shared.

Cultural practices provide opportunities for emotional experiences and give meaning to them. These practices promote or hinder the occurrence of emotions. For example, social life in the United States is characterized by practices that emphasize individual values and specific achievements. A frequent exchange of compliments and encouragement are common, as well as institutionalized awards for special achievements (e.g., "scholar of the month" or "teacher of the year"). Individuals experience these practices, which allow more for frequent experiences of joy and pride. At the same time, these emotions acquire a specific meaning related to these experienced conditions (Mesquita & Albert, 2007).

Culture offers *contexts for normative forms of emotion expression* through rituals (e.g., birthday parties or funerals) or informal interactions (e.g., conversations between friends, meeting colleagues for a drink after work). These normative forms are also conveyed through the media. Tsai (2007) has argued that cultural differences between Asian and North American culture relate to the impact of ideals: European-Americans aim at positive affects related to stimulation and excitement, whereas Asians prefer positive affects related to balance and calmness. A comparison of the facial expressions in popular women's magazines and men's magazines in the United States (*Cosmopolitan*, *Vogue*) and Hong Kong (*Chinese Cosmopolitan*, *Nano*) yielded that an excited smile was significantly more represented in the American magazines, compared to Chinese ones, reflecting these differing norms. This variations could also be confirmed for children's books (United States-Taiwan comparison) (Tsai, Louie, Chen, & Uchida, 2007).

Cultural knowledge about the appropriate experience, display, and regulation of emotions is also provided through socialization practices by caregivers, as they transfer cultural knowledge to the next generation. Caregiver socialization goals and strategies are guided by their subjective beliefs, which are often referred to as ethno-theories, because it is assumed that they reflect shared cultural beliefs. Ethno-theories may refer to general or specific socialization goals (e.g., Friedlmeier, Schäfermeier, Vasconcellos, & Trommsdorff, 2008) or to developmental beliefs, e.g., what the characteristics of a competent child include.

Several cross-cultural and mono-cultural studies investigate socialization strategies and their impact on children's emotional development (*for a review, see* Friedlmeier, Corapci, & Cole, 2010). A differentiation can be made between two cultural models of emotional competence. Western cultures stress the importance of promoting self-sufficiency, autonomy and independence in children (Greenfield, Keller, Fuligni, & Maynard, 2003). According to these norms and conceptions of emotions, caregivers emphasize the model of *individualistic emotion competence*. This model can be described as a self-reflective approach to individual emotional competence that is guided by an emotional coaching approach (Gottman, 1997; Gottman, Katz, & Hoven, 1997). Caregivers are aware of and accept a child's negative emotions, encouraging the experience of such emotions, providing comfort and assistance and a supportive self-regulation of distress. In contrast, an emotion-dismissing approach that is associated with a tendency to minimize, criticize, punish, or ignore children's negative emotion experience and expression, is less accepted as this approach is seen as detrimental to a child's emotional development (Gottman et al., 1997). In contrast, many East-Asian societies aim to foster "*relational*" *emotional competence* (Chan, Bowes, & Wyver, 2009). This approach is consistent with a cultural model of the individual being defined by relationships and a network of interdependent selves (Mesquita & Albert, 2007). Promoting an understanding of emotion display rules, and teaching the importance of interpersonal sensitivity are stressed.

These two models of emotional competence are also reflected in different preferences regarding emotion regulation strategies. Caregivers in Asian countries more often endorse strategies such as the unacceptability of expression, using the episode to teach the child a lesson, and reflection-enhancing responses, i.e., the caregiver does not encourage expression, but coaches the child to acquire the appropriate expression and regulation of emotion, without using dismissing strategies (e.g., Chan et al., 2009; Raval & Martini, 2009). The two models of competence—relational vs. individualistic—are not mutually exclusive, and both may be endorsed to different degrees. For example, Chan et al., (2009) developed a measure of these two models, and their study of mothers in Hong Kong showed a balance between both models, with a slight preference toward the relational emotion competence model.

In addition to these strategies, emotions themselves can be used as a socialization strategy to guide a child's emotions and emotion regulation in the desired direction. Emotions have a double meaning. They serve a purpose in motive-relevant episodes, but caregivers can use them to imply a higher level of action regulation by the child, i.e., to display appropriate and avoid inappropriate behavior, according to the social rules (Quinn, 2005). Emotions that can take on this function are *threatening* and the elicitation of fear, *shaming and teasing* in order to induce shame, *praise* and the elicitation of pride, or *empathy* and the induction of guilt. These emotional reactions are displayed by caregivers, in order to bind the children to social norms. Cultures may differ in their preferences and intensity of use of these emotions for socialization purposes.

## General Conclusion

This chapter has focused on the issue of how similarities and differences in emotions, within and across cultures, can be described and explained.

*An overview of the ongoing debate.* The overview of the debate between evolutionary and culture-relativistic approaches yielded a conceptualization of an emotion as a multi-component system and revealed the importance of conducting a cultural analysis of *all* components of a single emotion: (a) the causes of an emotion, (b) appraisal of the causes, (c) action readiness including expression, (d) bodily reaction, (e) feeling, and also (f) the normative evaluation of the emotion, including its regulation.

*A developmental perspective.* In handling the methodological complexity of such a comprehensive analysis, we argue in favor of supplementing the cultural analysis of emotions with a developmental approach. This contains a developmental reconstruction of: (a) how individual emotions emerge and develop over the course of ontogeny within different cultures, and (b) which sociocultural factors can be identified that trigger emotional modifications. An emotion can be identified as universal if it can already be observed at birth or if it adopts similar features over the course of ontogeny in almost every culture; an emotion can be identified as culture-specific if it is possible to refer to culture-specific conditions of socialization. These conditions inevitably evoke substantial and demonstrable modifications in several of the emotional components that transform the entire configuration into a different emotional quality. This developmental reconstruction of an emotional quality within and across selected

cultures can be used as an additional method for validating the classification of single emotions as either similar or different from one another.

*Findings from a developmental analysis.* Developmental research provides several insights that can constitute a starting point for a cultural analysis of emotions: (a) Neonates seem to exhibit a repertoire of five distinguishable emotions that can be labeled as types of distress, endogenous pleasure, interest, disgust, and a startled reaction and that are not identical with the so-called basic emotions. (b) The primary function of these emotions is to regulate social interactions between child and caregiver. The expressions of these emotions serve as appeals to the caregiver to act on behalf of the child in order to satisfy its motives. (c) From birth onward, both child and caregivers use expressions to regulate their interaction, and from birth onward, these expressions are modified by their mutual reactions and interpretations. (d) Therefore, expressions are the primary interface between cultural socialization and the psychological enculturation of emotions. (e) Using an emotion to regulate one's own behavior in a motive-serving manner is a secondary result of learning.

*Expressions as the primary interface for the development of emotions.* Expressions function mainly as culturally co-constructed signs that mediate and regulate the social interactions between members of a given culture. It is because of the appeal function that expression signs are culturally constructed and used by individuals. Expression signs are designed to have an effect on the receiver's intentions to follow the appeal and to signal approval in reciprocating to the sender through complementary expression signs. Emotionally loaded patterns of interaction that frequently occur in a given culture usually adopt a ritualized mode that includes culture-specific display and feeling rules (displaying grief vs. consolation; contempt vs. shame; admiration vs. pride). This ritualization provides a predictable frame of interaction for the involved members and channels their emotional feelings.

*The feeling component as internal feedback of the ongoing action readiness.* An analysis of the interrelations between the components of an emotion revealed that the subjective feeling of an emotion can be conceptualized as an internal feedback of expressions and bodily reactions accompanying an emotion. Research provides evidence that the feedback loop seems to be a universal feature of an emotion. To the extent that expressions and bodily reactions have culture-specific features, the subjective feelings

are also colored in a culture-specific form via the feedback loop. Furthermore, the level of self-awareness at which the feedback is experienced, also has a culture-specific coloring, because the way in which a person interprets his or her sensations as a quality of feeling (conceptual self-awareness) depends on the acquired emotional concepts.

*Sociocultural environments for emotions.* Finally, we dealt with sociocultural environments for emotions and presented several layers of cultural characteristics, from global cultural dimensions to emotion-specific norms regarding the appropriateness of emotional expression and feeling, which contribute to the emergence of similarities and differences across members of different cultures.

## Future Directions

*What are the universal or culture-specific meanings of expression signs?* In current emotion research, expressions are reduced mainly to a methodical index that is assigned to linguistic terms of emotions. There is, however, no unequivocal match between particular expressions and emotional labels. Therefore, it is useful to assess the meanings that members of a given culture assign to expression signs and to compare them cross-culturally as has already been done with linguistic terms of emotional states. As a result, expression signs used in a given culture can be gathered to form a culture-specific lexicon, and supply information as to which particular appraisal and action readiness each sign refers, and which particular appeal each sign signals to the receiver. This analysis would also enable a more fine-tuned interpretation of expressions displayed in an emotional episode.

An analysis of expressions has the advantage that no translation problem occurs, as is inevitably the case for linguistic terms. The same set of pictures or videotapes of expressions can be used in all cultures, although using pictures or videotapes of the same ethnic group may improve the ratings. It is, however, a challenge for the future to extract the appellative and semantic meaning of identifiable expression signs and to compile them into a lexicon with illustrative videotapes of all expressive channels (see Kottonau, 2010; Posner & Serenari, 2003; Wierzbicka, 1995, 1999).

*What are the developmental pathways to culture-specific emotions?* Up to now, the analysis of emotions as multi-component systems has revealed sound descriptions of culture-specific qualities, e.g.,

“Lung Lang” as a kind of Tibetan anger (Menon & Shweder, 1994), “Lajja” as a kind of shame in India (Shweder, 2003), “naklik” as a kind of care and love for Inuit people (Briggs, 1970). It remains challenging to reconstruct the developmental pathways of culture-specific emotions over the course of ontogeny and to identify the social interactions and experiences that are mainly responsible for inculcating these emotions. One aspect of this task is that of identifying the particular age period or developmental phase during which the emotion in question emerges. Another aspect is to uncover emotional and cognitive prerequisites that a person needs at his or her disposal, in order to acquire the emotion in question.

Particular attention should be paid to the impact of social rituals and the accompanying emotions displayed by the people involved, e.g., the interdependence between contempt/exclusion and the emergence of shame or the interdependence between admiration and the emergence of pride. Furthermore, some group-based emotions, such as national pride (or other kinds of belonging to a collective) seem to be promoted especially during social encounters that provide strong experiences of effervescence as a kind of socially shared excitement (Durkheim, 1912/1955). Taken together, a developmental analysis would bridge the gap between the universal emotional features of young infants and the culture-specific features of emotions such as *national pride*, *amae*, *fago*, *naklik*, etc.

*What is the impact of sociocultural environments on the development of emotions?* We still need to describe the pathways between cultural values, socialization goals, socialization practices, and children’s emotion skills much more comprehensively than has been actually the case so far. Emotion socialization is universal. Most parents in all cultures care about their children’s emotions, emotional well-being, and the acquisition of self-regulation. They are supportive, emotionally positive, and nurturing. Their caregiving practices already contain implicit messages about desirable emotion outcomes and cultural differences probably refer to the way support, nurturing, and warmth are expressed and how caregivers react to children’s emotional behavior. In order to assess these developmental pathways, emic and derived etic approaches, as well as a broad range of quantitative and qualitative methodologies are necessary. Furthermore, interdisciplinary collaboration between ethnologists, anthropologists, sociologists, and psychologists can enrich our scientific

knowledge about emotional development and emotion socialization.

Up to the present, mostly parents as socialization partners have been studied. Parents are highly relevant to children’s emotional development, but future research also needs to expand the sociocultural environment by analyzing the role of peer groups, teachers, neighborhood, and media as important contexts for shared meanings of emotions. As a further consequence, a more culturally sensitive approach, which takes a closer look at the particular developmental niche of children, may be an important step to overcoming the dichotomized view of cultural context, which continues to dominate the current research in this area.

# Ambivalence and Its Transformations

Emily Abbey

## Abstract

Humans are sign-creating and sign-using organisms. Humans use signs to organize their relation to the world, and the purpose of this chapter is to outline how new meanings emerge as the person uses signs. This chapter offers that new meanings emerge as the person attempts to overcome ambivalence. Humans make meaning in the present, but each sign addresses not only what is the case in the here-and-now but also what could be the case in the future. Assumptions for what could be the case in the future can function to guide the person toward one's goals—which are themselves semiotic constructions highly abstracted from the ongoing stream of experience. This chapter outlines a model for how meanings emerge on the basis of ambivalence between the present and future. The transformative power of ambivalence is discussed, and three levels of ambivalence are outlined. In the null condition, no ambivalence is present and meaning making stalls. Second, mild to moderate ambivalence leads to an erratic starting and stopping of the meaning-making process, with signs that tentatively control meaning without restricting change in the future. Third, maximum ambivalence leads to the construction of signs that preemptively try to determine the future, even though it cannot yet be known, effectively making an otherwise dialogical process momentarily monological.

**Keywords:** ambivalence, uncertainty, semiotic mediation, irreversible time, meaning making, ambiguity

It has long been observed that humans are sign-making and sign-using organisms. Humans make meaning using signs, which by definition *stand in* for other things and indeed for some, our ability to make and use signs differentiates humans from nonhumans. Vygotsky, for example, discusses “Buridan’s ass” (a hungry donkey standing between two equal piles of hay). This nonhuman cannot decide which pile to consume and therefore dies of starvation. A human, by contrast, could use a sign to tip the balance, rendering one pile more desirable and thus making the decision of which one to eat (Valsiner, 2000). Humans use signs to organize their relationship to the environment, and while in modern times few would draw as stark a distinction between human and nonhuman sign use

as the one depicted in the above example, understanding how humans make meaning using signs has become a central focus for many cultural psychologists (e.g., Valsiner, 1998; Wagoner, 2010; Zittoun, 2006).

As humans go about the process of meaning making, it is not hard to notice that individuals readily create multiple meanings for any given situation, constructing their relationship to the world in a variety of ways over time. A central task for cultural psychology then, is to understand how meanings emerge and change over time. Articulating a basic model of how meanings emerge through time can further our understanding of this central aspect of human thoughts, feelings, and behavior.

## Irreversible Time

Responding to the question of how meaning emerges begins through careful consideration of the temporal embeddedness of the human life experience. Human lives, rather than being separate from time, are rather deeply colored by temporality. Any given event, no matter how similar to a previous event, experientially is nonetheless unique by virtue of the fact that it occupies its own unique space, a space that changes continually on the basis of what has come before. As such, it can be said that humans live within an irreversible stream of experience, a stream where the concept of “sameness” does not apply.

Henri Bergson's (1913) notion of time-as-duration (*durée*) forms the basis for this claim of temporal embeddedness. The notion of duration provided numerous points of inspiration for how scholars conceptualized movement and change during the transition from nineteenth-century philosophy to twentieth-century science (e.g., Prigogine & Nicolis, 1971). So too, key figures in the history of developmental psychology have been influenced by Bergson's notion (e.g., Baldwin, 1915; Piaget, 1962; Vygotsky, 1994). As Bergson explains, the irreversibility of experience happens through a *pure duration* of the ego—where our consciousness is freed from keeping past and present experiences separate, and instead is allowed to endure through time. Bergson writes:

Pure duration is the form which the succession of our conscious states assumes when our ego lets itself *live*, when it refrains from separating its present state from its former states . . . it need not be entirely absorbed in the passing sensation or idea; for then it would no longer *endure*.

(Bergson, 1913, p. 100 emphasis original)

Much like a rolling snowball, Bergson goes on to point out, as the ego endures, the experiential whole is growing, and thus, ever-changing. Even actions that have been carried out many times before—e.g., viewing a still object from the same angle, in the same light—become tinged with novelty for the experiential whole is composed by a different, richer, accumulation of the past (Bergson, 1913).

### The Boundary Zone

Within irreversible time, therefore, novelty is an ever-present quality of experience. Given the swiftness of experiential shifts as the ego endures, the person can be said to live not within an elongated

**Figure 47.1** Boundary zone between here-and-now and unknown future

“stable” present, but rather, at the *boundary* of an infinitesimally small here-and-now and unknown future (Simao, 2011). In irreversible time, any notion of the present as one may commonly mean it can perhaps better be understood as merely a *boundary marker*, useful in delineating what is now known (the past) and through its realization—stipulation of the known—axiomatically introducing the next experiences as part of the unknown future (Matte Blanco, 1975, 1988). As depicted below, (see Fig. 47.1) our lives happen within what can be described as a *boundary zone* of the just barely known moment and the unknown future.

As contrasted with the notion of the “present” one usually assumes, the boundary zone is an ambiguous space (Abbey & Valsiner, 2005), for it is neither purely part of the present nor exclusively the future. Rather, it is part of the here-and-now and the future simultaneously.

### Sign Use in Irreversible Time: Preadapting to the Uncertain Future

Humans use signs to provide some sense of order within their experience, yet on the basis of what has been said so far, to order experience humans need not only account for the here-and-now, but also the uncertainty of the next moment. Within irreversible time, humans make meaning not only to relate to their immediate environments, but in an effort to be prepared for what might happen next—to preadapt to uncertainty.

As depicted in Figure 47.2 below, this means that in each contextualization the sign represents *what is* in the here-and-now (and in so doing, organizes the immediate moment), yet also creates an open field

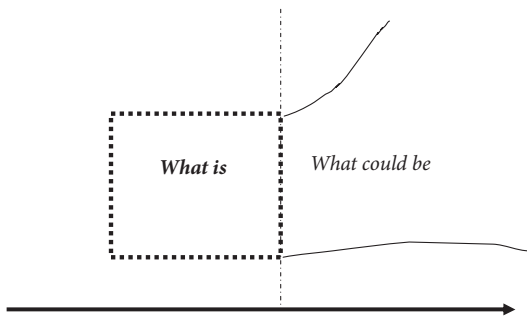

Figure 47.2 Openness of the sign to possible future meaning

of implications for *what could occur* in the future (Josephs, Valsiner, & Surgan, 1999).

For example, a person may hear a wailing noise in the distance. The representational significance of this noise is likely that “it is a siren.” Yet this is not the only sense of that sound. Simultaneously, the person also constructs possible ideas for what that sound could mean for the future—for example “the arrival of aid” or “danger is afoot.” The presentational meanings may be multiple, yet in all circumstances, having some sense of what comes next helps the person begin to plan for the next moment, allowing them to preadapt to uncertainty. For some, hearing a siren could indicate authorities will soon arrive to provide assistance.

### *A* <> *Non-A Sign Fields*

The relationship between the present and the future discussed here leads in an alternative direction to the one commonly explored. In science one is typically accustomed to accepting that the past influences the present. That said, it is less usual that one focuses on the conceptualization being presented here—the notion that the future influences the present. Such relationship between the present and future can be described formally in terms of “A” and “non-A.” Within this system, any mention of A (what is the case in the immediate moment) simultaneously refers to A’s opposite field, non-A (what could be the case in the future) (see Fig. 47.3 below). The non-A field is composed of all the possible

Figure 47.3 A and non-A

transformations that A—in the present—is not, but could become in the future (Josephs, Valsiner, & Surgan, 1999).

Critically, as in any duality, A and non-A are not exclusively separated from one another, but rather, exist on the basis of one another. Thus, in terms of the discussion above, the siren (A) would include a non-A field of possible future meanings, including “danger,” “arriving authorities to provide assistance,” etc. Of course the field of non-A meanings is fuzzy and vague, the person is not completely sure of what occurs next. A sense of approaching danger that may accompany a siren does not pinpoint what happens, yet it guides the person as he or she moves toward the unknown next moment.

### **The Centrality of Ambivalence in Making Meaning**

As the person goes about the process of actualizing the future from within a set of possibilities, he or she functions within the *ambivalence* of A and non-A. There is ambivalence for the person because each present sense is in tension with what could be the case in the next moment. Necessarily, if the future is reliably different from the present moment, each presentational non-A field creates a discrepancy with A, its representational sense. The ambivalence within meaning insists upon resolution. As the person sets out some sense of what is, this sense is immediately challenged by the presentational sense of what could be. Making a meaning—arriving at the next representational sense—is thus a process driven by the person’s work to overcome tension between the representational and an imagined presentational sense of the sign.

### *Transformative Power of Tension*

As an example of how the tension between two alternate interpretations of a situation can lead to the emergence of a new idea, take Bullough’s introspective narrative recounting the experience of standing on a ship’s deck as the vessel is suddenly enveloped in a cloud of fog. In his description of the event, Bullough describes how his immediate sense of the situation is one of danger—for one has little sense of orientation. Yet in his narrative, Bullough also describes how he simultaneously distances from this immediate sense, realizing that the being shrouded in fog could also be a peaceful experience. As seen at the conclusion of this narrative, as tension of these juxtaposed alternate meanings—danger and

peace—is overcome, a new meaning for the situation emerges. Bullough writes:

For most people it is an experience of acute unpleasantness. Apart from the physical annoyance and remoter forms of discomfort such as delays, it is apt to produce feelings of peculiar anxiety, fears of invisible dangers, strains of watching and listening for distant and unlocalised signals. The listless movements of ships and her warning calls soon tell upon the nerves of the passengers; and that special, expectant, tacit anxiety, and nervousness, always associated with this experience, make a fog the dreaded terror of the sea (all the more terrifying because of its very silence and gentleness) for the expert seafarer no less than the ignorant landsman.

Nevertheless, a fog at sea can be a source of intense relish and enjoyment. Abstract from the experience of the sea fog, for the moment, its danger and practical unpleasantness, just as everyone in the enjoyment of a mountain climb disregards its physical labour and its danger (though, it is not denied, that these may incidentally enter into enjoyment and enhance it); direct the attention to the features ‘objectively’ constituting the phenomenon—the veil surrounding you with an opaqueness as of transparent milk, blurring the outlines of things and distorting their shapes into weird grotesques . . . note the curious creamy smoothness of the water, hypocritically denying as it were any sense of danger; and, above all, the strange solitude and remoteness of the world, as it can be found only on the highest mountain tops: *and the experience may acquire, in its uncanny mingling of repose and terror, a flavor of such concentrated poignancy and delight as to contrast sharply with the blind and distempered anxiety of its other aspects.* This contrast, often emerging with startling suddenness, is like a momentary switching on of some new current, or of the passing ray of brighter light, illuminating the outlook upon perhaps the most ordinary objects.

(Bullough, 1912, pp. 88–89, emphasis added)

As Bullough’s narrative description makes clear, through tension new sense of a situation can emerge quite suddenly, creating novel meanings such as the “delight” portrayed here.

### ***Transformation through Tension in Poetry***

Another way to begin to understand the transformative power of tension involves considering what occurs when a person uncovers the meaning within a metaphor (Abbey, 2007). As a person

reads a given metaphor, again there is ambivalence, in this case between the literal and imagined senses of words. For example, in the metaphor “Let sleeping dogs lie,” the person must maintain both the literal sense of these words, as well as extend beyond them. It is by overcoming that tension that he or she arrives at the new meaning: not to recreate trouble where it has already been resolved. Ricoeur stresses this emergent quality of metaphor, showing how imagination *suspends* ordinary descriptive reference (Ricoeur, 1981), creating the discernable disturbance of the linguistic structure in poems through which a new reality emerges: “The suspension of the reference proper to ordinary descriptive language is the negative condition for the emergence of a *more radical* way of looking at things . . .” (Ricoeur, 1981, p. 240, emphasis added).

### **Three Levels of Ambivalence**

In daily life, new meanings emerge as the person is driven to overcome the ambivalence between representational and presentational senses of the sign. It is perhaps somewhat usual to think of ambivalence as a relationship of polar opposites. However, within the current framework, *ambivalence* can be defined as ***a tension produced by a system entailing a kernel and at least two vectors that are non-isomorphic in size and direction.*** In such a system, ambivalence can occur under all conditions except one, where the vectors are of exactly the same size and direction (Condition D; see Fig. 47.4, below). Condition A represents the most typical understanding of ambivalence: two equally strong forces pulling the individual in opposite directions. In the current framework, this represents the maximum degree of ambivalence between the present and the future. Conditions B and C produce ambivalence that is weaker, yet nonetheless present. In Condition B, although the two forces are not completely opposing, they create a tension between two different orientations. In Condition C it is the discrepancy in strength of forces that creates ambivalence.

This notion of ambivalence created by vectors of different sizes and directions borrows from Lewin’s (1936) topological psychology in which he offers the notion of a life space filled with forces that are of different degrees of attraction and repulsion. Lewin focused his work on the description of forces that were either exclusively positive or negative. That said, one can offer that ambivalence is also possible. In this latter case, the life space is composed by forces

Figure 47.4 Levels of ambivalence

that pull him or her in differing, if not outright opposing directions. Within the current model, the person necessarily experiences ambivalence caused by the future-oriented nature of human meaning making, where each sign's meaning represents and presents simultaneously.

### *Fluctuations in Ambivalence and Semiotic Emergence*

Within this model, increasing and decreasing levels of ambivalence construct a self-perpetuating process of meaning construction. The person makes some meaning, which entails a tension between the present and future. He or she attempts to overcome that tension by arriving at a new meaning, only to recreate ambivalence anew. On the basis of ambivalence, the emergence of signs can be understood as occurring within a number of conditions.

#### **NULL CONDITION: NO SIGN**

The null condition within this model represents the set of circumstances in which the person does not experience tension as they are not engaged in meaning construction. That is, the person makes no attempt to organize his or her relation to the world using signs.

#### **ERRATIC MEANING MAKING: FRAGILE AND MEDIUM SIGNS**

As soon as any person begins to try to make sense of the environment using signs, he or she exits the

null condition and tension immediately appears. The person starts to experience ambivalence on the basis of the contrast between a sign's representational and presentational sense. In this condition, the ambivalence is of a mild to moderate level, and as the person continues to overcome these tensions, new meanings emerge in a relatively erratic basis. The person concludes that one idea may be appropriate and then this sense shifts as his or her life experience shifts and new meanings are made. This process of striving toward meaning is based on the opposition created by the person, and is the basis for further transformation. Of course, the meaning-making process can be extinguished if the person abandons his or her quest to figure something out—to organize his or her relation to the environment. In this case, there is a return to the null condition until the person re-engages in an attempt to create order.

In terms of the current emphasis on meaning making as partially an attempt to preadapt to what comes next, this kind of meaning making, and this level of ambivalence can be seen as ideal. This is because the signs emerging in this process allow the person to create order for himself or herself that guides action in the present, while still allowing for possible transformations and deviations from that path in the future, should they become necessary. The person in this condition is generally open to the uncertainty that lies in the future, while actively preparing for it. He or she does not try to deny that uncertainty.

## BIFURCATION OF TRAJECTORIES: CONSTRUCTION OF STRONG SIGN VERSUS LOSS OF SIGN

### Strong Signs

If ambivalence escalates beyond the moderate level to the point where it is at its maximum level, this can lead to the construction of a strong sign. *Strong signs* are inflexible compared to fragile or medium ones. They set out a particular relation to the environment that is rigid, and is not open to modification, even that environment may change. A common example of this kind of meaning making is when a person is prejudicial in their thinking, accepting only one—and usually negative—characterization of a race, culture, or ethnicity as correct, and refusing to entertain any other possibilities. In terms of the preadaptive function of meaning making, clearly strong signs function poorly, for in their rigid stipulation of a person's relation to the world, they do not allow for changes as the person's experience necessarily shifts. Meaning making in situations of maximum ambivalence is no longer erratically flowing along with the changing world, but is unrealistically fixed.

### *Intolerance of Ambiguity*

What occurs during the formation of a strong sign corresponds with a phenomenon expressed as *dichotomizing* (Frenkel-Brunswik, 1949). In essence, when the experienced ambivalence—and the ambiguity it necessarily entails—becomes so strong that it is no longer tolerable, the person aims to create an artificial clarity. In essence, this involves reducing a dynamic and dialogical interaction to that which is monological. The process of this reduction is quite straightforward: first there is an attempt to split that which is ambiguous into two “pure” opposites. Then, there is an act of dichotomizing, during which those “opposites” are separated from one another, and where only one is accepted into the meaning-making process.

For example, an individual spying someone walking toward them late in the evening when it is dark may experience the ambivalence of whether this person is safe to interact with, or if they perhaps present a threat. To the extent that the ambivalence remains mild to moderate, the person may oscillate between different interpretations of the situation. However, at some moment that ambivalence may become strong, and the person—unable to tolerate the ambiguity of the situation—may (following Frenkel-Brunswik's logic) split the meaning of the

situation (e.g., there are “kind people” and “dangerous people”). Then, the individual may well monologize the meaning-making process, concluding that the person seen in the distance “must be out to get me” and rapidly flee the situation.

Such intolerance of ambiguity and the monologization of the otherwise dialogical meaning-making process it entails are not uncommon in situations where an individual feels threatened in some way (e.g., personally, psychologically, socially, etc.). That said, the monologization of the meaning-making process means such an individual may not necessarily adapt well to changes in his or her environment, as the otherwise semi-structured and open field of possibilities for the future has in essence been maximally restricted.

### Return to the Null Condition

There is another possible event that can occur when ambivalence reaches its strongest level. That is, the person feels so much tension that instead of using a strong sign, they literally abandon the meaning-making process in total, the sign disappears, returning the person to the null state. This is, in essence, an attempt to overcome high tension by disengaging in the meaning-making process altogether.

## Illustration

To better illustrate the above-described model, consider the following examples of meaning making given by a man we'll call Daniel<sup>1</sup>. The first example demonstrates the movement from moderate ambivalence to maximum ambivalence (and the accompanying intolerance), and then back down to mild ambivalence, and the erratic start and stop of meaning making that accompanies this level. The second example, by contrast, shows how maximum ambivalence can also lead to a return to the null condition, and an abandonment of the meaning-making process altogether.

### *Example 1: “The Children's Hospital”*

This first example draws from a narrative Daniel is telling about working as a volunteer at a hospital for children who are ill and underprivileged. As he begins to describe the situation, ambivalence is at a moderate level, and his meaning making moves in an erratic start-and-stop manner. He points out how many of these children have huge challenges, yet they reside in a facility that is ill-equipped to help them: “I worked with some kids who have such a struggle and they sit in this very small and

insignificant hospital.” He also notes a frustration that no one else is involved in helping the children, “I am the only volunteer.” To Daniel, these children, who rarely receive visits from their natal families, are suffering, and increased human interaction from volunteers would greatly reduce their suffering, providing some relief from their dreary days, and a basic sense of companionship.

As Daniel continues to recount and make sense out of his experience, he describes leaving the hospital one day, standing in the parking lot and looking out at the cars passing:

I wanted [after volunteering] to go out and stop every car that cost more than 50K and force ... them to sell it right there on the street and give all the money to the hospital. I thought ‘hmm, that’s not real charity ... that’s believing that I am somehow in charge of the world.’ I realized that, first off, people who want to spend that much money on a car, that’s their choice ... I can’t change that ... but what I can do is find more time ... to ... work at the hospital, which is my job ...

Looking in detail at this progression in light of the current model, it seems the moderate level of ambivalence Daniel had been feeling here reaches a maximum level:

WHAT IS: Looking out at the cars passing on the highway.

WHAT COULD BE: ‘I wanted [after volunteering] to go out and stop every car that cost more than 50K and force ... them to sell it right there on the street and give all the money to the hospital.’

Coinciding with this maximum level, Daniel’s meaning making reaches the point of monologicalization. For Daniel at this moment, it is as if the others passing by in their cars can only be understood as selfish and ignorant. So too, Daniel in this moment feels quite intolerant, and wants to take control of these individual’s lives.

The next lines of Daniel’s narrative show how quickly the level of ambivalence can fluctuate, given certain distancing strategies. Following this moment of maximum ambivalence and formation of a strong sign, Daniel reminds himself that he is not in control of the situation:

WHAT IS: Looking out at the cars passing on the highway.

WHAT COULD BE: ‘That’s not real charity ... that’s believing that I am somehow in charge of the world.’

In this moment of meaning making, Daniel allows uncertainty back into the meaning-making process, and on this basis, new ideas begin to emerge as the ambivalence drops. Daniel returns to a mild level of ambivalence, and the erratic stop-and-start nature of meaning construction continues:

WHAT IS: People can spend whatever amount of money they want on a car.

WHAT COULD BE: ‘The amount of money spent on a car is not up to me ...’

WHAT IS: ‘I can find more time to work at the hospital ...’

WHAT COULD BE: This is what I can do/control.

### ***Example 2: “The Grocery Store”***

This second example demonstrates how maximum ambivalence can lead to a return to the null condition. In it, Daniel is describing a recent exchange in a grocery store. The exchange involved a customer yelling at a store clerk because she could not understand the clerk’s accent. Again, Daniel’s meaning making begins with ambivalence at a moderate level, proceeding in a start-and-stop manner. He says, “There was a very angry woman in [the grocery store] this morning, screaming at the clerk in front of two of us, all because the clerk kept saying in Russian, ‘Please push yes’ and she couldn’t understand her.” He continues at the moderate level, saying that he himself and many of the others in line could understand the clerk: “The rest of us could understand her.”<sup>2</sup>

At this moment in his narrative, Daniel’s level of ambivalence appears to reach a maximum level, as he begins to form strong signs, depicting the woman categorically as a “tourist” and a “New York socialite.” He says, “The woman got nastier and nastier and nastier and she looked like a New York socialite. She had gold jewelry and a striped blouse and she just looked like a summer touristy person pushing her weight around ...”

Following this escalation, and the appearance of strong signs, instead of returning to moderate ambivalence as in the previous example, here Daniel instead returns to the null condition with the statement: “I just let it go.” In essence, seemingly within the ambivalence of the situation, Daniel opted to reduce tension by abandoning the meaning-making process.

### ***Fluctuations in Ambivalence***

In general, the ebb and flow of ambivalence drives the process of meaning construction. In these

two examples, one can understand the movement of meaning on the basis of tracking fluctuations in ambivalence. In the first example, ambivalence moves from moderate, to maximum, and then returns to a mild level. In the second, moderate ambivalence quickly becomes maximum, with a complete abandonment of meaning making, with a total reduction in ambivalence by the end.

Comparing these two examples, example one demonstrates well how a lower level of ambivalence can indeed allow one to better adapt to his or her environment in that it allows for flexibility. As Daniel's level of ambivalence reaches a maximum level, he becomes unable to adapt to his environment because he can only focus on the fact that the people around him are selfish and negligent to these children. It is not until the level of ambivalence is reduced that he is able to better adapt—coming up with the alternate ideas for ways that he can help children in the hospital.

That said, while Daniel's movement back to moderate ambivalence in example 1 shows the adaptive value of medium signs, the latter example also shows how in some moments abandonment of the meaning-making process may be the best way to avoid the rigidity entailed by the construction of strong signs. In some situations, there may be no way to distance from the situation in a manner that allows uncertainty to re-enter the meaning-making process. In this situation, the person faces the possibility of continuing in an unproductive fixated cycle of rigid meaning, or giving up entirely. It is likely that in some instances, a more adaptive solution is to simply do what Daniel does in this case, which is to abandon the meaning-making process for the time being.

## Conclusion

Ambivalence is a construct that has been used in many areas of psychology, however its value for understanding the process of semiotic emergence is only recently becoming clear. As humans make meaning, they are literally driven by overcoming the ambivalence between their present and future-oriented senses of a situation. In the process of overcoming ambivalence, one is led in various directions—either toward an erratic start-and-stop process of constructing fragile signs, in some cases to the construction of strong signs, or toward the abandonment of the meaning-making process altogether.

Indeed, the present model suggests that in general, development need not be understood as a

process that is only influenced by the past. Rather, as discussed here, the uncertainty of the future—as well as one's expectations about what might happen—are central aspects of the process of emergence. Conceptualizing development is a future-oriented phenomenon that is likely to bring new understandings to the field of cultural psychology, be these in the area of meaning making or otherwise.

## Future Directions

Emergent phenomena—such as the one discussed within this chapter—are inherently difficult to study. This is because inquiry of this nature requires explaining that which is not yet in existence using only two pieces of information: what is known, and what is expected (Valsiner, 2001, p. 53). Too often in psychology, researchers attempt to study emergent phenomena by way of methods that erase rather than maintain the time sequence of data, capturing only outcomes rather than the process of development, where emergence can be viewed as it happens. Development cannot be seen by looking at outcomes sequenced in time—even if those outcomes occur over a very short period of time, as occurs in time-series analysis. To document emergence, the researcher needs to gain access to the intermediary forms as transition occurs.

When considering the future research agendas then, it would appear important to ensure the use of methods that will allow the researcher to gain access to the process of transformation as it happens, and which allow those movements and shifts to be better understood. Possible methodological options for documenting emergence do exist, and herald back to the first portion of the twentieth century and the tradition of *Ganzheitspsychologie* (see Diriwächter & Valsiner, 2007). The method, which in English is often referred to as the “microgenetic method,” involves the investigation of emergence by treating forms themselves as merely boundary states, focusing instead on the intermediary forms. For example, instead of being interested in a series of outcomes  $A \rightarrow B \rightarrow C$ , a microgenetic study is concerned with the progression from A-B and B-C, (e.g.  $A \rightarrow ab \rightarrow B$ , and  $B \rightarrow bc \rightarrow C$ ). Historically, the microgenetic method has been used to study the emergence of visual percepts (e.g., see Wohlfahrt, 1925/1932) and general meaning constructs (Werner, 1954). So too, more recently researchers have begun to reincorporate such methods into developmental study (Abbey & Diriwächter, 2008; Siegler, 1996).

It follows that future research would benefit from careful consideration of methods, and might find value in adopting a microgenetic approach. Of course research methodologies themselves change each time they are used, as influenced by the particular phenomenon on the one hand, and theory on the other (Branco & Valsiner, 1997). That said, careful attempts to track the processes of change, and to make visible the conditions within which particular shifts occur will benefit this area of study.

# Guesses on the Future of Cultural Psychology: Past, Present, and Past

Aaro Toomela

## Abstract

In psychology today, three scientific approaches—three cultures—can be distinguished, each of them based on different epistemology: roots of the process-oriented science can be traced back to the Heraclitian philosophy; cause-effect science agrees with the Cartesian-Humean philosophy; and structural-systemic science, which in many respects is built on Aristotelian worldview. Science is an activity that aims at increasing knowledge and understanding of the world. In this chapter it is suggested that the three scientific approaches comprise a hierarchy in terms of explanatory power; process-oriented science represents scientifically the least effective way to understand the world and structural-systemic science is the most powerful. Cultural psychology of today is analyzed in the framework of the distinguished epistemologies and corresponding methodologies. It is shown that the process-oriented cultural psychology is represented, among others, by studies based on modern qualitative methodology; also several ideas from activity theory and indigenous cultural psychology belong here together with the principle of cultural relativism. Cause-effect science is represented by cross-cultural psychology, and partly by activity theory and indigenous cultural psychology, which are examples of mixed approaches. Finally, the structural-systemic approach was taken by almost abandoned today Vygotskian cultural-historical psychology elaborated by Luria. The near future of cultural psychology, I predict, will remain dominated by cause-effect science together with the process-oriented approach, which will strengthen its position a little. Nonscientific reasons why the most sophisticated structural-systemic approach will stay in the periphery of science are discussed. It is concluded that the future of cultural psychology, if it is to prosper as a science, lies in the past, not in the present.

**Keywords:** epistemology, culture of science, cultural psychology, hierarchy of scientific approaches

Cultural psychology aims at understanding properties of psyche that emerge in the interaction of an individual with his or her cultural environment. The overall state of cultural psychology today is confusing—instead of one psychology, fundamentally different cultural psychologies can be distinguished. This fact, in itself, does not imply any problem because the same phenomena can be studied and understood from different perspectives. In biology, for example, mechanisms of heredity can be understood by studying prevalence of certain diseases in families and also by studying genetic processes at

the molecular level of analysis. But it does not follow that all possible ways to study some phenomena are equally appropriate for science. Even more, it is important to realize that ideas about the world that is studied by sciences do not emerge only on the basis of studies of that world alone; scientific ideas include theories that are grounded on ideologies, which can be in direct contradiction with scientific observations.

For example, in the history of the biology of heredity in the Stalin-era Soviet Union, it was suggested that heredity is related not only to chromosomes

or genes, but equally to every particle of the body (Lysenko, 1948, 1952a). This idea did not emerge on the basis of empirical evidence but, in fact, despite an enormous amount of evidence that related heredity to chromosomes and not to other parts of the cells or the body. Even more, in the framework of this ideologically grounded theory, “empirical observations” were made of events that actually cannot happen; it was “discovered,” for example, that together with changes in the environmental conditions, one species can turn into another (Lysenko, 1952b) or that cells can emerge from substance with no cellular structure (Lysenko, 1952c). This theory—together with “empirical observations” that supported it—was rejected together with the rejection of Stalinist ideology under the pressure of theories that developed on the basis of empirical observations.

In cultural psychology, ideologically grounded directions can also be found; most notably in different qualitative approaches to culture, where political, social, moral, and ethical issues sometimes seem to define what is “right” and what is “wrong” in cultures and societies (cf. Denzin & Lincoln, 2005c). So, there are reasons to look into cultural psychology and ask whether all approaches that can be identified there are equally scientifically acceptable.

For distinguishing approaches to cultural psychology, the appropriate ground must be chosen. Usually content of the theories—about culture and mind—is taken for this ground. And yet this line of thought would not go far enough. Science and its theories are not only about the phenomenon under study; science is, simultaneously, a way of thinking, methodology for developing understanding of the world (Toomela, 2010c). Theory as a whole always contains methodological and substantial parts. For this reason, in this chapter cultural psychology is analyzed from both substantive and methodological perspectives.

### **Universal Laws or Constant Change?**

There are different ways to study culture and its relation to psyche. Two approaches could be distinguished already in the beginning of scientific studies of culture. Edward B. Tylor (1871) suggested that in studies of human culture, thought, and action, general laws and principles can be discovered. According to him, in physics and biology “the unity of nature, the fixity of its laws, the definite sequence of cause and effect through which every fact depends on what has gone before it, and act upon what is to

come after it” (p. 2) is recognized. The same should be done in studies of culture:

... let us take this admitted existence of natural cause and effect as our standing-ground, and travel on it so far as it will bear us. It is on this same basis that physical science pursues, with ever-increasing success, its quest of laws of nature.

(p. 3)

There was also another view, criticized by Tylor. He suggested that many scholars deny the possibility to study general principles of human functioning and yet, in their research practices, accept the idea of causal relationships and general laws:

Now it appears that this view of human will and conduct, as subject to definite law, is indeed recognized and acted upon by the very people who oppose it when stated in the abstract as a general principle, and who then complain that it annihilates man’s free will, destroys his sense of personal responsibility, and degrades him to a soulless machine.

(p. 3)

Similar approaches can be found in modern cultural psychology. Three approaches to cultural psychology can be distinguished today. Two of them aim at knowing universal principles and one aims at knowing the particulars. One dominant direction of research—most notably (but not only) so-called cross-cultural psychology—studies psychic differences between people from different cultures; on the basis of such findings, ultimately, universal models of psychological processes and human behavior that can be applied to all people of all cultural backgrounds should be created (cf., e.g., Matsumoto, 2001a, 2001b). In this research tradition persons from different countries, ethnic groups, or from groups distinguished before the study according to some other attribute, are compared. Thousands of scientific papers in this research tradition have been published in the *Journal of Cross-Cultural Research* and many other scientific publications.

The second—also universalist—approach to understanding culture and mind as a cultural phenomenon can be identified in the past. Vygotskian cultural-historical psychology, for example, aimed, similarly with cross-cultural psychology, at understanding general principles of culture-psyche relationships. At the same time, however, cultural-historical psychology focused on individuals. The cultural-historical approach, as will be shown in

more details below, is almost abandoned today. Even though there are many scholars who superficially seem to follow Vygotskian ideas (followers of the activity theory, for example), they ignore Vygotskian philosophical-methodological background and, consequently, distort the central ideas of this approach (Mahn, 2010; Toomela, 2000, 2008a; Veresov, 2010). It is exactly this largely ignored philosophical-methodological background that distinguishes two approaches that both aim at knowing universal laws and principles of culture-psyche relationships.

In the third research tradition, focus is on individuals and their ways of relating to their environments. In this tradition—or, more correctly, traditions related to terms such as *hermeneutics*, *post-structuralism*, *postmodernism*, *feminism*, and several others (cf. Denzin & Lincoln, 2005c)—it is usually assumed that there is no correct and objective way to define groups or other universal attributes of people before the study. According to this collection of views, the world is characterized by constant change and consequently understanding emerges in the very process of inquiry; this understanding is ever-changing, subjective, blurry—there is no single “truth” but many partial truths. Numerous examples of inquiries of these research traditions can be found, among other sources, in journals such as *Qualitative Inquiry*, *Cultural Studies*, and *Signs: Journal of Women in Culture and Society*.

In sum, three approaches to cultural psychology can be distinguished on the basis of the general aims of researchers: two approaches—let us call them *universalist*—look for universal laws, and one—process-oriented—for understanding blurry and ever-changing cultural processes. I am going to show that scientifically fundamentally important consequences follow from this distinction.

### ***Hierarchy of Scientific Knowledge***

At this point, different directions for further analysis could be taken. These directions, as I am going to discuss next, are related to different levels of scientific knowledge. Scientific knowledge is arranged into hierarchy of theories so that decisions made at a hierarchically lower level of analysis are grounded on the theoretical ideas of more general nature. Any lower-level theory, therefore, can be fully understood only in the frame of the higher-level theory. In modern science the highest, most general level is, as a rule, only implicit. For understanding the theoretical status of any field of

science, cultural psychology included, all levels of analysis must be made explicit. Next, four levels of scientific knowledge are distinguished.

The first and most specific level of analysis concerns actual research practices. In actual research practice, all theoretical notions must be operationalized—it must be decided how theory is “translated” into research methods. If, for example, culture is understood not as a fixed entity but as a phenomenon that is co-created by the researcher and the informant (Kincheloe & McLaren, 2005), then paper-and-pencil questionnaires with Likert-type answers are ruled out as research tools. Correspondingly, in order to understand different approaches to cultural psychology, research practices should be analyzed. However, these research practices cannot be understood without knowing the theoretical reasons that led to actual research practices; different operationalizations can follow from one and the same theoretical idea and superficially similar research activities may be based on fundamentally different theories. Therefore another, more general level of analysis must be taken.

The next level of knowledge is expressed in theoretical notions—this is the level of definitions. Conducting an analysis in this direction would take definitions of culture that underlie different approaches and analyze them. This direction, however, would miss very important aspects of the analyzed theories. For example, collecting all definitions of culture, either for each of the approaches separately or for all of them together, would allow us to categorize the definitions. This has been done before (e.g., Bauman, 1999; Kroeber & Kluckhohn, 1952), but with no considerable effect on the science of culture. It could not be otherwise—categorization of definitions always implies a choice of the dimensions that distinguish categories; consistent categorization should be based on the same ground. But, as it became evident above, incompatible approaches to cultural psychology can be distinguished; there is no common ground to categorize the definitions. The same definition in different approaches may mean entirely different things. So, it is not necessary to agree with Kroeber and Kluckhohn, who assumed that in science any classification is better than no classification. Classification based on misleading theory is misleading itself and not better but worse than no classification.

Particular definitions of culture in cultural psychologies are chosen on the basis of some implicit or explicit theory as a system of notions. Why a certain

definition is chosen, is justified by the theory about the studied phenomenon as a whole. Thus the third level of analysis would look for the reasons that guided identification of the phenomenon under study theoretically—it would be analyzed, what theory about the studied phenomenon grounded the choice of the definition.

This is not yet the most general level of scientific knowledge. The higher level was first distinguished in philosophy. Hegel (2005a), for example, made an interesting observation about unity of two kinds of thinking—about the phenomenon and about one’s own thought:

... knowledge thereby makes it clear that it has to do at least quite as essentially with its own self as with things. This twofold essentiality produces a certain hesitation as to whether what is essential and necessary for knowledge is also so in the case of the things.  
(p. 286)

Hegel was not the first philosopher to notice the importance of self-reflection in understanding the world. The idea that knowledge of the mind—soul—has a special place in the structure of knowledge as a whole can be found already in Aristotle’s works:

Holding as we do that, while knowledge of any kind is a thing to be honoured and prized, one kind of it may, either by reason of its great exactness or of a higher dignity and a greater wonderfulness in its objects, be more honourable and precious than another, on both accounts we should naturally be led to place in the front rank the study of the soul. The knowledge of the soul admittedly contributes greatly to the advance of truth in general, and, above all, to our understanding of Nature, for the soul is in some sense the principle of the animal life.  
(Aristotle, 1941b, p. 535, Bk I, 402<sup>a</sup>)

This idea applies to scientific knowledge today no less than it did millennia ago. Scientific activity is based on a special kind of thinking where thought about the phenomenon to be understood through studies is co-coordinated with thought about one’s own processes of thinking (Toomela, 2010c): A scientist, while formulating a theory about something, must simultaneously check her own thinking by asking, for example, do the theoretical conclusions follow logically from the premises? If the rules of thought—logic—are not followed, the theory becomes scientifically unacceptable independently of its content.

Scientists make their choices on the basis of their own thought mechanisms; these mechanisms are applied in studying any aspect of the world. Therefore this is the most general level that guides theoretical decisions in sciences. The three approaches to cultural psychology I distinguished are based on different epistemologies, on the differences in defining what scientific knowledge is.

### ***What is Scientific Knowledge?***

In order to proceed, theory of scientific knowledge as such is needed. The question is: what is scientific knowledge? Aristotelian thought is helpful here too. According to him,

We suppose ourselves to possess unqualified scientific knowledge of a thing, as opposed to knowing it in the accidental way in which the sophist knows, when we think that we know the cause on which the fact depends, as the cause of that fact and of no other, and, further, that the fact could not be other than it is.  
(Aristotle, 1941d, p. 111, Bk I, Ch. 1, 71<sup>b</sup>)

Here we see two important ideas. First, not all kinds of knowledge can be considered scientific. And second, scientific knowledge is knowledge of causes. Further, knowledge of causes is not simple, different kinds of causes must be distinguished and all of them must be known in order to have scientific knowledge:

We think we have scientific knowledge when we know the cause, and there are four causes: (1) the definable form, (2) an antecedent which necessitates a consequent, (3) the efficient cause, (4) the final cause.  
(Aristotle, 1941d, p. 170, Bk. II, Ch. 11, 94<sup>a</sup>)

Either explicitly or implicitly, all researchers would probably agree that they are looking for causes of studied phenomena. But disagreements become evident when theory of causality is analyzed—we find not one but many theories of causality. There are different kinds of causality and not all of them are equally taken into account in each particular theory of causality. A list of kinds of causes can be found in Chambers’ *Cyclopaedia* (Chambers, 1728a, 1728b). Under the entry “CAUSE” there is “First Cause” and “Second Cause” and many more. Under the “Causes in the School Philosophy,” there are: (1) Efficient causes; (2) Material causes; (3) Formal causes; (4) Final causes; and (5) Exemplary causes. In the other way, again, “Causes” are distinguished

into physical, natural, and moral. Or yet another way, “Causes” are considered as universal or particular; principal or instrumental; total or partial; univocal or equivocal, etc.

Scientific epistemology is not based only on the theory of causality. Another important distinction is made in terms of the degree of organization that is assumed to characterize the world. In the one end of this dimension it is assumed that there are universal laws and principles that characterize the world; in the other end of this dimension the world is seen as a series of unique events that cannot be explained by universal laws. The distinction between approaches to cultural psychology I made in the beginning of this chapter was made in this dimension. Yet, to understand fully epistemologies that underlie theories of cultural psychology, theories of causality must also be taken into account.

### ***Science Is a Cultural Phenomenon***

Epistemology is theory of knowledge; this theory guides decisions made in scientific activity. Science, would be classified as a cultural phenomenon by most cultural scientists. The concept of culture can be used in different senses—it can refer to hierarchy, where one culture is seen in some ways “better” or more advanced than the other; it can be used as a differential concept to account for the apparent differences between communities of people; and it can be used as a generic concept to refer to (usually human) universals (Bauman, 1999). The following description of the three epistemologies that can be distinguished in cultural science today should not be taken as something independent of cultural psychology—science of culture and culture studied by this science cannot be separated.

If three epistemologies can be distinguished, it follows, that three different cultures can be distinguished in the differential sense of the concept of culture. Furthermore, it turns out that not all epistemologies are equally appropriate for achieving the aim of science—to understand, to achieve scientific knowledge; thus culture in the hierarchical sense is also emerging in the following analysis. Finally, culture in the generic sense of the concept is also applicable to the question of epistemology; human knowledge-seeking without epistemology is not science by definition—existence of epistemology is a universal requirement for any science.

It is one of the most complex tasks of the science of culture to realize that science of culture is simultaneously science of cultural scientist. Without

realizing this important fact, cultural values, beliefs, irrational urges—many aspects of culture that should be extraneous to knowledge-seeking practices—may enter the structure of scientific thought and hinder the construction of scientific knowledge instead of helping to develop it.

### **Three Cultures of Science: Three Epistemologies**

We learn to know the world through observation. Observation is not a simple activity but a rather complex phenomenon that can be distinguished into kinds. I am going to discuss three epistemologies that can be recognized in psychology today. In several important respects similar epistemologies were described already by Hegel. He suggested that observation of the world has developed over several stages. First, *unreflective consciousness*, is characterized as follows:

The process [of observation] really takes place solely in the function of *describing*. The object as it is described has consequently lost interest; when one object is being described another must be taken in hand and ever sought, so as not to put a stop to the process of description. [...] There can never be an end to the material at the disposal of this restlessly active instinct. To find a new genus of distinctive significance, or even to discover a new planet, which although an individual entity yet possesses the nature of a universal, can only fall to the lot of those who are lucky enough. But the boundary line of what, like elephant, oak, gold, is markedly distinctive, the line of demarcation of what is genus and species, passes through many stages into the endless particularization of the chaos of plants and animals, kinds of rocks, or of metals, forms of earth, etc., etc., that only force and craft can bring to light.

(Hegel, 2005a, pp. 284–285)

So, observation can take a form of mere description where no clear boundaries or organization in the observed material can be defined. This form of observation goes on endlessly by extension and particularization.

Observation develops further and begins to look for laws:

Since the instinct of reason now arrives at the point of looking for the characteristic in the light of its true nature—that of essentially passing over into its opposite and not existing apart by itself and for its own sake—it seeks after the *Law* and the notion of

law. It seeks for them, moreover, as existing reality; but this feature of concrete reality will in point of fact disappear before reason, and the aspects of the law will become for it mere moments or abstractions.

(Hegel, 2005a, p. 288)

Laws that are discovered in this process of observation, however, give only a very limited and superficial understanding of the world:

But laws like these: animals belonging to the air are of the nature of birds, those belonging to water have the constitution of fish, animals in northernly latitudes have thick coats of hair, and so on—such laws exhibit a degree of poverty which does not do justice to the manifold variety of organic nature. Besides the fact that the free activity of organic nature can readily divest its forms of determinate characteristics like these, and everywhere presents of necessity exceptions to such laws or rules, as we might call them; the characterization of those very animals to which they do apply is so very superficial that even the necessity of the ‘laws’ can be nothing else but superficial too, and does not carry us further than what is implied in speaking of the ‘great influence’ of environment on the organism. And this does not tell us what properly is due to that influence and what is not.

(Hegel, 2005a, pp. 294–295)

At this stage of the development of observation, thus, universal laws are discovered. But these laws are just superficial descriptions with numerous exceptions and oversimplification of the observed phenomena; there is also no understanding why the observed universal regularities actually emerge.

The world is more complex than can be understood on the basis of observations of the nature and organic phenomena. Full understanding of the world is achieved when reason, the less developed form of mind, becomes spirit. Observation of the external world is that, which is available for reason; when the observer becomes self-conscious, the spirit emerges:

Reason is spirit, when its certainty of being all reality has been raised to the level of truth, and reason is *consciously* aware of itself as its own world, and of the world as itself.

(Hegel, 2005b, p. 457)

Putting purely speculative and philosophical aspects of this idea aside, Hegel’s idea can be interpreted as showing that the most developed form of knowledge is knowledge where the ideas about

observed phenomena of the external world become into unity with understanding oneself, with knowing the ways that the mind works.

The stages of the development of observation are hierarchically related to the understanding of the world. Hegel described several aspects of the world, which are hard or impossible to know by less developed forms of observation. For example, the idea of linear cause-effect relationships does not hold for many phenomena, such as the organic world:

[...] the organic is in point of fact just realized concrete purpose. For since *itself* maintains *itself* in relation to another, it is just that kind of natural existence in which nature reflects itself into the notion, and the moments of necessity separated out [by Understanding]—a cause and an effect, an active and a passive—are here brought together and combined into a single unity.

(Hegel, 2005a, p. 296)

Another aspect of the world that cannot be understood with less developed forms of observation is the relation of parts to whole. It cannot be understood that distinguishable parts have meaning only in the context of a whole, a whole that emerges in the process of relating parts:

In the systems constituting an embodied form (*Gestalt*) the organism is apprehended from the abstract side of lifeless physical existence; so taken, its moments are elements of a corpse and fall to be dealt with by anatomy; they do not appertain to knowledge and to the living organism. *Qua* parts of that sort they have really ceased to *be*, for they cease to be processes. [...] The actual expression of the whole, and the externalization of its moments, are really found only as a process and a movement, running throughout the various parts of the embodied organism [...] So that reality which anatomy finds cannot be taken for its real being, but only that reality as a process, a process in which alone even the anatomical parts have a significance.

(Hegel, 2005a, pp. 309–310)

Altogether, the idea that different epistemologies can be found in human knowledge seeking, is not new. It can be suggested that different epistemologies are just different but equally acceptable; Hegel’s ideas suggest, however, that some epistemologies may ground deeper and more comprehensive understanding of the world than others. This suggestion can be further supported by observation that the three kinds of observation distinguished by

Hegel, correspond well to the development of word meaning structure—the psychological construct that underlies the cultural development of both individuals and human societies (Vygotsky, 1960; Vygotsky & Luria, 1994; Vygotsky & Luria, 1930). Particularly, throughout history the scientific thinking has developed from thinking in so-called everyday concepts to scientific concepts and from there to systemic concepts (Toomela, 2010c). This line of development is hierarchical—later stages allow not only to possess more knowledge but also to know qualitatively novel aspects of the world, aspects that are not available for thinking with less developed conceptual structures (*see also* Toomela, 2003a, 2003b). Therefore it becomes essential to analyze epistemologies that ground different approaches in psychology because some of them may turn out to be scientifically not sufficiently justified.

It is possible to distinguish three epistemologies that have grounded research in psychology in general (Toomela, 2009, 2010e) and therefore in cultural psychology in particular as well. Each of the epistemologies is rooted in a different philosophical tradition. There is *process-oriented epistemology*, closely related to Heraclitian thought; *Cartesian-Humean cause-effect epistemology*; and *structural-systemic epistemology*, which is connected to the philosophy of Aristotle. Next I will outline the basic principles of each of them. First Aristotelian structural-systemic epistemology is described as most sophisticated. The other two—Cartesian-Humean and Heraclitian—turn out to be fundamentally limited versions of it.

I am going to give brief description of each of the epistemologies according to six aspects. First, I describe theories of causality that underlie each of the epistemologies. Second, epistemologies differ in the ways that processes are understood in principle; views on the idea of process, dynamics, change, and becoming are described. Third, degree of universalism that is assumed to characterize the world by each of the epistemologies is provided. Fourth, both the particular theory of causality as well as assumptions about the degree of organization of the world are related to beliefs about whether the world is in principle knowable in all of its aspects or not. Fifth, I connect the philosophical roots of the epistemologies to their realizations in cultural psychology today. And finally, epistemologies are described in terms of methodology—each of the epistemologies grounds a different view on how, in principle, the world should be studied in order to know it.

## ***Aristotelian Structural-Systemic Epistemology***

### **THEORY OF CAUSALITY**

Aristotle distinguished four causes—today they are known as *material*, *formal*, *efficient*, and *final cause*, respectively—that all should be known in order to possess scientific knowledge:

In one sense, then, (1) that out of which a thing comes to be and which persists, is called ‘cause’, e.g. the bronze of the statue, the silver of the bowl, and the genera of which the bronze and the silver are species.

In another sense (2) the form or the archetype, i.e. the statement of the essence, and its genera, are called ‘causes’ (e.g., of the octave the relation of 2: 1, and generally number), and the parts in the definition.

Again (3) the primary source of the change or coming to rest; e.g., the man who gave advice is a cause, the father is cause of the child, and generally what makes of what is made and what causes change of what is changed.

Again (4) in the sense of end or ‘that for the sake of which’ a thing is done, e.g., health is the cause of walking about. (‘Why is he walking about?’ we say. ‘To be healthy’ and, having said that, we think we have assigned the cause).

[...] This then perhaps exhausts the number of ways in which the term ‘cause’ is used.

(Aristotle, 1941c, pp. 240–241, Bk. II, 194<sup>b</sup>)

I am going to show later that Aristotelian view on causality is remarkably similar to modern system theories. The following quote links his views to the modern ones more directly:

All the causes now mentioned fall under four senses [...] some are cause as the substratum (e.g., *the parts*), others as the essence (*the whole*, *the synthesis*, and the form). The semen, the physician, the adviser, and in general the agent, are all sources of change or of rest. The remainder are causes as the end [...]

(Aristotle, 1941a, p. 753, Bk. V, 1013<sup>b</sup>, emphasis added)

So, material cause is not just material, it is *parts*, formal cause is not just some form, it is *whole* and *synthesis*. Therefore we can suggest: description of causality involves the concept of a whole that is composed of parts in specific relationships (*synthesis*). This is a definition of the system: “A system can be defined as a set of elements standing in interrelations.” (von Bertalanffy, 1968, p. 55).

## VIEWS ON PROCESS

The idea of structure is often viewed as static; it is suggested, for example, that structural theories cannot explain developmental change (Smith & Thelen, 1993). In fact, static or a developmental perspective may characterize some modern scientific approaches, but structural view according to which parts can be distinguished in a whole, was dynamic in Aristotelian philosophy. Understanding that not only some aspects of the world, but the whole nature is dynamic in its essence pervaded all his thought:

From what has been said, then, it is plain that nature in the primary and strict sense is the essence of things which have in themselves, as such, a source of movement; for the matter is called the nature because it is qualified to receive this, and process of becoming and growing are called nature because they are movements proceeding from this. And nature in this sense is the source of the movement of natural objects, being present in them somehow, either potentially or in complete reality.  
(Aristotle, 1941a, p. 756, Bk. V, 1015<sup>a</sup>)

The idea of dynamics, change, becoming, was directly related to the four causes he distinguished:

[...] all causes are beginnings. [...] 'Cause' means (1) that from which, as immanent material, a thing comes into being, [...] (2) The form or pattern, i.e., the definition of the essence [...] (3) That from which the change or the resting from change first begins; [...] (4) The end, i.e., that for the sake of which a thing is; e.g., health is the cause of walking.  
(Aristotle, 1941a, p. 752, Bk. V, 1013<sup>a</sup>)

## DEGREE OF UNIVERSALISM OF THE WORLD

Aristotle assumed that limited number of laws determined the processes in the world:

It is clear then that our principles must be contraries. The next question is whether the principles are two or three or more in number. One they cannot be, for there cannot be one contrary. Nor can they be innumerable, because, if so, Being will not be knowable [...]  
(Aristotle, 1941c, p. 228, Bk. I, 189<sup>a</sup>)

So, the number of laws or principles that characterize nature cannot be one but also not infinitely many; the latter point he made clearer in this way:

But if the *kinds* of causes had been infinite in number, then also knowledge would have been

impossible; for we think we know, only when we have ascertained causes, but that which is infinite by addition cannot be gone through in a finite time.  
(Aristotle, 1941a, p. 715, Bk. II, 994<sup>b</sup>)

Thus, only one principle is not sufficient to explain the world that is more complex; but the number of principles cannot also be too large because in that case knowledge becomes impossible. Yet, it does not follow that Aristotle ignored the idea of uniqueness:

The universal is more knowable in the order of explanation, the particular in the order of sense: for explanation has to do with the universal, sense with the particular.  
(Aristotle, 1941c, p. 228, Bk. I, 189<sup>a</sup>)

He essentially suggested that unique is not explained—unique does not belong to scientific knowledge but rather to the world of senses. This idea fits well with Hegel's distinction of different kinds of observation, provided above: description of the sense-world has no limits, the number of different descriptions can be extended endlessly whereas the world for the more developed observation is that, which is explained with the help of universal laws and principles.

There is one important idea more in Aristotle's views on universality. According to him, the world of constant change characterizes foremost the world available for senses; the world beyond senses, however, has also stable characteristics. When criticizing the views of Heraclitus and his followers, especially Cratylus, who assumed that the world is characterized by constant change only, he suggested:

And again, it would be fair to criticize those who hold this view for asserting about the whole material universe what they saw only in a minority even of sensible things. For only that region of the sensible world which immediately surrounds us is always in the process of destruction and generation; but this is—so to speak—not even a fraction of the whole, so that it would have been juster to acquit this part of the world because of the other part, than to condemn the other because of this.  
(Aristotle, 1941a, p. 746, Bk. IV, 1010<sup>a</sup>)

It can be conjectured from the last quote that the superficial description of the sense-world that immediately surrounds us is not an appropriate way for gaining scientific knowledge, knowledge of universal principles—these principles characterize

especially the world beyond appearances. This idea leads us to the next issue—Aristotle’s views on whether the world can be known in principle.

#### KNOWABILITY

Indeed, we know the world through senses; if senses are deceptive, then perhaps scientific knowledge is not possible? Aristotle knew that the world of senses can be deceptive:

Regarding the nature of truth, we must maintain that not everything which appears is true; firstly, because even if sensation—at least of the object peculiar to the sense in question—is not false, still appearance is not the same as sensation.

(Aristotle, 1941a, p. 746, Bk. IV, 1010<sup>a</sup>)

Yet, at the same time he assumed that the principles of the world—universals that, according to himself, characterize especially the world beyond senses—can be known. There is no contradiction in Aristotle’s thinking; he did suggest the way how scientific knowledge can be obtained—this knowledge emerges when understanding of the sense-world is built not directly and only on the basis of what was perceived. Rather, as I also mentioned above, scientific knowledge emerges when a scientist coordinates knowledge about the observed world with knowledge about his or her own thinking; I bring the relevant quote again here:

The knowledge of the soul admittedly contributes greatly to the advance of truth in general, and, above all, to our understanding of Nature, for the soul is in some sense the principle of the animal life.

(Aristotle, 1941b, p. 535, Bk. I, 402<sup>a</sup>)

#### MODERN VIEW

Aristotelian epistemology in its exact form is not followed in sciences today. Yet there is one group of approaches to sciences that share basic principles that Aristotle proposed. This group of approaches shares the view that understanding means description of the structure or system of the phenomenon under study. In psychology, structural view was common before World War II; it can be traced back to the beginnings of scientific psychology in the nineteenth century. Wundt, for example, suggested that attributes of psychical causality can be discovered by studying Psychological Elements, Psychological Compounds, Interconnections of Psychological Compounds, and Psychological Developments. Only on the basis of knowledge from studying the mentioned aspects of

mind, Psychological Causality and its laws can be formulated: “There is only *one* kind of causal explanation in psychology, and that is the derivation of more complex psychical processes from simpler ones.” (Wundt, 1897, p. 24).

Vygotsky, founder of the cultural-historical psychology, explicitly followed a similar approach to the study of culture and mind. According to him, in order to understand mental phenomena, it is necessary to describe: (1) The components they are made of; (2) the specific relationships between the components that comprise a whole or structure of the phenomenon; and (3) development, how the phenomenon emerges and changes in time (Vygotsky, 1994). With, perhaps, less emphasis on development than Vygotsky had, such structural understanding was shared by many scholars of that time (see for these views, e.g., Koffka, 1935; Köhler, 1959; Ladd, 1894; Titchener, 1898, 1899; Werner, 1948; Wertheimer, 1925). Later, the structural view was synthesized into so-called *systems view*, which shared with the structural view the idea that phenomena can be understood as systems (von Bertalanffy, 1968). These more recent views, however, rely excessively on mathematical analyses of variables instead of qualitative analyses of the structure of the studied phenomena *per se*. Recent developments in quantitative systems theories, by relying on quantitative methods of data interpretation, in principle rule out the possibility for understanding the qualitative nature of structures and therefore are by themselves essentially nonstructural (cf. Michell, 2010; Toomela, 2008c, 2009).

Theories in modern physics, chemistry, and biology are very often structural. All the chemical formulas describe structures—wholes composed from distinguishable elements or parts; biological theories of a gene and of a synapse are examples of structural theories as well. Thinking in modern medicine is structural-systemic also (Toomela, 2005). Altogether, structural-systemic understanding of the world is common; it was also common in psychology but, after World War II, structural-systemic worldview was replaced with another epistemology for no scientific reason (Toomela, 2007, 2008b; Toomela & Valsiner, 2010).

#### METHODOLOGY

Three central characteristics of the methodology of science based on structural-systemic epistemology can be identified. First, scholars of this kind of science—and in accordance with Aristotelian

epistemology—explicitly base their scientific activity into the philosophical-theoretical context of scientific thinking. Vygotsky, for example, relied heavily on the ideas of Hegel, Engels, Marx, and Spinoza. Doing this, he did not accept blindly the philosophical ideas proposed by others but rather developed them in accordance with the aims of science and its methodology (Mahn, 2010). It can be said that all eminent thinkers in psychology of the beginning of the twentieth century were not only educated in philosophy but took philosophical ideas critically, becoming philosophers of science by themselves (Gillespie & Zittoun, 2010; Lamiell, 2010; Michell, 2010).

Vygotsky (1982) distinguished method of studies—the “technology” of experiment—from the methodology; method of cognition that determines the aim of a study, the place of a science and its nature. Both methods and methodology were explicitly developed by the structural-systemic scholars. Their methodology was based on the assumptions that the world is characterized by universal principles and that these principles are not directly observable but are knowable through scientific studies.

Second, methods of the structural-systemic science are qualitative. These methods, again in accordance with Aristotelian epistemology, differ substantially from the modern qualitative approaches to psychology and social sciences. The main difference lies in the understanding that mere observation allows description but not scientific knowledge in Aristotle’s sense of the concept. Scientific method must include experiments, artificial constraints on study situations purposefully introduced by researchers (Toomela, 2008b, 2009, 2010b, 2010e).

And third, structural-systemic epistemology directs scientific studies to identify parts of the whole, the specific relationships in which the parts are, and the process of the emergence of the whole from parts. Consequently the methods of this kind of science are constructive—there are two complementary ways to establish what the elements are. First, the hypothetical elements are put together in theoretically predicted relationships to see whether the expected whole emerges. Second, it is observed whether the whole changes in a theoretically predicted way when a specific part of it is removed or a relationship between parts is destroyed. This method is essentially experimental, but experiment aimed explicitly at identifying parts, relationships between parts, and properties of the whole that

emerge in the synthesis of parts. Such methods were extensively used in cultural and neuropsychological studies by Luria (cf. Luria, 1969, 1974; Luria & Yudovich, 1956).

### ***Cartesian-Humean Cause-Effect Epistemology***

Descartes and Hume understood causality in the same way—both of them agreed that the world beyond senses—appearances—is not knowable in principle and therefore the only kind of cause that can be known is that of the efficient cause.

#### **THEORY OF CAUSALITY**

Descartes’ understanding of causality is not entirely different, but is a fundamentally limited version of Aristotelian thought. According to Descartes, there are only efficient causes in the world. As he rejected the possibility for other causes, his understanding of the efficient cause was also different from Aristotelian:

I call ‘absolute’ whatever has within it the pure and simple nature in question; that is, whatever is viewed as being independent, a cause, simple, universal, single, equal, similar, straight, and other qualities of that sort. [...] The ‘relative,’ on the other hand, is what shares the same nature, or at least something of the same nature, in virtue of which we can relate it to the absolute and deduce it from the absolute in a definite series of steps. The concept of the ‘relative’ involves other terms besides, which I call ‘relations’: these include whatever is said to be dependent, an effect, composite, particular, many, unequal, dissimilar, oblique, etc. [...].

(Descartes, 1985d, p. 21)

So, *cause* is: independent, simple, universal, single, equal, similar, straight, etc. *Effect*, in turn, is: relative, dependent, composite, particular, many, unequal, dissimilar, oblique, etc. This description also gives us the idea about how the causes and effects are related: effects can be deduced from causes in a series of steps. The cause-effect relationship, therefore, is linear, no reciprocity is possible here.

A slightly different approach to causality, even though similar to Cartesian in looking for efficient causality only, was taken by Hume. According to him,

Similar objects are always conjoined with similar. Of this we have experience. Suitably to this experience, therefore, we may define a cause to be *an object*,

*followed by another, and where all the objects, similar to the first, are followed by objects similar to the second. Or in other words, where, if the first object had not been, the second never had existed.*

(Hume, 2000, pp. 145–146)

Altogether, this epistemology proposes that only efficient causes characterize the knowable world.

#### VIEWS ON PROCESS

Epistemology according to which there is only one kind of causality, that of the efficient cause, is also constrained in conceptualizing processes: process can be only the series of effects that follow from causes. According to Aristotelian view, all kinds of causes are beginnings, processes, and therefore different kinds of processes can be identified and studied in the structural-systemic epistemology. In cause-effect epistemology, there can be no explanation of emergence of new forms besides just the mere statement that the cause of the emergence of an effect was ... the cause. Descartes explicitly rejected Aristotelian views on becoming and change (cf. Descartes, 1985d). For Descartes, causes contained everything that was observed in the effects:

Now it is manifest by the natural light that there must be at least as much <reality> in the efficient and total cause as in the effect of that cause. For where, I ask, could the effect get its reality from, if not from the cause? And how could the cause give it to the effect unless it possessed it? It follows from this both that something cannot arise from nothing, and also that what is more perfect—that is, contains in itself more reality—cannot arise from what is less perfect. (Descartes, 1985b, p. 28)

As causes are more perfect than effects, effects contain nothing that is not already in their cause. Such a view leads to static understanding of the world. As causes possess everything that is observed in the effect, no novelty actually emerges in cause-effect relationships. There is, thus, no true becoming and change, only less perfect effects follow from more perfect causes. Also theories become very simple in this epistemology: if processes are just about cause-effect relationships, then theory becomes complete when the causes of effects are identified.

#### DEGREE OF UNIVERSALISM OF THE WORLD

In cause-effect epistemology, world is covered by universal principles. There are fewer laws than

events in the world because one cause can give many effects:

Besides, we find in the course of nature, that tho' the effects be many, the principles, from which they arise, are commonly but few and simple, and that 'tis the sign of an unskilful naturalist to have recourse to a different quality, in order to explain every different operation.

(Hume, 2000, p. 185)

Descartes, in fact, went even further by declaring that there is only one true cause:

First I tried to discover in general the principles or first causes of everything that exists or can exist in the world. To this end I considered nothing but God alone, who created the world

(Descartes, 1985a, pp. 143–144)

Thus, Cartesian-Humean cause-effect science assumes that world is organized according to general principles that are at the same time causes.

#### KNOWABILITY

In everyday life, we constantly take into account all four kinds of causes distinguished by Aristotle. We would not try to construct a bicycle from potatoes or make bread from stones. Such examples look almost ridiculous, but cause-effect epistemology in fact rejects knowledge of material causes—parts from which wholes are built. So, why did two brilliant philosophers reject all causes but efficient? Generally, the reason was the same—both of them assumed that knowledge about the world beyond appearances is not available for humans in principle. The justifications, though, were different.

Descartes suggested that world beyond appearances cannot be known:

However, although this method may enable us to understand how all the things in nature could have arisen, it should not therefore be inferred that they were in fact made in this way. Just as the same craftsman could make two clocks which tell the time equally well and look completely alike from the outside but have completely different assemblies of wheels inside, so the supreme craftsman of the real world could have produced all that we see in several different ways.

(Descartes, 1985c, p. 289)

This passage gives also a hint as to why Descartes accepted only efficient causality. He suggested that

all efficient causes eventually converge to one—God. God, according to him, is:

[...] infinite, eternal, immutable, omniscient, omnipotent [...] all the perfections which I could observe to be in God.

(*Descartes*, 1985a, p. 128)

If God is omnipotent then it follows logically that only efficient cause can ground epistemology; all other kinds of causes are essentially constraints on what can happen. The idea of material cause suggests that not everything can be built from a given material. Formal cause is similarly a constraint—the whole is what it is because of the parts it contains; it would be another whole if the parts were changed. Final cause, also, constrains possibilities of existence; final cause, according to Aristotle, is closely related to development, emergence of new forms—there are things that have in themselves the source of movement to become a new form; this is the nature of such things, final cause that directs the processes of emergence (cf. Aristotle, 1941a). But if God is omnipotent, there can be no constraints on his will. Therefore no cause that is essentially a constraint can exist; God has no constraints.

Hume also suggested that the world beyond appearances is not knowable:

It must certainly be allowed, that nature has kept us at a great distance from all her secrets, and has afforded us only the knowledge of a few superficial qualities of objects; while she conceals from us those powers and principles, on which the influence of these objects entirely depends. [...] there is no known connexion between the sensible qualities and the secret powers. [...] the course of nature may change, and that an object, seemingly like those which we have experienced, may be attended with different or contrary effects.

(*Hume*, 1999, excerpts from pp. 113–115)

Logically, if only appearances can be known, it is not possible to know that which underlies them—the bread may look the same for us and yet may be composed from other parts (no material cause, thus, can be known); appearances can suddenly become into unexpected relationships, therefore also no final cause that should give certain unidirectionality to the series of events, can be known; also, the form itself may look one way to us but be essentially something different—no formal cause can be known as well.

But why is the world beyond appearances not knowable? It is not because there is God whose deeds cannot be understood by imperfect humans, as Descartes assumed; rather, limited knowability results logically from Hume's psychology. Hume thought that humans' thinking is based only on emergence of associations between observed events:

[...] principles of association [...] To me, there appear to be only three principles of connexion among ideas, namely, *Resemblance*, *Contiguity* in time or place, and *Cause or Effect*. [...] But the most usual species of connexion among the different events, which enter into any narrative composition, is that of cause and effect;

(*Hume*, 1999, pp. 101–103)

So, the only operation available for mind is to form associations between observed events as they appear to us. If this is the case then, indeed, other kinds of causes cannot be discovered because externally similar events may be based on different structures (i.e., on different material, formal, and final causes) and there is no way to distinguish internally different causes on the basis of associative thinking alone.

#### MODERN VIEWS

Aristotelian epistemology has developed into different structural-systemic epistemologies of today. Cartesian-Humean cause-effect epistemology— that can also be found in science today, especially in psychology and social sciences (Toomela, 2009)—has not changed considerably. Indeed, there is very little that can be different. If the basic idea is that causality means only efficient causality, then all the science has nothing else to do but to identify possible causes of possible effects, or just observe associations between events and call discovered associations that emerge more often than by chance, theories.

So in psychology today we learn that certain differences in aggressiveness can be caused by sex or gender; differences in human behavioral patterns are caused by differences in five factors of personality; success at work is caused by high intelligence; individualism, collectivism, masculinity or power distance is caused by culture, etc. Psychology has discovered thousands of such causal relationships; in all such cases the theoretical "explanation" for effects is that there exists a cause that was discovered by scientists. This is exactly what Humean science is doing:

'Tis evident, that all reasonings from causes or effects terminate in conclusions, concerning matter

of fact; that is, concerning the existence of objects or of their qualities.

(Hume, 2000, p. 65)

## METHODOLOGY

Cause-effect science is based on a coherent philosophical worldview. Yet, differently from the systemic-structural approach, in this worldview the epistemology is usually not discussed. This is a consequence of the worldview itself—for scientific knowledge it is sufficient to identify the causes, there is nothing more to discuss. So even if connection of the cause-effect science to its philosophical roots would be recognized, there is no urge to discuss other views or to question the epistemological ground of itself. This ground is just accepted.

In terms of methods, Cartesian-Humean science relies on quantitative procedures in the first place. This choice of methods can be directly connected to a Humean train of ideas:

‘Tis by habit we make the transition from cause to effect; and ‘tis from some present impression we borrow that vivacity, which we diffuse over the correlative idea. But when we have not observed a sufficient number of instances, to produce a strong habit; or when these instances are contrary to each other; or when the resemblance is not exact; or the present impression is faint and obscure; or the experience in some measure obliterated from the memory; or the connexion dependent on a long chain of objects; or the inference derived from general rules, and yet not conformable to them: In all these cases the evidence diminishes by the diminution of the force and intenseness of the idea. This therefore is the nature of the judgment and probability.

(Hume, 2000, p. 105)

Without knowing anything else but associations between events—on the basis of which efficient causality is discovered—then the only way to discover these causal relations is just to observe associations between events; the more there are observations, the better. It will also not be a problem if no perfect one-to-one correspondence can be found between causes and effects; any “statistically reliable” result is acceptable, the rest is just “measurement error”—error that can be attributed to kinds of causes that are not knowable for humans in principle.

Cause-effect science aims at discovering causes of effects. Experiments are used in this science occasionally for distinguishing between different

candidates for causes. This experimentalism, thus, is fundamentally different from structural-systemic constructive experiment; it is not the emergence or disappearance of the structure that is observed when hypothetical parts or their relationships are experimentally manipulated; cause-effect science experiment aims at establishing association between two events in a situation where, ideally, the supposed cause-event alone is manipulated.

## *Heraclitian Process-Oriented Epistemology*

Two epistemologies out of three that correspond to kinds of observation distinguished by Hegel have been described so far—structural-systemic self-reflective epistemology and cause-effect epistemology that aims at finding the laws, relationships between causes and effects. Hegel also distinguished simple and superficial description as a kind of observation. There is epistemology that corresponds to this kind of observation; I call it *process-oriented*. Philosophical roots of this epistemology can be traced back to Heraclitian philosophy. Even though only fragments from Heraclitus’ works have survived until today, these fragments together reveal quite a coherent worldview (Kirk, Raven, & Schofield, 2007). The fragments are hard to interpret for their original obscurity; the situation is further complicated by difficulties of translation of those fragments from Greek to English. In the following presentation I am going to use translations from different sources; the available more recent translations from Kirk, Raven, and Schofield (2007), and if not available there, from Freeman (1948). Diels-Kranz (DK) numbers are used to refer to relevant fragments.

## THEORY OF CAUSALITY

Heraclitus did not have theory of causality in the same sense that the later philosophers did—as much as can be decided on the basis of survived fragments, and also on the basis of Aristotle’s works, who summarized views on causality expressed before him. Yet, events in the world are related one to another. The world, according to Heraclitus, is constantly changing; this change is not completely random but follows certain basic principles. One form of the matter changes into another in a lawful way:

Fire lives the death of earth, and air lives the death of fire, water lives the death of air, earth that of water.

(Freeman, 1948, p. 30, DK22b76; see also fragments 31, 36, 90)

This process of change has three characteristics worthy of attention. First, there are no clear boundaries in the change of forms; opposites are related into continuous unity:

Things taken together are wholes and not wholes, something which is brought together and brought apart, which is in tune and out of tune; out of all things there comes a unity, and out of a unity all things.

(Kirk et al., 2007, p. 190, DK22b10)

And what is in us is the same thing: living and dead, awake and sleeping, as well as young and old; for the latter (*of each pair of opposites*) having changed becomes the former, and this again having changed becomes the latter.

(Freeman, 1948, p. 30, DK22b88, *see also* 62, 126)

Second, from the opposites in their unity, novel forms may emerge:

That which is in opposition is in concert, and from things that differ comes the most beautiful harmony.

(Freeman, 1948, p. 25, DK22b8, *see also* 51)

And third, the world is characterized by relativity—the same thing can have different meanings from different perspectives:

Sea is the most pure and the most polluted water; for fishes it is drinkable and salutary, but for men it is undrinkable and deleterious.

(Kirk et al., 2007, p. 188, DK22b61, *see also* 9, 13, 37, 60)

Taken together, in Heraclitian worldview, the world is characterized by constant change in boundary-less—and therefore continuous—unity. In this unity of the world some things may continuously change into their opposites; in other cases opposites may form a harmonious unity; and sometimes the same is not the same, but different depending on the perspective—things are relative. Causality in this view, thus, should be characterized by multiple determinations of events because there are different sources of possible changes.

#### VIEWS ON PROCESS

Heraclitus is best known today for his emphasis on the processes of change in the universe:

Upon those that step into the same rivers different and different waters flow ... They scatter and ... gather ... come together and flow away ... approach and depart.

(Kirk et al., 2007, p. 195, DK22b12 and 91, *see also* 6, 49a)

The more common (Platonic, expanded by Aristotle and others) interpretation of Heraclitian thought would suggest that Heraclitus emphasizes the absolute continuity of change in everything. Yet this interpretation does not take into account that Heraclitus did not completely reject the idea of universal principles; on the contrary, he repeatedly emphasized the universal principle, *Logos*, which underlies continuous and constant change in the world (*see also* next subsection). Perhaps the more correct interpretation of the Heraclitian view on change is that the world as a whole might follow the universal principle, be stable as such and yet, its constituent parts are changing forever (Kirk et al., 2007).

#### DEGREE OF UNIVERSALISM OF THE WORLD

According to Heraclitus, there is *universal principle*—*Logos*—that underlies changes in the world:

Listening not to me but to the *Logos* it is wise to agree that all things are one.

(Kirk et al., 2007, p. 187, DK22b50; *see also* 1, 2, 72, 114)

This universal principle seems to be related to fire, the archetypal form of matter:

Thunderbolt steers all things

(Kirk et al., 2007, p. 198, DK22b64; *see also* 30)

It is noteworthy that this universal principle, fire, is a form of matter that is in constant change. Change, thus, can be understood as universal principle.

Even though Heraclitus himself did not reject the idea of universal principle(s), his approach inevitably must lead to focusing on the individual, unique events in the world—despite his own words that called to follow the principles, the *Logos*. Followers of Heraclitus thought today may have not noticed at all his call to listening to the *Logos*, because Heraclitian thought was distorted already millennia ago—by Stoics and Sophists, especially Cratylus, whose thought has influenced Plato's and Aristotle's interpretation of Heraclitian philosophy (Kirk et al., 2007). Heraclitus, thus, is largely known today through the secondary sources where his views were distorted by overemphasizing his ideas about processes of change and by ignoring his understanding of universal principles that underlie the change. This could be the way how process-oriented epistemology found its roots in Heraclitian philosophy.

If one looks deeper into Heraclitus' philosophy, however, it can be seen that emphasis on change in

Heraclitus' philosophy actually is justified because this philosophy is fundamentally contradictory. There are five ideas in Heraclitus' thought that, together, must lead to overemphasis of change and underemphasis of Logos. First, as was discussed above, Heraclitus suggested repeatedly that the world is constantly changing and every moment is different from the previous—one cannot step twice into the same river. The universal Logos can be behind the entire world; but we live in the immediate world of constant change, where Logos is not obvious:

The real constitution [a thing's true constitution] is accustomed to hide itself.

(Kirk et al., 2007, p. 192, DK22b123)

If Logos is not obvious, it follows, second, that Logos must be hard to understand. Indeed, according to Heraclitus, it is hard to understand and accept universal principles; only an educated soul can get closer to it:

Evil witnesses are eyes and ears for men, if they have souls that do not understand their language.

(Kirk et al., 2007, p. 188, DK22b107, *see also* 1, 2, 17)

So, the majority of people cannot understand Logos; this understanding is not available to those with barbarian souls, souls that are not able to understand the language of senses.

So far, there is no contradiction yet—Logos is hard to understand, but not impossible. The following ideas, however, suggest that there is actually no way to know the Logos. The third reason for overemphasizing the change is that in the everyday world that surrounds us, there are no observable universal sources for different changes. There is the relevant fragment:

The wise is one thing, to be acquainted with true judgment, how all things are steered through all.

(Kirk et al., 2007, p. 202, DK22b41)

On the one hand, this fragment suggests that wisdom consists of understanding the Logos, the universal principle that underlies the change (*see* Kirk et al., 2007, for this interpretation). On the other hand, however, this fragment suggests that “all things are steered through all”—it can be conjectured that at least in our immediate world that surrounds us, everything can be related to everything. If so, then the universal principles cannot be discovered by observation of this immediate world because universal can be discovered only when some

things are *not* related. If every relationship is possible, there is no principle that could be discovered immediately around us. Heraclitus seems to support this interpretation by saying that even though the universal principle is operating everywhere, humans see the particulars:

God is day-night, winter-summer, war-peace, satiety-famine. But he changes like (fire) which when it mingles with the smoke of incense, is named according to each man's pleasure.

(Freeman, 1948, p. 29, DK22b67, *see also* 72)

Fourth, Heraclitus seems also to suggest that world, indeed, is not predictable; what happens every moment is not guided by universal principles but rather is like a child's play:

Time is a child playing a game of draughts; the kingship is in the hands of a child.

(Freeman, 1948, p. 28, DK22b52)

These two ideas—that everything is related to everything and that local changes in the world around us are not predictable—show that there is actually no way to know universals on the basis of observing the world around us. Heraclitus suggested—somehow consistently in his inconsistency—fifth, that the world is not fully knowable to humans (this issue is discussed in some more details in the next section).

Altogether, there is irresolvable contradiction in Heraclitian philosophy. On the one hand, there is universal principle, or principles, that underlie changes in the world. On the other hand, however, humans can perceive appearances and changes of appearances. From observation of the constantly and continuously changing unpredictable world with no clear boundaries—the world where everything is related to everything—it is not possible to conjecture these universal principles. It turns out that overemphasis of continuous and constant change in Heraclitian philosophy is not necessarily a distortion at all.

#### KNOWABILITY

Contrary to Aristotle and similarly with Hume and Descartes, Heraclitus suggested that the world is not fully knowable for humans; full understanding is accessible only for gods:

Human nature has no power of understanding; but the divine nature has it.

(Freeman, 1948, p. 30, DK22b78, *see also* 79, 83, 102)

It is not only the world around us that is not fully knowable; we are also not able to understand our own souls:

You would not find out the boundaries of soul, even by travelling along every path: so deep a measure does it have.

(Kirk et al., 2007, p. 203, DK22b45)

Knowledge should go beyond appearances:

The hidden harmony is stronger (*or*, ‘better’) than the visible.

(Freeman, 1948, p. 28, DK22b54)

but it is knowledge of appearances that we know and value:

The things of which there is seeing and hearing and perception, these do I prefer.

(Kirk et al., 2007, p. 188, DK22b55)

At the same time, however, appearances are deceptive:

Men are deceived over the recognition of visible things . . .

(Freeman, 1948, p. 28, DK22b56, *see also* 123)

Altogether, Heraclitian philosophy turns out to be internally contradictory again. Yet, the overall message that emerges is that the world beyond appearances cannot be understood by humans; there is hidden harmony in things, but it is not accessible for us mortals.

If the principles turn out to be hard to discover, or in fact impossible, as was discussed in the previous section, then what kind of knowledge is left over for humans? According to Hegel’s account of descriptive stage, discussed above, unreflective consciousness only describes appearances, this description continues endlessly because no universal conclusions emerge in this process. According to Heraclitus, knowing one’s own soul is not possible; therefore the “consciousness” is unreflective indeed. The only thing that can be done is to observe, to know many things:

Men who love wisdom must be inquirers into very many things

(Freeman, 1948, p. 27, DK22b35)

There is, however, no accumulation of knowledge; we can know many things and yet no true understanding—or very little—emerges from all this:

Much learning does not teach one to have intelligence . . .

(Freeman, 1948, p. 27, DK22b40)

Those who seek gold dig much earth and find little.

(Freeman, 1948, p. 26, DK22b22)

## MODERN VIEW

Heraclitian process-oriented worldview is very close, sometimes even looks identical, to epistemology that grounds modern qualitative approaches to research. It is important to mention here, that the following description applies to *modern* qualitative science, to the approach that emerged around the 1960s; there is another kind of qualitative approach—that which is used in structural-systemic science. This qualitative approach was common in psychology and social science in the beginning of the twentieth century. First the earlier qualitative approach was abandoned in North America; it survived in continental Europe until World War II and disappeared after that (Toomela, 2007; Toomela & Valsiner, 2010). Today the structural-systemic qualitative research has disappeared from mainstream psychology and other social sciences.

There are several characteristics that should characterize science grounded in Heraclitian epistemology. First, as no principles can really be discovered in observing the world, the process-oriented science must have loose identity and no clear methodological direction—there is just no way to demonstrate that one approach may be more appropriate for the aims of science than the other. This is the case with the modern qualitative approach—which actually is a loose collection of practically unrelated approaches:

The open-ended nature of the qualitative research project leads to a perpetual resistance against attempts to impose a single, umbrellalike paradigm over the entire project. There are multiple interpretive projects [ . . . ]

(Denzin & Lincoln, 2005b, p. xv)

The researcher as *bricoleur*-theorist works between and within competing and overlapping perspectives and paradigms. [ . . . ] As a site of discussion, or discourse, qualitative research is difficult to define clearly. It has no theory or paradigm that is distinctly its own.

(Denzin & Lincoln, 2005a, p. 6)

It follows logically, second, that without rational ground for choosing between ways of knowing the world, the science should become just an increasing collection of almost unrelated pieces; modern

qualitative science—using the words of the scholars in this tradition—is just a big mess indeed:

We are in a new age where messy, uncertain, multivoiced texts, cultural criticism, and new experimental works will become more common [...]  
(*Denzin & Lincoln*, 2005a, p. 26)

Next, Heraclitus suggested that the world of appearances—the only world available for us—is deceptive. This idea should lead to understanding that descriptions of the world can be interpreted in many different ways, it could even be suggested that descriptions are just constructions; perhaps descriptions are not really descriptions of the world but every description creates the world? Yes, indeed:

We have left the world of naive realism, knowing now that a text does not mirror the world, it creates the world. Further, there is no external world or final arbiter—lived experience, for example—against which a text can be judged.

(*Denzin & Lincoln*, 2005b, p. xiv; see also *Corbin & Strauss*, 2008; *Flick, von Kardoff, & Steinke*, 2004a, for similar ideas)

Fourth, such science should aim at describing particulars, individuals—because there are no universals and principles to look for. Science grounded in Heraclitian epistemology must be descriptive in the Hegelian sense; and it is:

Critical realists reject a correspondence theory of truth. They believe that reality is arranged in levels and that scientific work must go beyond statements of regularity to analysis of the mechanisms, processes, and structures that account for the patterns that are observed.

Still, as postempirists, antifoundational, critical theorists, we reject much of what the critical realists advocate.

(*Denzin & Lincoln*, 2005a, p. 13)

and:

Qualitative researchers, on the other hand, are committed to an emic, idiographic, case-based position that directs attention to the specifics of particular cases.

(*Denzin & Lincoln*, 2005a, p. 12)

Fifth, not only the way of scientific activity, but also the results of studies must be constantly questioned; in a boundaryless, continuously changing world there is no criterion for deciding which of the observations and following interpretations

is acceptable and which is not. Again, qualitative researchers reject the possibility for truth:

At some point we [qualitative researchers] ask, 'Did we get the story 'right'?', knowing that there are no 'right' stories, only multiple stories. Perhaps qualitative studies do not have endings, only questions.

(*Creswell*, 2007, pp. 44–45; see also *Denzin & Lincoln*, 2005a, and *Guba & Lincoln*, 2005, for similar ideas)

Altogether, there exists an approach to science that fits well to Heraclitian worldview; as the whole world, also one aspect of it—science—turns out to be characterized by constant and continuous change of boundaryless events flowing and flowing. This science can be shortly described in this way:

Upon those that step into the same science different and different discourses, texts, narratives and stories flow ... They scatter and ... gather ... come together and flow away ... approach and depart.

## METHODOLOGY

Similarly with Aristotelian structural-systemic approach, process-oriented epistemology is based on explicit philosophical-theoretical ground. This philosophical-theoretical ground, altogether, is different from Aristotelian in important respects. The fundamental difference lies in two assumptions about the world—degree of universality and knowability. For process-oriented epistemology, the world is a constantly and continuously changing, boundaryless individuality that is not knowable beyond appearances. These two assumptions, that ground process-oriented methodology, determine the choice of methods.

Superficially, modern qualitative approaches to science rely on a large variety of qualitative methods; among them: interviewing; direct observation; the analysis of artifacts, documents, and cultural records; the use of visual materials; and the use of personal experience (*Anfara & Mertz*, 2006; *Corbin & Strauss*, 2008; *Creswell*, 2007; *Denzin & Lincoln*, 2005c; *Flick, von Kardoff, & Steinke*, 2004b; *Silverman*, 2007). Yet, all these methods are in a certain sense one and the same—there is no single method that would go beyond appearances. In order to discover whether different underlying causes are expressed in apparently similar events, experiments—constructive experiments as used in structural-systemic science—are necessary. Process-oriented science, however, does not even have clear concept of causality—if the concept emerges, it is efficient cause alone that

is taken into consideration. This efficient causality is, in addition, different from Cartesian-Humean epistemology—there, independent causes lead to effects. In process-oriented epistemology, different patterns of different causes may lead to superficially similar effects (House, 2005). This idea fits well with original Heraclitian idea, as was shown above. And yet—the same approach acknowledges that the causes can never be fully known.

Also, the only thing that is recognized is that the same causes do not always lead to similar effects—multiplicity of efficient causes is applied only in case of different appearances (*see again*, House, 2005). What is not recognized in process-oriented methodology is related to understanding of externally similar events; the idea that different causes may be responsible for them is not taken into account. This possibility cannot be incorporated into theories already for methodological reasons—observation of appearances does not give any reason to suspect that external similarity may hide different causes.

Third, process-oriented methodology—sometimes explicitly, sometimes implicitly—rejects experiments; the procedures of qualitative research, or its methodology, are characterized as inductive:

[...] The logic that the qualitative researcher follows is inductive, from the ground up, rather than handed down entirely from a theory or from the perspectives of the inquirer.

(Creswell, 2007, p. 19)

Obviously there is no way to conduct experiments in inductive studies because experiment requires deduction. The idea that modern qualitative research could be inductive is actually deeply contradictory—*induction* is passing from singular statements to universal statements. But process-oriented epistemology denies universal principles, universal statements. Therefore it is not inductive but rather, by its methodology and methods, just an endless collection of descriptions of appearances; descriptions that do not even allow any inductive generalization. And if inductive generalizations in some qualitative approaches would have been made, the fundamental problem would still remain—theories cannot be verified and for this reason inductive logic is not acceptable for science (Popper, 1994, 2002).

### Three Cultures of Cultural Psychology: Comparison

So far, three cultures of science—each based on a different epistemology and consequently aiming at

a different kind of knowledge—are distinguished. With this distinction, it becomes justified to apply a differential concept of culture to these three sciences. Perhaps just distinguishing three sciences could somehow be interesting by itself, but the value of distinctions in science—and knowledge in general—is in the potential consequences of the distinction. It is possible to go further than just to declare the existence of three kinds of science.

I suggest that hierarchical concept of culture should also be applied with respect to these three sciences. It is usually assumed that hierarchical notion of culture is value-saturated (e.g., Bauman, 1999). Value saturation, however, is not necessarily related to hierarchical concept of culture (cf. Toomela, 2003a). Hierarchy is always defined with respect to some mental frame. If this frame is value-laden, the hierarchical concept of culture defined with respect to that frame will be value-laden as well. But the world around us is filled with other kinds of hierarchies that are value-free—such hierarchies were well-known for philosophers a long time ago (cf. Aristotle, 1984). These hierarchies characterize the world at large as well as the world of language specifically: language contains much taxonomy, for example. The word “animal” by itself is not better or worse than “horse,” “dog,” “elephant” and many other words that refer to particular kinds of animals.

### *The Notion of Hierarchy*

So, the term “hierarchy” is polysemous; in order to know what is actually meant by the “hierarchical concept of culture” it is first necessary to make clear, what exactly is meant by hierarchy. The term “hierarchy” can be used in four different senses; there is order hierarchy, inclusion hierarchy, control hierarchy, and level hierarchy (Lane, 2006). *Order hierarchy* refers to an ordering induced by the values of a variable defined by some set of elements. *Inclusion hierarchy* refers to a recursive organization of entities; this kind of hierarchy, also called *nested hierarchy*, is the organizational scheme that underlies taxonomies where a hierarchically higher-level category contains several lower-level categories that, in turn, may be further divided into subcategories. *Control hierarchy* is the kind of hierarchy that refers to power and other socially valued kinds of relations—hierarchy in this sense is used for value-saturated cultural concepts. Finally, there is *level hierarchy*; this concept refers to structures where units at one, hierarchically lower level compose a

whole with emergent qualities at another, higher level of hierarchy.

Discovery of the level hierarchy contains scientific knowledge—if, for example, the three distinguished cultures of science turn out to be hierarchically ordered in terms of levels, then scientifically important consequences follow. Level hierarchy here would imply also certain control or value-laden meaning. Namely, if three sciences that are based on different epistemologies, are ordered into hierarchical levels, then the most complex science—that comprises the top level of hierarchy—must also be most valuable, most appropriate for achieving the goals of science.

How so? This conclusion follows logically from the idea that the aim of science is knowledge. Knowledge can be understood in quantitative and qualitative terms—there can be more knowledge of the same kind and there can be more knowledge about qualitatively different aspects of the studied phenomenon. Qualitatively more different kinds of knowledge always implies quantitatively more as well because qualitatively novel aspects can be further elaborated quantitatively; the more there are new kinds of knowledge distinguished by scientists, the more there are possibilities for quantitative increase. In this context, more is “better.” It is not only more that is important; history of science knows many situations where discoveries led to understanding what are *not* important or useful facts.

If three distinct sciences comprise hierarchical levels, then it must be so that every next level both includes the previous as part, and extends qualitatively the range of knowledge that is aimed at. In that case, the hierarchically highest level is also the “best” ground for science. This is exactly the case with the distinguished epistemologies.

Further analysis could continue from the epistemological level to any more specific level of scientific knowledge, distinguished above: research practices, theoretical notions (definitions), or theory as a system of notions. In the following I am mostly discussing the three sciences in terms of the most specific level of analysis—research practices—because the intermediate levels often contain theoretical statements that turn out to be empty slogans that are consistently ignored at the level of actual practices. If theoretical statements do not correspond to actual research methods—i.e., if methods do not allow achieving the results declared to be the aims at the theoretical level—then the actual content of the theories is not determined by the slogans

but by the content of the information gathered in actual studies.

### *Process-Oriented Science*

As I suggested above, process-oriented science relies on modern qualitative methodology and methods. Generally, this methodology is based on the assumption that the world is unity that is characterized by continuous and constant change—processes. Processes constitute either a boundary-less world or a world where boundaries are fuzzy, permeable. What can be studied in this world is particulars, individual cases only. Universal principles exist—the world is characterized by constant change, for example—but these universals do not emerge as results of observations of those individual cases but rather from philosophical speculations. The world in this epistemology is knowable only in the limits of appearances; observation of those appearances may lead to many equally acceptable truths.

Methods used in this approach are all qualitative—there are many of them, but none of the methods used allow experimentation. This is the main reason why modern qualitative methods cannot go beyond endless description of superficial observations; why the methods do not allow to distinguish between different causes that may underlie externally similar events. One of the main obstacles a scientist faces is that every event in the world is at any moment multiply determined. Different combinations of such multiple determinations may lead sometimes to externally identical events. Also, sometimes all observed things are affected by some universal factor and yet the pattern of determinations leads to differences in behavior of these things despite the universal effect of some principle on all of them. Altogether, a scientist must discover the causes in situations where externally similar behaviors may be based on different causes and externally different behaviors may still be affected by universal causes.

Only by artificially—experimentally—manipulating with those multiple causes, it becomes possible to identify which of the causes, or patterns of causes, leads to which of the observed behaviors. For example, by simply observing behavior of the bodies around us, we see that some fall, some float in the air and some even “go up.” In order to discover that all bodies around us—with no exception!—are affected by gravity, conditions must be created that do not naturally exist on Earth; a physicist has to create a vacuum and observe the behavior of bodies

in the vacuum in order to discover that externally different behaviors rely on certain universals and actual behavior is determined by other causes such as the density of the bodies. Further, then it can be discovered that there are different flying objects—balloons, birds, airplanes. By experimental manipulations it becomes evident that flying of birds and balloons are based on different causes. There is a reason why humans did not go to the Moon by propeller airplane even though this is a flying machine. Balloons would also be inappropriate. Altogether, there is myriad of examples around us to demonstrate that knowledge can and should go beyond appearances—and that for the development of such knowledge, experiments are absolutely necessary.

There are other reasons for rejecting process-oriented science as fundamentally limited. I would like to point to two reasons more—these reasons emerge already on epistemological ground and show that process-oriented epistemology is internally hopelessly contradictory. Both of these reasons for rejection of this epistemology were formulated already thousands of years ago—by critics of Heraclitian worldview. First, scholars of the modern qualitative approach sometimes explicitly declare that they do not study the world but the words about the world. For example, Corbin and Strauss (2008) give a list of assumptions that underlies their approach to qualitative research. The first of these assumptions is relevant here:

Assumption 1. The external world is a symbolic representation, a 'symbolic universe.'  
(p. 6)

Modern qualitative approach may declare that there is no external "objective" reality around us at all. In that case, indeed, the only things to study are symbols in our minds. The doubt in the existence of the external world is not uncommon in qualitative research texts; for example:

We have left the world of naive realism, knowing now that a text does not mirror the world, it creates the world. Further, there is no external world or final arbiter—lived experience, for example—against which a text can be judged.  
(Denzin & Lincoln, 2005b, p. xiv)

If there would be really no objective external world, however, any study of it becomes meaningless because there would be nobody to tell the results of the studies. Those, who would listen, would also

be just symbolic constructs. And why to create symbolic constructs for other symbolic constructs?

Let us assume, however, that there is a universe external to the researcher. In that case the question emerges: what should be studied—the symbols or the world? We find the answer in Plato's *Cratylus*:

SOCRATES: But since there's civil war among names, with some claiming that they are like the truth and others claiming that *they* are, how then are we to judge between them, and what are we to start from? We can't start from other different names because there are none. No, it's clear we have to look for something other than names, something that will make plain to us without using names which of these two kinds of names are the true ones—that is to say, the ones that express the truth about the things that are. [...] it is far better to investigate them [the things that are] and learn about them through themselves than to do so through their names.

(Plato, 1997, p. 154, 438d and 439b)

Indeed, if contradictory or even mutually exclusive theories about the same phenomenon have been proposed, there must be a way to choose between them. Obviously the choice cannot be made on the basis of studying the theories as symbolic constructs; the world must be studied. Here modern qualitative researchers would perhaps object that there is no one truth, all truths are good. If so, then, again, there is no meaning in any study at all because what would be discovered would be just one more "truth" and one more and one more. All equally right. Such personal truths are not acceptable in science where knowledge is searched for. Knowledge always and by necessity contains exclusion of certain possibilities, otherwise everything could be everything else and no understanding would be possible. This leads us to the second fundamental flaw of process-oriented epistemology.

In consistently process-oriented epistemology, knowledge itself is impossible. This conclusion was made, again, by Plato. There are two reasons for this. First, knowledge must be about something, if this something changes into something else, then there is no knowledge about it anymore. If the world is changing *constantly*, then every next moment is new and there is nothing in the world about which it would be possible to know anything:

SOCRATES: Then again it can't even be known by anyone. For at the very instant the knower-to-be approaches, what he is approaching is becoming a

different thing, of a different character, so that he can't yet come to know either what sort of thing it is or what it is like—surely, no kind of knowledge is knowledge of what isn't in any way.

(Plato, 1997, p. 155, 439e-440a)

There is also a second reason to reject process-oriented methodology—knowledge itself cannot exist if everything is constantly changing:

SOCRATES: Indeed, it isn't even reasonable to say that there is such a thing as knowledge, Cratylus, if all things are passing on and none remain. For if that thing itself, knowledge, did not pass on from being knowledge, then knowledge would always remain, and there would *be* such a thing as knowledge. On the other hand, if the very form of knowledge passed on from being knowledge, the instant is passed on into a different form than that of knowledge, there would be no knowledge. And if it were always passing on, there would always be no knowledge.

(Plato, 1997, p. 155, 440a-b)

#### SOME EXAMPLES OF PROCESS-ORIENTED CULTURAL PSYCHOLOGIES

Altogether, there are epistemological, methodological, and methodical reasons to reject process-oriented science as a fundamentally limited and internally hopelessly contradictory approach to knowledge construction. Space limitations do not allow analyzing the whole cultural psychology today in order to know which of the approaches follow process-oriented epistemology. Another problem is that process orientation is sometimes mixed together with cause-effect science. So instead of discussing some clearly distinguishable approaches, I provide some more specific examples.

One characteristic of process orientation is rejection of clear boundaries between things and between processes. This principle applies also to definitions of studied phenomena. The result is that many qualitatively different phenomena are studied under the same name. There are many instances of such practices in cultural psychology. One question that researchers ask is does only “x” or also some “non-x” have this or that characteristic? One of such questions is: do animals other than humans also have culture? Culture is now attributed to primates (Whiten, 2000; Whiten et al., 1999), whales and dolphins (Whitehead, Rendell, Osborne, & Würsig, 2004), bowerbirds (Madden, 2008), and even insects (Coolen, Dangles, & Casas, 2005; Leadbeater & Chittka, 2007).

Since Tylor (1871), culture has been attributed by many scholars exclusively to man already by definition. The concept of culture must become fuzzy; its definition must change in the flow of studies in order to arrive to insect cultures. Culture in animals is often associated with social learning. But why reject these aspects of human life, that are specifically human? Science, for example. Philosophy. Arts. Formal institutions. What do we learn by discovering that in certain respects humans are similar to other creatures? Not very much beyond trivialities; already biology provides us numerous similarities among all forms of life. The category of “culture” has become fuzzy and, inevitably, no scientific knowledge can emerge in this way because in a boundary-less world we eventually learn that everything is the same. We arrive to Heraclitian Logos and together with it we have to admit that knowledge becomes impossible, as Plato demonstrated.

There are other examples in the field of cultural psychology where similar fuzziness is first introduced into the concept and then it is “discovered” that what was attributed to “x” can now be attributed to increasing range of “non-x’s.” Language is attributed to apes without realizing that definition of human language must include the functions for which language is used. Ape language is directive; orders are given there whereas humans from the very early stages of language learning begin to indicate, to share the focus of attention (Vauclair, 2003). For humans, language is a tool for thinking; semiotically mediated psychological processes emerge in humans (Vygotsky & Luria, 1930); so far there is no evidence that other species beside humans would develop semiotically mediated thought (Toomela, 2003a). Formal logic has been attributed to persons without formal education (Cole, 1996; Cole & Scribner, 1974) because the very same people who are not able to solve certain problems in the context of language alone are able to solve the “same” problems in the context of everyday activities. Formal logic has first turned into a not very formal and not very logic in the strict—Aristotelian—sense of the term and the result is that everybody, even pigeons are able to make formal logical operations, such as transitive inferences (cf. Higa & Staddon, 1993). Pigeons can discriminate between paintings by Monet and Picasso also (Watanabe, Sakamoto, & Wakita, 1995). It does not follow that pigeons “have” impressionistic art, or understanding of it. It only follows that pigeons can discriminate visual experiences; this is not a big discovery. The questions

whether somebody “has” or “does not have” some characteristic is not scientifically interesting to answer as such (*see also* Toomela, 2010a; Valsiner, 2003). Instead it should be asked whether externally similar behaviors truly emerge on the basis of similar causes—there is a lot of evidence to suggest that culture is a useful concept to be attributed only and exclusively to humans (Toomela, 2003a).

### CULTURAL RELATIVISM

Another idea in cultural studies that is grounded in process-oriented epistemology is that of cultural relativism. Boas suggested, “Civilization is not something absolute, but that it is relative, and that our ideas and conceptions are true only so far as our civilization goes” (Boas, 1887a, p. 589). The idea of cultural relativism is logically related to another concept, that of *ethnocentrism*, the view according to which “one’s own group is the center of everything, and all others are scaled and rated with reference to it” (Sumner, 1906, p. 13). According to the principle of *cultural relativism*, any culture cannot be understood from the position of another culture; consequently, cultures cannot be arranged into hierarchical order so that one culture is more developed or better than the other—because such a statement is possible only from the outsider’s viewpoint. Even more, the view that one culture is more developed or better than the other is by necessity ethnocentric, because the evaluation is given not by some machine but always by the representative of some culture—who, by definition, bases the evaluation not on personal and objective views but rather on views affected by his or her culture.

The majority of cultural psychologists today accept the idea of cultural relativism and therefore are against ethnocentrism; according to such a position, cultures are qualitatively different, but at the same level of development (e.g., Berry, Poortinga, Segall, & Dasen, 2002; Cole, 1996; Tulviste, 1988; van der Veer, 1996). I am going to suggest that the concept of cultural relativism is scientifically unacceptable for several reasons. It is unacceptable as principle *if*—as it is done today—it is used as undeniable law. In other words, the principle of cultural relativism is scientifically unacceptable if on the basis of it is decided that any scientific search for a hierarchy of cultures must be rejected *a priori*. There are several reasons why cultural relativism—as opposed to cultural hierarchy—cannot be taken for more than a theory or hypothesis.

First, cultural relativism as absolute principle is not scientifically defensible—in principle. The principle of cultural relativism implies that there are no—and can be no—dimensions according to which cultures could be hierarchically ordered. However, there is no scientific way to prove that something does not exist. Consequently, the idea of cultural relativism can be accepted as theory or hypothesis, but not as absolute principle. In principle a dimension may exist, according to which cultures can be arranged into a hierarchy.

Furthermore, cultural relativism calls for studies from the standpoint of the studied culture. In this way there will be no possibility even to discover universal principles—these can be discovered only when cultures are studied “from above”; it must be assumed first that cultures can be understood, at least in some aspects, by an outsider. The principle of cultural relativism rejects universals *a priori*; therefore, again, science based on such premises turns into a thing in itself that always finds what it looks for because it looks only where “support” for its theories can be found.

Third, in many applications, the concept of cultural relativism is not rational but value-saturated. The following quote is one of the many where the value saturation is obvious:

I do believe that Europe will evolve into a multiethnic and multicultural space, but in order to do so, masculinism, nationalism, and demented ethnocentrism have to be removed from the European mind-set, so as to stop constructing difference in terms of negative otherness.  
(Braidotti, 2000, p. 1062)

This quote demonstrates not only a passionate—and not necessarily rationally grounded—attitude toward the idea of ethnocentrism. This quote, curiously, demonstrates an ethnocentric viewpoint! Sumner (1906, *see* pp. 13–15) provided evidence that ethnocentrism was common among Tupis, Papuas on New Guinea, Mbayas of South America, Caribs, Kiowas, Lapps, Greenland Eskimos, Tunguses, Aivos, etc. Should we think that all of them were demented? Let us remind again: by definition, ethnocentrism is the view according to which “one’s own group is the center of everything, and all others are scaled and rated with reference to it.” (Sumner, 1906, p. 13). There is a group of people who accept only one viewpoint—that of their own group—the viewpoint of cultural relativism. Cultural relativism is, thus, also ethnocentric by undervaluing those

with ethnocentric views. I do not think calling ethnocentrism “bad” or “demented” and cultural relativism “good” or “nondemented” supports the development of science in any way.

I think the issue here is actually not about whether cultural relativism is one case of ethnocentric views or not—it is—but rather the question is: what is the basis of ethnocentric theories of any kind? Ethnocentric views based on opinions, values, feelings, should be rejected indeed—this is my own ethnocentric view. However, science is a quest for knowledge, for understanding the universe. *If* there are hierarchical phenomena in the world (culture, in our case), then science sooner or later either ceases to be a science and ignores facts; or accepts the facts and together with them the idea that cultures can be—on a certain rational ground—arranged into a hierarchical order.

Fourth, cultural relativism should also be rejected on epistemological and methodological grounds. The direction where to look for these problems is also indicated in Braidotti’s (2000) article. Her quote, provided above, ended one section in the article; the next section begins with the sentence, “The only constant in today’s world is change” (p. 13). This is the basic idea of process-oriented epistemology.

The relationship between Heraclitian epistemology and the concept of cultural relativism is too complex to analyze in necessary details in this chapter. Therefore I indicate only the epistemological and methodological problems inherent to this view already in Boas’ approach. The epistemological and methodological ground of the hypothesis of cultural relativism has not changed since his time and therefore applies today as well. So, Boas suggested that culture is characterized by constant change:

All cultural forms rather appear in a constant state of flux and subject to fundamental modifications.  
(Boas, 1920, p. 315)

From the analysis of Heraclitian epistemology, it must follow that it is not universals but particulars that comprise the knowledge that is looked for. Indeed, according to Boas, knowledge of universal principles does not ground explanation; explanation is in the description of particulars. This understanding is expressed in his opposition of two branches of sciences:

[...] the former trying to deduce laws from phenomena, the latter having for its aim a description and explanation of phenomena.  
(Boas, 1887a, p. 588)

It must follow that the focus of studies must be description of individuals, not universals and principles. So it is: “In ethnology all is individuality” (Boas, 1887a, p. 589), and “... the object of study is the individual, not abstractions from the individual under observation” (Boas, 1887b, p. 485).

Further, rejection of universal principles in Heraclitian epistemology is related to understanding that there is no clear causal structure of the world, including that of culture; rather, the culture should be characterized by an unclear and very complex causal net. Boas’ view on causality corresponded well to process-oriented science. First of all, causes are not directly observable; externally similar events can be based on internally different causes: unlike causes produce like effects (Boas, 1887a, 1887b). These unlike causes are complex:

[...] the development of similar ethnological phenomena from unlike causes is far more probable, and due to the intricacy of the acting causes.  
(Boas, 1887b, p. 485)

Also, there is no clear boundary between causes and effects; causes become effects and vice versa:

[...] in historical happenings we are compelled to consider every phenomenon not only as effect but also as cause.  
(Boas, 1920, pp. 315–316)

If causal structure of the world is so complex, then the methodology, in order to capture such complexity must follow certain principles. In Heraclitian epistemology, there is no link to arrive at universal principles on the basis of observations of everyday life. Therefore methodology of studies should be fully inductive; and it was for Boas (cf. Boas, 1887a). Also, observations should take into account a huge number of facts. Boas, indeed, suggested:

We have to study each ethnological specimen individually in its history and in its medium [...]. By regarding a simple implement outside of its surroundings, outside of other inventions of the people to whom it belongs, and outside of other phenomena affecting that people and its productions, we cannot understand its meaning.  
(Boas, 1887b, p. 485)

Study of *each* ethnological specimen in its history, medium, surroundings, other inventions, and other phenomena affecting people is an endless task.

Finally, despite recognition that externally similar events may originate from different causes, the study methods in process-oriented science are based only on observations of appearances. In works of Boas, expectedly, we find numerous lists of descriptions of appearances; the idea that culture is only about appearances is reflected already in Boas' definition of culture, where we find only external aspects of human behavior, reactions and activities:

Culture may be defined as the totality of the mental and physical reactions and activities that characterize the behavior of the individuals [...]

(Boas, 1938, p. 159)

Altogether, Boas epistemology and methodology correspond outstandingly well to Heraclitian process-oriented science. In this science, there are also universal principles—cultural relativism, for example—but these principles do not follow from facts but actually precede them. Such science can create only endlessly many descriptions of appearances but no principles follow from the observations. Boas himself thought that the approach to science he supported—an approach that was followed mostly by American anthropologists of his time—aimed also at answering general questions. European scholars of his time—who were more oriented toward structural-systemic science instead of the Boasian process-oriented approach—recognized the infertility of such descriptive work already a long time ago.

It may seem to the distant observer that American students are engaged in a mass of detailed investigations without much bearing upon the solution of the ultimate problems of a philosophic history of human civilization. I think this interpretation of the American attitude would be unjust because the ultimate questions are as near to our hearts as they are to those of other scholars, only we do not hope to be able to solve an intricate historical problem by a formula.

(Boas, 1920, p. 314)

Time has shown that the European perception of Boas' work was more accurate than his own understanding of it. Boasians may have had general questions near their hearts, but epistemological and, following from it, methodological limitations did not—and do not—allow answering those questions. Process-oriented science cannot discover universal principles or answer universal questions—these principles and questions are rejected *a priori* epistemologically and

methodologically even though they may exist in rhetoric of the theories of this science. In the case of cultural relativism, studies should aim at finding the universals rather than finding particulars—if the idea of universals is denied, then looking for possibilities to reject the theory, to falsify it in a Popperian sense, is scientifically more fruitful than an endless collection of descriptions of particulars.

Many more examples of process-oriented sciences could be provided. For example, certain principles followed in modern activity theory are rooted also in process-oriented epistemology (cf. Toomela, 2000, 2008a). Focus in this approach is not on structures but on processes; consequently activities are studied without taking into account characteristics of individuals—as elements of a structure of the activity. In this way, boundaries between categories—of an individual and culture, for example—also become fuzzy or disappear altogether. Activity theory is also characterized by the tendency for description that leads to fragmentation of the studies; the holistic nature of the mind is sometimes declared to be important but in actual research practices this universal principle is ignored. Indigenous psychologies' approach with its emphasis on the study of individuals in specific cultural contexts by scholars in that context corresponds methodologically also to process-oriented science (cf. Kim, 2001; Kim, Park, & Park, 2000). The list of examples could be continued but I think it is not necessary. Important is the principle—when process-oriented science grounded in Heraclitian epistemology is recognized in some approach to the study of culture, the weakness of the respective approach can be recognized as well.

### **Cause-Effect Science**

Cause-effect science aims at discovering universal causes for many effects; when the universal cause-effect relationship has been found, this relationship is called “principle” or “law.” Laws are found by studying covariations between events; these events are not distinguished according to the causes on the basis of which they emerge but only on the basis of superficial similarities, on the basis of appearances. For example, answers on a Likert scale on any item are treated as “the same” when different individuals have chosen the same number on the scale independently of the reasons why actual choices have been made; answers on the intelligence test are correct or incorrect independently of causes that led to the answer; generally—if similar “effects” follow similar

“causes” more often than by chance, cause-effect relationship is suggested.

A majority of cause-effect science relies on quantitative methodology where events are encoded as variables that are subsequently entered into some data-analysis procedure, such as analysis of variance, correlation, factor analysis, logistic regression, structural equation modeling, etc., etc. It does not follow, however, that cause-effect science can be only based on quantitative methodology. Cause-effect science is science where discovery of continuous—linear or nonlinear—cause-effect relationships is aimed at; it is any science where efficient causes, but not other kinds of causes, are looked for.

Cause-effect science is hierarchically—in the sense of level hierarchy—a more developed version of process-oriented science. As a developed version, it contains principles of process-oriented science that are modified together with the emergence of a new whole, that of cause-effect epistemology. Similarly with process-oriented science, cause-effect science relies on study of appearances. Descriptions of appearances, however, are not the aim of science in itself any more. Now it is assumed that some observations are scientific and others are not; the difference is in strict procedures that are applied in distinguishing between observations—only observations that reveal laws or principles are accepted as scientific, other observations lose their scientific significance. This is a qualitative change in scientific thought—change that adds novel ways to understand the world.

Superficially—this position is stressed from the perspective of the process-oriented approach—cause-effect science only loses information, it abstracts principles and laws from the endlessly rich world and therefore knowledge becomes “poor.” In fact, the opposite is true—laws and universals allow understanding more. There are two reasons why it is so. First, the world around us can be described in endlessly many ways—endlessly in the literal sense of the word. If science would stay in the stage of process-oriented epistemology, it would always be possible to find different descriptions even of the same events; and for sure, if there are no other descriptions at the moment, they can be created instantly. In this world, any statement can be opposed with the principle—“but it can be otherwise.” In the world that would be completely open for descriptions and interpretations, in the world where there are no universals, rules, laws, not only thinking, but life itself would be impossible: All forms of life

survive despite changes in the environmental conditions only because change of conditions can be predicted; prediction is possible only if changes in the environment repeat, if they follow certain “laws” or repetition (Anokhin, 1978; Toomela, 2010a).

Second, cause-effect science does *not* suggest that the world cannot be described in endlessly many ways. It also does *not* suggest that the world is ruled only by the discovered laws and principles. Rather, it suggests that knowing principles and laws is a special kind of knowledge—scientific knowledge—which can be achieved only by scientific procedures. These scientific procedures are not confined to maximally passive observations but rather are based on active participation of the researchers in the study; experiment becomes an important tool for attaining knowledge. Using these scientific methods, a new *kind* of knowledge is achieved, a qualitatively novel kind is added to the pool of knowledge—that of laws and principles. These laws and principles, thus, are “more” because that kind cannot be achieved by process-oriented science. Principles and laws are more, not less knowledge.

Yet, cause-effect science is still limited; it does not allow achieving different kinds of knowledge about universals. Shortly, the fundamental limitation of the cause-effect science is that this science studies efficient causes that affect things or phenomena, but it does not study, what the thing or phenomenon is. The problem is that in a given chain of events, always not one but many covariations between some characteristics of the events can be discovered. There is no scientific methodology that would allow distinguishing between cause-effect laws themselves. Let us take a simple example. The number of causes why a watch can break is not limited; it can break because of falling, becoming wet, too hot, too cold, becoming too old, etc. It is noteworthy that these efficient causes can be recognized far beyond the level of chance—with very high statistical reliability—and yet there would be no understanding whatsoever achieved as to what the watch is. Knowledge of such causes of breakage allows making many practical decisions; but it is not possible to fix the watch after it broke. A watchmaker does not have to know any of the efficient causes of breakage in order to fix the watch. So it turns out that cause-effect science is doomed to look endlessly for new and new covariations between characteristics of events. In this process, the things and phenomena that are studied are not understood by themselves; only laws of relationships between events are established. The reasons for

this limitation are discussed further in the section on the structural-systemic science, below.

### SOME EXAMPLES OF CAUSE-EFFECT CULTURAL PSYCHOLOGIES

#### *Cross-Cultural Psychology*

Perhaps the most dominant cause-effect cultural psychology today is that of cross-cultural psychology. This approach corresponds in its methods as well as epistemology fully to the Cartesian-Humean cause-effect science. It may seem that different sciences can be distinguished in cross-cultural psychology. For example, it has been suggested that three general orientations can be found there: *absolutism* that assumes that psychological phenomena are qualitatively the same in all cultures; *relativism* that assumes that all human behavior is culturally patterned; and *universalism*, according to which basic psychological processes are common to all members of the species but culture influences the particular ways these basic processes are expressed in behavior (Berry et al., 2002). Epistemologically and methodically, relativists sometimes follow the process-oriented worldview, as it was discussed above. Yet, in the context of the cross-cultural psychology, all three viewpoints share the same ground—any science that relies on quantitative methodology, which is the most common way of doing cross-cultural psychology—is cause-effect science. So, relativism as a branch of cross-cultural psychology should be distinguished from the relativism of the process-oriented methodology. In the former case, relativism aims at discovering universal causes and cause-effect relationships within what is called “culture” whereas the same aim characterizes absolutists and universalists at the level of many cultures. The distinctive characteristic of each of the approaches, thus, is just the level of analysis where cause-effect epistemology and corresponding methods are applied.

Cause-effect epistemology is reflected very explicitly in cross-cultural psychology. This epistemology is expressed, for example, in the vocabulary used in the theories. The following examples are from Berry with co-authors (2002). We find there linear relationships: “the *sequence* of ecology—culture—behavior came to be part of thinking about how to account for psychological similarities and differences around the world” (pp. 11–12, emphasis added). So, sequence helps to understand the *how* of something, cultural differences in this case. There are not just sequences but sequences of *influences*: “population-level *variables* . . . conceived as *influencing* the

individual outcomes” (p. 12, emphasis added). Here we find not only cause-effect relationships but also an understanding that it is variables that influence something; quantitative methodology is expressed in this vocabulary. True, in the same chapter it is also possible to find the idea of feedback; human beings are not only influenced by their environments, they also influence their environments: “individuals influencing their ecological and sociopolitical contexts” (p. 12). This “feedback” circle of environment → individual → environment relationships is called, following Boesch and Eckensberger, “*dialectical*” by the authors. The proposition that there is something dialectical in this chain of linear influences is not correct; or it is a fundamentally oversimplified version of dialectics. Because in dialectical relationships, a whole with entirely novel qualities emerges in the interaction of the things (cf. Engels, 1987; Hegel, 1969). In this oversimplified dialectics, novelty emerges as a linear consequence of the “cause”—individuals change because of their environments and environments change because of individuals. No hierarchical synthesis and novel level whole is defined in this chain of linear events. The whole and only business of cross-cultural psychology is finding cause-effect relationships.

#### *Dominant Value Systems*

Another set of examples of cause-effect epistemology can be found in the treatment of so-popular-today cultural “dominant value systems.” According to Hofstede (2001), his book “identifies five main dimensions along which dominant value systems in the more than 50 countries can be ordered and that affect human thinking, feeling, and acting, as well as organizations and institutions, in predictable ways” (p. xix). This one sentence expresses almost the whole essence of cause-effect science—there are causes that *affect*, the whole business has been to *identify* these causes; it becomes possible to *predict* events; quantity underlies the idea that countries can be *ordered* (variables used in quantitative data-analysis are created on the basis of this idea); and all the theory is based on appearances, *countries* are distinguished according to these dominant value systems. In which way country of origin becomes equivalent to culture of origin is a mystery. In fact, there would be no need to open this book in order to discover cause-effect science in it; the title of the book is *Culture’s consequences: Comparing values, behaviors, institutions, and organizations across nations*.

And what are the results of studies in cross-cultural psychology? Overall, a myriad of correlations between events has been described. Hofstede distinguished five dimensions of value systems: power distance, uncertainty avoidance, individualism-collectivism, masculinity-femininity, and long-term versus short-term orientation. One of these dimensions, that of individualism-collectivism, became an extremely popular subject of studies after the publication of the first edition of the *Culture's Consequences* in 1980. Thousands of articles have been published on it (as of April 24, 2010, there were 3,585 articles related to the keyword "individualism" in the PsycINFO database and 4,601 in the Web of Science). In these studies, the variable of individualism has been correlated with almost everything that came to the minds of the researchers; just to name a few: personality, partner support, maternal attachment, suicide, mate choice, occupational plans, work values, peer support, internet self-efficacy, leadership perceptions, cooperation, perspective taking, empathy, family-based HIV prevention, academic achievement, etc., etc. Altogether, the results of all these studies can be summarized shortly with Hegel's words: the "'great influence' of environment on the organism" (2005a, p. 295) has been discovered. Nothing less ... and nothing more.

Recently, it seems, scholars begin to realize that adding another construct to the list of correlates of individualism-collectivism is not very interesting. Quite in line with the cause-effect scientific ground, instead of summarizing all the findings in one great theoretical framework ... new dimensions have been recently proposed; in the future these can also be correlated with everything; so religion, socioeconomic status, and region within a country (Cohen, 2009) can be new candidates for the next several thousands of studies. Sure, there are many other dimensions according to which "great influence" of the culture on the individual can be discovered; but all this does not help to answer the question, what culture *is*; we only learn that there is something that *does* something, i.e., that *causes* something. I think science can give more.

#### *Activity Theory and Other Mixtures of Process-Oriented and Cause-Effect Sciences*

Cross-cultural psychology is not the only example of cause-effect sciences in cultural psychology of today. Another example of cause-effect science is that based on the activity theory. According to

*activity theory*, the emergence and development of the mind is determined by the activity that an animal or a human being is involved in (A. N. Leontiev, 1981). That view has been adopted by several modern scholars who claim, for example, that "the way of thinking is determined by the kind of activity" (Tulviste, 1988, *see also* Cole, 1996, for an analogous approach and Toomela, 2000, 2008a, for critique of the activity theory).

One idea is worthy of attention here. When discussing the limitations of the process-oriented approach, I suggested that activity theory contains principles that are akin to process-oriented epistemology. I also suggested that relativist cultural psychology in general can exist in process-oriented and cause-effect forms. Indigenous cultural psychology could also be an example of such science. Essentially I suggest that in some cases mixtures of process-oriented and cause-effect science can be found in cultural psychology. Recently, more and more often such mixtures are suggested to solve the shortcomings of quantitative (i.e., cause-effect) and modern qualitative (i.e., process-oriented) approaches (e.g., Gelo, Braakmann, & Benetka, 2008). So, finding of such epistemological and methodological mixtures is not surprising.

Yet, there are reasons to suggest that such mixtures do not solve the most fundamental difficulties of these two sciences. Limitations of each of the sciences could be solved if there are no fundamental limitations inherent to both of them. But there is a shared fundamental limitation that neither of the approaches is able to overcome: both of them are limited to interpretation of appearances. Modern qualitative methods do not use experiments at all; therefore the whole science is limited to theories about appearances. Cause-effect science accepts and uses experiments. But these experiments are used only for establishing which of the possible candidates the "true" cause is and which is not. In the beginning of this section (*cause-effect science*) more reasons were provided why cause-effect experiments have a limited value: externally similar results emerge on the basis of many different causes (a watch breaks because of falling, getting wet, etc.). Experiment may rule out certain hypothetical causes, but experiment in cause-effect science does not provide information about what the studied thing or phenomenon *is*; different things may look similar, cause-effect science cannot distinguish them any more than process-oriented science. Another *kind* of experiment, in fact another

*kind* of science is needed to overcome the limits of appearances.

### ***Structural-Systemic Science***

Structural-systemic science aims at knowledge about different kinds of causes; in addition to efficient cause, material cause (i.e., parts), formal cause (i.e., emergent whole) and final cause (which determines the direction of development) are looked for. Epistemology of this science does not correspond fully to its philosophical roots formulated in Aristotelian philosophy; structural-systemic science formulates its aims in terms of two central notions: structure and development. This science is fully aware of its philosophical-epistemological ground and is ready to modify it, if it is discovered that the epistemology does not correspond any more to observed facts. Structural-systemic science assumes that there are universal principles in the world, and that the world can be understood beyond appearances so that not only relationships between events can be understood but also what the things under study are. Aims of structural-systemic science are achieved by qualitative methods that, in the course of the development of knowledge, lead to constructive experiments, experiments where it is attempted to create the phenomenon or thing on the basis of the theory about what the thing is—what are its parts in which specific relationships.

Structural-systemic science is clearly hierarchically more developed and yet continuous to the cause-effect science: it accepts efficient causes as part of scientific knowledge, but adds to this kind other qualitatively novel kinds of knowledge, which were not searched for by hierarchically less developed cause-effect and process-oriented sciences. Similarly with both less developed sciences, structural-systemic science relies on descriptions of observations—obviously there is no other source of knowledge about the universe around us but that which is based on information that emerges in the sensory systems. Cause-effect science provides to this new science understanding of the value of artificially created situations in understanding the world. But the meaning of artificial situations is interpreted differently in the structural-systemic context. First, it is understood that different wholes emerge from the same parts in qualitatively different relationships. Therefore the quantitative methodology is rejected because it takes into account only quantitative covariative relationships between events. Second, it is understood that not events

but parts and kinds of their relationships must be manipulated in experiments; so the essence of the artificial study situation is also fundamentally different. In constructive experiments, it is not sufficient to manipulate with one variable so that everything else is kept constant. Rather, it is understood that manipulation must concern, one-by-one, *all* elements and *all* specific relationships between them that are predicted by the theory.

Here lies also the power of constructive experiments: they do not go on endlessly. In the case of cause-effect science, new causes of externally similar events can always be discovered—because causes in this epistemology are external to the studied phenomenon itself. So everything that may come into relationship with the studied structure becomes a cause, because properties of things change and novel “effect” emerges in every case, a thing comes into relationship with another thing. In structural-systemic science the external is not under study, but the thing itself. It is assumed—this assumption is well-grounded by achievements of physics, chemistry, and biology—that more than one but still a limited number of different kinds of structures may underlie externally similar phenomena. So there is a limit to scientific inquiry; this limit is determined by the structural varieties of the world, by what the things are. Anything can be affected by an endless number of other things that are external to it; but nothing externally similar can be built in endlessly many ways—otherwise not only knowledge but life would be impossible. This is because without constraints on structures—on causes that underlie the appearances—the world would be unpredictable.

Altogether, structural-systemic science is grounded on the most developed epistemology and methodology. It contains principles that allow selecting from scientific descriptions those that contain scientific knowledge, knowledge of causes of things and events. I think there are strong arguments to reject both process-oriented and cause-effect sciences as less developed and therefore also less powerful forms of science. Such rejection, of course, must be based on careful analysis of arguments provided for or against one or the other epistemology. There is also no *a priori* way to decide that no more developed science than structural-systemic can exist; perhaps it will be formulated in the future. Perhaps it is already formulated but not known to the author of this chapter. Yet, in the limits of knowledge that underlie the arguments provided above, structural-systemic science should be preferred to the other two.

## AN EXAMPLE OF STRUCTURAL-SYSTEMIC CULTURAL PSYCHOLOGY

Structural-systemic science is uncommon in today's cultural psychology. The best examples of it can be found in history. There is increasing evidence to suggest that pre-World War II continental European psychology was epistemologically, methodologically, and theoretically far ahead of the modern mainstream psychology (Toomela, 2007, 2010d; Toomela & Valsiner, 2010). History, thus, can be a valuable source for looking for future trends of cultural psychology.

The most consistent structural-systemic approach to the study of the mind was taken by Vygotsky and a limited number of his followers. Vygotsky's name is well-known today, but for concepts and ideas that have very little in common with his original approach. Now Vygotsky is often seen as a child psychologist who investigated cognitive development in the framework of mother-child interactions. He was not any of them; he was no child psychologist, he did not study only cognitive development, and he never studied mother-child interactions—Vygotsky was first of all a theoretical psychologist (Valsiner & van der Veer, 2000). Indeed, his explicit aim was unifying theory of psyche rather than understanding of some local psychological phenomena (Vygotsky, 1982). Today, many of Vygotsky's ideas have been distorted beyond recognition (Mahn, 2010; Veresov, 2010). Most certainly he was not the founder of the activity theory—the true founder of activity theory was A. N. Leontiev. Curiously, A. N. Leontiev with the creation of the activity theory departed from Vygotsky's theory in the early 1930s but returned in many aspects back to Vygotskian ideas in the end of his career (A. A. Leontiev, 1990). Modern activity theory is fundamentally different from Vygotskian cultural-historical psychology (Toomela, 2000, 2008a; van der Veer & Valsiner, 1991). The only consistent follower of cultural-historical psychology, who is relatively well-known today, was Alexander Luria.

As with the other two cultures of science—process-oriented and cause-effect—structural-systemic science relies on certain methodological principles that distinguish it from the others. Vygotsky did not use quantitative data-analysis methods; his approach was qualitative. It can be said that quantitative methodology was developed mostly after his death and perhaps he could not use all the wonderful quantitative data-analysis techniques available to researchers today. However, Luria, who had the opportunity

to adopt these methods also did not do it; he relied on qualitative methods as well. So, already in this respect, cultural-historical psychology must be distinguished from the modern mainstream (cultural) psychology—i.e., cause-effect science—which mostly relies on quantitative methodology.

The Vygotskian approach must also be distinguished from process-oriented sciences: cultural-historical psychology explicitly aims at understanding universal structural-systemic principles and methodologically relies heavily on experiments and artificially created study situations. Overall, I think, Vygotsky's approach was characterized by the following methods used for the theory development: (1) descriptive observations of appearances with subsequent analysis of them in terms of universal principles; (2) observations in artificially constrained situations; (3) "cause-effect" experiments for identifying efficient causes with the analysis of the results of these experiments in structural-systemic framework; and (4) constructive experiments. These methods were not used in a certain order but as complementary parts of the whole methodology. This methodology was also not a chaotic mix of arbitrarily applied methods that characterizes modern qualitative approaches (cf. Denzin & Lincoln, 2005c). Rather, all methods were chosen or constructed on theoretical grounds with a clear understanding as to what the researcher wants to know through the methods used and how the particular method corresponds to the questions asked as well as to the theory of the studied phenomenon. I provide a few examples about Vygotsky's methods.

(1) *Descriptive observations.* Vygotsky used many observations made by other researchers as well as by him. When discussing the characteristics of "primitives," he, for example, described the symbols used by Dakotas: a feather with a hole showed that the owner of it killed an enemy; a feather with an end cut off demonstrated that the owner cut the throat of an enemy, etc. (Vygotsky & Luria, 1930). All such descriptive observations were incorporated into a clear theoretical framework.

(2) *Observations in artificially constrained situations.* The classical example of this method is the method of investigating the formation of concepts (Vygotsky, 1996). In this method, the subject is presented with a set of objects that have one or more features in common—color, shape, height, and/or base surface. Each of the objects has a name—a nonsense word—written on their underside. A number of objects are placed in front of the subject

in a disorganized fashion. Then the subject is shown a name under one of the objects and he is asked to find other objects with the same name under it. The investigator observes all the choices made by the subject as well as the order of choices. This method is not scientific experiment in the common sense of the word; it is not used for distinguishing between competing theories or testing hypotheses. The method was first used for discovering patterns in behavior. In natural conditions, choices among alternatives can be based on an unknown number of characteristics. In this method, basis of choices was artificially constrained to color, shape, height, and base surface. Analysis of the observations was eventually formulated in the frame of the developmental theory of concepts.

(3) *“Cause-effect” experiments.* Structural-systemic science does not reject the idea of efficient causes but rather interprets efficient causes in the context of the whole—the structural theory of causality. An example of this kind of experiment used by Vygotsky is the method of double-stimulation (e.g., Vygotsky, 1983). In that group of methods, participants are first presented with some task, such as answering questions with a restriction that certain words or phrases are forbidden to be used. Then the whole procedure is repeated so that auxiliary means—color cards, for example—are introduced into the situation. By using those means, Vygotsky suggested, participants mediated psychical operations so that it helped to fixate attention at the correct forms of answers and avoid forbidden ones.

In these experiments, it was not the whole structure of mind that was studied element-by-element and relationship-by-relationship. Rather, one—“efficient”—cause was chosen and it was tested whether this cause, if introduced into the structure of the task, leads to theoretically predicted changes in the test performance. For cultural-historical psychology, however, this kind of experiment was not the last step in the theory building.

(4) *Constructive experiments.* Vygotsky himself did not use constructive experiments extensively. The full power of them was utilized by Luria and his disciples in neuropsychological rehabilitation (Luria, 1948; Tsvetkova, 1985). In this approach, first, the structure of mental processes of healthy persons is theoretically formulated. In the case of localized brain damage, next, the person is thoroughly investigated in order to establish which particular cognitive components of the mental structures are damaged and which components survived. Then, on

the basis of this diagnostic investigation, the neuropsychologist answers the question, what components in which relationships would theoretically ground the same function that is lost? And then the plan of educational activities is created for the patient. In the process of guided learning—neuropsychological rehabilitation is essentially a set of directed educational activities—it is not the “old” structure of the function that is restored but rather an entirely new functional system is constructed so that a whole function emerges that is externally similar to the lost function but internally relies on a different structure. Remarkable success of Vygotskian-Lurian theory of neuropsychological rehabilitation not only corroborated the theory of psyche but also provided ground for further development of the theory.

Taken together, structural-systemic science, so rare today, has demonstrated considerable theoretical sophistication and remarkable applied utility that far exceeds accomplishments of modern process-oriented and cause-effect sciences. Structural-systemic science relies on all basic kinds of methods, from descriptive observations as the most primitive sources of scientific knowledge to most powerful constructive experiments where the studied phenomenon is actually recreated on the theoretical basis. The latter method is available neither to process-oriented nor to cause-effect sciences, which both are unable to provide knowledge about what a studied thing is—what is its structure. Cultural psychology today has made a qualitative leap back from its structural-systemic ground to epistemologically and methodologically fundamentally limited process-oriented and cause-effect sciences. It is not the first time in the history of human culture that future direction can be found in the past and not in the elaboration and extension of the present.

### **Future Directions of Cultural Psychology**

I think there is sufficient ground to distinguish three cultures of science—process-oriented, cause-effect, and structural-systemic. Furthermore, the first of them is epistemologically and methodologically the least developed, the least appropriate for achieving the aims of science—knowledge; and the last is the most developed. I am convinced that both the theoretical reasons I provided, as well as the list of examples described, can be extended considerably to support these propositions. It would seem natural now to suggest that the future of cultural psychology lies in the structural-systemic science. History of human culture in general, as well as

history of psychology in particular provides, sadly, many examples that fit too well with the expression that was born in the end of the Soviet Union: We wanted as better but it came out as usual! (*My hoteli kak luchshe, a poluchilos' kak vseгда*).

Cause-effect science and structural-systemic science could be clearly distinguished already a long time ago—the former dominated in North America and the latter in continental Europe before World War II. Goodwin Watson, one of the founders and the first president of the Society for the Psychological Study of Social Issues described eight major trends that characterized continental European psychology (Watson, 1934). These trends were essentially descriptions of the structural-systemic science. Watson ended his article with the prediction:

The eight major trends previously noted continue. German psychology is still more thoughtful, more qualitative, more subjective, more concerned with wholes, more insistent on understanding the particular case, more apt to make typological and characterological studies, more interested in achieving insight, more concerned with schools and systems. Although many brilliant psychologists have left voluntarily or been forced to leave, this cultural tradition is likely to continue for many years. (p. 771)

... but “it came out as usual.” Cause-effect science became dominant after World War II and, a few decades later, even less developed process-oriented psychology entered the field and occupied the place of structural-systemic psychology. It is a separate issue why it happened. For sure, there were no scientific reasons to abandon structural-systemic principles (Toomela, 2010d; Toomela & Valsiner, 2010).

So, in predicting the future of cultural psychology, I will not suggest that structural-systemic science will take its leading position soon. Eventually, it should happen and cause-effect science will give way to structural-systemic as it has done in physics, chemistry, and biology. I hope. But it is very unlikely that this change is going to take place in any near future. Already Kuhn observed that paradigms are hard to change (Kuhn, 1970). There are reasons to suggest that the forces that will eventually lead to the development of cultural psychology back to the future cannot be found inside of the process-oriented or cause-effect sciences. Because both of them rely on epistemology that fundamentally restricts self-development, these

epistemologies are not able to transcend their own limitations.

Perhaps the most fundamental limitation of the both process-oriented and cause-effect sciences is that there is no possibility to receive negative scientific feedback in either of them. In process-oriented science, the number of ways how anything can be described is not limited. Any description is as good as the other and therefore this science cannot discover any obstacle on its way. In knowledge, however, if anything goes then nothing is worthy.

Cause-effect science has limitations on the kinds of knowledge—only universal cause-effect relationships are scientific knowledge. Yet, there still is no constraint on the number of cause-effect relationships that can be discovered. This time the problem lies in the object of studies—it is not the thing or phenomenon itself, but the efficient causes that are extraneous to it. Again, the number of possible other things that can interact with the thing under study is in principle not limited. Therefore it is always possible to discover another efficient cause, and another, and another. Cause-effect science, therefore, also cannot have negative feedback that would reveal the fundamental limitations of this science. True, differently from process-oriented science, local negative feedback is possible here: hypotheses about causes may in experiments turn out to be wrong. But after such local drawbacks, another candidate for a cause can always be discovered. Overall, the cause-effect science has no internal information about limits of itself.

The situation is different with structural-systemic science. Both local and general kinds of negative feedback are possible here. Every time a researcher does not succeed with incorporating any of the four kinds of information—from descriptive observations, observations in artificially constrained situations, cause-effect experiments, or constructive experiments—into a theory about the phenomenon, local negative feedback is received. If such negative feedback continues to accumulate in fields that study qualitatively different things and phenomena, sooner or later problems at the higher level of scientific knowledge, up to the epistemological level, can be discovered. Out of the three sciences outlined in this chapter, only the structural-systemic has deeply reorganized its epistemology; theory of structures is not a replica of Aristotelian causality whereas in the other two sciences no significant changes have been introduced into the Heraclitian and Cartesian-Humean epistemologies, respectively.

Furthermore, it is not only lack of negative feedback that holds the development of science back and keeps the less developed forms of it alive. The epistemological ground of the less developed sciences protects also against invasion of more developed principles into it. So, process-oriented science may acknowledge the achievements of cause-effect science—but only as one kind of description that is in addition, according to them, poor. The idea of a continuously changing, boundaryless world rejects the idea of universals *a priori*. Therefore any information that could show the value of knowledge about universals is rejected as well.

Cause-effect science essentially denies the possibility to know the world beyond appearances—today this principle is usually accepted without the researchers realizing it; it can be discovered easily, however, by analyzing the actual research methods applied in this science. Here, again, possibility to know the thing under study, and not only efficient causes of external influences on it, is rejected *a priori*. Therefore any structural-systemic knowledge simply does not make sense for cause-effect science. In the best case, achievements of the structural-systemic science are translated into the primitive language of efficient causes without even noticing that the whole essence of the theories has been fundamentally distorted in this process. Many examples of such translations can be found; achievements of the structural-systemic scientists, such as Kurt Koffka, Kurt Lewin, Wolfgang Köhler, Lev Vygotsky, Jean Piaget, among many others would provide a very long list of them. So, from the perspective of the cause-effect science, nothing novel has been created by structuralists, because the novelty is first removed, and after that it is declared that what was found is all the same cause-effect science.

Cultural psychology of today is not going to change soon—because it is heavily dominated by the cause-effect science, the science that is in principle not able to discover its own limits. This domination goes far beyond directly scientific issues—here the cultural nature of the distinguished sciences comes into the foreground. In this context, I think, it is sufficient to look into the brilliant analysis of the socially constructed nature of the science of psychology by Kurt Danziger (1990). He demonstrated that science is not a tale of Sleeping Beauty; there are no princes—investigators who would awake the sleeping objects of inquiry and turn them into psychological knowledge by the magic kiss of research.

According to Danziger, science is not only about the ideas discovered or constructed in the process of studies. Results of scientific activity are, first of all, constructed on certain epistemological and methodological grounds. Personal limitations of researchers are determinants here. But a new discovery or idea is far from sufficient for the development of scientific knowledge. Next, the results of scientific activities must be accepted by other researchers in the research community. We saw above, that structural-systemic knowledge cannot be accepted by cause-effect science in principle. Even that would not hinder the development of the more developed forms of science—the whole history of science is in a certain sense creation of new scientific knowledge by individuals who proposed ideas that contradicted those of the mainstream of that time; in fact these ideas often contradicted the ideas of everybody else in the human society. The fundamental problem lies in the third—wider—aspect of the context where science is embedded, “*professional environment*” in Danziger’s terms. Scientists do not live outside of the world; they are human beings who have needs; including the most basic needs. If the results of the more developed science are not accepted as scientific knowledge, the professional environment rejects this science—there will be no research support, no positions available in the professional institutions, no external consumers of knowledge products and skills—no way to be a scientist.

Here may also lay the hope for structural-systemic science—many decisions about the future of science are made not by other scientists but are grounded in politics and economy. If the structural-systemic science learns to sell itself, it has some hope. There may be some more hope. Perhaps some members of the research community become just bored from endlessly increasing the list of either superficial descriptions of appearances or efficient causes and take a more challenging task—they can accept the possibility that, as scientists, they can be wrong not only locally but also in principle. Structural-systemic science offers this challenge together with ways how to proceed when fundamental epistemological problems have been discovered—a better epistemology can be formulated in that case.

Altogether, as history of human thought has demonstrated repeatedly, all ways are open for us. In the near future, most likely the cause-effect science remains in the dominant position because for outsiders it looks more scientific than mere description that everybody can do. As cause-effect science

has some relatively obvious limitations, process-oriented science has also some hope to strengthen its positions. If not otherwise, there is a possibility to create hybrids of the two and declare that such hybrids solve the problems inherent to one or the other taken separately.

These scenarios would be basically versions of the general historical trend: past-present-present-present-present-present. I hope researchers become bored from their endless tasks and turn to structural-systemic science. This historical trend is described by the sequence past-present-past, or, in the longer historical perspective, past-present-future-present-(past) future. There are good teachers to discover; in the era of printing and the Internet, it will not matter so much that these teachers died some time ago. We still can take lessons from them.

Finally, as (I hope) a structural-systemic scientist, I must admit that I can be fundamentally wrong. Perhaps there is another way to the future; perhaps some past-present-future direction is also possible. Anyway, there are reasons to be curious about the future of (cultural) psychology. Even if the “present” continues, it will be interesting to study the causes of this rigidity of the human mind.

# Culture in Constructive Remembering

Brady Wagoner

## Abstract

The present chapter explores novel ways of thinking about what it means to remember and how precisely culture is involved in this process. Since Plato, the dominant metaphor for conceptualizing memory has been that of a spatial “storage.” In contrast to this, Frederic Bartlett advanced an alternative temporal metaphor of remembering as “construction.” If we push his metaphor further—with the help of cultural psychology—then we can say memory construction is done by agents using cultural “tools” such as language and narrative. In this chapter, Bartlett’s theory is contextualized, elucidated, critiqued, and developed with the help of a number of other thinkers. The ultimate aim of the chapter is to go beyond Bartlett and arrive at a thoroughgoing culturally inclusive psychological theory of remembering. Although Bartlett clearly situated remembering within a social process, he did not provide a social mechanism through which acts of remembering become possible. By contrast, Mead, Halbwachs, and Vygotsky have argued that remembering becomes possible through signs or symbols that experientially carry us outside of our embodied first-person perspective into the perspectives of social others. The activity of remembering is itself a process of dynamically integrating suggestions from self and others. The tension between perspectives is what drives the process of remembering and ensures its creativity and constructiveness.

**Keywords:** Memory, construction, Bartlett, metaphor, schema, signs, narrative, tension, agency

## Introduction

I would have you imagine that there exists in the mind of man a block of wax . . . When we wish to remember anything we have seen, or heard, or thought in our own minds, we hold the wax to the perceptions or thoughts, and in that material receive the impression of them as from the seal of a ring. Whatever is so imprinted we remember and know so long as the image remains.

—Plato, *Theatetus*, pp. 191D–191E

Remembering is not the re-excitation of innumerable fixed, lifeless and fragmentary traces. It is an imaginative reconstruction, built out of the relation of our attitude towards a whole active mass of

organized past reactions or experience, and to a little outstanding detail which commonly appears in image or language form.

—F.C. Bartlett, 1932, p. 213

The above quotations describe two radically different ways of thinking about what it means to remember: in the first, memory is understood as a spatial storage of sensory impressions, whereas in the second it is a wholly constructive activity involving imagination, feeling, and a synthesis of past experiences. For most of psychology’s short history, it has tended toward the first perspective. This is unfortunate because it is only the second perspective that provides us with an adequate starting point to bring

culture into the process of remembering. To be fully consistent, from a constructivist perspective, means taking mind out of the head and situating it in the unfolding interaction between an organism and its social and physical environment. In so doing, we can begin to conceptualize the ways in which past experience is agentially accessed, formed, and transformed through social cultural means, in interaction with actual or internalized others.

The argument of the present chapter can be put bluntly: Rather than simply cuing something internal, social others and cultural tools participate in and constitute the very process of remembering by providing the cultural framework or scaffold through which memories are constructed. To argue this thesis, the present chapter first examines some of the conceptual problems encountered by storage theories of memory by way of a historical and conceptual analysis of memory metaphors. It then goes on to explore Bartlett's alternative theory of remembering and how it can be developed to give the social and the cultural a central place in the process. To this end, a number of classic and contemporary sources are borrowed from, including the following: George Herbert Mead's theory of the social act is used explain how it is possible get out of our selves in remembering and to begin to theorize the perspectival dimensions of remembering; Maurice Halbwachs's theory of the "collective memory" helps to contextualize remembering at the societal level, in the projects of different social groups; and Vygotsky and recent work in cultural psychology then provide a means of giving agency back to the remembering individual—and analyzing the role of various cultural resources in remembering—while at the same time situating individuals and resources in the broader social cultural world to which they belong.

### **Bringing metaphors of memory to life**

All knowledge is ultimately rooted in metaphorical (or analogical) modes of perception and thought.

Thus, metaphor necessarily plays a fundamental role in psychology, as in any other domain.

—Leary, 1990, p. 2

Metaphors involve a dynamic "interaction" (Black, 1962) or "schematizing" (Werner & Kaplan, 1963) between the *object* in question and the metaphorical *vehicle* used to describe it. In other words, the object is constructed in terms of the vehicle. For example, in the metaphor "argument is war," the aggressive and oppositional aspects of

"argument" are foregrounded whereas others are hidden. Using an alternative metaphor, such as "argument is dance," new properties of the object can be seen (Lakoff & Johnson, 1980). In science the constructive nature of metaphor can be highly "generative" of new ways of thinking about and exploring a scientific object (Danziger, 1990a)—take, for example, Niels Bohr's revolutionary idea that the structure of the atom might resemble the solar system. At the same time, however, metaphors can impede scientific advancement when we forget that the way we describe our object is metaphorical and begin to believe in its literal truth. Theorists call this a *dead metaphor* as opposed to a *living metaphor*, which has the potential to revive our creative capacity for seeing the world anew by allowing us to take a new perspective on an object (Ricoeur, 1977; see also Burke, 1935, on "perspective by incongruity").

The idea that the memory is a place in the mind/brain, where experiences are *stored*, has become a dead metaphor and as such creates obstacles for thinking about memory differently. In this section, I will bring metaphors of memory back to *life* by investigating their historical origins and analyzing what is revealed and hidden with the description of memory as storage. This will then open up the possibility of developing fruitful alternative metaphors of memory that explore aspects of memory concealed by the storage metaphor. To accomplish the task of historically analyzing the metaphors of memory, I will draw principally on the work of Danziger (2001, 2002, 2008), Draaisma (2000), and Roediger (1980).

### ***Memory As Social Agent***

The storage metaphor of memory dates back to ancient Greek society. It was Plato who first made memory the property of individuals by positing a space in our minds—"a gift from the god Mnemosyne"—where memories are kept (see above quotation). Before Plato, in the age of Homer and Hesiod, the word "memory" (*mnēmē*) and its derivatives were probably only used in the context of oral performance of epic poetry or delivering a speech at a banquet—the Goddess Mnemosyne was also said to have invented language and words. The incredible feats of memory required for the performance of epic poems (which sometimes lasted several days) were not believed to come from something *inside* the performer but rather from the goddess Mnemosyne or her daughters, the muses,

**Figure 49.1** A Greek mosaic of Mnemosyne inspiring a speaker at a banquet.

who inspired the performer (see Fig. 49.1). Thus, memory here is a social relation. Moreover, concern over strict accuracy is hardly relevant in this context of memory—no single written record even exists to compare with the performer’s version. Rather, the performer learns the story by listening to other performers and creatively adapts it in the context it is told. In these circumstances, variations of the “same” story proliferate. This pre-Platonic notion of remembering clearly fits a *cultural* and *constructive* conception of remembering with its emphasis on *activity* (rather than “the memory” as a *substance* in the head), the commemorative function of remembering, the guidance of social others (in this case divine beings), and the imaginative adjustment of the material to social context.

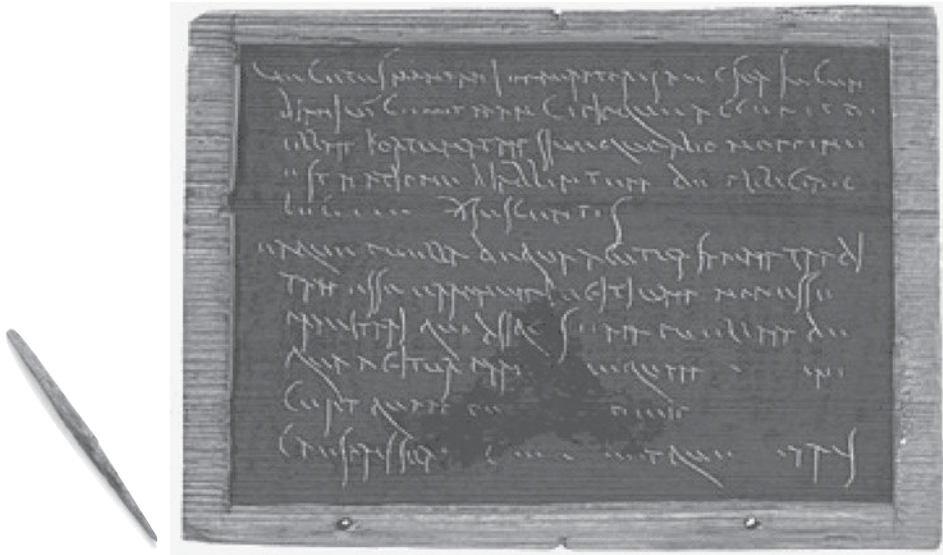

It is interesting to note that anthropologists and historians have noted similar conceptions of memory as a social relation in their research sites. For example, Vitebsky (1993) has characterized dead ancestors among the Sora in India as “Memories.” For the Sora, the deceased are not simply understood as attachments in time past; rather, they are active in the present and are attributed the power of pulling the living into death. Even more, Sora may have memories of the deceased’s death as experienced by the deceased. The deceased (active Memory) must be negotiated and appeased for the living to continue on with their life. Here memory is personified and given agency (cf. Valsiner’s analysis of play in an article titled “I create you to control me”—Valsiner, 1999). This conceptualization of memory of the dead as an active negotiation can be found in Medieval Europe as well. Its disappearance

is a result of the German reformation (Koslofsky, 2002). The Medieval Christians believed that most souls went to purgatory and were in continual need of the living. This changed with Luther, who argued that souls “sleep” until judgment day. The dead’s symbolic change of place coincided with the physical dislocation: Congested cemeteries in city centers were becoming public health hazards and were thus banished from the city limits. Interestingly, the psychological effect of this was not at first the disappearance of the dead from the lives of the living but, rather, that they were transformed from benign to malignant beings. In all these cases, memory is conceptualized as an active being outside the head.

### *The Inscription Metaphor*

#### PLATO’S METAPHORS

Plato’s originality was in making memories the properties of individuals—who have good or bad memory depending on the quality of their wax—and by generalizing this concept of memory to other contexts in which something previously learned is consciously brought to bear on the present. His use of writing as a metaphor for this process was not accidental: Just as the idea of divine inspiration was borrowed from the social practices of the day, so, too, was Plato influenced by the newly emerging social practice of writing, with which he would have become acquainted through his schooling. This is an early case of what Gigerenzer (1991) calls the *tools-to-theories heuristic*. Plato’s particular choice of wax tablets (see Fig. 49.2) for his metaphorical source is interesting in that they were not used for purposes of long-term storage. Wax tablets were useful because

**Figure 49.2** Wax tablet and stylus used in ancient Greece for writing

they could be easily erased so that the surface could be reused—thus, their function was for relatively short-term purposes, such as school exercises, notes, and memos. Marking a tablet was a simple means of *reminding* oneself of something, in the same way we write to-do lists today. For Plato, *reminding* was to be distinguished from *remembrance* or *recollection* (*anamnēsis*)—that is, recovering the knowledge of the Ideal Forms, already possessed at birth. In fact, implicit in his account of “remembrance” is a social metaphor, Socrates the “midwife” of Truth. For example, in the *Meno*, Socrates guides a slave boy to discover (or, in Plato’s terms, “to remember”) complex mathematical Truths through the social facilitation of dialogue. Thus, Plato also provides us with a theory of remembering with some similarity to the social perspective mentioned earlier.

The metaphor of writing was just one *possible* description of memory for Plato. For example, in the *Theatetus*, Plato also described memory as an aviary to explore the distinction between *possessing* and *having* knowledge. Birds in one’s aviary are *possessed*, but one has to hold them in one’s hand to *have* them. This is still a spatial storage metaphor of memory but it differs from an inscription metaphor in that it captures the feeling of *searching* for something (i.e., struggling to grab the right bird from the aviary) when we remember rather than *reading* from a stationary tablet. Plato’s diverse descriptions of memory are explorations of the phenomena, all of which conceive memory differently than his

contemporaries. As such, they are very much still *living metaphors*. In time, however, what was an innovative new perspective on memory became the only possible way of conceiving the phenomena—that is, a *dead metaphor*. In Aristotle, Plato’s metaphor of a wax tablet is already given a literal physical interpretation. Aristotle defined memory as “the having of an image regarded as a *copy* of that which it is an image” (Aristotle quoted in Casey, 2000, p. 14, my emphasis). Images are said to enter through the senses and are then imprinted on the physical body as a material trace in the same way a ring is imprinted on a wax tablet. This literal interpretation of inscription was retained through the Middle Ages, where advice was given to improve one’s retention of material by warming the back of one’s head!

#### **PERSISTENCE OF THE INSCRIPTION METAPHOR**

Memory as inscription (whether it is on wax tablets, parchment, paper, phonographs, or magnetic tape) has been by far the most common metaphor of memory in Western civilization. Part of the reason for this is the ubiquity of using marks as reminders. From pre-historic times, humans have been making marks on surfaces, in the form of images or symbols, as a kind of mnemonic device (see Donald, 1991). This practice reached a new level with the development of writing, which has held a central place in Western civilization since Plato. The other reason

for the dominance of inscription as a metaphor is the flexibility of the metaphor itself. Inscriptions or traces can be conceived quite literally as physiological changes made to the body or more figuratively as a symbolic representation of the thing to be remembered, such as words. This latter conception makes it possible to consider abstract drawings, written words, grooves in a record, digital code, and so forth as representations of the object to be remembered. The ancient *Art of Memory* (Yates, 1966), held in high regard until the sixteenth century, develops alongside this metaphor. In the “method of loci” technique developed by the Greeks and Romans, a person memorizes the layout of some building, street, or other well-lit geographical entity and then puts symbolic images, representing items to be remembered, in the discrete *loci* of the space. When the person needs to retrieve the information stored there, he or she walks in the space and decodes the images. Thus, wax tablets are substituted for imagined places as the surface on which the person inscribes.

In psychology, early advocates of the discipline, such as Wundt and Herbart, explicitly rejected memory as a scientific category because it was hopelessly tainted with commonsense ideas. Their vision for psychology as a discipline aimed at general knowledge construction, however, was abandoned for one that was closer to commonsense, and as such could easily be applied to different social institutions (see Danziger, 2001). In contrast, Ebbinghaus’s (1885/1913) explicit investigation of the “Memory” (the title of his book—the first of its kind in experimental psychology) was quickly appropriated by emerging educational institutions, because it was seen to offer advice for teaching children. Ebbinghaus (1885/1913) memorized lists of non-sense syllables (literally “meaningless” stimuli composed of a consonant, vowel, and consonant—for example PEV) and then tested himself to see the rate they were forgotten (“the curve of forgetting”), how well they were remembered as a function of their position in the list (“the serial position effect”), how much time it took to relearn them after they had been forgotten (“saving”), and so forth. Indeed, this study did share something in common with the rote learning of lists done in formal schooling. Ebbinghaus’s use of non-sense syllables was likely motivated by his use of the inscription metaphor of memory, which he explicitly used to conceptualize his results:

These relations [experimental results] can be described figuratively by speaking of the series as being more or less deeply engraved in some mental

substratum. To carry out this figure: as the number of repetitions increases, the series are engraved more and more deeply and indelibly; if the number of repetitions is small, the inscription is but surface deep and only fleeting glimpses of the tracery can be caught; with a somewhat greater number the inscription can, for a time at least, be read at will; as the number of repetitions is still further increased, the deeply cut picture of the series fades out only after ever longer intervals.

(1885/1913, pp. 52–53)

How does this persistent metaphor of inscription construct memory as an object? In other words, what does it reveal and conceal? Danziger (2002) points out how inscription carries with it three fundamental assumptions about memory:

1. Three distinct phases: The use of writing as an external memory technology requires three distinct activities separated in time: *Writing*, *storage*, and *reading*. Contemporary psychology has replaced wax tablets with a computer disk but the three distinct phases remain and are now called “encoding,” “storage,” and “retrieval.” Randall (2007) has recently suggested replacing the computer metaphor of memory and its three phases with a “compost metaphor,” which has the “organic” and inter-related activities of *laying it on*, *breaking it down*, *stirring it up*, and *mixing it in*.

2. The individuated trace: Writing leaves a trace that is distinct from other traces. This assumption is reinforced in the contemporary psychology laboratory by using material that can be easily itemized and counted, such as non-sense syllables and word lists (Mori, 2010). The individuated trace hides that memories often blur together into a generalized image. Also, remembering is often incorporated into one’s whole body and performed in context (Connerton, 1989).

3. The decontextualized text: Writing is a particular genre of communication very different from external or inner speech (Vygotsky, 1986), in that the text retains its form and meaning irrespective of the social context. Everyday conversational remembering, in contrast to writing, is highly dependent on context (Middleton & Edwards, 1990).

One additional assumption, related to the other three, should also be introduced here:

1. Spatializing memory: Writing implies a space or place upon which it is done (see also

the *Art of Memory*—Yates, 1966). That place has generally been located “in the heads” of individuals. Alternatively, remembering might be thought of *temporally*. This requires us to attend to remembering as an unfolding process, situated in the interaction between organism and its environment, its past and its present. This is one of Bartlett’s (1932) key ideas to which I will return in the next section.

### ***Towards Alternative Metaphors***

It would be too simplistic to say that the various *storage* metaphors of memory are “untrue.” Each does reveal something about the phenomenon and may lead to some practical use—for example, the development of the *method of loci* (Yates, 1966) or improved methods for rote learning in schools. But every metaphor also conceals something: in this case the temporal, cultural, contextual, and constructive nature of remembering is hidden from view. It is disadvantageous to the advancement of science to forget the constructed nature of scientific objects and believe these objects simply *are* the metaphorical description we give them—this is especially true in the social sciences. By examining the metaphors of memory above, we are now in a better position to develop new ways of thinking about remembering with the use of alternative *living* metaphors. In what follows, I will examine Bartlett’s alternative to the storage conception of memory and further develop it with the help of a number of other theories.

### **Situating remembering: from storage to action**

I have never regarded memory as a faculty, as a reaction narrowed and ringed around, containing all its peculiarities and all explanations within itself. I have regarded it rather as one achievement in the line of the ceaseless struggle to master and enjoy a world full of variety and rapid change.

—Bartlett, 1932, p. 314

### ***Bartlett’s Experimental Program***

Bartlett’s approach to remembering was developed in direct opposition to the storage conception. In the first chapter of *Remembering: A Study in Experimental and Social Psychology* (1932), titled “Experiment in Psychology,” he criticizes the inadequacy of Ebbinghaus’ (1885/1913) non-sense syllable method to the phenomena of memory and mind more generally. Bartlett argued that (1) it is impossible to fully remove meaning from stimuli

that require a human response; (2) attempting to do so creates wholly artificial conditions with little generalizability to everyday life; and (3) this method ignores equal, if not more important, aspects of remembering, such as meaning, imagination, and emotion.

In contradistinction, Bartlett described remembering as an “effort after meaning” and advanced an experimental program to study it as such, using complex stories and images, with an analytic focus on understanding holistic human responses as they are related to an individual’s personal and social history. Bartlett is most famous for his *repeated reproduction* experiment in which a single subject reproduces a Native American folktale called *War of the Ghosts* at increasing time delays (e.g., after 20 minutes, a week, a year). The foreign story comes to look more English: “hunting seals” changes to “fishing,” supernatural elements are rationalized away, and the whole narrative structure is transformed. In conversation with his subjects, he found they would link the unfamiliar story to something familiar to them: one of his subjects commented that the story was “like I read as a child.”

Bartlett also used other methods for studying remembering. In the *method of serial reproduction*, a subject’s reproduction is shown to another subject to be reproduced at a delay, which is then shown to yet another subject, and so on. Then there is the *method of description* where a subject describes a set of images after a time delay. And finally the *method of picture writing* involves a subject memorizing pictures corresponding to words; at a later time the experimenter calls out words for which the subject is to write the corresponding pictures. A number of methods were also used in *Remembering* to explore “perceiving and imagining,” highlighting the fact that Bartlett did not see these as unrelated processes. In all these experiments, Bartlett found subjects’ interests, affects, ideals, and previous experience played a central role in how stimuli were perceived, imagined, and remembered.

### ***Bartlett’s Theoretical Assumptions***

Bartlett’s research program was guided by a number of distinctive assumptions about the mind:

1. The multiple bases of cognition: Bartlett recognized the importance of the social, the psychological, and the biological bases of cognition and attempted to bring them together in his theorizing (see Saito, 1996, 2000). His work clearly

reveals the impact of contemporary developments in anthropology, psychology, and neurology. He attempted an integration of these ideas that brings together the biological-functional and the socio-cultural features of mind.

2. Mind as active process: Bartlett consistently used the gerund form of mental verbs to emphasize ongoing psychological processes over static things—for example, the title of his book is *Remembering* rather than the *Memory*. Furthermore, he described all well-developed psychological processes as involving an “effort after meaning” (cf. Ganzheitspsychologie’s notion of “striving for the whole”—Diriwächter & Valsiner, 2008). In other words, the mind does not mechanically respond to inputs like a machine, but rather it has purposes in the world, it strives to construct an intelligible world in which to act by “connecting something given with something other than itself” (Bartlett, 1932, p. 227).

3. The unity of mind: The mind operates as a whole, not as a number of separate faculties. Therefore, it is unfeasible to make sharp distinctions between perceiving, recognizing, remembering, imagining, and thinking (see Edwards & Middleton, 1987). They are all manifestations of a unitary mind and as such differ in *degree* but not *kind*. For example, imagining is freer and involves multiple settings, whereas remembering is focused more on a single setting, although Bartlett’s experiments clearly show other settings do play a significant part in remembering. This idea of mind’s unity is also central to “organismic” theories, such as those of Goldstein, Werner, and Whitehead.

4. Feeling and attitude: An “attitude” said Bartlett (1932, p. 191) “has to be treated as belonging to ‘the whole’ subject, or organism.” It is an organism’s holistic “felt” way of relating to the world through which different parts come into focus. Elsewhere, Bartlett (1925, p. 17) said feelings arise “whenever . . . a response is held up, obstructed in some way, or [ . . . ] the cognitive material involved in the making of a response is blurred, vague or indefinite.” In other words, when one’s habitual activity is interrupted, a feeling or attitude provides a quick means of reorientation to the world (cf. Rosenthal, 2004). Higher psychological responses (i.e., responses involving consciousness) are said to begin with an attitude turned to the past, a point I will elaborate on below.

When we apply this general framework to the phenomenon of remembering, the question of accuracy of memories is subordinated to the question of

how an organism uses its past in its ongoing transactions with the environment. From this “functionalist” perspective, remembering many details with strict accuracy may actually be dysfunctional. In his study of the mnemonist Shereshevsky, Luria (1987) told us that Shereshevsky’s memory for details was limitless; however, rather than benefiting him, it interfered with his ability to generalize from the particulars (see also below). His life was simply a vast collection of details without integration, and as such the job of a professional mnemonist was all that really suited him. By contrast, normally functioning individuals remember the *gist* of an event together with a few outstanding details. This provides the individual with a past that can be flexibly used to deal with an uncertain and changing environment.

### *The Concept of Schema*

#### BARTLETT’S FORMULATION

To theorize this process of flexibly using past to adapt to the present environment and prepare for the future, Bartlett developed the concept of “schema,” which he explicitly borrowed from the Cambridge neurologist Henry Head. Head (1920) provided examples of brain-damaged patients who have lost the ability to coordinate one movement with the next:

Let him close his eyes and let the hand be picked up and the hand and arm moved. He may be able to localise the spot touched on the skin surface perfectly well, but he refers it to the position in which the hand was, because *he has entirely lost the capacity to relate serial movements.*

—Bartlett, 1932, p. 199, my emphasis

This striking case of schematic breakdown makes clear that localizing a sensation in space requires fitting it to the past and present combination of sensations of one’s entire body. If one’s corporeal schema is severed, then there is no way of coordinating sensations in time and space; thus, they take on this strange isolated character in experience.

A schema here is an indivisible series of temporally organized body postures, such as climbing the stairs or making a stroke in tennis. At a more psychological level, an example of a “low-level schema” would be recalling a phone number: the stream of numbers comes to us as a temporal flow. The same numbers could not be remembered in reverse order in the same way.

Bartlett generalized the concept of schema (from its corporeal origins) to apply to any “well-developed

organic response,” including “visual, auditory, various types of cutaneous impulses and the like, at a relatively low level; all the experiences connected by a common interest: in sport, in literature, history, art, science, philosophy and so on, on a higher level” (Bartlett, 1932, p. 201). He said that he preferred the terms “active developing patterns” and “organized settings” to “schemata” but continued to use the latter nonetheless.

Whatever name is given to the concept, the general idea is that any present response is possible because it becomes part of an organized set of past reactions, which are “actively doing something all the time” (p. 201). In other words, any reaction utilizes existing schema but at the same time further develops them, in a fashion analogous to Piaget’s notions of assimilation and accommodation. Thus, an action has a dual existence, being generated out of both an organism’s past and the demands of its present situation. The past is carried forward *en masse* and flexibly adapted to the novel features of the present situation.

#### RE-APPROPRIATIONS OF SCHEMA: COGNITIVE AND DISCURSIVE PSYCHOLOGY

Psychologists since Bartlett have interpreted the schema concept in a number of ways. On the one hand, this is the result of Bartlett’s variable use of the concept (Norway, 1940), a problem that often occurs when thinkers use highly technical terms (Billig, 2011). On the other hand, the various interpretations of “schema” is an outcome of the constructive assimilation of knowledge (as it moves from one social group to another) that Bartlett (1923, 1926, 1928, 1932) himself theorized (for a history of appropriations of Bartlett’s ideas, see Johnston, 2001).

Cognitive psychology has mostly taken “schema” to mean a generic knowledge structure where experiences are stored, thus assimilating Bartlett’s novel metaphor of memory to the familiar storage metaphor. This conception is apparent in Mandler and Johnson’s (1977) notion of “story schema,” a universal and abstract story “grammar” that selects which discrete parts of a story are memorable and forgettable. These psychologists have moved beyond a simple storage metaphor to a hierarchically organized model, but this model still *spatializes* memory and locates it in the head (Roediger, 1980). As such, this conception does not incorporate Bartlett’s (1932) key insight that psychological activities are *temporally* organized into a continuous stream of serial movements in context. A second problem is

that Mandler and Johnson (1977) assume “story schema” is the same for anyone in any society and at any historical time period. Thus, they also ignore Bartlett’s interest in linking schema to the customs, traditions, and values of *specific* social groups, a point I will further elaborate on below in the section “The Social Context of Remembering.”

At the other extreme of interpretation is discursive psychology’s understanding of schema as discourse conventions—they point out Bartlett’s preferred term was *organized setting*. Their analysis becomes one of comparing differences in discourse between one social context and another, rather than between a stimulus and a subject’s later memory of it (Middleton & Edwards, 1990).

Discursive psychology analyzes precisely what cognitive psychologists have ignored (i.e., social context) and understandably so, because the discursive approach challenges the wider validity of processes observed in an experimental context. Middleton and Edwards (1990), for example, compare the differences in conversationally remembering a film as part of an experiment and post-experiment, by leaving the tape recorder running after the “experiment” finishes. They find that in the experiment, subjects focused on sequentially ordering and connecting events, whereas post-experiment, the focus shifted to evaluations of the film and emotional reactions to it. Istomina (1975) also found that creating an experimental task resembling a meaningful activity in children’s lives greatly improved their memory for lists of words when compared to standard “neutral” experimental tests (see also Mistry et al., 2001). Thus, there is no way to divorce psychological processes from the context in which they occur: Experiments are themselves a particular context, which like all contexts shape the psychological processes embedded within them.

Discursive psychology significantly develops the social contextual strand of Bartlett’s schema concept—by carefully comparing discourse conventions between specific contexts—but the approach also leaves aside another important characteristic of schema—namely, that “memory is *personal* [...] because the mechanism of adult human memory demands an organization of ‘schema’ depending upon an interplay of appetites, instincts, interests and ideas peculiar to any given subject” (Bartlett, 1932, p. 213, my emphasis). In discursive psychology, the personal and experiential qualities of a memory (marked as belonging to *my* past) is

irrelevant insofar as it does not contribute to the collective project of remembering.

### MORI'S RE-EMBODIMENT OF SCHEMA

Mori's (2008, 2009, 2010) innovative interpretation of Bartlett's schema concept takes a middle road between cognitive and discourse approaches by acknowledging that remembering occurs in social context, usually in discourse, while at the same time focusing on the personal dimensions of remembering in his analysis. To do this, Mori has created an experiment in which subjects *navigate* around a university campus and a month later *exchange* their experience with another subject who navigated a different university. Thus, each subject has knowledge of two university navigations—one direct and the other indirect. Two weeks after the *exchange*, subjects are *interrogated* about what happened during the navigations by a third subject who believes the subject navigated both universities. This is followed by two additional *interrogation* sessions taking place at 2-week intervals—an adaptation of Bartlett's (1932) method of repeated reproduction. It is important to note that Mori's experimental set-up does not attempt to separate psychological processes from context but instead tries to *model* the social context of being interrogated or giving testimony in court.

In his analysis, Mori (2008) has compared a subject's narrative for the direct and indirect experience of navigation to discover their different "organization of schema" for each experience. He finds that the narrative of direct experience of an environmental navigation takes the form of what he calls "agent-alteration"—that is, referring to agents of action (self and other) alternatively, such as "I did ... then **he** did ... so **I** did." This parallels the alternating action between agent and environment that Gibson (1979/1986) called "perception-action cycles." In the narrative form of indirect experience, by contrast, "agent-succession" dominates, whereby the agent is referred to successively—for example, "I did ... then **I** did ..." These same differences in narrative form were also found in the testimony of a murder defendant regarding different memories (Hara et al., 1997), thus suggesting Mori (2008) has successfully *modeled* the context of an interrogation in his experiment. Mori (2008) has also identified four other differences in narrative form, of which I will only briefly mention two: multiple descriptions have been given to an object and it has been unstably named in the narrative of the direct

experience, whereas poor descriptions of the object and a single name were given in the narrative of the indirect experience.

The *temporal* and *contextual* nature of Mori's schema concept needs to be stressed here, for it clearly develops these features of Bartlett's (1932) concept. In remembering, we, in a sense, re-experience the temporal unfolding of cyclical contact with the environment, although we also change the experience in the process of doing so—Mori (2008) has pointed out that in the repeated reproduction of the direct and indirect experiences, the differences between them gradually disappear. Memories are not localized in the head but, rather, in time and place: The past time of an experience becomes embedded in present time of remembering it, and in both past and present temporalities the person finds themselves in contact with an environment. Mori (2008, p. 313) has made this general point about a memory's temporality and contextuality eloquently:

Pre-modern people asked why things burnt. Their answer was that they had phlogiston (burnable stuff) in them. Psychologists once asked why we remember our past and answered that we had engram (memory trace) in us. They were both mistaken. People now know burning is one type of oxidation. So what is remembering? It is an emergent activity (often communicative) that is restricted by both rememberers' duration of experience and the present situation in which it is performed.

### *Bergson's Distinction*

Bergson (1911) made a similar claim long ago when he argued that because the brain was necessary for actualizing memories does not mean that memories reside in the brain. Similarly, bicycle's chain is essential to its motion but we would not say that the motion resides in the chain but, rather, in the whole system in which the chain is a part. It has already been argued above that thinking of memories as stored in a spatial location is misleading. Rather, we might say memories are to be located in *my* personal past and the places I have been. This is why Bergson (1911) made a fundamental distinction between perception and memory. He admitted perception involves memory but said that it does so only to interpret what is present, and as such differs only in *degree* from matter. By contrast, memory is always distinctly *of the past* and thus differs in *kind* from perception.

Most of psychology, in contrast to this distinction, has inherited an empiricist's conception of perception and memory, whereby perception is reduced to the effect of static and isolated impressions on the sense organs, which in turn create a representation in the theater of the mind. Memories are then simply a dulled form of the perception. Ecological theories of perception, such as Gibson's (1979/1986), argue that perception is better described as an unfolding activity that holistically weaves together past and present as subject acts on the world than as sensations passively impressed on the mind. In this framework, individual perception does not, on its own, provide discrete units of experience that can be stored away as isolated traces to be remembered later; rather, it shows a "duration" of experience, which is only differentiated into memorable objects and localized in experience with the help of social means (Halbwachs, 1925). It is to this process of self-reflection and the social differentiation of experience that we turn.

### Remembering as "turning around on one's own schema"

When a self does appear it always involves an experience of another; there could not be an experience of a self simply by itself. The plant or the lower animal reacts to its environment, but there is no experience of a self.

—Mead, 1934, p. 195

The schema concept by itself did not yet explain, for Bartlett, what is involved in remembering as an "emergent" human activity; rather, it explained how the past manifests itself in an individual's non-reflective engagement with the world. To locate specific information about the past, "the organism has somehow to acquire the capacity to turn around upon its own 'schemata' and construct them afresh" (Bartlett, 1932, p. 206). In other words, it must become "self-reflexive." In doing so, the organism ruptures its seamless flow of activity in the world by evoking schemata that are not present, thus stimulating action outside of the particular parameters of the here-and-now situation. When this happens, schemata become "not merely something that works the organism, but something that the organism can work" (p. 208). This is the point at which consciousness arises and the environment becomes dual: Past and present differentiate such that the organism can now use the specific settings of its past to control itself in the here-and-now so as to prepare for an imagined future. In Bartlett's words,

past schemata are made the "objects of his reaction" in the present (p. 202). Let us look more closely at exactly what is involved in remembering as a self-reflective process.

### *The Process of Reconstruction*

Bartlett (1932) says that remembering begins by setting up an *attitude* (i.e., a holistic feeling orientation), such as "doubt, hesitation, surprise, astonishment, confidence, dislike, repulsion" (pp. 206–207), toward an object or event. One way of setting up an attitude is by naming an object—for example, in Bartlett's experiments using the Native American story *War of the Ghosts*, one subject began by saying, "[It's not English," and another, "like I read as a child." When we remember, we turn our "attitude towards the massed effects of past reactions [i.e., schema]" (p. 208), and proceed to construct a memory of the object or event "largely on the basis of this attitude, and its general effect is the justification of the attitude" (p. 207). In other words, we first get a general *impression* of the material that guides us in reconstructing the probable details.

Rather than a smoothly flowing process, like the operation of schema in habits, remembering as a self-reflective process is hesitant and jerky: The person begins to remember, reaches a point of ambiguity and says to oneself, "This must have gone there." In these moments of ambiguity, individuals may choose from a variety of schemata to fill in gaps in memory. It should be noted here that "construction" and "distortion" are not synonymous; construction is a fundamental process of remembering that can lead to both accurate and distorted memories.

### THE FUNCTION OF IMAGES

In moments of ambiguity, *images* often also arise to provide a quick solution for action. Bartlett's *schema* concept is used to explain the *generalization* and *homogenization* of experience that occurs in remembering. By contrast, images *particularize* remembering by generating a *plethora* of details. They do this by "picking bits out of schemata" (p. 219) and thus break apart the seamless flow of schema, giving self-reflexive remembering its jerky character.

Images can also aid in the formation of attitudes—for example, an image might spontaneously come to mind when asked to recall a story, which in turn can be used to set up an attitude to the schema from which the image comes. Bartlett has told us how only one subject remembered the two town names from the Native American story *War of the*

*Ghosts*. This imagery enables her to set up an attitude toward the story as a whole so that she can proceed to reconstruct the story. Images are then used as navigation points in the reconstructive process.

At first sight, the image concept seems to sneak in a storage theory of memory through the back door. The difference is that in Bartlett's theory, images are actively constructed based on an organism's interests and emotions and change according to them. Also, images have to be understood as functioning to facilitate an organism's action: Bartlett (1925) said images arise out of cross-streams of two dominant conflicting tendencies to action as a way of enabling a quick unambiguous response in the face of uncertainty.

Bartlett (1916b, 1932) has distinguished two kinds of images—"visual" and "vocal." Both serve the same function of breaking schemata, but their character differs in many respects. First, visualization is said to carry certainty with it, whereas vocalization is accompanied by doubt. This is the case because of visual images' vivid, rich, and exciting expression in consciousness. Because of these characteristics, when a subject is torn between a visual and vocal memory of an object, they will choose the former. Second, vocalization is a direct expression of meanings, whereas meanings have to be developed out of visualization. Therefore, remembering through visualizing appears "jerky" in comparison with vocalizing. Bartlett also commented that subjects tend to prefer the use of one of these modes in their engagement with his experimental tasks, which he can say because he used some of the same subjects in multiple experiments.

#### **SHERESHEVSKY'S MEMORY: A COUNTER-EXAMPLE?**

As further illustration of this process, consider the abnormal case of Shereshevsky, in which no reconstructive process seemed to occur. Luria (1987) has told us the reason for Shereshevsky's near flawless memory for details was his vivid mental imagery and extreme synaesthesia, where stimulation of one sensory pathway simultaneously leads to the automatic experience in another. Consider his description of the experience of remembering:

I recognize a word not only by the images it evokes but by a whole complex of feelings that the image arouses. It's hard to express . . . it's not a matter of vision or hearing, but some overall sense I get. Usually I experience a word's taste and weight, and I don't have to make an effort to remember it—the

word seems to recall itself. But it is difficult to describe. What I sense is something oily slipping through my hand . . . or I'm aware of a slight tickling in my left hand caused by a mass of tiny, lightweight points. When that happens, I simply remember, without having to make the attempt.

(1968, p. 28)

Shereshevsky formed detailed and enduring mental *images* of the material to be remembered. He also set up an *attitude* toward the material, although for him it is much more than a general impression, as it is for most of us; rather, it was a complex code for details. This enabled him to effortlessly remember some material in its entirety and rigorously check the veracity of his recall against the whole-body feeling that the object had created for him. If any details were different in recall, then he would immediately sense it. His eidetic-synaesthesia was an extreme form of abilities we all have (i.e., we all use attitudes and images in remembering); however, because these worked so flawlessly for him, schematization never got off the ground.

#### **A THEORY IN DEVELOPMENT**

Bartlett's (1932, Chapter 10) "theory of remembering" is highly phenomenological and does not provide a precise mechanism for how we escape our embodied action in the here and now—that is, how to "turn around on one's own schema." In two places in *Remembering*, Bartlett explicitly stated, "I wish I knew how it was done" (pp. 206, 209) and in an unpublished paper, written at the end of his life, he defended the phrase "turning around on one's own schemata" as simply a "description" of what he found, rather than an "explanation" of the process (see Bartlett, 2008, pp. 4–9). This gap in his theory is one reason why the concept of schema was rejected by Bartlett's students (e.g., Oldfield & Zangwill, 1943). In one place in *Remembering*, Bartlett did locate the origins of this process in complexities of human social life where "the 'schema' determined reactions of one organism are repeatedly checked, as well as constantly facilitated, by those of others" (Bartlett, 1932, p. 206), but this idea remains undeveloped. An explanation of how "turning around on one's own schema" is possible requires the theoretical support of the pragmatist philosopher and social psychologist George Herbert Mead.

#### ***Becoming Other to Ones Self***

Mead (1934) argued that we are able to self-reflect because we can take the attitudes of others toward

our Self. This process is made possible through symbols and position exchange. Self emerges out of a naturalistic process of social interaction. A child becomes reflexive (i.e., they can turn around on his or her own schema) when he or she is able to take the perspective of another toward him or her self. This develops out of the participation in institutionalized “social acts” (i.e., acts directed at others), through stable social positions (in reality, play, or imagination), such as buying and selling, giving and receiving, hiding and seeking, talking and listening, teaching and learning, and so forth. In so doing, the child simultaneously embodies divergent perspectives (or “attitudes”) for the same social act.

These divergent perspectives (e.g., buying and selling) are paired through the “vocal gesture,” which is heard from both sides of a social act. A gesture becomes “significant” (i.e., a symbol) when the gesture-maker takes the attitude of the other in the social act toward himself or herself, thus becoming both subject and object in experience. They know how the other will respond to the gesture because they have been in that social position before. When this communication is turned inward, it becomes inner thought, and externally paired social positions become the architecture of the self (Gillespie, 2006). Reflection is a process of taking up these different social perspectives toward one’s self—that is, becoming other to self. This is possible because the significant gesture is able to experientially transport us from one perspective to another.

#### FIELD AND OBSERVER PERSPECTIVES

Mead’s theory can help explain a number of observations about remembering that have been explored by cognitive psychology. First, at least since Freud (1899), it has been recognized that when remembering we can find ourselves in either first- or third-person perspectives. These two perspectives have come to be known as “field” and “observer” memories, respectively (see Nigro & Neisser, 1983; Robinson & Swanson, 1993). Remembering often involves moving between the two perspectives. This would be expected if Mead were right that the symbol allows us to experientially move from one perspective to another, opposite perspective.

The tendency in this research has been to take the presence of an observer as a sign of false memories; however, the two perspectives could also be seen as signs of different strategies of remembering. Movement from first- to third-person perspective

may be a change from embodied to increasingly distanced and language-mediated strategies.

We know from our own experience that an action physically perceived from the first-person “field” perspective is often elaborated in remembering as if we witnessed it from the perspective of others. I also found this happening in the reverse direction in a conversational repeated reproduction experiment I did using Bartlett’s *War of the Ghosts* story. From subject’s gestures, it was possible to see their taking on the protagonist’s position in the story when remembering it—for example, “crouching” down when the protagonists hide behind a log. Putting oneself in the first-person perspective in remembering a story could be seen as a strategy of encoding a memory into one’s body. To my knowledge, no one has systematically explored this phenomenon.

Relating this work to Mori’s (2008) experiment described above, we would likely find the more an experience is narrated, the more likely we will experience it from an “observer” perspective and, as Mori (2008) found, the more the memory will take on a conventional form. In Mead’s (1934) language, subjects increasingly take the perspective of a “generalized other” (i.e., the perspective of a whole social group) toward their memory, whereas the first-person experiential qualities of making contact with an environment become less prominent.

In sum, Mead’s theory situates the perspectival dynamics of mind and memory transformations within a broader social process, whereas it remains largely “in the head” in cognitive psychology’s formulation, although in a more active form for this theory than traditional storage theories of memory.

#### METAMEMORY: OBSERVING AND CONTROLLING REMEMBERING

Cognitive psychology has developed the notion of “metamemory,” which Flavell and Wellman (1977, p. 4) originally defined as “[An] individual’s knowledge of and awareness of memory, or of anything pertinent to information storage and retrieval ... [For example,] a person has metamemory if he knows that some things are easier to remember than others, is aware that one item is on the verge of recall, while another is wholly irretrievable at present.” This conception posits two levels to remembering (the “object level” and “meta-level”), which are related through “monitoring” (where information from the object level is observed by the meta-level) and “controlling” (where meta-level directs information flow at the object level).

For example, telling research participants that they will be asked some misleading questions about their memories neutralizes the memory “distortion” affects made famous by Loftus’s (1975) automobile accident experiment, where she suggested that there was a broken light at the scene (there was not) and found subjects mistakenly remembered the broken light. Of course, these suggestions are entirely probable. Yet, neutralization of the suggestion has still occurred if subjects have been told they were asked misleading questions some time after they were asked (Blank, 1998, 2009). This suggests we are not the memory dopes suggestibility research often makes us out to be. Instead, we agentically use various social influences in controlling our own remembering: Subjects actively appropriate misleading questions, which in turn shape their memories in a particular direction. These tools of remembering can easily be abandoned or blocked by the subject if he or she is given reason to mistrust them.

Instead of considering social suggestions as simply potentially distorting influences, they need to be reconceived as providing the framework for remembering to happen in the first place. When others are not present, we still *self-suggest* to remember, taking the perspectives of internalized others toward our Self. Suggestions become layered in the process of remembering, some blocking the influence of other suggestions whereas some are supporting (Valsiner, 2001). Thus, we need to move away from the notion that the social simply corrupts individual rationality and adopt the more “social” social psychological perspective, in which the individual only becomes rational through social interaction, as Mead’s theory would have it. To do this, we will now look more closely at the social embeddedness of remembering.

### The social context of remembering

It is in society that people normally acquire their memories. It is also in society that they recall, recognize, and localize their memories.

—Halbwachs, 1992, p. 38

Bartlett was well-aware that his experiments were only “social” in a limited sense. They did not, for example, explore how the presence of social others might shape remembering. What they did do was to powerfully show that a group’s norms, customs, values, and beliefs had a directive influence on an individual’s remembering, even outside of the direct presence of the group. In this respect, he was clearly

working within a more “social” social psychological perspective, in which new properties emerged from interaction in groups that could not be predicted from the psychology of individuals (*see* Greenwood, 2004). Bartlett (1932, p.254) said:

We may ... legitimately speak of customs, traditions, institutions, technical secrets, formulated and unformulated ideals and numerous other facts which are literally properties of groups, as the direct determinates of social action ... They are correctly regarded as group properties, because they come into being only as the group is formed, and if the group disintegrates they pass away.

Analysis, therefore, requires exploring the relationship between individuals’ acts of remembering and their history in various social groups. This is one reason why Bartlett thought that individual reactions (even in controlled experiments) had to always be interpreted in light of their history. Although Bartlett utilized a more open interpretive method of analysis in the laboratory, experimentation itself limited possibilities for exploring the place of the social in remembering by setting a restricting social context of remembering where subjects tended to focus on details and less on meaning. In 1929, however, an opportunity presented itself to collect field data in Swaziland, South Africa. It is from these field notes that he goes on to more explicitly address the question of social influences on remembering.

### Social Groups and Social Schema

Commonsense still leads people to talk as if a person’s memory was good or bad in itself rather than good or bad at remembering a particular kind of material. Plato had also said that an individual’s memory was good or bad memory—in the sense of retaining information—depending on the quality of his or her “block of wax” (i.e., memory faculty). In contrast to this, Bartlett (1932, 2008) thought his experiments and fieldwork made clear that *memory is domain specific and socialized by the group*. Contemporary studies on memory expertise (e.g., on chess players and waiters) seem to also conclude that impressive memory abilities result from skills to meaningfully organize information in a particular content domain (*see* Ericsson et al., 2000, for a review). Interaction in groups guides individuals to selectively attend to and meaningfully elaborate on some material. Let us consider more closely how Bartlett theorized this process.

Bartlett notes that social groups develop “preferred persistent tendencies” or “social schemas,” which set up a structure through which members orient to the world, selecting what aspects are memorable and forgettable. For example, he asked a Swaziland herdsman for “a list of the cattle bought by his employer the year previously, together with whatever detail he cared to give” (Bartlett, 1932, p. 249). The herdsman had merely overheard the transaction a year earlier and had nothing to gain from it. However, cattle dealings were an important social activity within this community; as such, it was not unexpected that the herdsman would remember the transaction with incredible detail, making only two “trifling errors.” The opposite will occur (i.e., radical reconstruction of the material) when the material to be remembered comes from outside the social group—for example, a foreign folktale or picture. In this case, the material will be significantly transformed through assimilation, simplification, and constructive elaboration into a familiar cultural form. Bartlett (1932) called this process *conventionalization*.

#### CONVENTIONALIZATION

A powerful example of conventionalization comes from the anthropologist Nadel, who was directly influenced by Bartlett. Nadel (1937) was doing fieldwork in Northern Nigeria on the Nupe tribe but also had contact with the Yoruba tribe. Although the two groups lived in the same material environment and had similar levels of technology, they developed entirely different, almost antagonistic, cultures. For example, whereas the Yoruba had a rationalized hierarchy of deities each with their specific function and power, the Nupe believed in an abstract and impersonal power. Similarly, the Nupe had ornamental decorative art, whereas the Yoruba focused principally on the human figure. In short, Yoruba culture tended to involve integrated and concrete meanings, whereas Nupe culture focused on abstract unconnected details. Nadel saw an opportunity to test Bartlett’s ideas about group influences on recall and constructed a story to give to children from both groups. He hypothesized that children would transform the story in the direction of their group’s preferred persistent tendencies. Indeed, he found that the Nupe children tended to loosely fill in details that were inessential to the narrative progress. By contrast, Yoruba children changed the story toward logical coherence of narrative structure by adding rational links between events.

In both Bartlett’s and Nadel’s research there is a focus on *specific* social groups, the cultural conventions particular to them, and their influence on the thought processes of individuals. Bartlett also explored the influence of social schema particular to the context of World War I, when many of his experiments were carried out. For example, he described how, when one of his subjects—who lived among people who were constantly talking about and expecting air raids—was presented with a pointing hand, he said immediately that he had seen an anti-aircraft gun firing at a plane (Bartlett, 1932, p. 244). In his serial reproduction experiment, Bartlett noted how the excuse given by one of the young men for not going to battle, in the *War of the Ghost* story, was changed to “elderly relatives ‘would grieve terribly’ if he did not return” (p. 129). New social schemas can thus emerge under certain social conditions. Bartlett also saw this happening with a group’s folklore, which for him was a primary means of discovering a group’s preferred persistent tendencies. For example, the Swazis, who had been subjugated by the Zulu, developed a narrative whereby a stronger figure (e.g., a lion) was tricked by a weaker but clever figure (e.g., the weasel) (p. 260).

#### *Social Frameworks of Memory*

In formulating his social psychological theory of remembering, Bartlett drew on the ideas of the French sociologist Maurice Halbwachs, although with some reservations. Halbwachs followed his mentor Durkheim in arguing that memory only becomes possible out of participation in a collective. However, rather than abstractly theorizing about “society” as Durkheim did, Halbwachs preferred to discuss concrete social groups, such as family, religious, and class groups. In belonging to various social groups, an individual takes part in different “social frameworks” through which his or her experience takes shape, becomes memorable, and can later be retrieved.

#### WHAT ARE SOCIAL FRAMEWORKS?

A social framework is essentially a series of condensed images of the past and a structure to order and give them meaning. For example, families often express a moral quality inherent in their group with pronouncements like, “in our family we have long life spans,” “we are proud,” or “we do not strive to get rich.” A family’s collective memories will tend to center on vivid images that concretely express an abstract evaluation of a group and its members;

stories are told of individuals that seem to sum up their character as defined by the group. The very names of our family members are surrounded by a certain aura and set of associations, long after our family members pass away. Halbwachs was clear that the group does not need to be physically present for it to exert its influence, because the person carries the group's perspective within him or herself.

Our memories remain collective . . . and are recalled to us through others even though only we were participants in the events or saw the things concerned. In reality, we are never alone. Other men need not be physically present, since we always carry with us and in us a number of distinct persons.

—Halbwachs, 1980, p. 23

In addition to vivid images, language is a primary mechanism by which individual experience is linked to these social frameworks. Through naming and categorizing experience, social frameworks enable the differentiation of individual experience into meaningful social forms. In language the individual takes the perspective of the group toward his or her own experience (cf. “taking the perspective of the other”—Mead, 1934). Even in dreams, the most private of experiences, an individual still uses language (and with it social frameworks) to comprehend the fragmentary images that incoherently succeed one another. The irrational and unordered consciousness found in dream also demonstrates what happens to memory when social frameworks are only minimally active. Halbwachs also critiqued experimental psychologists' assumption that they were studying an individual mental faculty when they conducted research on memory in a “neutral” laboratory. Again, in using language, subjects necessarily place themselves in social frameworks. The illusion (for both laypeople and psychologists alike) that memories originate purely in the individual consciousness comes from the fact that individuals belong to multiple social frameworks, which contrast and reinforce each other in such a way that they create a unique perspective in the individual but still an irreducibly social one.

#### **SOCIOLOGICAL DETERMINISM OR PSYCHOSOCIAL TENSION?**

Halbwachs's concept of social framework is close to Moscovici's (2000, 2008) concept of “social representation,” which is unsurprising given their shared Durkheimian ancestry. Both concepts point to a group's particular commonsense mentality by which

it understands the world and itself. Additionally, both theorists situate individual minds at the intersection of different groups' ways of thinking. However, in Moscovici's theory, it is very clear that there is a dynamic and generative tension between individuals and social groups: group ideas must always be mediated by individual consciousness. There is some disagreement regarding whether Halbwachs took a strong Durkheimian approach in regarding collective memories as over and above individuals, determining their thought processes. Bartlett devoted Chapter 18 of *Remembering* to explicating and critiquing Halbwachs for saying that the group itself has a mind that remembers. In this account, the individual becomes a kind of automaton of the group's will. By contrast, Bartlett (1932) was explicit in saying that remembering occurs *in* the group, not *by* the group. Whether Halbwachs was actually making this claim that groups themselves remember is debatable, although it is certainly the case that Halbwachs overemphasized the collective nature of social consciousness at the expense of the actual thought processes of individuals.

More recently, Middleton and Brown (2005) have suggested that in fact Halbwachs was closer to Moscovici's position of there being a dynamic and productive tension between individuality (itself a product of sociality) and society. For one, individuals are continually moving between different frameworks, positioning and repositioning themselves within these frameworks. Reavey and Brown (2009) have theorized, in an article analyzing memories of sexual abuse, that the process of remembering is itself driven by attempts to resolve discrepancies of meaning, for example, between individual and collective points of view. Victims' therapists tell them that they were helpless children without any agency in the events. But the victims themselves continually reconstruct the events around points of potential agency. It is these kinds of ambiguities that keep the memories alive. Each act of remembering temporally stabilizes the memory, but the tension between personal experience and a group's social framework ensures continual reconstruction of the memories by individuals.

#### ***Summary of Social Theories of Remembering***

Bartlett's, Mead's, and Halbwachs's theories converge on the idea that an individual's remembering needs to be understood in relation to the social groups to which he or she belongs and the position

he or she occupies in those groups. Bartlett, however, did not provide a clear mechanism to connect interactions in social groups with an individual's ability to turn around on his or her self. His concept of schema includes both the somatic self (i.e., the purely embodied engagement with the world) as well as the reflective self, without clearly differentiating the two. Mead and Halbwachs, by contrast, argued that to turn around on one's self, one has to take the perspective of social others—thus, the reflective self is inherently a social self for them. Bartlett did recognize the primacy of the social in remembering but did not adequately theorize the social mechanism in the psychological act of remembering. In the next section, we will look more closely at the social genesis of mind and explore the concept of tension as the driver of remembering.

### **Mediated memory: from knots to narrative** *Vygotsky's Dramaturgical Metaphor of Mind and Memory*

[E]very function in the cultural development of the child appears on the stage twice, in two planes, first, the social, then the psychological, first between people as an intermental category, then within the child as an intramental category. This pertains equally to voluntary attention, to logical memory, to the formation of concepts, and to the development of will.

—Vygotsky, 1987, p. 145

This quotation from Vygotsky is well-known to cultural psychologists, although probably more from the 1978 translation *Mind in Society*. It is certainly true that Vygotsky was making the claim that higher psychological processes have social origins (similarly to Mead) as most neo-Vygotskians have emphasized; however, exactly how this occurs has been largely lost in translation. Not everything that appears on the social plane is *internalized*, nor is the psychological plane simply a reproduction of the social plane. How then can we conceptualize the movement between the two?

Vygotsky was developing a dramaturgical metaphor for the development of mind, in which drama appears on two *planes* (external and internal) but only one *stage*. Veresov (2010) points out that the word “category” (appearing twice in the above quotation) had a definite meaning for Vygotsky. In pre-revolutionary Russian theatre criticism, it meant a “dramatic event, collision of characters on stage.”

A dramatic tension first is experienced externally between actors and second is re-experienced as a dramatic event within an actor. A good example of this is having a heated argument with someone. Zeigarnik (1967) has shown that unfinished tasks (where tension remains as in an open argument) are better remembered than finished tasks. When the argument is later recollected, it is not merely replayed but, rather, the tension is generative of new interpretations and responses. Furthermore, the other actor is evoked and made a participant in our inner drama. In this way, the internal drama *is* a social relation; the other is always implicated in higher psychological functioning.

“Tension” is a polysemic word, giving rise to a number of variants, such as “at-tention,” “in-tension,” and “con-tention.” All these words express a general sense of being pulled in opposing directions—in these cases, the pull comes from social others. For example, in attention my gaze is pulled to something pointed out by an actual or internalized other (Abbey, 2012). Tension between actors generates “signs,” which may later be reconstructed and used when tension arises on the psychological plane. Vygotsky's most famous example is pointing, which begins as the child's failed attempt to reach an object. When the adult interprets the gesture as meaning the child wants the object and brings it to them, the child learns to act out this gesture on stage with and for the adult to make them fetch the object. In re-orienting the gesture from the object to the adult, it changes from *reaching* to *pointing* and becomes meaningful and, as such, a sign. To complete the story, the child might later use the pointing gesture in private to control their own activity—for example, to focus their attention on a particular object.

### **SELF-REGULATION THROUGH SIGNS**

Meaning construction is essential to this process of sign mediation. Vygotsky and Luria (1930) used the example of tying knots on a rope—a memory technique that was widespread in many preliterate societies. Making a knot on a rope to remember something gives the knot *meaning* (e.g., that someone owes me a sheep). Meaning transforms the knot from a neutral object into a sign. Paralleling Marx's description of a tool as a device to control and master nature, Vygotsky describes the sign as a special kind of psychological tool used to control and master oneself. This is possible because the sign has

“reverse action”—it acts back on its creator. Thus, in constructing a “sign,” we come to control ourselves from the outside. We use signs when we write notes to ourselves in our planner, put an image of a pig on our refrigerator to remind ourselves of our plans to lose weight, or bring back objects from a vacation to remember the trip. At the societal level, we build monuments, designate important days in the year, and tell special stories about the community to bring the past into the present. Vygotsky (1931, p. 86) puts it eloquently,

The very essence of human memory is that human beings actively remember with the help of signs. It is a general truth that the special character of human behaviour is that human beings actively manipulate their relation to the environment, and through the environment they change their own behaviour, subjugating it to their control. As one psychologist has said [Dewey], the very essence of civilization consists in the fact that we deliberately build monuments so as not to forget. In the knotted handkerchief and the monument we see the most profound, most characteristic and most important feature, which distinguishes human from animal memory.

—quoted from *Bakhurst*, 1990, p. 210

Signs are constructed in situations of tensions and in turn extend natural abilities to overcome the problem encountered—thus, with signs we operate in a *zone of proximal development*. Naturally we can remember seven plus-or-minus two pieces of information at a given time (Miller, 1956); however, with the aid of simple memory technologies, such as “chunking” information into meaningful units, the number can be vastly increased. In fact, the practice of organizing a book into chapters, sections, and paragraphs (as in the present book) is an external memory technology developed in Middle Ages to aid memory (Danziger, 2008). Thus, a purely “natural” process of evolution or biological maturation is insufficient to explain the impressive advances in memory ability in human history and ontogeny; Vygotsky thought we would instead have to look further to the socially constructed “technologies” of memory found in societies around the world. Knots on a rope, monuments, notes in one’s planner, and souvenirs from a vacation are all technologies of memory, but perhaps the most fundamental of these is language and narrative, to which we now turn.

## *Remembering through Language and Narrative*

### CHILDREN’S EMERGING MEMORY ABILITIES

Contemporary studies of children’s emerging memory abilities have emphasized the importance of language and narrative in remembering (e.g., Nelson & Fivush, 2004a, 2004b). In early conversations about past events, children contribute only a few brief and fragmentary details. Children of 2 years begin to remember events that occurred weeks or maybe even months ago, but they still lack the language tenses and temporal markers to effectively organize their experiences in time—for example, “yesterday” and “tomorrow” may be used for any day that is not today (Harner, 1982). Rather, they rely on adults to supply most of the content and to order it into a coherent narrative.

Thus, research on the development of children’s memory indicates that the very ability to remember depends on cultural tools or signs, such as language and narrative. As Vygotsky’s theory would have predicted, the adult first asks questions and makes suggestions to the child to stimulate his or her remembering and provides a conventional narrative structure to organize experience in such a way that it can be communicated (cf. Halbwachs’ “social frameworks”). Later the child uses the same kinds of questioning and narrative structure to stimulate his or her own remembering and organize his or her own experience.

Interestingly, research on children’s development of memory abilities has tended to focus on suggestion as a positive factor, in contrast to the negative significance it has in eyewitness testimony research (see “Metamemory” section above). For example, one of the most commonly talked about distinctions in this developmental literature is between “low” and “high” parental elaborations (usually maternal) in talking about the past, the latter being correlated with a positive outcome such as greater recall by children later (e.g., see Reese et al., 1993). Thus, we are left with a contradiction: Suggestion is both a requirement of memory but tends to lead to “distortion,” at least as it has been set up by experimental psychologists.

### THE CONSTRUCTION OF NARRATIVES

For narrative construction to occur, there must be a tension or problem. A canonical *script* as described by Shank and Abelson (1977)—such as the expected series of events involved in going

**Figure 49.3** Narrative construction of events. From Bresc6, 2008, p. 7

to a restaurant—does not constitute a narrative. Such events are “pointless” rather than storylike (Bruner, 1991). But if the waiter brought a cooked cat (“the chef’s special”) out on a plate, this would provide the necessary “breach” or “violation” of normative expectations for narrative construction. In Bruner’s (1991, p. 11) words, “narratives require such scripts as necessary background, but they do not constitute narrativity itself.” Thus, unlike Bartlett’s concept of schema, there is a clear difference between habitual action and narrative mediation. Narrative is a reflexive “effort after meaning” (Bartlett, 1932) in a situation of ambiguity and tension caused by unmet expectations; it is an attempt to bring the unexpected into a familiar social framework (Fig. 49.3). As such, the concept of “narrative” overlaps with Mead’s “generalized other,” Halbwachs’s “social frameworks,” and Bartlett’s “social schemas” and “conventionalization” discussed above. To quote Bruner:

[Narrative] is a precondition for our collective life in culture. I doubt such collective life would be possible if it was not for our human capacity to organize and communicate experience in narrative form. For it is the conventionalization of narrative that converts individual experience into collective coin which can be circulated, as it were, on a base wider than a merely interpersonal one. Being able to read another’s mind need no longer depend on sharing a narrow ecological or interpersonal niche but, rather, on a common fund of myth, folktale, “common sense.” [...] story is the coin and currency of culture. (2002, p. 16)

The advantage of using the concept of “narrative” is that it can easily be conceptualized as a psychological tool agentially used by someone in remembering. Not everyone will use the tool in the same way or with the same level of mastery. Furthermore, its developmental history can be explored through the contexts in which it is internalized—for example, narrative patterns of dialogue are first seen between parent and child; later the child is able to use those

patterns instantaneously without adult aid or direct awareness.

Wertsch (2002) provides an excellent example of using the concept of “narrative” in research on collective remembering. He makes a distinction between “specific narratives” (involving particular people, places, and actions) and “schematic narrative templates” (which are the general frameworks from which specific narratives are constructed). The latter concept is explicitly developed from Bartlett’s notions of “schema” and “an effort after meaning.” In Wertsch’s (2002) research, he has found that Russians tell their history within the schematic narrative template of “triumph-over-alien-forces”—that is, an outside aggressor leads to internal crisis, which is only overcome by the heroism of the Russian people. This narrative template is unwittingly applied to historical events as different as the 1918–1920 Russian civil war and World War II. Moreover, its use by Russians can be traced back to Soviet-sponsored schooling, where history textbooks all told a similar story. In short, the narrative template “triumph-over-alien-forces” is the tool by which Russians make sense of themselves and their history. It is the mechanism of commonsense agentially used (sometimes even with irony) by those who went through the Russian education system.

### *The Social and Psychological Mediation of Remembering: An Illustrative Example*

Sign mediation occurs on both social and psychological levels. Others influence us through suggestions, but those influences can be blocked, changed, or elaborated on at the next moment by another suggestion from another or our self. The concept of sign mediation directs us to explore the actual process of remembering, where different social and psychological suggestions are layered together, and various tools and strategies of remembering come into play. Bartlett convincingly demonstrated that remembering is constructive and that it makes use of cultural resources but did not systematically explore the concrete process of remembering; rather,

his focus was on the outcomes of that process. We only know, for example, *that* “conventionalization” occurs, not precisely *how* it occurs.

To overcome this methodological neglect of Bartlett’s approach, I turned his method of repeated reproduction into a conversation task. In speaking aloud to another, we simultaneously stimulate our own thinking in hearing ourselves speak; thinking comes into being through speaking (Mead, 1934). This provides an opportunity to access some (although not all) spontaneous processes of remembering in conversation.

As with Bartlett’s experimental set-up, subjects read the *War of the Ghosts* story and waited 15 minutes before reproducing it. In the reproduce phase, however, subjects were instructed to discuss and write down the story they had read earlier. The following excerpt, from the end of a pair’s first reproduction, highlights several processes of mediation, as well as the dynamic interplay between schemas and imagery in reconstruction that Bartlett theorized (*see* the section “The Reconstructive Process” above):

**The original story:**

... He told it all, and then he became quiet. When the sun rose he fell down. Something black came out of his mouth ...

**Conversation reproduction:**

Bill: He told his story and then became quiet. Right?

And then the sun sets [0.5] or something

Henry: Well, he goes to sleep

Bill: It didn’t say anything about sleep. In the morning he stood up and died

Henry: Woke up and died

Bill: All right, so he became quite after telling the story. Ahh, a photographic memory would be awesome right now. Ok now we’re to the point where he woke up. Did they say he woke up?

Henry: I don’t think he stood up

Bill: I thought he

Henry: I don’t think he stood up. I think he did wake up

Bill: Ok, so he woke up (writes). Something black

Henry: came out of his mouth ...

**Written reproduction:**

... He said many villagers on his own side had been killed, and although he had been hit he wasn’t sick. He went to sleep. In the morning he woke up, something black came out of his mouth ...

The excerpt begins with Bill reaching a point of ambiguity and tension in remembering the story.

At a schematic level, he knows that something to do with the *day–night cycle* comes next, and he has some imagery of up–down movement, but forming the fog of memory will require a constructive effort. The ambiguity of his memory is recognized in Bill’s meta-memory comment, “a photographic memory would be awesome right now.”

Bill first makes a suggestion of what might be in the memory gap (“the sun sets”) but at the next moment puts his own suggestion in question with the tagline “or something.” This cycle of suggestion and its evaluation (either intra- or interpersonally) was a frequently observed strategy in my sample of 10 pairs. With it, subjects essentially turn recall into recognition, a fill-in-the-blank test to multiple choice test. Recognition is easier than recall; thus, if one has a general sense of the content of what is missing, constraining the possibilities (in this case, something at the intersection of the *day–night cycle*), it can be a very powerful strategy to extend one’s memory capacities.

Suggestions of what might be in the gap multiply on the interpersonal level. Henry suggests that “he goes to sleep,” but Bill immediately rejects this and instead suggests “he stood up.” This is again rejected and replaced with “he woke up” by Henry. “He woke up” is therefore co-constructed through dynamic interchange. A suggestion does not lead to the passive adoption of another’s memory (as it is often conceptualized in suggestibility research), but rather the perspective of the other’s utterance is used as a dialogical counterpoint to construct a new response, adopting some aspects and rejecting others. In other places in their conversation, a similar co-constructive process leads to accurate memory of the original: For example, “hunting” → “looking for seals” → “hunting seals.”

Bill and Henry form a coherence account of the story by using cultural resources, such as social conventions surrounding night and day (people sleep at night and wake up in the morning) and the metaphorical language utilizing the up–down dichotomy (e.g., people wake up and fall asleep). These cultural resources lead them to conventionalize the story—that is, they transform it in the direction of a familiar cultural framework. Their solution that the protagonist woke up is entirely plausible event for this part of the story. We can see from this example how natural memory capabilities could be *extended* through cultural resources if more familiar cultural material were used, in which case construction would likely lead to a close approximation of the original.

The operation of narrative mediation in this example can be seen in Bill and Henry's use of temporal markers ("sun sets" and "morning") and rational links between events (e.g., he must have gone to sleep before waking up) to temporally organize their account. In other places in my data set, I also found subjects using "schematic narrative templates" (Wertsch, 2002): Three of the ten pairs in my sample came up with the idea that the protagonist of the story was himself a ghost. Nowhere in Bartlett's data does this addition appear, nor do replications of his work using *War of the Ghosts* mention it. Why would this idea come up persistently now? A number of recent Hollywood movies have developed a schematic narrative template with a surprise ending whereby we find out the main character is a ghost, although we thought he was a living person in communication with ghosts throughout the film (e.g., *The Sixth Sense* and *The Others*). Without being aware of it, subjects seem to be drawing on this schematic narrative template to help them make sense of the strange story and remember it. In the process, they end up transforming it.

### **Conclusion: the construction metaphor**

In this chapter I have moved away from the notion that "the memory" is a faculty that stores sensory impressions. The storage metaphor of memory focuses on "memories" as individuated asocial traces, spatially located in the heads of individuals. As an alternative approach, I have developed Bartlett's metaphor of remembering as the activity of construction. From this perspective, the temporal nature of remembering comes into focus—that is, memories in the process of being "built." Extending this metaphor, we ask what "tools" are used by an agent to perform this activity: the tools of remembering *are* social relations, broadly conceived as anything that belongs, or has at one time belonged, to the intermental plan of activity—thus, they are inherently linked to communication, culture, and society. Using these social tools, we escape our confinement in the here-and-now situation by experientially moving outside of our embodied first-person perspective into the perspectives of social others. In this way, we learn to extend our natural capacities of memory and to experience and recollect the world through meaningful social forms, such as language and narrative. Thus, metaphor (in the broad sense of the word, inclusive of language and narrative) is involved in both the construction of memories and the construction of theories of memory!

### **Future directions: methodology in the making**

Pushing the metaphor of "construction" further, we can say that there is a direct relationship between the tools used in remembering and the form in which a memory is constructed. Just as the ancient Egyptians could not build higher than the pyramids with the technologies of their day, so, too, are memories constrained and enabled by the tools we use to build them. One avenue for future research will be to explore the power of various social tools to shape memories in different directions. This will be broader than characterizing tools and techniques of remembering as promoters of accuracy or distortion, as is currently done. It is widely recognized by contemporary memory researchers that memory is functional; yet, the methodological focus continues to be on demonstrating memory errors, pointing out the "sins of memory" (Schacter, 2001). Instead, the analytic focus should be on different *directions* of qualitative change, as in Bartlett's, Mori's, and Nadel's research. To study qualitative changes, quantitative analysis can be used, but it will have to do more than simply count how much is remembered or distorted for different experimental or nominal groups.

In exploring directions of change, we will need to understand variability of memories between different members of the same social group. Variability can be seen in the memories themselves and the tools and strategies used to construct memories. Similar tools and strategies can lead to different memories (on the dimensions of veracity, experiential qualities, content, etc.); likewise, similar memories can be arrived at through different tools and strategies. Although individuals might share a common framework and thus also tools and strategies of remembering, it is individuals as agents that construct memories. Again, there is a discrepancy between cognitive psychology's theoretical assumption that the mind is active and the neo-behavioral methodology of showing how various independent variables *cause* effects registered by dependent variables. To truly study the active mind, we need to study it in action, in the concrete process of remembering, rather than simply the outcomes of that process. Classic research paradigms like Loftus's suggestibility research might be transformed into process-oriented microgenetic experiments (Wagoner, 2009) to study remembering *in vivo*, as I have done with Bartlett's method of repeated reproduction (*see above*).

Finally, it has been argued that remembering is not a context-free faculty or skill but, rather, a social and culturally embedded activity. Discursive psychologists have made important initial steps in analyzing how social contexts shape remembering; however, much still needs to be done. For example, we know very little about how various forms of social relationships put different constructive constraints on remembering. From his field observations in Swaziland, Bartlett (1932) theorized that in relations of subordination, remembering would take a more reproductive form, whereas remembering among equals would generate more constructiveness. These power dynamics are essential to everyday remembering; just consider how remembering occurring between patient and therapist, friends, a police interrogator and suspect, a parent and child, an employer and employee, a teacher and student, or among members of different social groups. A systematic investigation into different forms of social relations (e.g., power symmetries and asymmetries) on the process of construction awaits future research.

## How Can We Study Interactions Mediated by Money as a Cultural Tool: From the Perspectives of “Cultural Psychology of Differences” as a Dialogical Method

Toshiya Yamamoto, Noboru Takahashi, Tatsuya Sato, Kazuko Takeo, Seonah Oh, and Chengnan Pian

### Abstract

Money is usually seen to be exchanged with anything that has an equivalent exchange value in the society in which a market economy prevails. When we define economic activity in the broadest sense, money is one specific form of the medium that mediates between people. In this chapter, we will discuss the role of money from the viewpoint of cultural psychology. At first, after briefly reviewing the previous research on the psychology of economic activity, we will show money and possessions are embedded in human relationships and their meanings are not separable from them. The meaning of “my belongings,” for example, “this money (or possession) is ‘mine’” is not determined based on the simple and dichotomous distinction between mine and others, and the possibility (and/or the impossibility) of the transfer of them is decided under the control of social norms that are held in common within a group of people. Second, we will explain how such norms are realized on the basis of our methodology—which we call that of cultural psychology of differences. Thirdly, we will give an overview of our Pocket Money Project, where we have analyzed the relationship between money and children of the four East Asian countries: Japan, Korea, China, and Vietnam. While this project is a case study conducted based on our methodology, the readers will know how the structures of norms, which make the economic activity possible, are different between different cultural groups, and how we can recognize them.

**Keywords:** pocket money, economic activity, East Asian countries, money as a cultural tool, cultural psychology of differences, dialogical research method, expanded mediational structure (EMS)

Money is usually seen to be exchanged with anything that has an equivalent exchange value in a market-economy society, and is seen to play a role as a neutral measure that makes it possible to transfer any goods between people. There exists economic activity in market economies at the global level, which deviates from the principle of equivalent exchange—such as financial assistance from a developed country to a developing country. And a market economy in itself is possible only on the basis of natural environment outside of the market. We define economic activity in the broadest sense, such that it not only means the exchange of useful

resources between people based on the market rules, but also is the transfer of resources from people to people in general, including unidirectional donation and exploitation of them. Then money is one specific form of the medium that mediates between people. In this chapter, we will discuss the role of money in the broadest sense from the viewpoint of cultural psychology.

At first, we will briefly review the previous research on the psychology of economic activity, where we will show money and possessions are not only treated unidimensionally and metrically on the basis of the exchange value but they are embedded

in the human relationships and their meanings are intertwined with them. The meaning of “my belongings,” for example, “this money (or possession) is ‘mine’” is not determined based on the simple and dichotomous distinction between mine and other’s, and the possibility (and/or the impossibility) of the transfer of them is decided under the control of social norms, which are held in common within a group of people. Second, we will explain how such norms are realized (or more precisely, seem to be realized with regulatory force from the viewpoint of people in the group), and how researchers extract and objectify them from a layperson’s daily life. The methodology we propose here we call “*cultural psychology of differences*,” with which we try to explain how culture and cultural differences emerge and are recognized by people. And third, we will show the outline of our Pocket Money Project, where we have analyzed the relationship between money and children of the four East Asian countries: Japan, Korea, China, and Vietnam. While this project is a case study conducted based on our methodology, the readers will know how the structures of norms, which make the economic activity in the broadest sense possible, are different between different cultural groups, and how we can recognize them.

### **Money, Possessions, and Active Agents in Cultural-Historical Perspectives** *Active Agents of Economic Activity*

In the neoclassical economics, people have traditionally been seen as homo economicus who take actions for maximizing utility, and each individual selectively acts rationally based on the subjective value criteria, which are expressed by his or her preference. It has been criticized, sometimes poking fun at the unreality of its premise.

The hedonistic conception of man is that of a lightning calculator of pleasures and pains who oscillates like a homogeneous globule of desire for happiness under the impulse of stimuli that shift him about the area, but leave him intact. He has neither antecedent nor consequent. He is an isolated definitive human datum, in stable equilibrium except for the buffets of the impinging forces that displace him in one direction or another. Self-imposed in elemental space, he spins symmetrically around his own spiritual axis until the parallelogram of forces bears down upon him, whereupon he follows the line of the resultant. When the force of the impact is spent, he comes to rest, a self-contained globule of desire as before (Vebren, 1898, pp. 389–390).

Recent research on experimental economics has shown that people who are active agents of economic activity are not ahistorical rational utility maximizers, such as calculating machines, but are cultural-historical subjects who pay close attention to the intention of others and take actions based on, or influenced by, the background cultural norms (e.g., Camerer, 2003). People’s recognition of the fairness of the distribution of reward has been tested by using the *ultimatum game*. In the ultimatum game, one of the two participants, a proposer, is given a fund and is instructed to distribute it to the other participant, a responder. The responder decides to accept or reject the offer from the proposer. If the responder accepts the proposal, both participants can get the reward based on the proposer’s offer, and if the responder rejects the offer, both cannot get the reward. If the participants are both rational and selfish homo economicus, it is reasonable that the responder should accept any proposal above zero and the proposer will offer the least amount to the responder. However, empirical data significantly differ from this theoretical prediction. Meta-analysis by Oosterbeek, Sloof, and van de Kuilen (2003) showed that on average, the proposer offers 40% of pie and the responder rejects 16% of the proposals. Henrich et al. (2004) tested the ultimatum game, the dictator game, and the voluntary public goods game with people from 15 ethnic minority groups in the world. Results revealed that there exist bigger differences between groups than the differences shown between developed countries. People’s economic behavior is influenced by the institution and beliefs about the benefit of cooperative behavior within the groups (*for more historical analysis of cultural difference of markets, see Abelshauser, 2005*).

### **Money and Possessions**

Zelizer (1989), following Simmel, summarizes features of market money and sorts these out into the following five characteristics: (1) it is described only by economic terminology, (2) it is qualitatively homogeneous, (3) it is completely secular, neutral, and anomic, (4) it commercializes everything, and (5) it automatically implements those aforementioned. However, money and possessions bear polysemy, which cannot be described only by a one-dimensional value structure. In our lives, we find many things hold subjective values and those values differ from market values they have. Memory-laden objects including gifts, family photographs, souvenirs and mementos, heirlooms, antiques, and

monuments are typical examples (e.g., Belk, 1991). We can find numerous examples that indicate that possessions carry subjectively important meanings for individuals. For the aged, roles are given to possessions in providing control and mastery, moderating emotions, cultivating the self, symbolizing ties with others, constituting a concrete history of one's past (Kemptner, 1991), and particular importance is attached to symbolic items such as photographs and keepsakes (Csikszentmihalyi & Rochberg-Halton, 1981). On the other hand, we feel strong pressure and recognize it as a threat to ourselves when we lose our possessions. Goffman (1961) shows those who are hospitalized or institutionalized in prison remarkably lose the sense of self when their possessions are expropriated. Additionally, loss of possessions resulting from theft or disaster accompanies a strong sense of loss and depressing feeling (Belk, 1988). After all, as James and Simmel point out, those of mine (possessions) are extensions of self (extended self) as well:

... a man's Self is the sum total of all that he CAN call his, not only his body and his psychic powers, but his clothes, and his house, his wife and children, his ancestors and friends, his reputation and works, his lands, and yacht and bank-account. All these things give him the same emotions.  
(James, 1890, pp. 291–292)

... material property is, so to speak, an extension of the ego, and any interference with our property is, for this reason, felt to be a violation of the person.  
(Simmel, 1950, p. 322)

In the case of children, their structures of self and their ways of perceiving their possessions as their extensions differ from those of adults (Furnham & Jones, 1987; Yamamoto, 1991; Yamamoto & Pian, 1996). When elementary-school children are asked if their parents can control their possessions, children in lower grades tend to give more positive replies. This tendency is found regardless if they live in European countries such as England (Furnham & Jones, 1987), or in Asian countries such as Japan (Yamamoto, 1991) and China (Yamamoto & Pian, 1996). Additionally, children in higher grades tend to reply that they have discretion to determine who can use their belongings, though they have ambiguous feelings of the ownership of money given by parents. This tendency also can be found in both Europe and Asia. Age-derived characteristics indicate some common denominators in respective

cultures. However, what is more important is that the structure of self, interpersonal relationship, and its structure have culture-specific characteristics and thus cognition of “mine” greatly varies, as discussed later.

Although people have the strong notion that money is free from specific human relationships and abstract, they keep away from using it in some cases. A typical example is money as a gift (Pieters & Robben, 1992). In the case of a gift, a sender gives an item for which the sender made efforts in making or selecting it, and a receiver accepts it. In the specific relationship between a sender and a receiver, a gift exists as a symbol that represents a specific effort (or goodwill) of a specific person. For the sender and the receiver, the value of the gift does not represent the practical value based on its usefulness, which means even trivial knickknacks can be important gifts (Csikszentmihalyi & Rochberg-Halton, 1981; Wallendorf & Arnould, 1988). Money transposes the value built on a specific individual relation and/or experience like this onto the criteria used for all other items and grades such values—therefore, money is shield. So far—considering the subject and the object, which are both parts of economic activity, we argued that a subject in an economic activity should be understood not only as homo economicus who performs abstract and rational economic activity independent of the context of particular interpersonal relationship, but also as a subject who performs cooperative activity with others. We also argued about the importance attached to possessions' subjective value and their nature of being extensions of self as economic activity objects, and about the unique nature of money, which mediates exchange as an economic tool, especially when it emerges as a gift in a particular human relationship. It is clear that mere observation or analysis of economic activities of equivalent exchange is not sufficient to comprehensively grasp human economic phenomenon from the viewpoint of cultural psychology. We have to find the viewpoint that helps us comprehend general human economic activity, including the one prevailed with market economy as one special configuration of such activity. We will explain the reason from the following three viewpoints.

First, equivalent exchange is always derivative and subsequent in general economic activity in terms of human history development from phylogenetic and ontogenetic viewpoints. Equivalent exchange is only one of many various forms of

communication to exchange resources, and it cannot be seen as general economic activity. Second, in the modern society prevailed by a market economy where equivalent exchange is positioned to initiate entire social production and consumption, some activity performed by a subject that exists out of the market, such as a family and a government, always exists. Market activity is established out of market economy on the basis of the human relation, which is established on a framework different from the one of market economy, such as the relationship in family and with friends. And it is supported by the natural environment, which makes the production of goods possible. As indicated by the case where economic activity causes external diseconomy to the trading activity in the market, additional consideration to the human economic activity is needed. It is performed only in natural environments, and economic activity in the market is established only when it is supported externally. Thus, market economy merely is a part of establishing varieties of human relationships under the whole of all economic activity. Third, economic activity in the market itself is culturally diversified with strong regional characteristics, and a theory that gives no consideration to such diversity obviously covers only a narrow range. We have to grasp economic activity, which is resource-mediated communication among people and includes market economic activity, as being an essentially cultural activity.

### **Cultural Psychology of Differences and Economic Activity**

Next, we shall explain our viewpoints when analyzing human *resource-mediated communication*, in other words, economic activity as cultural activity in nature. We use the term “cultural,” focusing on the following two points and propose the argument with those points in view. The first is, as so far discussed in cultural psychology and expressed by Vygotsky’s triangle, that the human mind has mediational structure comprised of historically and socially established media and the structure is to be the human nature when compared with other species. It is obvious that people can perform the activity of exchanging gifts or money only with this mediational structure. Second, as so far discussed in cross-cultural psychology and indigenous psychology, mediational structure represents not only human characteristics in general but also the uniqueness of a specific group of people. The phenomenon where an identical market economy system develops with

different cultural characteristics among countries and regions can be discussed only when this viewpoint is considered.

In the cultural psychology of differences that we propose, we conceptualize the minimum unit for human behavior analysis using the schematic concept of Expanded Mediational Structure (EMS) as the minimum unit (Yamamoto & Takahashi 2007). With the concept of EMS, we do not argue assuming a subject out of relations or a group beyond a subject. Rather, we view that a relational structure, wherein interacting subjects take normatively mediated actions for objects that mediate interactions, is established each time in a gestalt manner by the subjects’ practical actions. Likewise, in this argument, we consider that those interacting subjects, in addition to the norms that represent communality characteristics (which represent the quality of relationship with others) beyond those individual subjects, emerge each time in the relational structure, and thus analyze the emergence of a sociocultural phenomenon from the viewpoint of a “relationally emerging individual.” (Yamamoto, 2011) Using the notion of *communality*, we intend to refer to the nature of something that appears to be shared with other people or within a community. As we shall explain later, a group functionally substantializes itself in such relation while signs and tools assume ontological positions in an intersubjective structure of mutual understanding.

We will explain basic viewpoints of our cultural psychology of differences and rationally marshal the meanings of cultural research for researchers, including us, who cannot break loose from their own presence as cultural existence, but, nevertheless, while the study itself carrying cultural characteristics as their essential nature.

### ***EMS as a Basic Unit of Normative Interaction***

Behavior and recognition at a phylogenetically or ontogenetically rudimentary stage—which is established with a relatively simple contextual structure—change as such behavior and recognition develop or evolve into the one based on more complex element-to-element relationships. As just described, when several elements emerge in a gestalt structure, we here describe it, generally using the expression “individual elements are ‘mediationally’ established.” For example, when a certain human behavior is established under influence of others, we can say “the human behaves, mediated by others.”

Also, when a subject emerges as taking a certain role in the subject's relation with others, it can be said the subject "is mediated by others and emerges as a subject with specific role." (*For understanding the philosophically extended notion of role, which might reconstruct our viewpoint, see Hiromatsu, 1996.*)

EMS is the concept to refer to a general mediational structure found in our phylogenetically created sociocultural practice. For now, we explain what the concept of EMS implies in an orderly manner, starting from the active-passive duality of human basic nature, which makes interactions possible.

Human beings differ from any material substance in terms of an object because it emerges as an active object for the party who sees him or her as a person. Moreover, the important point in establishing interactions is that a person has both active and passive natures. A person's action to the other is established only when the person actively works on the other and the other receives it passively. When subjects sustain interactions, such active-passive relations are linked. More specifically, when A actively acts on B, B is passively affected by the action of A. Then, in turn, B becomes an active subject and acts on A, thus A is passively affected by this action of B. Like this, actions are linked, and, in each case, a subject which emerges as an active subject is mediated by the other who actively acts on the subject. We call this *subject-mediated behavior* (SMB).

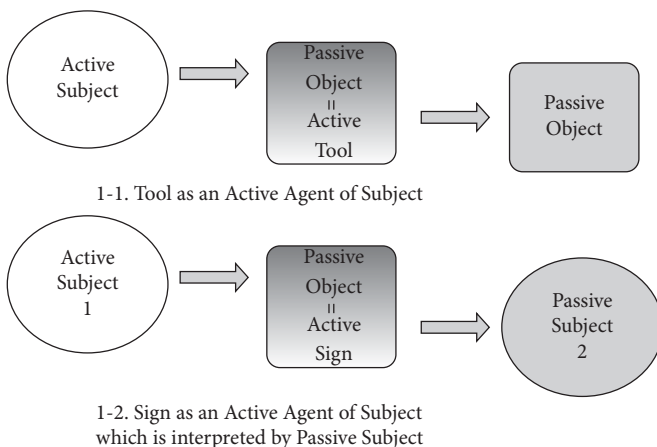

This active-passive duality is the basic nature of interacting subjects, and its prototype can be found in the situations where active nature and passive nature are integrated, in a figure-ground reversal manner, just like "see = seen," and "hold = held." Interactions are established when subjects with

such duality differentiate between a subject with an active aspect and a subject with a passive aspect while mutually changing their mutual aspects (so-called *role exchange*) in turns.

When a subject's active behavior is established, incorporating a certain physical object (*object-mediated behavior*; OMB), the object becomes a "tool," which works on a different passive object as extension of the subject (Figure 50.1). Also, when the passive subject understands it, the physical object emerges not as a mere substance but as a "sign," which expresses some sort of intention of the active subject (*see Figs. 50.1 and 50.2*).

When subjects' interactions are mediated by the signs established in the aforementioned way, a subject's behavior in this scheme is based on interpretation of the other's intention infused into the behavior mediated by an object, which is a sign as well (OMB) and, thus, such behavior becomes an SMB as the response to this OMB. Any kind of communication, which is a chain of interactions mediated by an object such as language or a substance, is based on the structure of dual-mediated behavior (DMB) where SMB and OMB are combined as seen in Figure 50.2 (Yamamoto, 1997).

The meaning infused into an object as a sign or implied by the sign cannot be determined merely by the physical nature of the object, it also determined by the subjective structure of meanings which has been discussed as the matter of arbitrariness in signifiant-signifie relation of signs. A normative structure—such as syntax and semantics, which constrains the ways to interpret a sign—becomes necessary. In addition, a behavior as a response to an action of the other is selected out of almost infinite,

**Figure 50.1** Tool and sign as agents. (a) Tool as an active agent of the subject; (b) Sign as an active agent of the subject which is interpreted by passive subject.

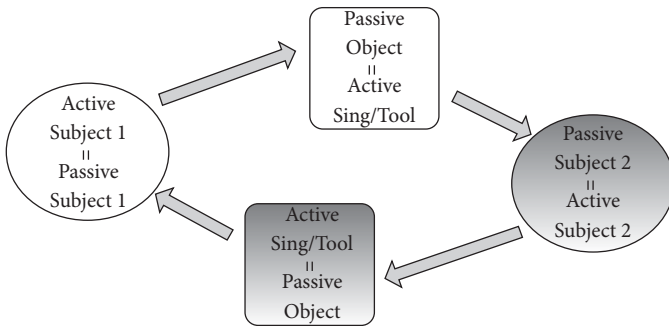

Figure 50.2 Dual mediated behavior.

numerous alternatives under normative constraints (Yamamoto, 2000). In linked interactions, normative elements, which set bounds to both interpretation of signs and selection of behaviors, mediate mutual relations.

In summary, stable and sustained interactions have the structure where OMB of subjects produce meaningful SMB mediated by the normative elements shared among the subjects, which brings us the concept of the EMS (see Fig. 50.3).

Subjects' interactions using money as a tool are obviously included in this structure as a part of human sociocultural interactions. Money as a physical object emerges between subjects as an object with social meaning. A subject's action of giving (or not giving) it to the other indicates the intention of the subject, which results in a trading activity in a certain condition. Mediated by normative constraints when selecting a behavior like "what and how to buy (or not to buy)," the trading activity becomes possible under the constraints of the norms that determine the activity as deviation or obedience.

As we shall specifically illustrate later, cultural characteristics that emerge from economic behavior and relation including the pocket money phenomenon do not emerge in the formal structure of behavior of exchanging equivalents in the market. Rather, they emerge as group-specific constraints (a structure of meaning), which are different from those of other groups when qualitatively selecting interactions, such as what specifically can be an object in exchange, how the exchange process should be, and if it should be market exchange or gift exchange. When regarding money as being mediated by a cultural norm, money functions not only as an economic tool for equivalent exchange in the market but also as a culture tool to build the human relationship with cultural significance (Yamamoto & Takahashi, 2007).

Therefore, we describe how culture emerges within specific interactions with others using the concept of EMS, and explain how we can understand practices of researchers who recognize culture, and how we can underpin our methodology based on such understanding.

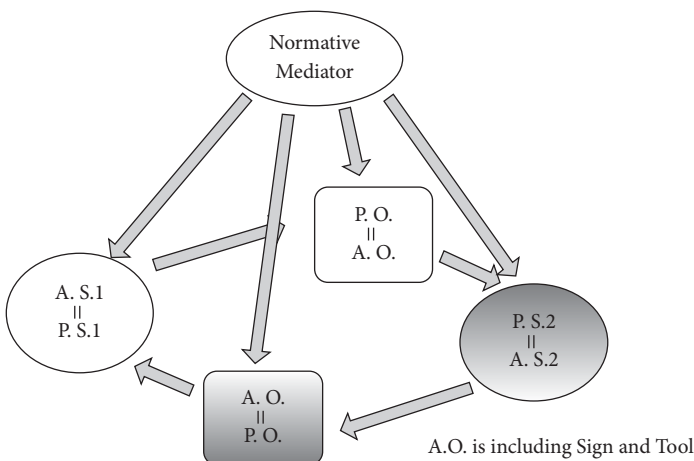

Figure 50.3 Expanded Mediation Structure (EMS).

## *Emergence of Culture*

We are able to differentiate two kinds of notion of culture. The first is the notion that is typical to Vygotskian theory. It has emphasized universal character of the human mind, which essentially differs from the other animals. We already have schematized such universal mediational character of human practice with our concept of EMS. The second is the notion that is typical to cross-cultural psychology. It has emphasized the differences among social groups. To understand the character that is specific to a certain culture (A), it is necessary to compare it with the other culture (not A), so that the understanding of culture A is established solely with the contrast of the other culture. We can say the understanding of culture A is mediated by the other culture. We claim that to understand the dynamism of culture is possible only under the condition that we consider the two levels of mediational structures simultaneously. Based on the first level, we are able to act culturally only as the human mind, which has mediational structure and based on the second level we are able to appear as cultural agents only when the character of us are understood with the contrast of or as mediated by other types of cultural agents. Human understandings of culture are established as such intersubjective and communal recognitions that have mediational structure in its nature, which enable us to realize the cultural group as a substantialized one through a dynamic interaction process. Based on those dynamics of culture, we become able to analyze the dynamic process of cultural phenomena, including cultural conflicts that appear at the same time both as interindividual and intergroup interactions. Here we illustrate the second aspects of the culture with the concept of EMS.

Culture, which is specific to a certain group, is found in the realm of physical objects as products with a typical style among the group members. It emerges in a subject's socio-psychological aspect as a typical action and/or a typical mental pattern among the group members. In either case, the following three requirements are satisfied in common:

First, regardless of a physical object, an action or mental act, it emerges as result of a subject's intentional activity.

Second, it does not only emerge as a result of one individual's intentional activity but emerges as the one shared among people.

Third, it emerges as the one that is shared not with people in general but with the people who

belong to a specific group, but is not shared with people of different groups.

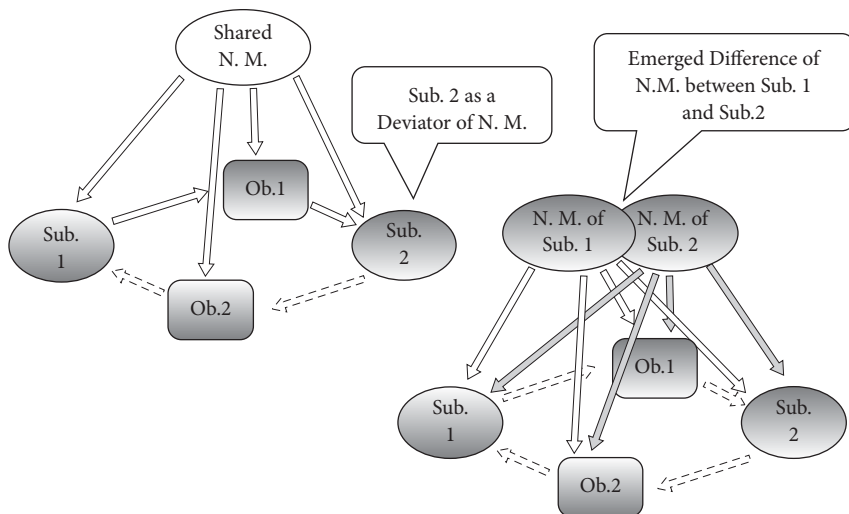

In this way, regardless of culture found in an object or culture found in a subject's activity, it is natural to assume some kind of group as the substantial agent behind the cultural phenomena that is seen as responsible for the culture. Nevertheless, in our cultural psychology of differences, for the purpose of avoiding the aporia resulting from the individual-group dualism, we do not assume a substantially fixed individual or group, but view emergence and function of culture from the standpoint of a relationally emerging individual. Moreover, we grasp action of cultural research as isomorphic meta-culture practice.

Following this logic, it can be concluded that culture emerges from moment to moment as "difference in normative mediator" (Yamamoto, 2011) in specific and concrete interactions and determines a configuration of interactions while functionally substantializing a group, which we shall explain later. Cultural research becomes one of meta-recognition practices around such functional substantialization. Both processes can be schematized for explanation, using the concept of EMS.

First, we will explain how culture emerges in our daily life practices. Most of our daily interactions are established without any particular awareness of the norms that attach meanings to each other's actions and objects. However, for some reason, when interactions do not go well, a person tries to find a cause of failure and consciously adjusts the relation with intent to restore smooth interactions. At that time, what matters in the interactions is the normative mediator, specifically speaking—what is the appropriate action and the appropriate interpretation of the situation? Failed interaction raises our awareness of normatively mediated relation and prods us to tune such interactions.

Roughly speaking, the cause of interaction failure can have possibly two directionally different attributes. One attribute is deviation by the person and/or the other from the person's own norm that the person becomes conscious of and absolutizes (*see* Fig. 50.4, left side). In this case, the subject emerges as a deviator. The norm is recognized as the common constraint that both of the interacting subjects should follow, and the attempt is made to adjust the relation somehow by correcting the element, which is regarded as having deviated from the norm.

However, when the person becomes conscious of the norm, the norm is never recognized as the one

**Figure 50.4** Two types of attribution of failed interactions.

specific to individual culture. It emerges merely as “the obligatory norm a person should follow.” The interacting parties share the same norm and implicitly accept each other as the one who lives on the basis of the same communality, and the cause of failure is attributed to the individual who disturbs the normative relation.

The other attribute is the case where the cause of failure is attributed to difference in the normative mediator (*see* Fig. 50.4, right side). Both subjects recognize their own behaviors as the ones in accordance with the norm and insist the other subject’s behavior deviates from the norm. Thus, the difference in fundamental understanding between both parties becomes obvious. The failed interacting party emerges as the other who has a different normative mediator or different communality. Therefore, the cause of interaction failure cannot be attributed to an individual but to a group beyond the individual. This is where a cultural group with different communality emerges.

The important point here is that we regard behaviors of individual subjects as emergence of certain communality even though specific interactions of individuals are practically an issue. In this case, behind an individual before us, we foresee the presence of a group of people who share communality with the individual. “I” emerge not as an individual but as a member of a group, “us,” and you emerge not as an individual but as a member of a group, “you” (Oh, Sato, Takahashi, Yamamoto, Takeo, & Pian, 2008). One’s own normative consciousness,

which was regarded as “being natural” without any assumption up to that moment, is relativized. Thus the normative mediator is regarded as the one which “we” unconsciously shared in our own daily life practices and emerges as the cultural norm that supports “our” communality different from “yours.”

Culture emerges before us, taking a concrete form. But this does not mean that a human group with certain concrete extension exists at first and then the culture is recognized as some nature of the existing group. Instead, based on the fact that a particular behavior of an individual subject before us emerges with communality, a group to which the communality belongs is conceived, and then, the deductive recognition initiated from the group is established to explain the individual before us. For this reason, a cultural group is, at any time, constructed and reified virtually and socially from particular interactions.

### ***Substantive Nature of the Normative Mediator and Culture***

As described above, a norm emerges as something relative and arbitrary, not as something absolute. However, we should not consider the norm to be a mere unsubstantial fiction, because, as long as a subject tries to interact smoothly with the other, it becomes inevitable to generate normative mediators somehow with the other as necessary, and the subject has to follow the norm in order not to deteriorate the subject’s social practice. In order to establish a certain social practice and participate in the social

practice, the subject has no alternative but to follow the norm on which the practice is based. Therefore, any subject within a social practice cannot escape from some sort of normativity based on such practice in principle, and, in that context, the normativity emerges as an absolute substance, takes objective character on it, and defines the subject's practice intersubjectively. We will describe the structure like this: a norm functionally substantializes itself.

Likewise, our research object, money, is also substantialized functionally in social practice. Money here does not mean money as material such as metal, paper, or electronic information, but as a tool that people use as a medium to establish a social practice. Money, which is a mere substance as material, establishes a social practice including exchange of goods only when meaning is found beyond its function as material. As far as being involved in such a social practice, money is functionally substantialized with a meaning as such, incorporating economical normative nature.

As described above, when the subject's norm encounters a different norm, the subject's own norm emerges as a cultural norm in the contradistinctive relation to the different communality that the different norm has. A subject who established such culture recognition may force the subject himself or herself, and the other, to follow the norm or constrain recognition and actions of the subject, and the other, under the name of the cultural group. The forcing subject emerges not as an individual but as an agent that personifies the will of the group. At that time, before the subject, culture emerges with a socially binding force beyond the specific forcing individual. In this way, culture without physical reality emerges before a subject involved in a social practice as the one with transcendental power that controls the subject and is functionally substantialized as if it were an externally existing physical substance. (Of course, this logic is generally applicable to the functional substantialization of any social group.)

As described so far, in our cultural psychology of differences, we understand an ontological position of culture, underpinning the intersubjective practical recognition of the communality. A subject finds it in a series of practical interactions with the other as a communality difference between them, and such finding again defines the direction of the subject's behavior to be cultural. Unsurprisingly, cultural characteristics of money are found in such a communality difference.

As you see, our cultural psychology of differences does not reduce culture to an individual that exists out of relation or to a group that is regarded as existing substantially beyond individuals. Rather, it understands culture from the viewpoint of a relationally emerging individual with communality beyond individuals with intent to avoid the aporia of the individual-group dualism, which traps culture research. When looking at culture from a third-party viewpoint, culture is the recognition that is configured and changes each time in accordance with the context of practice. From that aspect, culture is relative. But, culture emerges with absolute substantive nature before a subject within the context of the practice. Through understanding of such a situation, cultural psychology of differences affirmatively accepts that culture includes the contradiction between fiction and reality in nature.

From this viewpoint, the following example, which appears to be an incomprehensible contradiction when viewing culture as a single-objective substance, can be seen and accepted as very natural phenomena that reflect the essential character of culture. When an American sees the Golden Pavilion (Kinkakuji-Temple) in Japan, the American may see oriental Buddhist culture, while a person from Japan may naturally view that as Kitayama culture, a culture in a medieval age, or as the fusion of Japanese aristocratic culture, warrior or Samurai culture, and Zen culture. However, either view can be correct. Similarly, an identical phenomenon may emerge as different cultures, depending on subjects who recognize communality (different people see different cultures), which is one of the essential characteristics of culture. In addition to that, even for an identical subject, the phenomenon may emerge as different culture, depending on the contexts in which the subject finds the phenomenon (the subject sees different cultures at different times), which is also an essential characteristic of culture.

Moreover, as it is impossible to completely define a group of those who carry one specific culture, a substantially fixed group as the subject carrying culture cannot be externally predetermined. For example, it is impossible to completely define when Chinese Han culture started, from which region to which region Han culture exists, and who carries Han culture. The extension of a culture is completely vague in terms of time, space, and members and always changes (Fei, 1989), which is also an essential characteristic of culture. On the other hand, for example, even when the extension

is defined using administrative classification such as those who are registered as “Han people,” practices and languages among those registered people are extremely diverse in fact. Likewise, even when Han culture is described following certain criteria, numerous exceptions need to be added to such a description. As those examples indicate, the inside of a cultural group, which is seemingly fixed and defined by an external standard, always varies and changes—which is also an essential characteristic of culture.

We believe culture can be analyzed without impairing its dynamism only when we consider that culture is functionally substantialized all the time as necessary, keeping such contradictions as its essential elements, instead of identifying culture with a substantial group that is predefined and fixed by certain criteria.

### ***Cultural Psychology of Differences as Meta-Culture Recognition Practice***

When we understand culture without assuming a culture as fixed substance which always emerges as being identical and as objective substance which always seen as being the same object by anyone and when we recognize culture to be functionally substantialized with the power to control and define the direction of a subject’s recognition and social practice, what does our action of studying individual cultures as concrete objects mean? What differs between such actions of a researcher’s and a layperson’s culture recognition in our daily lives?

First, what we should affirm is that there is no fundamental structural difference when culture emerges before us in daily life or before researchers. In other words, even when a researcher objectifies culture viewing from the sidelines, culture emerges as a result of recognized communality difference between the researcher and the other, which relies on the context. The researcher who recognizes “different culture” in such a way starts to study culture as an object.

This remains the same in principle when the researcher’s own culture is studied as an object. For example, when a Korean researcher becomes aware of the researcher’s own culture, the researcher finds the culture as something specific to Korean and different from Japanese and Chinese culture. In such a way, an encounter with the communality different from the researcher’s own communality brings the viewpoint of objectifying his or her own culture, thus the researcher studies his or her own culture

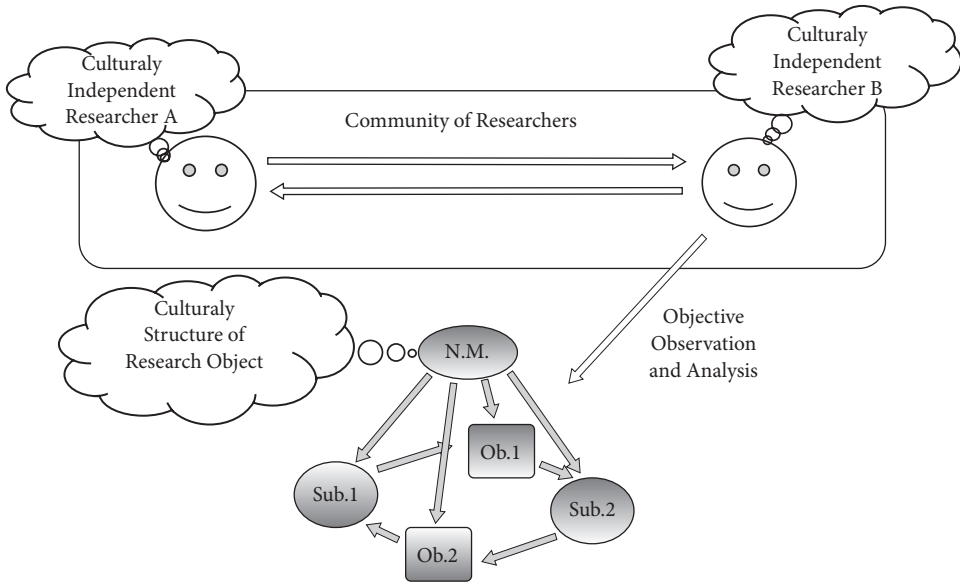

as the alienated or objectified own communality. Culture, whether one’s own or other culture, is mediated by different culture, objectified, recognized, and substantialized.

Second, what we should affirm is that, critical and qualitative difference exists between recognizing one’s own culture and recognizing other culture. Based on the communality of our daily life, we recognize others’ communality as a gap or difference resulted from deviation from our communality and reaffirm our communality mediated by others’ communality. Therefore, ethnocentric understanding of other culture is unavoidable fate when establishing culture recognition.

On that basis, researchers seem to adopt two extreme standpoints for the purpose of overcoming this ethnocentrism issue. The first standpoint is that a researcher steps aside from meaning (or manners of interpretations, hereinafter, interpretations/meanings) the researcher possesses as a person living in a culture and analyzes from the “universal viewpoint” as a researcher, the structure established in people’s interactions and recognition without being realized by themselves, and tries to describe the structural difference among different cultures (see Fig. 50.5). However, from the standpoint of cultural psychology of differences, the following should be reserved regarding “universality” there.

This is assumed not to be influenced by the researcher’s particular cultural characteristics but to be something sharable among researchers beyond cultural characteristic differences, thus creating a community of researchers, which is separated from the world of daily life. In that sense, this is the “universality” with special communality, which enables research practice and enables their community. That is not shared necessarily with those who live in the meanings of the daily life. This does not directly help researchers establish the communality with those who live in daily life, either. Researchers’ communality qualitatively differs from that of those who live in the world of daily life. Naturally, from the viewpoint of cultural psychology of differences, research practices of pursuing such “universality” and communality itself are understood as one attributive culture; therefore, some transcendental peculiar privilege cannot be accepted without question of the practice of such culture recognition.

Another standpoint is that of a researcher who is deeply involved in the daily life practice of a person who lives in a different culture, and who participates in the world of practice for the purpose of

**Figure 50.5** Objective research of culture.

being ideally on the same level with the member of the culture in terms of understanding the emerging manner of interpretations/meanings of daily life. In order to overcome ethnocentrism, a researcher keeps him or herself away from the ethnocentric viewpoint to the utmost extent and gets deeply involved in the cultural practices of others instead of establishing universality aside from the viewpoint of those who live daily lives.

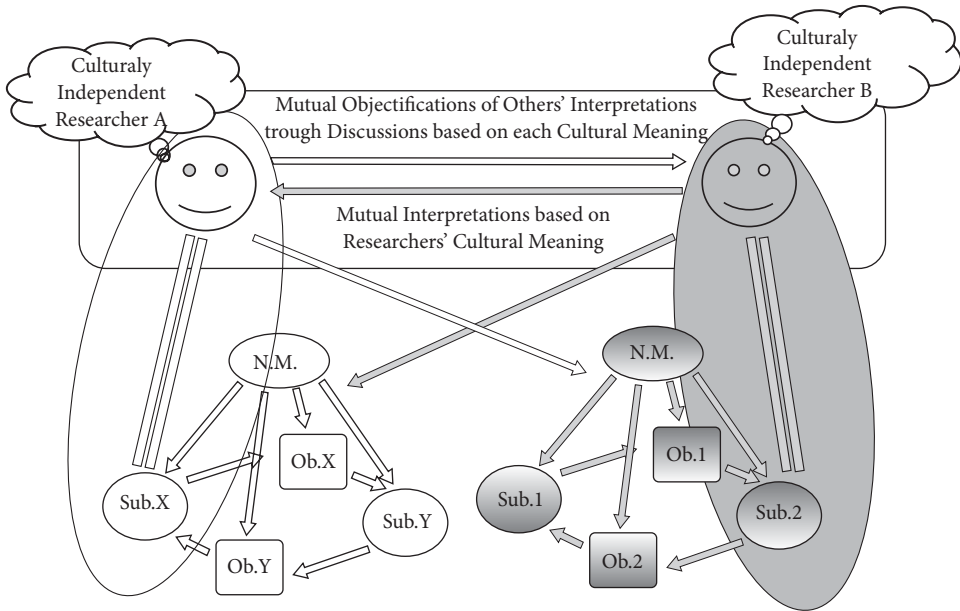

The most ideal style of the research like this would be for a researcher to study the culture the researcher belongs to (indigenous psychology). However, as described earlier, a researcher who performs participant observation can be a researcher in comparison with those who live daily life because of the fact that the researcher can look at the culture from the outsider viewpoint, find difference between cultures and objectify the culture. And, it is communality difference that makes interpretations/meanings of daily life into something “cultural.”

Based on those understandings, cultural psychology of differences adopts the third way. That is researchers, who have different cultural characteristics and acknowledge their ethnocentric understanding of others as being unavoidable, mutually analyze their interpretations/meanings of daily life, and discuss the analysis (see Fig. 50.6).

Similarly with laypeople who live daily lives, researcher A tries to understand the meaning implied by the action of the other by his or her understanding

of meaning (“ $\alpha$ ”) that he or she generates in his or her daily life as a person A. Understandably, the other, B, lives in different communality and thus researcher A fails to understand B’s interpretations/meanings of daily life activities (“ $\beta$ ”) based on A’s understanding of meaning (“ $\alpha$ ”). Therefore, A’s interpretation (“ $\alpha$ ”) occasionally becomes something completely strange or unacceptable for B. This is where B, as a researcher instead of a person who lives daily life, points out the problem about “ $\alpha$ ” and conversely analyzes “ $\alpha$ ” to bring forward B’s understanding of “ $\alpha$ ” to researcher A. Obviously, B’s understanding of “ $\alpha$ ” sometimes turns out to be an inappropriate understanding for researcher A and prods researcher A to argue from researcher A’s viewpoint as a person who lives daily life.

When using the EMS schematic, this process can be explained as follows. Researcher A and researcher B exchange their understandings of interpretations/meanings,  $\alpha$  and  $\beta$ , as objects and thus their communication is established. For researcher A to establish the communication where researcher A’s understanding of the meanings of objects is shared, researcher A uses the normative mediator that A has as a person who lives daily life. However, A’s such understanding fails to be shared with researcher B and the communication fails. Viewing from the opposite side, B’s normative mediator is not shared with researcher A. Under such a circumstance, the natures of their own normative mediators, of which

**Figure 50.6** Dialogical structure of cultural psychology of differences.

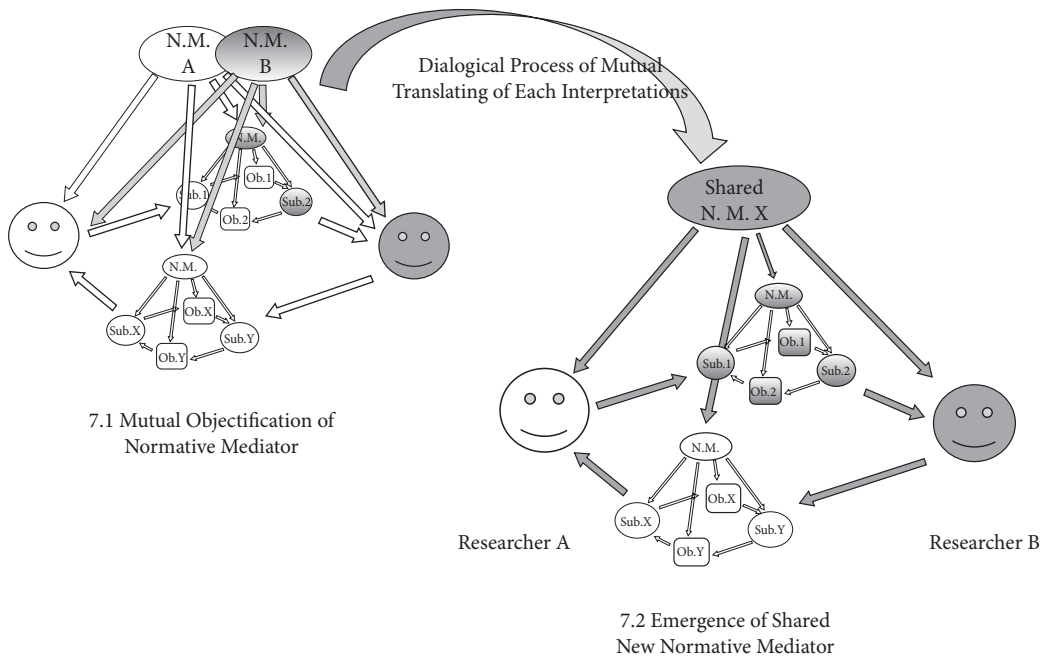

they were not conscious, raise their awareness separately, and such difference emerges as the object for intentional adjustment (see Fig. 50.7a).

Here, cultural psychology of differences does not set the direction toward the task of discovering an abstract general structure out of the semantic worlds of those parties. It paves the way so that those parties can objectify such difference based on their understandings of meanings and attain common understanding of meaning at a meta-level. This process can be compared to language translation where the other's understanding of meaning is translated and understood through a translator's own understanding of meaning. As in the case with language translation, both parties never agree perfectly, but, they can have commonality to the extent that they can communicate. At that time, researchers A and B in the communication surrounding their interpretations/meanings of  $\alpha$  and  $\beta$  create the meta-level common interpretations/meanings, X, and reposition their interpretations/meanings  $\alpha$  and  $\beta$  in X for sharing. This can be regarded as the establishment of new normative mediator X (see Fig. 50.7b).

What researchers do here is not to objectively perform descriptive analysis of the object from the outside of interpretations/meanings in daily life. The following explanation will help you understand the difference easily. In the case of a conventional objective analysis, correctness of the analysis is urged regardless of what a person who lives daily life

subjectively thinks or denies regarding the analysis. Whereas, in the case of an analysis in cultural psychology of differences, we pursue intersubjective agreement of data interpretation among persons who have culturally different background including both researchers and research objects (or researchers who have the same background with them). For this purpose, we, as researchers, ask persons who live daily life as research objects (or ask researchers who have such a background), "Do you also agree with our understanding or interpretation of meaning about your behaviors?" and entrust the persons with the judgment on success or failure of the understanding. If we are not able to reach agreement, then the interpretation have to be modified. By establishing such a mutual relationship, cultural psychology of differences is established. In that sense, the methodology of cultural psychology of differences is dialectical in nature, providing grounds for validity of understanding in relation with others. That is a kind of communication system for mutual understanding based on difference between parties and the tool for dialectical culture practice to generate new meta-communality in such dialectical relation.

Here, we should point out one important point. As described so far, when researchers who have their unique cultural characteristics establish a scheme where those researchers build up meta-understanding of each other's culture on their own cultural characteristics, this newly established

**Figure 50.7** Dialogical process of cultural psychology of differences. (a) mutual objectification of normative mediator; (b) Emergence of new shared normative mediator.

scheme for understanding (EMS) naturally relies on the context comprised of the combination of those individual researchers. Therefore, even when the generality beyond researchers' ethnocentric viewpoints is obtained in this scheme, the generality preliminarily cannot claim the generality out of the context. Whether or not the established scheme for understanding can be shared with a third researcher who has a different cultural background can be verified only in dialectical relationship with the new researcher. If the scheme cannot be shared, researchers, including the third researcher, need to undergo the same process to find another scheme for common understanding at a meta-level. In this way, without assuming God-like fair and universal generality, we incrementally generalize based on specific and concrete contexts. We call such research methodology "concrete generalization."

### ***Cultural Psychology of Differences and Cultural Characteristics of Economic Activity***

In order to analyze economic phenomena from the viewpoint of cultural psychology, we believe it is crucial to consider people's economic activity as a part of general communication activity that mediates resources extensively including gift exchange. In

addition to that, it should be critical to understand money not only as a mere economic tool because of its function as an equivalent exchange media, a mark of value and a means for storing value, but also as a cultural tool that helps us create our own world of daily life, forming human ties. When viewing in that way, establishment and development of a market economy itself is a cultural phenomenon in its nature, which provides us with clues to cultural-psychology-based analyses on the phenomenon where market-economic activities in different countries and regions still show strong specific features of their societies in spite of expansion of globalism.

In this section, we explain how to concretely understand cultural characteristics of economic activity from the viewpoint of cultural psychology of differences, which grasps human sociocultural practices using the conceptual tool, EMS.

Economic activity emerges as something cultural when economic interactions that a subject has smoothly developed with one party cause failure with another party and the difference between communalities underlying their economic interactions—not the deviational behavior of the subject or the other party—emerges as the cause of the failure. For example, human-relationship-oriented trading, importance placed on stable trading, trading that is not

necessarily contractual, slow and opaque decision-making, and tough demands for quality and delivery are described as specific features of Japanese economic interaction, which are different from those in Europe and America (Economic Planning Agency of Japan, 1986), and frequently cause conflict. This situation has been treated as difference in the normative mediator in EMS. At that time, it can be found that the economic activity in the market, which initially appears to be neutral action, is actually mediated by a cultural norm.

There are three solutions for failure. The first one is to cancel economic interactions and return to the prefailure state. The second one is to place one of two (or more) conflicting normative mediators in a more powerful position than the other normative mediator so that the other one will follow. The third solution is to look for ways to create meta-normative mediators, which adjust both parties through understanding of their conflicting normative mediators. In cultural psychology of differences designed to develop the recognition of cultural characteristics that dialectically overcome ethnocentrism, the way to understand cultural characteristics of economy is the development of the third process.

Moreover, as is clear from the gestalt nature of EMS, the cultural characteristics emerging in a subject's economic activity represent not only the normative mediator's cultural characteristics that determine the activity but also the cultural characteristics of the subject who participates in the activity, as well as the cultural characteristics of the meaning that the exchanged objects have. Therefore when cultural psychology of differences analyzes economic activity as an object, it handles the issue considering a subject, an object and a norm are to be interrelated as a whole.

From now, we introduce a series of our studies about children and money that we continuously conducted in Japan, China, Korea, and Vietnam as an analysis example from the viewpoint on economic activity in a broad sense. Findings in those studies were cultural characteristics that constrain and define the direction when using money, the learning process of mastering pocket money (allowance), which is the cultural tool with such cultural characteristics, an aspect of the formation process, namely, cultural development process of a subject who masters pocket money as a cultural tool, and the process of dialectical practice where we, researchers, find out such cultural characteristics. Through them, we learn how involved

cultural characteristics are in the formation of our economic activity.

The marks used in the following analysis, such as "Japan," "China," "Korea," and "Vietnam," may appear to be presented as if certain substantial groups were fixed and conceived beforehand. However, as is evident from the discussion so far, those are merely the specific-context-dependent, contradistinctive structures that emerged in our comparative examination in which we dialogically and mutually examined limited data among our researcher group and tried to find the scheme for unifying and grasping the examination results.

While Japan and Korea are usually seen as ethnically homogeneous nations, China and Vietnam contain a wide variety of ethnic groups, and the data are from only few cities for each country like Osaka, Tokyo, and Gunma in Japan, Beijing, Shanghai, and Yanji in China, Seoul and Cheju in Korea, and Hanoi in Vietnam, etc. Therefore it should also be noted that characteristics of the countries with quotation marks do not reflect ethnic diversities and regional differences of these countries. In addition to that, the researchers conduct the research not as culturally independent psychologists but as those who have their own identities about the nationalities, so the discussion about the interpretation of data is inevitably framed consciously and/or unconsciously with them.

Then, we do not objectively present some universal structure of an object beyond that. It is not something arbitrary that can be described in various ways, but emerges as a kind of necessary image in the context of the dialogic examination process. Considering that, we insist that those structures themselves indicate one process in dialogue and one stage in such process, and thus essentially cannot be separated from the context of our cultural research as a consistently dynamic process in nature.

### **Outline of the Pocket Money Project**

In this project, researchers from four countries in East Asia, which are Japan, Korea, China, and Vietnam, collaborated and pursued research on children's relationships with money in each country, combining various methods. The methods we adopted are roughly categorized into three types: (1) researchers from each country visit households in their counterparts' home countries and interviewed parents and children; (2) researchers observed children shopping at supermarkets, mom-and-pop candy stores, stationary stores, and bookstores and

interviewed them; (3) researchers conducted questionnaire surveys on students in the 5th grade, the 8th grade, and the 11th grade in each country, to ask questions about how they get and use pocket money, right and wrong judgment on and tolerance toward use, and the impact of money on their parent-child relationship and friendships.

We call the methodology on which this project is based “cultural psychology of differences,” whose rational details were explained earlier. Cultural psychology of differences can be summarized as follows. When we study culture, we study it assuming that researchers cannot study certain specific culture from an objective position in terms of epistemology or methodology. And, understanding the culture involves mutual activities where researcher a (= concurrently, a member of culture A) tries to understand the practice implemented by a member of different culture B (layperson) meanwhile researcher b (= concurrently, a member of culture B) tries to understand the cultural practice implemented by the member of culture A. Cultural psychology of differences is to pursue research practice with this perspective. This project was designed to pursue this, not between two parties, but among participants from different countries. The aforementioned four countries were selected because they satisfied linguistic requirements (researchers from two countries can communicate at least among them using the researchers’ own or their counterparts’ native language) and geographical requirements (project members can observe and participate in interviews and discuss with researchers) for implementing such research practice, and thus researchers from those four countries participated in this project.

When comparing cultures, discussions were based on Asia-versus-West-like dichotomy represented by independent versus interdependent self (Markus & Kitayama, 1991) and collectivism versus individualism (Hofstede, 1980; Triandis, 1994). Nevertheless, cultural psychology of differences regards the way to recognize cultural “difference” as an issue. In that sense, any comparison is not an issue as long as the comparison is made among different cultural groups. Moreover, from the epistemological viewpoint, the same difference between any given two groups can be found (Watanabe, 1969, Ugly Duckling Theorem). From that aspect, there is no reason to think cultural psychology of differences overrides other comparisons when comparing somewhere in Asia with somewhere in Europe or America.

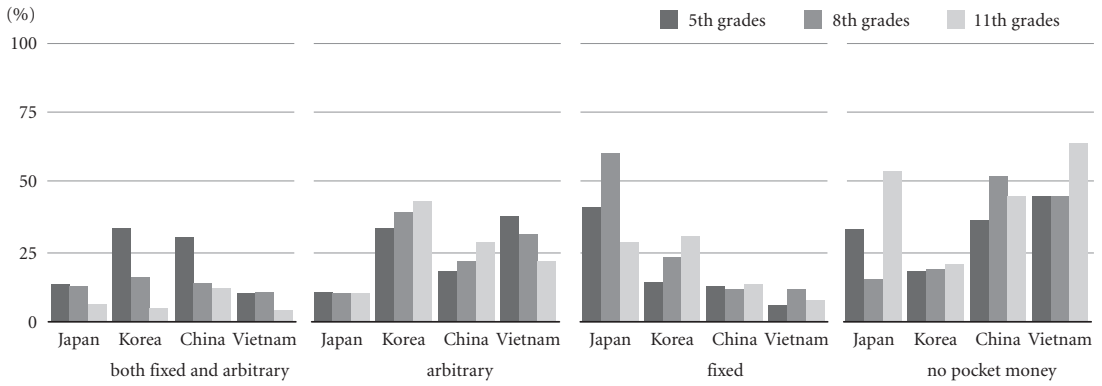

Research practiced in cultural psychology aims not to create a static difference inventory. Rather, a researcher who is also a member of a certain culture comes across and is surprised at daily life practice (cultural practice) of a member of the other culture, and the researcher, in turn, reflects on the researcher’s own daily life practice to deepen mutual understanding and empathy. In this way, the other culture emerges dynamically and emotionally, and theorizing this process is what cultural psychology addresses as the issue. Implementing practice to understand different culture in such a way will prescribe a practical solution for members from the countries, which have historically had a strained relationship, to understand mutually through conflicts and surprises.

In the following section, we will first discuss cultural difference in the parent-child relationship mediated by money. Then, we analyze the normative structure concerning use of money. Ultimately, through the analysis on how such structure emerges before the researchers who study cultural psychology, you will clearly understand that cultural psychology about economic relationship (in short, money) inevitably requires the methodology, which we call “cultural psychology of differences.”

### ***Cultural Difference in Parent-Child Relationship Mediated by Money***

#### **JAPAN**

We shall start with a very simple question: “How do children receive money from their parents?” Many Japanese children respond that they receive fixed amounts of money at fixed intervals when compared with children in other three countries (see Fig. 50.8). In interviews, not only children but also parents responded, “I do not give money to my child in that way at present, but intend to do so when my child becomes slightly older,” or “I tried to give money in such a way, but my child failed to manage it well, therefore I think it is too early for my child.” As those responses indicate, giving a fixed amount of money at a fixed interval is considered to be favorable and giving money in such a way as a child grows older is regarded as a favorable change. In addition, many distinctly responded that the money given to a child was thereafter the child’s own money. Figure 50.9 shows the responses made to the statement, “A parent does not have to return the money he or she borrows from me.” Similarly, many children in Japan gave affirmative answers to the statement, “A parent should keep word in any

**Figure 50.8** The ways children get pocket money in the four countries.

circumstance when he or she promises to give me pocket money,” while support to the statement, “Pocket money is given by my parent, therefore, it is my parent’s,” was considerably low.

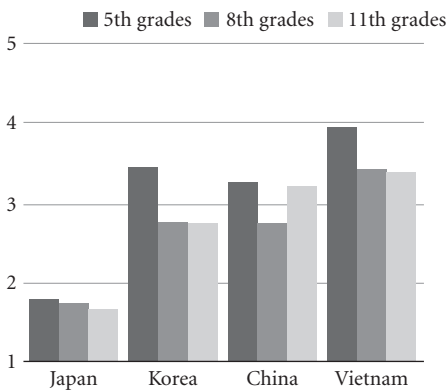

Concerning the question of who will pay money when children buy books and snacks, responses made by children in Japan roughly fell into four categories. The first one is for the items that parents pay for regardless of age of their children. Payments for study books, transportation expenses, school fees, and foodstuff for home consumption are included. The second category is for the items that children did not use their money for when they were in primary school but start to pay for themselves as they grow; for example, buying friends a meal and gambling with friends. This indicates children expand their own worlds out of control of their parents. The remaining two other categories share similarity with

each other. Those are for the items that parents paid for before and children pay now by themselves. This indicates responsibility of using money shifts from parents to children, and payments for various items, such as toys, CDs, clothes, and movies, are included in those categories. The way to obtain goods changes as children grow, and children in Japan change their use of pocket money they receive from their parents at their own discretion.

When summarizing those results (and their specific features become distinctive when compared with the results obtained in the other three countries, which we shall explain later), it can be interpreted that money-mediated relationships of children in Japan with their parents is influenced by the goal to be “independent” from adults so that parents accept children’s territories and respect such territories as the children’s right, which both parents and children should protect. However, such “independence” is only in the Japanese context and is not common among other three countries.

#### KOREA

Children in Korea irregularly receive unfixed amounts of pocket money in general (see Fig. 50.8). What was extremely different from Japanese children were their responses to the questions concerning money interchange of children with their parents. Concerning the statement, “I can demand money of my parent when money is insufficient to buy what I want,” children in Korea made more affirmative responses than children in Japan, and the statement, “It is not good for a parent to borrow money from his or her child when he or she does not have small change,” had the lowest support in Korea among the four countries.

**Figure 50.9** The average answer to the item “Repayment not wanted from parents” in the four countries; 1=totally against; 2=somewhat against; 3=neutral; 4=somewhat in favor; 5=totally in favor.

Concerning the items classified by who pays to buy them, they basically fell into the categories similarly with those in Japan. The first one is for the items for which parents pay regardless of age of their children, such as tuitions. The second category is items for which children did not use their money when they were in primary school but start to pay for by themselves as they grow, for example, buying friends a meal and gambling with friends. The third category is items for which parents paid before but now children pay by themselves. Between Korean and Japanese, some fell into different categories, but, except for some minor but seemingly important differences, they shared the same pattern. This indicates children expand their own worlds out of control of their parents. However, the last category was unique to Korea. This category includes items for which parents paid when children were in primary school and children receive money on as-needed basis when they are in high school (10th to 12th grades), including expenses at amusement parks and expenses to buy their clothes.

As indicated by the second and third categories, when children in Korea grow, they create their own living world out of their parents' control as children in Japan do. However, their way of receiving and using pocket money and attitudes toward money interchange between children and parents differ from those in Japan. In Korea, money is flexibly interchanged between children and parents through negotiation as seen in the cases where children demand it from parents when children need money and children accommodate parents with money when parents need money. Such flexible money interchange between parents and children can be said to be the "independence," or mutual dependence, which is specific to children in Korea and is different from that in Japan.

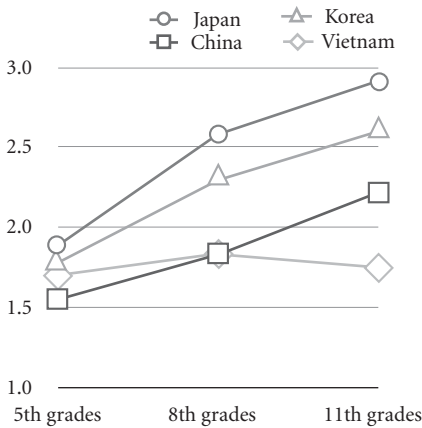

#### VIETNAM

In the case of children in Vietnam, many do not receive pocket money in the first place, and money does not penetrate into children's lives as it does in Japan and Korea (*see* Fig. 50.8). Even in interviews, children said they would buy snacks using money intended for breakfast or the change they got when they ran errands. Their attitudes toward money considerably differed from those of children in Japan. In all countries, when children receive large amounts of money, like New Year's pocket money, many parents manage such money. In the case of children in Vietnam, children sometimes ask parents to keep

their money, for example, "If I keep it, I may lose it or use it for something bad, so I trust my parents with the money." They are also negative toward receiving pocket money as compensation for doing their household chores. They said, "As everybody does household chores, receiving pocket money by doing them is bad," or "(Doing household chores is) something like duties. My parents gave birth to me and raise me, so, helping is them is natural."

Responses made in Korea and Japan to the questions and statements concerning money interchange between parents and children were contradistinctive, but, those in Vietnam and Japan were poles apart in a different sense. Many responded affirmatively to "A parent does not have to return the money he or she borrows from me" (*see* Fig. 50.9), while few gave affirmative answers to "A parent should keep their word in any circumstance when he or she promises to give me pocket money," which is opposite in Japan. Responses to "I can demand money of my parent when money is insufficient to buy what I want" were affirmative as seen in Korea, but, what it means in Vietnam is different from what it means in Korea. In Korea, responses are made in the context that money interchange with parents can be flexible. However, in Vietnam, there is no strained relationship related to the "my-money-versus-my parents'-money" mentality. Rather, money is the parents' own, therefore, children can be given money from parents only when necessary.

Compared with other countries, children in Vietnam have fewer opportunities to get money and use it. In addition, they are very cautious about money. On that basis, they tend to judge their given money as belonging to their parents. When children are asked if they can use money for their own pleasures such as buying CDs and their clothes, more and more children in the other three countries judge they can do so as they grow older. We consider this to reflect expanding children's living world of independence from their parents. However, in Vietnam, such tolerance does not rise as children grow older (*see* Fig. 50.10). This can be explained by the aforementioned reason. Children's paying for school fees and daily necessities and foodstuff for home consumption using their own money is not evaluated positively in Japan, and in particular, children's paying school fees using their money is evaluated negatively (regarded as being not good). However, in Vietnam, it is evaluated positively as a good deed. As observed so far, in Japan, children's territories are to be protected instead, and those that

**Figure 50.10** Average answer to the items related to “play” in the four countries; 1=not permitted; 2=must receive parent’s or guardian’s permission; 3=freely permitted.

go beyond those territories (school fees and food-stuff for household consumption are out of those territories) are not desirable. In Vietnam, money is basically possessed by parents and under parents’ control, therefore, using money for family or parents’ benefit is a good deed.

**CHINA**

As in the case with Vietnam, many children in China do not receive pocket money (see Fig. 50.8). Also, children in China respond negatively to the statement, “I can demand money of my parent when money is insufficient to buy what I want.” Also, what was shared in interviews indicated a strained parent-child relationship with strong love. The following is the interview we had when we asked a respondent which would be better: to use money and buy what the respondent wanted or to save money.

Child: I think it’s better to buy a thing.  
 Child: When I buy a thing, it’s my own, but, when I save money, my mother uses it in case of necessity.  
 Questioner: Your mother uses your money in some cases. Does it happen to you quite often?  
 Child: Yes, it does.  
 Questioner: At that time, will your mother pay you back?  
 Child: No.  
 Questioner: Yanjin (pseudonym), do you want her to return it to you?  
 Child: I want.

A different child answered that the child was sometimes asked by the parents to buy daily

necessities using the child’s money. The parents answered they made the child use the child’s money in that way because it was not good for a child to have a lot of money, and the child replied it should be natural because it was the parents’ money. Different from Japan, where parents consider their children’s feelings and rights in advance, parents in China use their children’s money half-forcibly, regarding it as parents’ money, and parents in many cases directly express their feelings such as love and anger. For example, in an interview, parents who said they did not control their child’s use of money and left money to the child’s discretion remembered an event when the child used a lot of money for play although the child should have saved it. The parent could not control the anger and continued to talk about that without giving the interviewer any chances to interrupt. In that sense, questionnaire responses of children in China and Vietnam show a similar tendency. However, different from the cases of the children in Vietnam for whom money is clearly possessed by parents, children in China face their parents’ strong emotions and, in ways commensurate with that, money mediates the parent-child relationship.

In this way, when observing a normative structure which exists in each country through comparison, we find an identical behavior (or a response to an identical question) may have different meanings among different countries. Thinking of the children in Japan that “parents should repay when parents use children’s money” is considered to be immature reaction, which proves the child’s inflexibility, in the Korean context. And it is considered to be deviation from the norm that my money is parents’ own according to the Vietnamese context. On the other hand, in the Japanese context, negative responses to this statement are supposed to be an immature reaction that fails to separate children’s territories from those of parents. Likewise, even when the same responses are made, they are made occasionally because of different reasons in different cultural contexts. Parents’ using their children’s money is not unreasonable, because money is initially the parents’ own in Vietnam, money is to be interchanged between parents and children in Korea, and children have no choice but to accept it because of the power relationship between parents and children in China.

In the research practice of cultural psychology of differences, researchers who live in their own cultures mutually try to understand meanings of

behaviors in different cultures (norms that govern behavior) while reflecting upon their own culture of understanding. Descriptions in this section are normative structures in different cultures that were extracted as the result of such practice. Then, how do those different normative structures emerge before researchers in the research practice? In order to simplify, we shall take ratings regarding treating friends (ogori, which means to purchase something, usually foods or snacks for friends) and Dutch treat in Japan and Korea as an example of contradistinctive behavior found in two countries for detailed analysis.

***Treating a Friend (Ogori) in Korea and Dutch Treat in Japan: When Norms Emerge***  
**STATICALLY EMERGING CONTRADISTINCTIVE STRUCTURE**

Children in Korea and Japan rated different items, such as snacks, books, deposits, and contribution to a church, by whether or not using money for them is right/wrong, or acceptable. When cluster analysis was carried for each country by pattern commonality (change of right/wrong evaluation and tolerance levels in accordance with average age), three distinctly common groups were extracted. One commonality is that items are classified into three groups of high, medium, and low in terms of both right/wrong evaluation and tolerance levels. Another commonality is that tolerance levels for all items become higher as age increases in each country. The items that belong to the highly valued group are nearly common between Korea and Japan: Items for which using money is supposed to be socially desirable such as contribution, savings, gifts for family members, stationary, and study books, are included in this group. Remarkable difference was found in the group for which both right/wrong evaluation and tolerance levels were low. Gambling belongs in this group both in Korea and Japan. In addition to that, in Japan, items like school fees, buying friends snacks and meals, and lending a friend money are included in this group. On the other hand, those items belong to the medium group in Korea. This indicates the contradistinctive structure between Japan, which is negative to directly paying money for friends such as ogori, and Korea, which is not very negative to money-mediated friendship.

Korea and Japan show significant difference in response to the questions and statements that directly refer to friendship concerning money. As the result of factor analysis on questions and statements, two

factors were extracted. One of them is included in the statements such as, "Treating or being treated is not good," and "Borrowing even small amount of money from a friend causes trouble to the friend." The statements and questions that include this factor consistently obtained high scores (support) among children in Japan. Another factor included in the statements such as, "I do not hesitate to lend my friend money when the friend is in trouble," and "Buying my friends snacks is more fun than having them alone." Different from Japan, children in Korea consistently show high support to the statements and questions that included this factor.

Interviews in Japan and Korea also disclose the contradistinctive structure concerning money-mediated friendship like "negative" Japan versus "supportive" Korea. Examples of children in Korea: "An extremely big amount becomes burden, but, a small amount is acceptable (8th grade, female)"; "When I buy for a friend, the friend will buy for me next time, and when I don't have money, a friend buys for me, which is good (4th grade, male)"; "Treating each other is good. Paying only for myself appears to be unkind (8th grade, female)"; and "It does not become [a] burden (11th grade, female)." On the other hand, examples of children in Japan are as follows: "Buying snacks is bad, because it's [a] waste of my money I saved very hard. (3rd grade, female)"; "Bad, because it's money my father worked [for] and earned (3rd grade, female)"; and "(Treating is) not good, I think it's not good. Don't you think being equal is better? (11th grade, female)."

Nevertheless, we should be careful when viewing such contradistinctive structure statically. Even in Korea, some made negative remarks about treating. Likewise, in Japan, some children made affirmative remarks about treating. Korea: "It depends on a person. Some don't [mind] being treated, and some others want to pay for themselves (9th grade, male)." Japan: "Buying snacks for friends is acceptable (2nd grade, male)"; and "We buy snacks for friends, exchange candies, [buying] snacks is not bad (3rd grade, female)." In fact, even in Japan, when we observed children shop at mom-and-pop candy stores and supermarkets, we occasionally saw that a child bought snacks to share with friends.

Observation Example 1: At the big supermarket, 6<sup>th</sup>-grade boys A and B. At 5:00 p.m., they came into the store. They were glancing at cartoons, but did not seem to look for any specific book, just looking at books. After that, they went to the sweets corner at

the 1st floor, and A chose two candies and paid at the checking counter. He gave one to B, and then, while sucking the candies, they went upstairs looking at toys at the 2nd floor.

The first issue is why we find a static contradistinctive structure in daily life practices, which are actually incoherent or contradictory and include various elements. The second issue is how such contradistinctive structure is related to daily life practices. The third issue is the ontological position that the found contradistinctive structure assumes. We shall analyze our research practice to respond to those issues.

### EMERGENCE OF A NORMATIVE STRUCTURE

Japanese researchers who live in the Japanese culture read interviews held in Korea, and raised simple questions when discussing with Korean researchers: “When you treat someone, the person would feel obligated to treat back. Don’t you think you put a burden upon the person?”; “In Japan, we do treat, but, it is because of hierarchical relationship, which means we would not treat in the case of equal relationship”; and “Well, a parent gives pocket money to his or her child, so, using that money for someone else is very bad, isn’t it?” Those simple questions strongly frustrated Korean researchers who affirmatively repeat treating in their practical lives: “If I eat alone even though the other does not, why do you think it can be equal?”; “I will buy when I have money, and my friends buy for me when I don’t have money. But, such friendship does not imply any hierarchy”; “Pocket money is used not only for myself but also for others”; and “Parents discipline their children to eat with their friends when they are together.” Even in the discussions among researchers, a paired contradistinctive structure emerges disclosing the conflict between “us” (Korean researchers) who affirmatively support treating and “you” (Japanese researchers) who deny treating.

Such paired structure emerges steadily even in interviews.

Japanese researcher: Which happens more often, treating each other or splitting a bill?

Korean child: Splitting a bill happens more, and it seldom happens that someone pays all.

Japanese researcher: Ah? It has long been in that way?

Child: As I’m a student, I don’t have a lot of money, I put my money together to pay for myself.

Japanese researcher: When going Dutch, in that case, in Japan, each pays for what each ate, but, which case do you mean, do you mean dividing all equally?

Child: No, that is not the case, add all, calculate the total, and split.

Japanese researcher: After all, you split it. As was expected. What Dutch treat means slightly differs.

Korean researcher: Different.

Japanese researcher: Dutch treat is slightly different.

Korean researcher: Different.

Interviewer: Ah, then, well, treating is not very good?

Child: Well, I do not feel it’s not good. I treat when necessary.

Interviewer: A-ha, when it is necessary. I see. So, it does not mean it is not good.

Through interviews with Korean children, researchers from Japan heard those children give answers that indicated that “going Dutch” was different from that in Japan and they did not regard treating as being not good. Thus, the researchers “discovered” differences. To verify, they repeatedly asked children questions and found such differences to be consistent.

In a different interview, a mother who initially pointed out danger of treating referring to juvenile delinquent problems, talked about her own treating experience and, while we interviewed her on negative valuation in Japan, she finally supported treating, with some conditions like “If that is a small amount,” or “If she or he is a good friend,” mentioning “If going Dutch all the time, I feel it selfish.”

For children, it should be an unprecedented and very strange experience to talk with a stranger from a foreign country and be asked questions. In addition, the stranger asks questions about the child’s common practices, which the child usually implements but has never subjectively thought about before the questions were asked. Feeling embarrassed, the child recalls the child’s own usual behaviors and answers, finding reasons for those behaviors. This is the typical interview we had. In our interviews, we asked children what children would think about opinions in Japan (in a different country) that treating others is not good because pocket money is for themselves, and that treating is not good because treating others will make others (who were treated) feel obligated. With those questions, the child recognizes that the behavior the child and other friends unconsciously implement is regarded as being negative, and the child and parents who are interviewed start to talk

about the logic of “their behaviors” systematically as culture beyond individuals like “I” and “myself.”

Treating is not unique only to Korea. Many in Korea also say treating is perceived as a big burden in daily life and many usually go Dutch. On the other hand, when observing children in Japan, it is not very rare to encounter situations where they treat their friends. In an interview, in addition to the voice of an interviewer as an individual, the other (as nature) beyond an individual emerges before a child and a parent. Here the interviewer appears to them not as a neutral researcher, but as a “member” of Japan who represents Japanese culture. Voices of the interviewees in Korea included personal voices by which each individual interviewee talked about personal experience. Nevertheless, those voices also included the voices to advocate their “correctness beyond individuals” in opposition to others, which they explored and found through the interviews with Japanese as others. During the interviews, the voices to tell the reality and the voices to tell the philosophy and culture exist concurrently. In that sense, the voices of interviewed children and parents themselves become polyphonic.

### Summary

Our pocket money research disclosed the following three points. The first is that money is not merely a simple tool for exchange in the frame of market economy but also serves as a tool to mediate human relationships in different cultures and those norms mediate its use as such a tool. The second point is that norm structures differ among cultures and an identical behavior has different meanings. When a norm structure in a certain culture is identified, the meaning of the behavior also becomes clear. However, the third important point is that this structure does not exist as a consistent preference in a cultural group but emerges dynamically in research processes, which we can perceive only when it is crystallized and becomes static. Cultural psychology of differences does not aim to extract such crystallized “culture (cultural difference)” as substance but intends to demonstrate the possibility of “understanding” (different) culture through analyses including those on the crystallization process and develop the prescription for that. This is not to know crystallized “culture.” But, it is to know the crystallization process, which deepens the insight about “understanding” of (different) culture and shows the practical way to “understand.”

### Future Directions

In this chapter, based on the theoretical perspectives of cultural psychology of differences and our empirical data, we proposed that money as a basic tool supporting economic activity in the market is not a mere tool for exchanging goods, but a cultural tool for connecting people, which should be understood from a broader theoretical framework. Economic activity is one of actual examples of human communication in general, represented as EMS, which includes multilayered mediational relationships in it. The medium of economic activity not only has characteristics as a tool, but also is a possession of agent of the activity and has appeared for him/her as a resource having its own value for controlling. Money, in the context of the individual concrete human relationship, appears as having different norms in different social groups. Culture, then, appears as differences of mediational characteristics of norms, and such differences are generated, realized, and functioned each time when communication between people in different social groups is performed. Our project, whose objective is to shed light on the cultural meaning of people’s practices around money, becomes possible as the meta-dialogical practice between researchers, who themselves have different communality.

Economic activities of human beings have much broader characteristics than we have discussed. We, cultural psychologists, are standing just at the start line of the frontier of this new research horizon. Here, we will propose only a few points of future directions of the research from our theoretical viewpoint. First, we need to theoretically establish the basic characteristics of money as a culturally universal economic tool on the grounds of cultural psychology. There appears to be a deep conflict between money as a universal tool and money that has specific meaning in specific cultures, when a global market economy quickly spread into a society. Next, we need to analyze multifaceted and multilayered relationships of economic activities from the perspective of EMS. Economic activities in the market, from the direct exchange between people to government’s economic policy making and global companies’ economic activity, are developed simultaneously, or in other words multilayered structure of the economic communication in the market is becoming. Whereas EMS presented in this chapter mainly focused on the relationships between individuals, it builds networks and/or hierarchical structure of socioeconomic systems. And third,

cultural psychology of differences will propose a theoretical framework to educational practices for understanding different cultures and ameliorating conflicts between them in the global market. Present-day globalization is not the process toward the monotonous stable economic system, but the process of continuous networking between active agents of a variety of cultures, while they repeatedly meet and part with high fluidity across the border. Understanding other cultures is not to make static inventory of differences between other cultures and his/her own, but to experience instability of his/her own seemingly stable communality and to generate new communality, i.e., normative mediation, with people of other cultures each time. Our research is in itself a part of meta-dialogical activity trying to reconstruct researchers' culturalities or communalities, and has a role to create dialogues between people in different cultures and a new communality.

## Acknowledgments

Our project was supported by Grants-in-Aid for Scientific Research of JSPS. The members were Ito Tetsuji (Ibaraki University, Japan), Kim Soon-Ja, Choi Soon-Ja (Daejin University, Korea), Zhou Nianli (Huadong Normal University, China), Wo Jianzhong (Beijing Normal University, China), Phan Thi Mai Huong, Nguyen Thi Hoa (Vietnamese Academy of Social Sciences, Vietnam), and the authors of this chapter. And the cooperators include Zhang Yingmin, Watanabe Tadaharu (Beijing Normal University), Kominato Mai (Tanaka Institute for Educational Research, Japan), Li Changhan (Yanji International School of Technology, China), Lee Yung-Woon (Korea), Hyun Jung-Hwan (Seoul Theological University, Korea), and many other people.

## Abstract

This chapter deals with cultural construction of life courses—in illness and in health. Patients—or people who have fallen ill, in general—are usually treated by the health-care institutions as “vehicles of disease” as they are assigned new social roles in the medical setting. The inner world of patients has been respectfully disregarded as residual features of no central importance. Even as two disciplines—medical sociology and qualitative nursing research—have recently tried to transform the situation, their way of understanding patients’ narratives and meaning making processes should be of enlightening value for the medical profession. Assuming a process-oriented research standpoint that takes the notion of time seriously is imperative for such efforts. Since the social power of the medical profession intrinsically controls the patients’ lives—in or out of medical settings—a new type of qualitative research on illness and wellness as built from the viewpoint of patients is needed. Both micro-ethnography and a qualitative approach in cultural psychology are promising and useful approaches for applying to this new mission. Thick description of one’s daily life is needed and it might be called “life ethnography.” Theoretically the notions derived from Trajectory and Equifinality Model (TEM) such as zone of finality and multifinality are useful to understand the personal-cultural construction of the feeling of being (and staying) alive—and well.

**Keywords:** Trajectory and Equifinality Model (TEM), promoter sign, future perspective, life with illness, multifinality

A key axiom in medical anthropology is the dichotomy between two aspects of sickness: disease and illness. Disease refers to a malfunctioning of biological and/or psychological processes, while the term illness refers to the psychosocial experience and meaning of perceived disease.

(Kleinman, 1980, p. 72).

Open-ended plasticity occurs when organisms respond to new stimuli by constructing new adaptive developmental paths or trajectories

(Ginsburg & Jablonka, 2007, p. 221)

For a long time, it has been thought that the idea of culture is the one that relates a person with a

specific location—country, community, or the like. The uses of the term in history of anthropology reinforced that idea. However, cultural psychology—building on the centrality of the notion of signs as emphasized by Charles S. Peirce, which is also traceable in the work of Lev Vygotsky—has the possibility of offering a theoretical base that allows us to think about culture without being “caught” in any particular place. Valsiner (2001, p. 32) insisted that “culture belongs to person,” since culture is functioning within the intrapsychological systems of each person. And it is through signs that culture acts as the mediator within a person.

In this chapter we look at sickness experience as cultural organizers of human lives. As the quotation indicates at the top of this chapter, Kleinman (1980) insisted that two aspects of sickness should be differentiated: disease and illness. Then we take the notion of illness more seriously than one of disease. Earlier Eisenberg (1977) pointed out this discrepancy between illness and disease. He said that patients suffer *illnesses*; doctors diagnose and treat *diseases*. And also he said that illnesses are experiences of discontinuities in states of being and perceived role performances. Diseases, in the scientific paradigm of modern medicine, are abnormalities in the function and/or structure of body organs and systems. And the patient represents and implies a person being patient from the medical doctor's viewpoint.

We aim to invalidate the notion of *the patient* as "person who must be patient"—and follow all the orders of the medical system. Instead, we focus on the person's "*life with illness (LWI)*"—it is a life with extra difficulties (introduced by the disease)—yet it is a person's life filled with all the ordinary pleasures and disappointments. We all know illnesses are experiences of discontinuities in states of being and perceived role performances (Eisenberg, 1977). Even so, a person should not be called as "patient=suffering person." S/he lives with illness. *Life with illness* is one of the forms of human life. And it leads to the construction of its own peculiar kind of culture.

### **How Trajectory Equifinality Model (TEM) deals with Life with Illness (LWI)**

The Trajectory Equifinality Model (Valsiner & Sato, 2006; Sato et al., 2007, 2009) provides a good frame for understanding ruptures and reconstructions in personal culture under the conditions of sudden pathogenesis. TEM is the method to describe persons' life courses within irreversible time. The term *equifinality* is widely known because of Ludwig von Bertalanffy, who is the founder of General Systems Theory (Bertalanffy, 1968).

Equifinality is the principle that in open systems a given end state can be reached by many potential means. It emphasizes that the same end state may be achieved through many different means, paths, and trajectories. Variability of trajectories means richness of life. So the very first place of the conceptual adventure, equifinality and the trajectories that converge upon it are highly intertwined with

each other. Bertalanffy preferred equifinality better than "goal," equifinality isn't the dead-end-like goal point.

The reason why TEM is suitable for describing LWI is because TEM has incorporated the notion of a *polarized equifinality point*—an imaginary complementary class of usual and/or singular events that might exist—in contrast to the equifinality point that represents healthy life. Both the equifinality point and the polarized equifinality point are devices for relativizing the value system in existence. The polarized equifinality point is the place in irreversible time at which the personal culture of the person with illness becomes transformed into a new form. Here one can observe a new value system in its cultural emergence. That can happen in many ways—multifinality is useful for describing the person whose experience leads to new culture and new aims in life.

In medical sociology there exist investigations of patients' lives from the perspective against an official medical system. The study of chronic illness trajectory model by Corbin and Strauss (1991) is one of such studies. However studies from medical settings easily confound the patients' perspectives and the perspective of the medical system that is controlling patients' lives. The orientation of illness trajectory then should be criticized from the describing of the lives of people with illness. TEM is recognized as a promising method for the illness trajectory framework.

We propose the importance of the microgenetic approach especially in describing the life of patients or persons who are ill; in general, psychological research on human beings as medical patients has been rising since the latter half of twentieth century. At first, medical sociology and the studies of nursing became focused on research of social "deficits" of the patients (Parsons, 1951a). Then, patients from non-middle-class backgrounds did not fit well into the social regime of medical settings, and that misfit needed to be studied. Ethnography emerges as a useful resource because the mission of ethnography is to depict culture.

### **Illness Trajectory Framework from Nursing Research and Medical Sociology *Historical Context of Ethnography: The Archeology of Anthropologies***

Ethnography is defined as the art and science of describing a group or culture (Fetterman, 2008).

This term also refers to qualitative methodology or reports to describe a behavior pattern of the people through fieldwork (Lecompte & Preissle, 1993). Ethnography originated from early (cultural) anthropology and spread to other social sciences. Each discipline has its own way of studying diverse customs, so the deliverables are widely variable in the same “ethnography.” For example, micro-ethnography is commonly-used type of ethnography in psychology. Micro-ethnography is the study of narrowly defined cultural groupings such as a school classroom. Micro-ethnography is suitable for the study of “Life with illness,” especially the refractory and/or progressing disease.

To understand the features of micro-ethnography, let us start with looking back at the history of the anthropologies. This chapter gives weight to ethnography as methodology and explains how it is used in psychology today. Ethnography originated from early (cultural) anthropology, more properly from Bronislaw Malinowski’s work in the 1920s (e.g., Malinowski, 1922). He was also the pioneer of “empirical” fieldwork—and he also worked in the field—where he developed currently accepted anthropological research methods (such as participant observation). The term “*empirical*” implies another kind of anthropological research. Though now the anthropologist seems to be a fieldworker, as a person who actually goes to his research field, the typical anthropologist before Malinowski was not. This old type of anthropology could be called “*armchair anthropology*.” Armchair anthropologists depended on speculative discussion and got the data for their research from others who actually visited a field—usually places far away from their academic homes. The problem is, of course, all of their discoveries could easily become products of fantasy. Fieldwork, and ethnography as its product, got a foothold because they were expected to be a method to describe human life and behavior more directly.

The political aspect of anthropology cannot be ignored when we look back at its history. A number of anthropologists in the past worked as a part of a national strategy because ethnography was useful for understanding the culture of the people in their colony. This colonial anthropology aimed to make their colonial occupation easier and firmer by collecting the information about the different cultures through the European ways of seeing. Actually, the early “positive” anthropology transformed from armchair anthropology with using the real observation of the field, however the aim of anthropology

could not be transformed. This academic program should obey the interest of government and follow the mission to know the “native” of conquests/colonial lands (see Kuklick, 1991). The cooperation among government and anthropologists became pronounced in war time, especially during World War II (WWII). The study by Ruth Benedict is one of the notable examples. In her book, *The Chrysanthemum and the Sword*, as a cultural anthropological study, she showed indigenous features of Japan (Benedict, 1946). Although the book was published after WWII, the content was based on her war-time research. To understand the culture of Japan was considered to attribute to a strong position of control after the war.

New uses of ethnography are being adapted in urban sociology (see Kharlamov, 2011). Fieldwork and ethnography already attracted another discipline of social science in the 1920s. Sociologists in the United States applied those methods for exploring their interests. The so-called “Chicago school” tried to study a different culture within their own country. For example, Cressey (1932) described the social world of dancers and guests in the ballroom, and Whyte (1943) proposed the collision of local and total society as a cause of delinquency through observing various groups and communities in a slum district of Boston that was mostly inhabited by immigrants from Italy. Urban sociologists transformed the meanings of the term “ethno” from ethnic group in another country into some group who have different cultures in the same area (country). Subjects of research also could be varied.

“Anthropology of science” provides a unique example. Bruno Latour took a laboratory as his research field. A laboratory is not only the place of production of scientific knowledge but also the community in which scientists practice their daily works in a unique manner. In *Laboratory Life* (Latour & Woolgar, 1979) and *Science in Action* (Latour, 1987), he studied how the scientific truth was made, focusing on the process and network. One of the most important keys to this process is to grasp the local practice as it proceeds with time and build upon social relationships. Today, it is not enough to know about an unprecedented field. We may apply these perspectives to another more significant issue.

### ***Life Ethnography***

Recently, the subfield of life ethnography has emerged as a type of ethnographic research to describe the lives of people. People, especially those

who have incurable and progressive diseases, face continuous transformation of their symptoms and body. Life ethnography should not eliminate time, because the disease process is an ongoing and never-stopping experience.

The key points of life ethnography can be summarized into following points:

1. **Description of the system** of “life with illness”; patients live with various factors affecting their lives including caregivers, technology, institutions and so on. They also each have a historical and cultural background. Each researcher may take different methods to write a life ethnography, but it is important to understand the life of a patient within their network.

2. **Understanding each case** through exhaustive fieldwork.

3. **Notion of time and the emergence of signs of guidance**—e.g., “the aim of life.” Ethnography is to discover how people create signs that make them behave in various ways.

Mundane (daily) diaries and medical documentation are useful for understanding “time-full” process. The new possibility of bridging between medicine and psychology has just emerged. Life ethnography of refractory and/or progressive disease brings us the new exciting challenge. That is the dynamism under the maintenance process with the immobile body.

Although each discipline, including psychology, has different rules for describing a phenomenon with ethnography, the following points are shared in common:

1. Understanding human behavior including the context of his/her living through fieldwork.

2. Multi-method: participant observation, interview (both dialogue and group), document study and so on.

3. Generating hypothesis that is suited for explaining the phenomenon systematically through gradual focusing.

The unit of description—how and what should be described—differs between disciplines. There are a few exceptions to these methodological trends, but to summarize: anthropologists focus the structure of relative, ritual, customs, and so on; sociologists place more importance on institution; psychologists place a special emphasis on behavior, speech, and interaction of the people. This type of ethnography is called “micro-ethnography” because it is a

method for disclosing microgenetic behaviors and psychological processes.

The term “*microgenetic*”—originating in Heinz Werner’s version of rendering the notion of *Aktualgenese*—is important for describing human behavior within a specific time and space, or *chronotope*. According to Bakhtin’s conception, the *chronotope* refers to the interconnectedness of time and space in literature. The word “chronotope” literally means “time space” and is defined by Bakhtin (1984) as the intrinsic connectedness of temporal and spatial relationships that are artistically expressed in literature. Today, this notion is applied to narrative analysis. Life ethnography and narrative analysis of the life with illness become important promising areas in cultural psychology. Because we can understand that a disease experience is not only a biological/physiological event but is a socioculturally constructed event.

Life ethnography fits well with medical anthropology. Medical anthropology focused on the social processes and cultural representations of health, illness, and the nursing or care practices. Alan Young showed how the concept of post-traumatic stress disorder (PTSD) was made into a disorder (Young, 1995). Disorder tends to be attributed to personal problems, but it cannot be constructed without medical and political background. Arthur Kleinman showed how the experience of chronic patients could be transformed, focusing on their narrative (Kleinman, 1988). Symptoms of chronic disease are not experienced as pure medical meaning, but experienced as a bio-psycho-social meaning. And illness is not simply a personal experience; it is transactional, communicative, and profoundly social. But again, we use “life ethnography” for emphasizing “life of person with illness” not of a patient in a medical setting.

### *Illness Trajectory Model*

Life of patients and/or developmental process of patients rarely gain a primary focus in psychology. Mental illness is an exception, because this is the main target of clinical and/or abnormal psychology. This is a clear gap in our knowledge—lives of patients should be treated from a psychological perspective. We have developed the new framework for it—the look at persons’ construction of their future life pathways based on reconstructing the past. Anselm Strauss and his colleagues started studying chronic illness in patients as early as 1960. Following intensive work, they focused on the conceptualization of managing and shaping the course

of an illness (Phipps et al., 2003). Furthermore, Corbin and Strauss (1991) developed a chronic disease trajectory framework following over 30 years of research on a variety of chronic illnesses. Because their model/framework is grounded on the research and practice of nursing, this is welcomed by nursing care models of different chronic diseases such as cancer, trauma, diabetes, mellitus, and stroke, among others (Kabinga & Banda, 2008). Corbin and Strauss's chronic illness trajectory model prescribes that the life course of chronic patients should be divided eight phases (they later added one more phase). Specific nursing management steps are invented for each phase. Illness, instead of disease, implies that lives of patients are embedded in social, cultural, and family context.

Although the phases from the chronic illness trajectory model are static and useful for nursing management, they are not useful for the lives of patients. Burton (2000) summarized the eight phases (instead of nine) of the illness trajectory framework:

The first stage in a trajectory (pre-trajectory) occurs before the onset of symptoms, and consequently before a formal diagnosis is made. This emphasizes the importance of illness prevention within a framework for managing chronic health problems. When signs and symptoms appear (trajectory onset), these can pose a significant threat to the physical, social or psychological integrity of an individual (crisis phase). The onset of symptoms may precipitate a period of illness that requires active intervention, usually in an in-patient setting, to prevent the worsening of symptoms, or the prevention of complications associated with the effects of the illness (acute phase). Where intervention is effective, a period of stability may be reached which will require varying degrees of intervention to maintain individual health (stable phase). An individual will, however, experience challenges to their recovery either directly or indirectly associated with their illness which require a reappraisal and adaptation of interventions, usually without admission to a hospital setting, to promote coping and stability (unstable phase). Responses to these challenges to recovery will at some point, however, be unsuccessful, and the patient's recovery may deteriorate (downward phase) to such a point that the patient may be terminally ill (dying phase).  
(Burton, 2000)

Corbin and Strauss's trajectory framework sets the illness trajectory up as a series of phases. Trajectory phasing represents the many different changes in status a

chronic condition can undergo during that course (Corbin & Strauss, 1988, p. 16). Phases are not simple time durations. They depend mainly on physical symptoms. A bio-psycho-social model of disease is not disregarded, but symptom-oriented phasing is necessary for the medical setting. Their framework as a grounded theory was developed from an extensive research program on *dying*, and was refined in studies that included a range of settings and patient groups (Corbin & Strauss 1992; emphasis added).

The aim of medicine is to save lives—which really means overcoming disease until the moment of death. So the value systems of patients' lives are embedded in a simple and/or uni-dimensional medical meaning system. This is inevitable. So if we want to think of the "life itself" of a patient, we need to think about the life trajectories that are far from the medical setting. The word "life" is not an antonym of the word "death." It implies daily activity (everyday life) and course of individual (life course, lifelong development).

When a patient goes to the doctor, he/she is seen not as a person who needs help with his or her health, but as a person who has an affected area to be treated. Even worse, he/she is seen as a potential component for the medical factory! Here Bakhtin's notion of *addressivity* (Moro, 2004) provides us the analyzing viewpoint in the microgenetic level. Sometimes modern professionals, including medicine, lose the addressivity of his/her profession. Medical professionals tend to deal with a patient as a part of an ill body rather than as a human being.

A patient is treated as an anonymous body by medical professions, i.e., medical techniques direct to an faceless body. These states may be the lack of *addressivity* (Bakhtin, 1986). It is also a trait of the outlook of modern human beings. If the (dialogical) act doesn't conclude without the addressee, the act of the medical-care personnel doesn't conclude. Moreover, the problems are acute—the patient cannot reply to the medical discourse. The lack of dialogue will bring patients the feeling of imperfection and the duty of "concentrating on treatment." However, the person tends to live with the expected prospects, and the person cannot help thinking about the thing after treatment. If the present medical-care personnel are busy, it seems possible to adopt a system including a support person such as a Child Life Specialist (CLS). A CLS is a pediatric health-care professional who works with patients, their families and others involved in the child's care in order to help them manage stress and understand

medical and various procedures (Armstrong-Dailey & Zarbock, 2001). CLSs are trained professionals with expertise in helping children and their families overcome life's most challenging events. They focus on the psycho-social development of children, and encourage effective coping strategies for children and their families under stress (Swanson, 2005). For a productive research orientation, different perspective is needed. For a productive research orientation, we need to focus on the living process of patients rather than the dying process of patients. Here, we rename the living process "life trajectory."

### **Life Trajectories for the Person with Illness**

Life trajectory approach, not illness trajectory approach, focuses on each illness person's life—not the process for dying. It's a thick description for the lived life of a person with an illness. Depicting dynamics of living may lead to understanding the thickness of life. Pursuing life trajectories depends on the new methodology of Trajectory and Equifinality Model (TEM; Valsiner & Sato, 2006; Sato et al., 2007; Sato et al., 2009). In the case of uses of TEM, researchers focus on subjectively important events of the person and treat those as the equifinality points (EFPs). The history of TEM is interdependent on the development of the notion of Historically Structured Sampling (HSS; Valsiner & Sato, 2006) the function of which is to replace the standard random sampling techniques for systems that do not satisfy the axiom of independence of its elements. All human systems consist of non-independent parts and cannot be "randomly" sampled. From the viewpoint of sampling philosophy and technique, the procedure of HSS consists of "equifinality sampling" i.e., the equifinality point in which researchers have an interest is the experience to focus on.

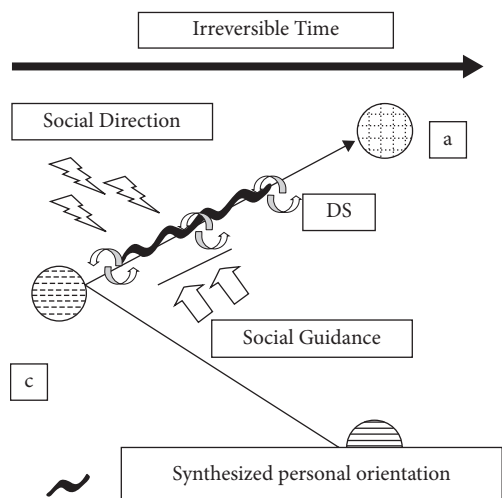

Sato et al. (2007) emphasized that equifinality does not imply sameness—which is an impossible condition in any historical system. And the more important thing is setting the polarized equifinality point in TEM. Since equifinality point depends on the researcher's focus and/or research questions, EFP only shows one aspect of phenomena. We need to show some kind of complement set of EFPs. So we set up polarized EFP (PEFP) for neutralizing the implicit value system of researchers. PEFP makes researchers notice the possibility of invisible trajectories. Since the setting of PEFP might be regarded as the pluralizing of the finality points, it implies the multifinality of the life. TEM has focused the

trajectory in the past for equifinality point, but now, the description of future perspectives of each person is regarded as a new practical issue of TEM.

TEM has been developing for a few years quickly and the notion of multifinality is the promising brand new idea to depict the uncertainty of ongoing life within time.

*Bifurcation point* is the location on a trajectory when and where new direction emerges. Bifurcation point (BFP) is a point that has alternative options of where to go. What would happen at the BFP?

According to Sato and Valsiner (2010), we can see in Figure 51.1 the two opposite powers that conflict between social direction and social guidance. Each person is supposed to have his/her original orientation to EFP. It is called "*Synthesized Personal Orientation*" (SPO) and SPO reflects the fluctuated orientation and open-systemic nature of a human being within irreversible time (Sato, Hidaka, & Fukuda, 2009). A person proceeds with one's orientation as an open system (which means orientation is not internally derived) and struggles to realize his/her own orientation against the social directions (SDs) with support of social guidance (SG) supplied by the intimate social relationships. The focus on social direction derives from Valsiner's (2001) idea and it should be defined as some kinds of sociological cultural power. It might be said to include "common sense," tradition, social norm, and social pressure. On the other hand SG is the power of defense against the social direction. SG is the power supplied from the intimate persons such as a family,

**Figure 51.1** The making of the future: BFP as the point of transformation and blooming time (Sato & Valsiner, 2010)

friends, teachers, and others. Simply speaking, SD is defined as the power of inhibition to go to EFP, and SG is defined as the power of promotion to go to EFP.

**Lessons from Life of Intractable and/or Chronic Disease and Notion of Finality: Uncertainty and Genesis of Multifinality**  
*The Patients' Life of Intractable and/or Chronic Disease*

Akasaka (2009) examined how people with chronic inflammatory bowel disease (IBD) live with their illness and describe their experience of pain. IBD is a group of inflammatory conditions of the colon and small intestine. And it is an illness of uncertain etiology. Six patients with IBD were interviewed regarding their medical history and experience of illness. From their descriptions, four steps in the process of coming to terms with their illness were identified: “confusion; fear of change,” “seeking an explanation and encountering a diagnosis,” “uncertainty; seeking future,” and “reconstructing meaning.” Because the IBD is an illness of uncertain etiology, the third phase of “uncertainty” has a double meaning. These are uncertainty of cause and uncertainty of prognosis. And patients tend to illusorily correlate the hypothesized cause and their worsening symptoms.

Nishida (2010) examined communication deficiencies and misunderstandings between care receivers and caregivers through one in-depth case study. In this case, the care receiver suffered from a severe progressive disease (amyotrophic lateral sclerosis, ALS) and lived in a single household. The study finds the following problems in the patient’s situation:

1) caregiving services were subdivided among a number of separate subgroups by provider and this grouping seems to be lack of organization from the receiver’s position;

2) though the patient had difficulty in self-determination as his disease progressed, nobody played a coordinating role in providing care. Both patients and caregivers struggle with oppression, but avoid straightforward communication—because patients need the care to live and caregivers need to keep their jobs.

Hidaka (2010) has engaged in life ethnography work with the ALS patients. He says that it’s important for patients not only to respond to a life-threatening condition, but also to express their experiences and get involved in patients’ advocacy activity. Some

patients have used them to write a book or report for telling their experience to the society. Capacity of patients’ communication has been developed based on new computer technologies.

However, there are problems for continuous use of assistive technology. A research showed one-third of assistive technology is abandoned within 3 months because of the lack of effective supporter(s). On the other hand, in a few exceptional cases, a few patients have been using assistive technology continuously with a supporter. Hidaka (2010) reported one person with ALS using his cheek for communication at home with 24-hour-a-day care. This person should stay in bed during the whole day with a respirator, but he can enjoy using a computer for writing and communicating others. His activity is supported by many people around him. These include family members, medical and co-medical staff, and the peer supporter. The peer supporter is a person with the same disease (in this case, ALS) and has a specialized skill (in this case, computer technology). The peer supporter knows both disease and technology, so he can deliver necessary and sufficient support for the person with the illness in bed during the whole day. In this case, the person with severe ALS got ALS a long time ago and now he has finality that was never construed before his pathogenesis.

***Frame of Transition Process of Pathogenesis of Intractable and/or Chronic Disease***

These are three examples of uncertainty in the life with illness. And uncertainty is the important feature of the transition process of becoming patients. We can identify the frames of transition as follows. Frame is the key concept, which is derived from Fogel’s (2006) work on dynamical system approach. Salgado and Gonçalves (2010) insist that frame is not a static concept but runs in sequence.

The frames from the perspective of life ethnography and life trajectory approach are below. Here we use the term “frame” to focus on the meaning-making process of a person with illness.

**Table 51.1 Frame of transition process of pathogenesis of intractable and/or chronic disease**

Singular finality
Evaporation of finality = Uncertainty
Zone of finality
Multifinality

Finality is the key concept of Trajectory and Equifinality Model (Valsiner & Sato, 2006; Sato et al., 2007; Sato et al., 2009). Before getting an illness, a person has the singular finality of a healthy (and usually means normal) person, which is unique to each person. Each person could have their own finality respectively. But if person got an illness, the finality he/she has had is usually under crisis. The finality evaporates and uncertainty emerges.

From the theoretical demand of TEM, a singular finality should be relativized by another complementary finality, i.e., polarized EFP. For the TEM, the polarized EFP (PEFP) should be set so that the model might avoid evaluating the life course by a dominated single voice. Being affected by intractable and/or chronic disease is a moment when a previously formed finality (for healthy person) should evaporate. Then a PEFP should replace the EFP, but it's difficult. Because not only EFP but also PEFP has been set for the healthy person. PEFP is not a second-best finality for new patients. So both EFP and PEFP vanish simultaneously. Then uncertainty emerges.

Uncertainty is the period during which patients are in most unstable condition. For considering aspects of uncertainty, Hermans's theory of dialogical self in globalization era is useful. In the context of globalization, Hermans and Dimaggio (2007) referred to the notion of uncertainty. They define the experience of "uncertainty" as a condition where different authors ascribe alternative meanings. So a more detailed description is required. They see the experience of uncertainty as composed of four aspects: (a) complexity, referring to a great number of parts that have a large variety of relations; (b) ambiguity, referring to a suspension of clarity, as the meaning of one part is determined by the flux and variation of the other parts; (c) deficit knowledge, referring to the absence of a superordinate knowledge structure that can resolve the contradictions between the parts; and (d) unpredictability, implying a lack of control of future developments.

The experience of uncertainty characterizes a situation of multi-voicedness (complexity) that does not allow a fixation of meaning (ambiguity). Positioning as a healthy person is at stake and an "I-as-patient" position is not easily formed. Some kind of multi-voicedness emerges. Not a voiceless but a multi-voice situation creates uncertainty.

Some persons in uncertainty may hear no voice and need a voice from others. Others may hear a lot of voices from others and be confused about which voice is adequate.

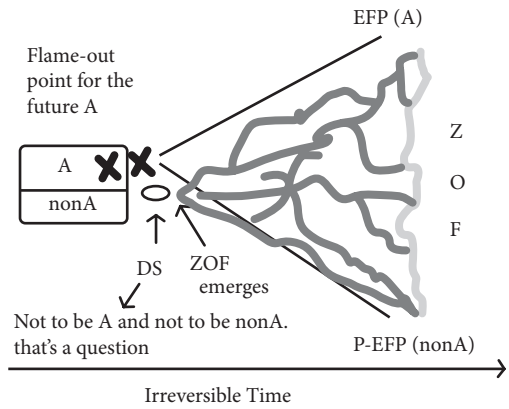

Figure 51.2 Zone of finality

Struggling with such a vague situation, a "new" patient begins to accept the condition. And a position of "I-as-patient" is added to the repertory. After an uncertainty period, a new finality should be formed but it might be ambiguous. The zone of finality (ZOF) appears. (See Fig. 51.2.)

Under a "usual" life, each individual has his/her own aim. It depends on the value system of healthy people. And equifinality point of an ex-healthy person should disappear when he/she gets severely sick. And a new equifinality point cannot emerge soon after such a rupture. He/she tends to lose desire to achieve the original aim and sometimes a person loses the aim of life (some might choose to die). So when a flame-out or wreck experience evaporates the EFP, an alternative finality should emerge. But it's difficult to clarify this second-best finality, so the finality should be ambiguous and form the zone of finality. Here we use "zone" instead of "point."

Then the role of dialogical self is important. The person who is suffering should ask oneself (self-dialectically), "So what is the next aim? Which way should I take?" Even though one cannot answer this question, one should begin to start new journeys. Even a next finality is neither clear nor discrete.

### Quality of Life and Beyond On Measurement of "Quality of Life"

Quality of life (QoL) is one of the well-known concepts in psychology and related areas. There are so many measurement scales of QoL now. We wonder whether *quantitative* measurement of *quality* of life is possible. It's an ironic contradiction. In the measurement of quality of life, the QoL of refractory and/or progressive diseases seems to be evaluated as low and valueless, because their sickness gets worse and—such

development means an increase in hopelessness. For example, the patients with ALS disease gradually get worse—in the end they cannot move any muscle. Persons who gradually lose their muscular power should stay in bed all day and cannot move by themselves. Yet some patients can establish contact with friends and family by using Internet technology (IT). They manage to control IT devices with the muscles they can use. One person uses cheek muscles for controlling a computer. Another uses left-foot muscles. Then can write books, paint, and so on. They are enjoying their lives in their own way.

Given this reality, any score of an activities of daily living (ADL) questionnaire misleads us to estimate the quality of life to be low specifically when the score is regarded as the index of improvement. Barthel Index (BI) is a scale used to measure performance in basic activities of daily living. ADL scales focus upon a range of mobility, and self-care tasks, and ignore issues such as pain, emotions, and social functioning (Fayers & Machin, 2007). BI consists of many daily living activities. In one example of feeding, the standard is below. BI is evaluated by using in Japanese medical situations:

- 10 = independent,
- 5 = partial help with eating or needs help cutting,
- 0 = unable.

So—if the person can't spread butter, the evaluator gives him 5 points to indicate the need for "help with eating." Spreading butter is the anchor to rate the level of feeding activity. Here we must note that even if spreading the butter might guarantee a good level of ADL, a person who cannot spread the butter should not be regarded as low ADL. But is this right? The item of ADL only reflects the viewpoint of medical professions.

Let us consider the functional independence measure (FIM) (Keith, Granger, Hamilton, & Sherwin, 1987). The FIM measures 18 items over six different domains by a 7-point scale: (a) self-care, (b) sphincter control, (c) mobility, (d) locomotion, (e) communication, and (f) social cognition. These items are construed from the viewpoint of medical professions, not from the patients' viewpoints. And more importantly (that means worse), scores on such items are difficult to change with the patients' situations.

### ***Equifinality for the Person with Chronic Disease and/or Progressive Disease***

What's the equifinality for the person with chronic disease and/or progressive disease? Parsons

(1951b) proposed the *sick role concept*. The *sick role concept* consisted of four main principles:

1. The sick person is not at fault for being sick;
2. The sick person is excused from usual (everyday) responsibilities;
3. The sick person must get well as soon as possible;
4. The sick person must seek professional help.

"Being sick" is not simply a "state of fact" or "condition" (Parsons, 1951b). The sick person is exempt from normal social roles. He/she should try to get well and also has to say "push myself to the max." Maxim one, first, is the institutionalized definition that the sick person cannot be expected, by "pulling himself together," to get well by an act of decision or will. In this sense also, he is exempted from responsibility, as he is in a condition that must be "taken care of." Maxim two, the second closely related aspect, is the exemption from normal social role responsibilities (p. 437). Maxim three is the definition of the state of being ill as itself undesirable with its obligation to want to "get well." And Maxim four seems reasonable, but let us not forget that any imbecilic act is prohibited and supervised by people surrounding the patient.

One criticism of Parsons's sick role is that there are limits to its application. It is good for a person with an acute disease but not for a person with a chronic disease (such as diabetes mellitus, hypertension, and arthritis). How do we think about the patients with refractory and/or progressive diseases? Is there no hope? Parson's sick role is not cut out for the patients with refractory and/or progressive diseases. Patients really want to "get well" as Parson's maxim three says, but maxim four never will be completed. On maxim two, they don't make themselves be exempt from mundane social roles, instead, taking normal social roles such as being a father or mother and using it as motivation for struggling with their difficulties. As Parson's four principles of sick roll indicate, the life should totally change compared with before being sick. Patients' aims and finality should be transformed. Usually, a healthy person has his/her finality from the healthy person's viewpoint. Being healthy and free of illness is one of the popular wishes for a "normal" person. Being healthy is so ordinary to many people, it's difficult for healthy people that health status is not permanent. And they often have anxiety, complaint, and other negative feelings to pursue their wishes and dreams. Based on the health state, many people struggle to live. And

the premise (i.e., healthy state) is never doubted. Getting a disease is a very big rupture and it deconstructs all aspects of life without disease. Singular finality decays and uncertainty emerges.

Here let's consider disease as an adorable dimple. The noun *patient* is a denominative noun. This noun comes from the adjective word, "patient." Disease could be regarded as some positive feature like dimples on one's cheeks. Being sick is not a role but an "individual characteristic" or "personal quality." Not "disease" itself, but "life" with disease should be regarded as respectable. Even though the concept of QoL has gradually been accepted as an important therapeutic goal for chronic diseases in the most recent two decades, there is some confusion in the procedures to measure QoL and the aim to measure QoL.

Measurement of QoL has been developed by psychometrician, so quantification is regarded as an important principle. And quantification leads us to focus on the "objective" aspect of life experience of patients. If QoL of patients' life should be grasped from their subjective sphere, then we would need another kind of methodology.

### ***The Person as a Co-Investigator in Research***

George A. Kelly published *The Psychology of Personal Construct* in 1955. He assumed the human is a scientist. That means people seek to make sense of the world as we experience it by building and testing hypotheses about "how the world works." Then each person creates and maintains an individual way of interpreting the world. He called this individual frame of interpretation a personal construct. The personal construct system made by this empirical process was called a personality (Kelly, 1955). Inspired by the scientific exploration of Kelly's work, Hermans and Bonarius (1991) regarded the participants in psychology studies as "co-investigators." This means that the subject/participant should also be allowed to take a much more active role in psychological research. Between investigator and participant of intersubjective communication constructs of interaction, such a process of interaction should not be understood as the communication of the professional and the layperson (i.e., patient). This intersubjective interaction should be regarded as the coalition of two different kinds of the professionals; the researcher has specific knowledge, and the researchee is also a specialist who knows the special condition of his/her own self (Hermans & Kempen, 1993).

The Schedule for the Evaluation Individual QoL (SEIQoL; O'Boyle et al., 1991; O'Boyle et al.,

1992) which is one of the methods of measuring QoL, might be also influenced by Kelly's position. The SEIQoL is designed to measure three elements of QoL: (1) those aspects of life a person considers crucial to his/her QoL, which are elicited by means of a structured interview, (2) current functioning satisfaction with each aspect, (3) the relative importance of each aspect of QoL, which is measured by deriving the weight the person assigns to each in judging overall QoL (O'Boyle, 1994). Actually, the investigator asks the question of participants, "What are the important 5 domains for your QoL?" in the administration manual (O'Boyle, et al., 1995). The especially important one is the process where five QoL domains are nominated. When this measurement is carried out as Hermans and his colleagues say, the intersubjective conversation is composed between the patient and the investigator of the patient's QoL domains. The patient can nominate any situation as the content of own QoL-related item. The situation inevitably includes his/her value system, beliefs. And the item is useful for the investigator to understand that patient. Because the nominated item reflects the aspects of the patient's self. If "Health," "Family," and "The relationship with medical staff" are called QoL items, they reflect the patient's value system. In other words, the patient conveys individual QoL to the investigator, from the specialist of his/her own life. Then, the investigator could learn about patient through using SEIQoL (i.e., patient's illness, ordinary experience, and individual situation) from their narratives and dialogical conversation are not only good for measuring individual QoL but also knowing the individual meaning system. In addition, when the patient can't list five domains, the investigator gives examples from his/her experience and an existing domain's list. Just then, the patient becomes an investigator who researches for the domain that relates to individual QoL within him- or herself. The investigator will help to expand choices of the patient's QoL domains as a co-investigator, not for study but for the patient.

### **Theoretical Implications**

#### ***Epigenesis is Not Necessary for Multifinality***

Waddington (1956) had an interest in explanation of the linking of genetic and environmental factors in development. In Waddington's own words,

One can make a mental picture ... of development of a particular part of an egg as a ball running down a valley. It will, of course, tend to run down to the bottom of the valley, and if something temporarily pushes it up to one side, it will again have a tendency

to run down to the bottom and finally finish up in its normal place. If one thinks of all the different parts of the egg, developing into wings, eyes, legs, and so on, one would have to represent the whole system by a series of different valleys, all starting out from the fertilized egg but gradually diverging and finishing up at a number of different adult organs (Waddington, 1966, p. 49).

Waddington's landscape (Fig. 51.3) implicitly links to the increasing entropy. But in a human's life, some kinds of conversions appear. This is what we call equifinality points. Multifinality is not what Waddington suggested. His model's main character is a solid ball, which is a closed system. It never interacts with the surrounding field and never has the future perspective. The open systemic nature of human is disregarded in Waddington's theories.

### ***Multifinality from the Perspective of Life with Illness***

The notion of equifinality originates in Driesch's biological work. Driesch performed a series of experiments intervening with sea urchin cells during division and causing them to fragment. Instead of forming a partial embryo, Driesch found that the cells formed an entire one. Here the same final state may be reached from the different initial conditions and from different ways. This is what Bertalanffy (1968) called equifinality. Despite Driesch's vitalist general philosophy, von Bertalanffy built his organismic perspective on the basis of the multi-linear developmental model along similar directions (Fig. 51.4).

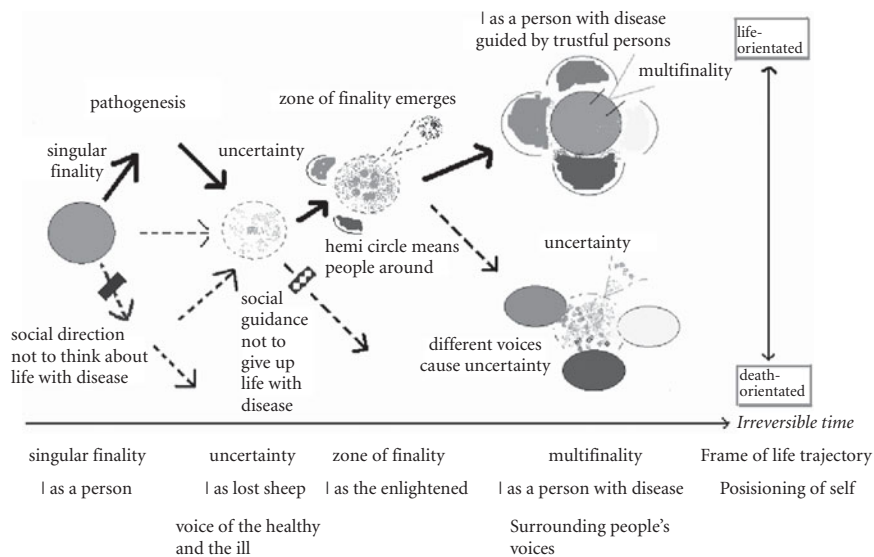

Life is ruptured when a person gets a disease. *Singular finality* is decayed and uncertainty

emerges. Overcoming one's disease is the new aim and medical professions assist patients. It fits to treatable diseases. If patients recover fully, this story is not so bad. But, what if it is an intractable and/or chronic disease? From the viewpoint of patients, unclear prognosis image is formed (*zone of finality*), but this vague finality is repressed by clear finality derived from medical professions. Dominant messages from medical professions should be transformed into alternative messages from the perspective persons with disease. Some research on intractable disease patients has pointed out that uncertainty is the key notion of the state. In general, the well-planned equifinality point "A" disappears, then uncertainty emerges. The future is not clear. First, there is no voice to hear, then voices from medical professionals come next. Finally, many voices appear and make the person confused. Uncertainty reflects a complex process. However, the single finality from one voice is dangerous for the patients. Although multi-voiced situations make patients confused, some other finalities should emerge. *Multifinality* is the notion for opposing the dominant story from the medical profession only. Multifinality ensures an atmosphere in which patients in the uncertain situation can select freely patients' own ways of living. Multifinality in one's own historical trajectory should not measure the variable in a person but should understand the whole person with illness.

The notion of multifinality in this paper has two interwoven connotations. For understanding "QUALITY" of "LIFE" (Caution, it is not the abbreviation of QoL) with severe disease, we

**Figure 51.3** Waddington's "Epigenetic landscape" (Waddington, 1966, p. 49)

**Figure 51.4** Hypothetical trajectories of intractable disease persons.

should distinguish different types of multifinality. Deconstructing the singular finality of the healthy person and reconstructing finality is a kind of multifinality. And constructing and differentiating the finality as a person with illness is another one. And an item-generating system for QoL such as SEIQoL is needed. In usual quantitative scales on QoL, items on the scales are provided from medical profession's perspective.

### ***Multifinality as a Spatial Extension of Finality***

TEM is a new methodology derived from such a demand that is embedded in the context of ethnography. TEM has been developing for a few years quickly and the notion of multifinality is the brand new idea to depict the uncertainty of ongoing life. Social sciences, including psychology, benefit from utilizing the notion of multifinality because this can depict the emergence process of future perspective in the living. It's especially useful for treating the dynamic of living with disease. Parsons (1951) proposed the sick role concept. "Being sick" is not simply a "state of fact" or "condition" (Parsons, 1951b). The sick person is exempt from normal social roles. Lacking a role means losing the guides from the world. An uncertain future emerges and then DS occurs. Self struggles to encounter the promoter sign, which leads the sick person to certain future. Thick description of the lived life might be achieved by TEM with some notions such as Hermans's dialogical self and positioning. Dialogical self is

the spatial extension of self. And Hermans clearly looked at the era of globalization. Researching the diversity of finality all over the world is a challenging task for cultural psychology. Hermans (2008) suggested that extension of the self in space leads to the study of the dialogical self as the interface of globalization and localization. TEM doesn't actually have the spatial viewpoint, but TEM can be applied to understand the different models of the sign in various cultures. The notion of multifinality brings us, especially people living and struggling with disease, such a new journey.

The restriction of activity resulting from illness causes the low QoL of patients and creation of alternatives leads to higher QoL of patients. The Schedule for the Evaluation Individual QoL (SEIQoL) stands on a constructive approach and is a tool for understanding the patient's QoL from the patient's perspective. Patients can decide their important domains for a custom-made QoL score. Constructing multiple QoL domains is really promising support for the patient. Family, medical professionals, and other people around the patient should bear such important task. TEM, from the perspective of time, and SEIQoL, from the perspective of place are both necessary for understanding the daily life of persons with disease. And the notion of multifinality bridges the time and place. The living experience of persons with illness should be understood from the perspective of chronotope and it means cultural psychology must open the door to new research and a new practice paradigm.

## Concluding Remarks

In cultural psychology, that general mechanism is found in the functioning of signs (semiotic mediation) (Valsiner & Rosa, 2007, preface). Culture can be seen as a systemic organizer of the psychological systems of individual persons—culture “belongs to” the person. Again, culture “belongs to” each individual person. It is irrelevant that the persons “belong to” culture, ethnic group, or country, since culture is functioning within the intrapsychological systems of each person. Here culture is applied to an each subgroup of human being.

The person with a disease must be regarded as “having their own culture.” Such a view brings the authenticity to the so-called “patients.” In this chapter, we focused on the culture and/or meaning making of a person with illness. We proposed not to use the word “patient” because this is too often a medicalized word. This is because cultural psychology aims to describe the living person’s life.

Social sciences, including psychology, benefit from utilizing the notion of multifinality, which makes it possible to depict the emergence process of future perspective in the living. TEM is the new methodology that is embedded in the context of ethnography. TEM has been developing for a few years quickly and the notion of dialogical self from Hermans makes it possible to understand the moment a healthy person confronts getting an illness. We should treat patients’ lives within irreversible time from the ill perspective.

## Future Directions

In this chapter, we proposed to focus on *life with illness* (instead of *patients’ lives*) as one of the forms of human life. And this leads to the construction of its own peculiar kind of culture. From the viewpoint of cultural psychology derived from the “sign” psychology of Vygotsky, culture is not necessary to hold the notion of actual time and actual place. The person is influenced by multiple signs of many “cultures.” So we should focus the person to know culture within the person. *Life with illness* prepares to open the door to turn to a brand new form of cultural psychology. And its main premise is, “culture within person, not person within culture.”

## Psychology Courting Culture: Future Directions and Their Implications

Jaan Valsiner

### Abstract

Eleven propositions for future development of culture in psychology are outlined, based on the 51 contributions to this handbook:

- (1) History of psychology includes valuable resources for innovation in psychology in general and cultural psychology in particular;
- (2) cultural psychology can assume no single cultural system as normative;
- (3) cultural psychology needs to construct culture-inclusive research methodology that is free from the sociopolitical constraints of the “quantification imperative”;
- (4) cultural psychology needs close conceptual links with contemporary biological sciences—especially developmental biology;
- (5) cultural psychology shares conceptual concerns with other social sciences—anthropology, archaeology, urban sociology—and benefits from its unity with those;
- (6) cultural psychology studies structured oppositions that give rise to new cultural forms through human actions;
- (7) the future of cultural psychology should include studies of fixed-feature objects;
- (8) cultural psychology investigates regulatory processes of nonlinear kinds (in contrast with assuming models of linear causality);
- (9) cultural psychology creates data from various sources: cultural processes and products;
- (10) cultural psychology needs to elaborate the notion of participation that stands at the intersection of person and society, and
- (11) cultural psychology needs to develop a meta-reflexive stand in the form of cultural psychology of social sciences.

The macrosocial context of globalization works in favor of the integration of culture in psychology since the worldwide encounters of persons of varied backgrounds render mutual understanding necessary. Such understanding is possible on the basis of the know-how of cultural psychology.

**Keywords:** future, culture, psychology, methodology, globalization

Science is totally opposed to opinions, not just in principle but equally in its need to come to full fruition. If it happens to justify opinion on a particular point, it is for reason other than those that are the basis of opinion: opinion's right is therefore always to be wrong. Opinion *thinks* badly; it does not think but instead *translates* needs into knowledge. **By referring to objects in terms of their use, it prevents itself from knowing them.**

—*Bachelard*, 2002/1938, p. 25, boldface added

Culture is the source of both knowledge and opinions—and our task in this final chapter is to keep the science of cultural psychology from being hijacked by the latter. For example—an opinion that “culture matters for psychology” does not help us to specify how that—whatever is considered culture—enters into the actual interplay of psychological functions. In this sense, social sciences create their own impasses by relabeling “person is individual” into “person is social,” or “thought” into “cognition.” The relabeling entails opinions—shared or contested in scholars’ discourses. These disputes may be lively, and leave the impression of creativity. Yet in reality they are mute—they block inquiry by insisting that the new “black-box explanation” they insist upon, is in itself an explanation. For example, statements “*X is caused by culture*”—often made in counter-argument to “*X is caused by genes*”—are both statements of opinions that block, rather than enable, further inquiry. The opinion is the final station of the moving train of thought.

The mechanism of such end of inquiry is simple. It operates by the economic feature of the common sense. When one creates a label—a nominal cause—the focus of the discourse is removed from *how can we discover the ways in which complex processes work into the processes work* by way of *X that causes them*. The attribution of a category membership becomes a declared cause—or at least one that becomes interpreted as if it were a cause. As the attributions are often generic and operate at the level of general perspectives, such discourse becomes precisely the arena of expressions of opinions that Gaston Bachelard so vehemently dismissed back in 1938. Such opinions neither open a new field for inquiry, nor contribute to solutions to old problems.

There are other epistemological obstacles to solving the question of how culture exists in the *psyche* as well. In our common sense we are used to operating with mutually exclusive notions. The best example comes from the ever-recurrent efforts to explain human psyche through attributions to either of two general categories—the *nature* (genes, etc.) or the *nurture* (the upbringing, social conditions, etc.). Different researchers take positions in favor of one versus the other—or sometimes even talking of *interaction between* both—yet these opinions explain nothing and are not generative for future research. For example, child psychology is filled with such disputes. At times attributability of causality goes to the “inborn”—at other time to “the acquired”. Such flip-flopping between attributions of causality

for development is no solution. Thus “either-or” issue has been overcome in contemporary epigenetics since the 1960s. It is only when the general categories offered for the field are left without causal insertions—such as the history of the notion of the self in immunology (Löwy, 1992)—that their generative role for actual innovative inquiry can proceed.

### **Future Perspectives Elaborated: Eleven Propositions**

This handbook has systematically included the view of the future as a regular theme in all of the chapters—and the editorial goal of mine here is to arrive at a kind of meta-synthesis of all the promises that thinking about culture has for psychology. In other terms—how could this “third coming”<sup>1</sup> of culture into psychology become successful in terms of revamping the science, rather than being a passing fashion.

How did culture re-emerge in contemporary psychology over the recent decades? Its first appearance took the form of honoring the traditions of psychology that treated culture—like gender, socioeconomic status, or school grade—as a variable. This led to the establishment of the cross-cultural psychology research community since the 1960s where culture operated as an index variable, making comparisons between different “cultural groups” possible. Such comparisons have prepared the ground for the “unpacking” of the notion of culture as it operates within each person. While cross-cultural psychology is a part of differential psychology (established as a part of psychology by William Stern in 1911), the up-and-coming (by the 1990s) cultural psychology belongs to general psychology. The transition from the differential to general psychology’s view on culture is evident in the central web resource of cross-cultural psychology (<http://orpc.iaccp.org/>, established by Walter Lonner and currently edited by Wolfgang Friedlmeier). The goal of cultural psychology is to explain the ways in which human cultural constructions—rituals, stereotypes, meanings, etc.—organize and direct human acting, feeling, and thinking in different social contexts (Cole, 1996).

I have repeatedly pointed out elsewhere (Valsiner, 1997, 2000, 2007, 2009a, 2009b) that the key to longevity of culture in psychology is the development of new methodology that is *culture-inclusive* (Valsiner, 1989). Of course the two ways in which culture is represented in our times—as a *container* and as a *tool* (see Figure 1 in Introduction to this Handbook)—renders that notion of culture

inclusivity into a realm where choices need to be made about these representations. Looking through the chapters in this handbook, I was pleased to see that the “container” image of culture is gradually vanishing. We still may observe authors using it as a kind of shorthand (“*in* this culture X, phenomenon A has been found, but not *in* culture Y”) but it is not a relevant part of theorizing. Instead, our discourses are moving to statements like “*through* cultural resources P and Q, phenomenon A can be observed by some persons in society X, at times.” The work on culture as a semiotic and symbolic resource (Zittoun, 2012) and in movement of human beings (Beckstead, 2012; Gillespie, 2006, 2010, Gillespie et al., 2012; Märtsin & Mahmoud, 2012) illustrates this movement of our ideas toward their future.

So—we can outline the ways in which the culture as a psychological tool enters into our suggestions for future directions. Such suggestions for future directions are themselves opinions of the authors—yet these are opinions informed by the work covered in their chapters. As such, they can be viewed as germinal states of new directions—or at least that is my opinion! Looking through all the chapters in the handbook, it seems a set of “families of directions” emerge from our collective discourse. These can be formulated as a set of propositions.

***Proposition 1: History of Psychology is Not an Enemy of Innovation for Cultural Psychology***

A number of authors (Baerveldt & Verheggen, 2012, E. Boesch, 2012, Diriwächter, 2012, Jahoda, 2012, Magnus & Kull, 2012) emphasize the need to learn from the history of the sciences—psychology, language sciences, sociology, anthropology, biology—to find ways how our contemporary and future cultural psychology could productively proceed—or at the least avoid conceptual dead-end alleys that other disciplines have been caught in, in their pasts. This entails a **constructive look at history of science**—one that is often rejected in many sciences. Here our taking the constructive look allows us to see how scientific progress in a field is not merely the change from one positively flavored fashion to another (e.g., from “behaviorism” to “cognitivism” in psychology) as if that guarantees progress in knowledge. Rather, we can look at productive “upstarts”—such as *Völkerpsychologie* (Diriwächter, 2012), the differentiation and integration theory of Heinz Werner (Valsiner, 2005), the *Umwelt* theory of Jakob von Uexküll (Magnus & Kull, 2012),

William Stern’s personology (Lamiell, 2003), or Lev Vygotsky’s and Jean Piaget’s basic ideas (van der Veer, 2012, van Oers, 2012) as fruitful sources for further theoretical constructions. History becomes a tool for the further—cultural—construction of the field of cultural psychology. As a result, we find out that culture and mind are not different from one another—but facets of the same whole (Jahoda, 2012). So, the question is: how do they work together within the same whole—in the activities of an intentional person who lives in the present while anticipating the future?

***Proposition 2: Cultural Psychology Can Assume No Single Cultural System as Normative***

Both cultural anthropology and cultural perspectives in psychology were historically born in the European contexts, and could be seen as bearing the marks of sciences built on the needs of nineteenth-century expansion of colonial spheres of influence in the world. By the twenty-first century, that social process has changed—first ending the colonial dominance in the twentieth century, and currently entering into the new predicament of globalization with all its socio-economically positive and negative implications. Hence cultural psychology today—and in the future—cannot treat any cultural condition in any country now (e.g., the United States or European Union today) or in history (e.g., the ways thinking and cultural practices were organized in Ancient Greek *polises*) as normative. Cross-societal comparisons—like “the Americans are more X than the Japanese” that abound in cross-cultural psychology—are therefore indeterminate and difficult to interpret. It is usually the case that one of such comparison partners is set as a norm—and the other(s) treated as deviation(s). If “the American child” (a nonexistent abstraction across the wide range of Amerindian-Black-Hispanic-White and across the “welfare” to “CEO bonus-receiving” conditions) is said to be given one’s own bedroom after getting home from the maternity hospital, then the comparison with “the Japanese child” (another nonexistent abstraction glossing over similar heterogeneity in Japan—Lebra, 2004) who is said to be sleeping together with some other family member all through the childhood years—carries implicit normativity. “The American child” is seen as such—the norm—and “the Japanese child” becomes considered as at least an exotic different case or sometimes assumed to be even “problematic”—an “aberration”. The

reality may be precisely the opposite. A historical focus on family lives over centuries would make the “Japanese pattern” the norm for most of the World, and the environment of “the American child” a case of aberration—that could be labeled as “deprivation” (of close contact), “abandonment” (even if only for nighttime), or even “abuse”! It is easy to see how such wordplay changes the social positioning of the user of the language terms (Harré, 2012).

The relativity of such opinionated labels should make their nonsolid nature clear. It has implications for our science. The future of cultural psychology cannot be built on such imports of silent normative assumptions—in either direction. Thus, a mere reversal of the normative claim—considering joint sleeping a universal norm and treating “the American child” as a “night-time tactilely and emotionally deprived” case would amount to mere reversal of the location of the implicit norm. Instead, the future of cultural psychology entails transcending such remnants of the “we” *versus* “the exotic others” contrasts, and looks at the shared general backgrounds (e.g., functions of sleeping) and their multiple cultural forms in different societies, and at the variation within any society. This focus on overcoming implicit normativity in cultural psychology has been the trigger for the emergence of the “indigenous psychologies” movement in the second half of the twentieth century (Chakkarath, 2005).

The “indigenization” of psychology is inherently ambivalent. It emerges in the context of Occidental misrepresentation of the Orient (Chakkarath, 2010) that is imbued by prejudices. While initially being demonstrations of the sophisticated nature of local cultural systems, the tradition of “indigenous psychologies” raises the constructive issue for the future: How can indigenous psychologists find a common definition of their discipline and their relationship to other culture-sensitive psychologies, including cultural psychology? Furthermore, psychological methodology can profit from indigenous psychologies’ know-how (Chakkarath, 2012)—yet it needs to be charted out how that know-how could constructively revamp psychology’s methodology (Branco & Valsiner, 1997). What emerges is the call for developing methodology to look and self-hybridizing persons in the contexts of heterotopias (Kharlamov, 2012). We are all “indigenous”—confronted by the expectations to develop into another state, while retaining our “original identity.” The fitting example is that of an “ancient souvenir” seller at the entrance to a tourist site (Schmid, 2008; van der Spek, 2008),

or the selling of “Hispanic foods” in a separate aisle in a regular North American supermarket. All of psychology is indigenous—Germany, where psychology emerged in the eighteenth and nineteenth centuries, could be viewed as a discipline growing out of the customs and representations of an indigenous society. It was a society unified by language, yet disunited by the political-administrative orders of around 1,500 different aristocratic enclaves. It was further disunited—already in the sixteenth century—by the North/South separation of the Protestant and Catholic areas. For all intents and purposes “Germany” at the time was a heterogeneous social conglomerate within which psychology emerged through its own indigenous German language terms (e.g., *Geist*, *Seele*) that up to now have no fitting translations.

Furthermore—being indigenous means being on one’s road to transcend that state—develop. All persons—and their social contexts—are constantly undergoing development, and to capture “the true state” of a person—or of a society—is an impasse for a social science. In the globalizing world, people are constantly relocating themselves and their minds. They, allow their minds to be exposed to TV dramas and Twitter messages, and embrace all new technological innovations with fascination. Following this, scholars in their analyses escape binary oppositions between “culture-as-it-was” and “culture-as-it-is-becoming”—in society (Rasmussen, 2012) or within the mind (Valsiner, 2007). Cultures are always in the process of development. Turning to different indigenous psychologies for discovering the range of various concepts can bypass the cultural blinders of one society’s heritage.

***Proposition 3: Cultural Psychology Needs to Construct Culture-Inclusive Research Methodology that Is Free from the Sociopolitical Constraints of the “Quantification Imperative”***

This is possibly the central proposition on which the survival and future development of cultural psychology depends (Toomela, 2012; Toomela & Valsiner, 2010; Valsiner, 2007, 2009a, 2009b). How can scholars in their analyses, escape circular arguments concerning individual/culture/collectivities and local/universal processes—the question raised by Rasmussen (2012) is being answered by Toomela (2012) in the theoretical realm. Traditional models of linear causality do not fit for complex cultural phenomena (Beckstead et al., 2009).

It is precisely here where history of the sciences provides us insights of why our contemporary science has reached a plateau, and how some of the customs of psychology are social rather than epistemological constructions (Cowles & Davis, 1982; Danziger, 1990, 1997). The General Linear Model and its causality image (A causes B) that stands behind the turning of methods (such as analysis of variance into theories (Gigerenzer, 1993). Turning any method—quantitative or qualitative—into a theory is an inductive move that puts into place of the theory all the initial assumptions of the method (Gigerenzer & Sturm, 2007). New methodology of cultural psychology is necessarily a process-based synthetic direction in methods construction. It involves units of analysis that are not numbers, but process structures (Valsiner et al., 2009).

The root metaphor of the question of units in psychology has been the contrast between water (H<sub>2</sub>O) and its components (oxygen and hydrogen)—used in making the point of the primacy of the Gestalt over its constituents widely in the late nineteenth to early twentieth-century thought. The properties of water are not reducible to those of either hydrogen or oxygen—water may put out a fire, while the constituents of it burn or enhance burning. Hence the whole—a water molecule—is more than a mere “sum” of its parts. Furthermore, it is universal—the chemical structure of water remains the same independent of whatever biological system (e.g., human body, cellular structure of a plant) or geological formation (e.g., an ocean, or in a water bottle) in which it exists. Lev Vygotsky expressed the general idea of what a unit of analysis needs to be like in psychology:

Psychology, as it desires to study complex wholes ... needs to change the methods of analysis into elements by the analytic method that reveals the parts of the unit [literally: breaks the whole into linked units—*metod ... analiza, ... razchleniyushhego na edinitsy*]. It has to find the further undividable, surviving features that are characteristic of the given whole as a unity—**units within which in mutually opposing ways these features are represented** [Russian: *edinitsy, v kotorykh v protivopolozhnom vide predstavleny eti svoistva*].<sup>2</sup> (Vygotsky, 1999, p. 13)

Vygotsky’s notion of units fits into the general structure—emphasizing the unity of parts and focusing on their relationship. Yet it is easy to see how Vygotsky’s dialectical units—into opposing

parts of the whole—goes beyond the water analogy. Water does not recreate itself into new form—while human cultural processes do. The adequacy of the quantification of such processes needs to be examined every time the researcher opts for the use of quantitative methods.

***Proposition 4: Cultural Psychology Needs Close Conceptual Links with Contemporary Biological Sciences***

Keller (2012) emphasized the need for developing an integrated concept of culture and biology, and Christophe Boesch (2012) provided an example of where culture and biology meet in the study of primate culture. Theoretically such unification would emerge from contemporary epigenetic thought (Tavory, Jablonka, & Ginsburg, 2012) and has already been elaborated for developmental science (Gottlieb, 1997). Return to the history of the studies of the meaningful organism-centered relations with the environment (the *Umwelt*—see Chang, 2009, Magnus & Kull, 2012) allows cultural psychology to overcome the use of exclusive categorizations (such as “individualism” *versus* “collectivism”—Sinha & Tripathi, 1994) and to treat the opposites as mutually intertwining functional parts of the whole system. Such a move entails abandoning the strategy of defining citizens of a country as “a cultural group” (Keller, 2012)—as the imprecision of notions like “*the American* [meaning U.S.] culture” or “*the Indian culture*” is counterproductive to our development of knowledge. Such homogenizing any heterogeneous conglomerate of many cultural practices—which are constantly undergoing transformation—through the use of country labels to specify “a culture” is a conceptual impasse (Chaudhary, 2004; Chakkarath, 2012). Contemporary cultural anthropological studies share that concern leading to seeing culture (and society) in terms of fluid, dynamic, and relational notions (Rasmussen, 2012). A similar direction can be observed in developmental psychology (Keller, Poortinga, & Schölermerich, 2002).

***Proposition 5: Cultural Psychology Shares Conceptual Concerns with Other Social Sciences and Benefits from Its Unity with Those***

The need for such interdisciplinary synthesis results from the realities of twenty-first-century living—rather than from the various tendencies of social policies of the disciplines involved. As

Rasmussen (2012) emphasizes, culture and society and the persons comprising them can no longer be reduced to clear-cut, essentialized entities, and their localities are no longer always literal, geographical, or neatly bounded. This claim gets further support from the unification of theoretical realms of archaeology (Gonzalez-Ruibal, 2012), educational (Daniels, 2012) and urban sociology (Kharlamov, 2012). Human beings live in places—they modify space by way of cultural construction of its meanings. Their intentional actions (E. Boesch, 2012; Eckensberger 2012) lead to the creation of symbolically encoded spaces that have been studied by geographers, sociologists, and environmental psychologists—yet with no direct focus on their cultural organization. Cultural psychology can become the field that unites the variable perspectives from these disciplines. The movement in cross-cultural psychology toward including culture as a concept—rather than a variable—is a promising step in that direction (Kitayama & Cohen, 2007). This movement specifies how cross-cultural psychology in its focus on comparisons of groups from different societies (“cultures”) is striving to set up an explanatory toolbox for making sense of complex and varied human phenomena.

**Proposition 6: Cultural Psychology Studies Oppositions (Gegenstand)**

It is time for psychology at large—and cultural psychology in particular—to return to the study of tension-filled oppositions that generate novelty. This means a careful reconsideration of the history

of dialectical philosophies of Fichte, Hegel, and their later nineteenth-century followers, whose role in the history of psychology is mostly overlooked in the twentieth century (Valsiner, 2012). That ignoring has its sociopolitical roots and can hence be explained—yet the restoration of inquiry of social sciences in directions that include observations of unity of opposites in one whole is a valuable new direction. It has already happened in one area of psychology—the investigations of the Dialogical Self (Hermans & Gieser, 2012) and in positioning theory (Harré, 2012). The tradition of looking at multivocality of the mind (Brockmeier, 2010; Wertsch, 1991, 1995, 2002) and history (Boyer & Wertsch, 2009) have set the stage for further work in this direction.

Return to the focus on the oppositions—the *Gegenstand*—entails a move away from an essentialistic view of phenomena (see Fig. 52.1A) to that of a relational and oppositional one (see Fig. 52.1B).

Most of psychology has been hostage to explanation of psychological phenomena that are categorized together (e.g., examples of avoiding entering into social encounters in public settings, classified together as “being shy,” i.e., X-ness  $\rightarrow$  X in Fig. 52.1A) by an essence projected into the human psyche as if it were a cause (“shyness” as a personality trait is assumed to explain “being shy” phenomena). In contrast, the *Gegenstand* view (see Fig. 52.1B) considers “X-ness” (“shyness”) to emerge from the tension that results from goals-oriented movement and the “barriers of resistance” to such movement (see Stephenson, 2005,

1.A. The projection of causes

1.B. Analysis of oppositions

“x-ness” emerges from the tension between the goal-directed movement (arrow) acting upon resisting barrier, resulting in tension

**Figures 52.1A and 52.1B** From essentialist concepts to *Gegenstand* tensions. 52.1A: The projection of causes; 52.1B: Analysis of oppositions.

p. 565, on Goethe's focus on sensuous experiencing; see also Ingold, 2004, on feet as culture-creating tools). *Gegenstand* is a structured opposition that triggers tension—and the latter can lead to various states—*status quo* of the tension, overcoming of the tension, or abandoning of the movement. The barriers that set the stage for tensions in the human case are conditions of culturally structured environments. The analogy with biology brings us to emphasize the processes on borders—membranes—as Marsico and Iannaccone (2012) amply demonstrate (also see Marsico, Komatsu, & Iannaccone, 2012). Methodologically, that perspective entails the study of human actions in relation to culturally meaningful internalized (“Girls are not good at mathematics.”) or externally presented (“Smoking kills!”) signs in the human life-worlds.

What would be the impact of the *Gegenstand* view for the future of psychology is that the axiom becomes accepted: psychological processes are inherently dialectical (Verhofstaat-Denève, Adrianssens, Braet et al., 2000). It would refocus the discipline from its current efforts to empirically prove that commonsense notions of the human psyche are true (Smedslund, 1995, 2009) and move toward the systemic and dynamic look at the actual flow of the psychological functions. Cultural tools and meanings operate upon tension-filled oppositions creating possibilities for the emergence of ever-new oppositions—while overcoming the present ones. That would make human developmental psychology possible (Valsiner & Connolly, 2003), and would provide further impetus to the study of how various kinds of risks (Heyman, 2012) are constantly constructed and reconstructed in human social activities. Return to the new uses of hermeneutics (e.g., Kirschner & Martin, 2010) promises innovation in the understanding of the dynamic complexity of the cultural psyche.

***Proposition 7: Cultural Psychology Includes the Study of Fixed-Feature Objects***

There is much to gain from joint work with archaeology where the objects found from different historical periods are carriers of cultural meanings. Gonzalez-Ruibal (2012) emphasizes the future study of interactions between human psychological processes and material culture beyond cognitive technologies and explicit symbolical objects. Psychologists interested in material culture have often focused on explicit cognitive or mnemonic technologies and artifacts—maps, computers, GPS,

compasses. Yet many other types of cultural objects are involved in both social and spatial orientation and are, therefore, worth of study by psychologists. In fact, other categories of cultural objects, such as houses or cars have been taken into account by cultural psychologists in their recent work. Their point in common is that they are artifacts explicitly inscribed with meaning. These may be buildings—or ruins that result of devastation after natural catastrophes (Groh, Kempe, & Mauelshagen, 2003) or wars.

The focus of cultural psychology is on people openly making statements with objects. Cultural psychologists can expand their research and include things that do not seem too relevant or meaningful at first sight, things that are overlooked or taken for granted by human actors. A number of contributions to this handbook (Beckstead, 2012; Kharlamov, 2012; Yamamoto et al., 2012) lead us in this direction. The result is recognition that these seemingly simple objects are representing culturally structured everyday life activities that are overdetermined by meaning complexes. The redundancy of cultural regulation leads to the construction of simple objects—ranging from chastity belts to cooking utensils, wedding rings, and cars. As Gonzalez-Ruibal (2012) points out, cars have to be explored in relation to urban space and houses, but also in relation to late-modern technologies of the self. Cars for many are extensions of their self—so are cellular phones or earrings. Real things also have to be confronted with virtual things and with the products of the cultural and moral imagination. How does such imagination lead to new cultural objects? The creation of Facebook is an example worth cultural-psychological study—in unison with disposable baby diapers, war memorials, and of the history of iconoclasm (Besançon, 2000; von Grunebaum, 1962).

***Proposition 8: Cultural Psychology Creates Data from Various Sources: Cultural Processes and Products***

The product/process distinction is important; some data sources provide evidence only of products (e.g., archeological finds from centuries or millennia ago)—others, only immediate and transitory (e.g., objects become transformed into something called *garbage* when put into ordinary looking boxes or sacks called *garbage bags*). These cultural products are generated by their corresponding processes—which give meaning to the products.

Most of the data psychology that has accumulated are product-type data—questionnaire answers, Likert scale marks on paper and on computer screen, etc. These data usually reflect opinions of the respondents, rather than the processes that lead to the expression of such opinions. The latter are similar to the temporality of the garbage—they can be changed, reformulated, and in all cases they retain their essential structure. Thus, an empty bottle thrown into a garbage can has similar temporal nature to a French person making an off-hand comment “Sarkozy is a Nazi” in a Paris café. That is an opinion—a forceful one—yet its (or its contraries’) value for the social sciences is negligible. In cultural psychology we need empirical data that may begin from the static picture of an opinion—but proceed to the analysis of how such opinions are generated (Salvatore, 2012). The processes of creating utterances are our focus of attention (Haye & Larain, 2011).

Psychology also abandons its data—the accumulated raw data, once analyzed, are usually thrown away (or shredded—another cultural task of maintaining secrecy that has created new tools). This is in dramatic contrast with paleoanthropologists who would carefully preserve every little bit of an excavated *Homo habilis* skeleton. Imagine Louis Leakey—after a discovery of a fossil bone and its careful description—throwing it out as it is no longer necessary. That would be considered—at least in scientific circles—a crime against humanity (and against its history). Yet in psychology such destruction of raw data has been rampant. Psychology does not possess common reference phenomena, and rarely reuses data from different historical periods. An example of how such use could benefit cultural psychology is given by Watzlawick and Valsiner (2012).

Furthermore, cultural psychology can benefit from treating new objects as data. Mass communication messages—TV “soap operas” or popular magazines for women, bike enthusiasts, or content lists of chemicals on water bottles—are all potential data sources. Literature—in the form of fiction, poetry, “self-help” books, or travel accounts—is a fertile resource for cultural psychology (Ionin, 2004; Valsiner, 2009d). The use of mass communication messages is particularly crucial since these messages play key roles in the guidance of human cultural regulation of their everyday conduct (Puche, 2012). This intersects directly with the social limits that have emerged and set upon contemporary inquiries

in the social sciences—although interviewing a living person about her suicide plans may require multiple approvals from “human ethics” watchdog institutions, pondering about the depths of the human psyche through reading and interpreting the characters created by Leo Tolstoy, Erich Maria Remarque or Orhan Pamouk are free of such constraints. It is rather unnecessary to recode the identity of Anna Karenina as “participant number 007” or “Olga K,<sup>34</sup>” and ask her to sign a consent form that promises referral to psychological counseling services should our interpretations of her suicidal ideations be traumatic for her. Aside from this obvious benefit to use classic literature as psychological data there are conceptual advantages that warrant the inclusion of literature as a data source for cultural psychology (Valsiner, 2009d).

***Proposition 9: Cultural Psychology Investigates Regulatory Processes of Nonlinear Kinds (in Contrast with Assuming Models of Linear Causality)***

Similarly to biological sciences (Tavory et al., 2012), cultural psychology’s explanatory models are of a cyclical nature involving the central notion of regulation by some part of the system of other parts. The move into the realm of regulatory models for cultural psychology entails careful look at the mutual feed-forward relations between parts of the system, and their hierarchical regulation. Culture amplifies interindividual variability (Maruyama, 1963, 1995) and through that makes empirical evidence always new in its forms.

New sources of empirical evidence for cultural psychology require new ways of looking at the creation of “the data.” The narrative direction in cultural psychology works at the intersection of “small” and “big” stories (Bamberg, 2006) where a tension can be observed. Breakthroughs in the look at higher-order psychological functions—such as moral feelings linked with divinities (Haidt, 2008; Jensen, 2010)—exemplify the reality of the study of cultural means that function in their hierarchical order.

The *hierarchy of levels* of organization is an inevitable given for all cultural psychology. If the systemic perspective is taken seriously, it necessarily entails at least two hierarchical and unilaterally nested levels—the whole and its parts. The latter are by definition at a level lower than the whole to which they belong. A special case in this move is the focus—brought to our future directions by Rasmussen (2012)—on how can the culture

concept be reformulated to encompass virtual aspects of human life? Psychology so far has paid little attention to anything that is absent from the observable phenomena—in the field or in the laboratory. Yet the inclusion of culture in psychology makes it imperative to include the virtual side of the regulatory system in our picture. While getting a glimpse of food, I, for some reason—not visible—look for a fork or for chopsticks—rather than using the hand. The part of the cultural regulation system that guides me—irrational (from immediate observer's point of view)—acts invisible, yet crucial.

***Proposition 10: Cultural Psychology Needs to Elaborate the Notion of Participation***

*Participation* is a general concept that has haunted the social sciences ever since Lucien Levy-Bruhl's query into Bororo self-identity as *anaras* (red parrots). Here the notion is given in its abstract form. Contemporary efforts to bring culture to psychology deal with the notion of participation in its concrete sense—persons' taking part in the activities of the community. Barbara Rogoff's notion of *participatory appropriation* entails acceptance of transformation of cultural forms into novel states (both by persons and by groups). The notion of *guided participation* refers to how individuals change through their involvement in one or another activity, in the process of becoming prepared for subsequent involvement in related activities. This is a process of becoming, rather than acquisition. It may be abstracted in terms of action spheres (Joerchel, 2012) that focus on the human activities in between persons. Likewise, one can look at such spheres at the border of the past and the future (*see* the TEM model, Sato et al., 2007, 2012).

The active person participates through individual activity (Rogoff, 1992, 2003). López, Najafi, Rogoff, and Arauz (2012) provide further elaboration on how participation could be considered. Yet participation is constrained—directed by the social institutions that set up its expected (and required) forms, and rule out others (Chaudhary, 2012). Participation in social roles—such as gender (Madureira, 2012) or military roles (Hale, 2008)—entails coordination of persons' subjective inventions of themselves with social rules set up for regulating precisely these subjectivities. The discovered differences in reasoning styles between geographical areas (Nisbett, 2003) are likely to be explained by different forms of participation processes in intersubjective encounters (Komatsu, 2010). Charting

out different forms of participation—structured by social goals and the dialogical relation between rights and duties (Moghaddam et al., 2012) would make the notion of participation well-situated in its varied contexts.

***Proposition 11: Cultural Psychology Needs Self-Reflexivity—Emergence of the Cultural Psychology of the Social Sciences***

Psychology traditionally has had limited self-reflexivity on its own role as a science in varied contexts of societies. Cultural psychology cannot be blind to its own embeddedness in the varied social conditions where its know-how may be exploited—or just used—by various macrosocial institutions (Ratner, 2012). This is particularly crucial in the twenty-first century with all the ambivalence of globalizing processes moving around the world as voraciously as hurricanes.

There are a number of descriptions of how science is done (Knorr Cetina, 1999). The academic world has changed in the direction of increased dependency of science upon administrators—or large research teams. The move of knowledge construction refocusing from individuals to research teams leads to social distribution of the areas of acquired competence between researchers. Yet the ideas are created by a mind—who certainly is embedded in a social relationship network—which may provide the root for the idea. Thus, paradoxically, in our era where patenting of inventions becomes extended to intellectual properties, the very ownership of these seems to vanish into the intragroup relationships within increasingly large research teams.

**THE SOCIOPOLITICAL LANDSCAPE**

It would be naïve for a new branch of a discipline—cultural psychology—to ignore the sociopolitical constraints that govern the whole knowledge construction enterprise in the social sciences. Contemporary sciences are governed by institutionalized social power relations—that are exemplified by the conditions of getting and retaining academic jobs, research funding, access to social capital construction, and so on. The major journals of psychology that are far from the globalizing process still remain controlled by researchers from primarily one country. According to Arnett (2008, p. 607) in six major North American psychology journals (owned by the American Psychological Association the editorial boards consisted of 82% scholars located in the United States (range of variability 75% to

100%). This is in complete reverse contrast with the leading journal of cultural psychology—*Culture & Psychology* where the World’s academic community is appropriately represented (only 21.5% North American). Emergence of new serial publications all over the world is an example of internationalization of the discipline and diffusion of the monopoly of social power of publications.

Under such conditions of institutionalized collaboration, it is the cultural and social psychology of research teams that emerges as a critically relevant topic for investigation in itself. International collaboration brings about a new form of sudden contact (Moghaddam, 2006) between psychologists. That contact brings issues of teamwork into focus. It also leads to radical rethinking of the nature of “the other”—one’s research collaborator from a far-away country and very different local context where realities of what “I” consider to be “research” may have very different meanings. In that context, the ways in which the persons who are studied by psychologists—at times called “observers,” then “subjects,” and now “research participants” (Bibace, et al., 2009)—become relevant far beyond the question of “politically correct” language use in a scholarly publication. However, the data accumulated in contemporary psychology do not reflect such sudden contacts—they mostly come from WEIRD (Western, Educated, Industrialized, Rich, and Democratic) people who are emulated by the North American college students (Henrich, Heine, & Norenzayan, 2010). This indicates a major gap in psychology’s knowledge base that cultural psychology can help to fill.

### **Conclusion: How Can Future Directions Become Present Realities?**

Cultural psychology is growing. It is by now a truly international field of scholarship, and its interdisciplinary exploration is on the rise as well. However, there are continuing concerns about the future well-being of this developing scholarly enterprise. It has taken a long time for the field to overcome the lures of deconstructionism and move into a constructionist mode. Most of the heated discussions in psychology are about positioning—who is “right,” who is “wrong,” and where am I in relation with them? Surely little new can emerge from such realignment within the social field. There are many oversights that need to be dealt with—how to fit empirical methods to phenomena and theories? How to re-think interviews, focus groups,

experiments, questionnaires, etc. along the lines of the open-systemic and meanings-focused axioms of cultural psychology?

Most importantly: *cultural psychology needs to work out and formalize the ways in which its methods can be adequately generated.* Without such a connecting link between cultural meta-level perspectives and theories and phenomenologically sensitive empirical research tactics, all the creative efforts to study culture’s role in the psychological functions is likely to fail. Psychology at large needs to return to the task to construct general theoretical frameworks of sufficient abstractness to fit in any sociocultural context. Psychology has been close to the common language depictions of its phenomena—which gives us some consolation of being in touch with these phenomena, but makes generalizations difficult. Probably new terminology is needed. Chemistry went through such a move from common language terminology to abstract formalization from the 1830s to the end of the nineteenth century (Klein, 2004). Psychology started off in a similar direction only in the beginning of the twentieth century (e.g., James Mark Baldwin’s effort to create a developmental logic—Valsiner, 2009c)—and became caught in the web of inductive operationalism. Furthermore, as history proceeded over the course of decades, the discipline became sidetracked by the move of its center from Europe to North America, and the avalanche of local applied needs. Science—like all developing phenomena—moves ahead through cycles of improvement and regressions. The contemporary return to culture in psychology can participate in its own development—or its demise.

### **Notes**

1. After *Völkerpsychologie* in the 1860s to the 1920s and “culture and personality” tradition in the 1950s.
2. It is important to note that the intricate link with the dialectical dynamicity of the units—which is present in the Russian original—is lost in English translation, which briefly stated only the main point in a summarizing fashion: “*Psychology, which aims at a study of complex holistic systems, must replace the method of analysis into elements with the method of analysis into units*” (Vygotsky, 1986, p. 5). Yet it remains unclear in the English translation what kinds of units are to be constructed—those that entail oppositional relationships between parts—while in the Russian original it is made evident.
3. Like Freud created “Anna O.” out of Bertha Bettelheim.
