*This page intentionally left blank*

The *Oxford Library of Psychology*, a landmark series of handbooks, is published by Oxford University Press, one of the world's oldest and most highly respected publishers, with a tradition of publishing significant books in psychology. The ambitious goal of the *Oxford Library of Psychology* is nothing less than to span a vibrant, wide-ranging field and, in so doing, to fill a clear market need.

Encompassing a comprehensive set of handbooks, organized hierarchically, the *Library* incorporates volumes at different levels, each designed to meet a distinct need. At one level are a set of handbooks designed broadly to survey the major subfields of psychology; at another are numerous handbooks that cover important current focal research and scholarly areas of psychology in depth and detail. Planned as a reflection of the dynamism of psychology, the *Library* will grow and expand as psychology itself develops, thereby highlighting significant new research that will impact on the field. Adding to its accessibility and ease of use, the *Library* will be published in print and, later on, electronically.

The *Library* surveys psychology's principal subfields with a set of handbooks that capture the current status and future prospects of those major subdisciplines. This initial set includes handbooks of social and personality psychology, clinical psychology, counseling psychology, school psychology, educational psychology, industrial and organizational psychology, cognitive psychology, cognitive neuroscience, methods and measurements, history, neuropsychology, personality assessment, developmental psychology, and more. Each handbook undertakes to review one of psychology's major subdisciplines with breadth, comprehensiveness, and exemplary scholarship. In addition to these broadly conceived volumes, the *Library* also includes a large number of handbooks designed to explore in depth more specialized areas of scholarship and research, such as stress, health and coping, anxiety and related disorders, cognitive development, or child and adolescent assessment. In contrast to the broad coverage of the subfield handbooks, each of these latter volumes focuses on an especially productive, more highly focused line of scholarship and research. Whether at the broadest or most specific level, however, all of the *Library* handbooks offer synthetic coverage that reviews and evaluates the relevant past and present research and anticipates research in the future. Each handbook in the *Library* includes introductory and concluding chapters written by its editor to provide a roadmap to the handbook's table of contents and to offer informed anticipations of significant future developments in that field.

An undertaking of this scope calls for handbook editors and chapter authors who are established scholars in the areas about which they write. Many of the nation's and world's most productive and best-respected psychologists have agreed to edit *Library* handbooks or write authoritative chapters in their areas of expertise.

For whom has the *Oxford Library of Psychology* been written? Because of its breadth, depth, and accessibility, the *Library* serves a diverse audience, including graduate students in psychology and their faculty mentors, scholars, researchers, and practitioners in psychology and related fields. Each will find in the *Library* the information they seek on the subfield or focal area of psychology in which they work or are interested.

Befitting its commitment to accessibility, each handbook includes a comprehensive index, as well as extensive references to help guide research. And because the *Library* was designed from its inception as an online as well as a print resource, its structure and contents will be readily and rationally searchable online. Further, once the *Library* is released online, the handbooks will be regularly and thoroughly updated.

In summary, the *Oxford Library of Psychology* will grow organically to provide a thoroughly informed perspective on the field of psychology, one that reflects both psychology's dynamism and its increasing interdisciplinarity. Once published electronically, the *Library* is also destined to become a uniquely valuable interactive tool, with extended search and browsing capabilities. As you begin to consult this handbook, we sincerely hope you will share our enthusiasm for the more than 500-year tradition of Oxford University Press for excellence, innovation, and quality, as exemplified by the *Oxford Library of Psychology*.

## ABOUT THE EDITOR

### **Jaan Valsiner**

Jaan Valsiner is a developmental cultural psychologist. He is the founding editor (1995) of the major international journal *Culture & Psychology* (Sage) and Editor-in-Chief of *Integrative Psychological and Behavioral Sciences* (Springer, from 2007). He is also the recipient of *Alexander von Humboldt Prize* (1995) for his interdisciplinary work on human development.

# Introduction: Culture in Psychology: A Renewed Encounter of Inquisitive Minds

Jaan Valsiner

## Abstract

This introductory chapter outlines the historical picture of the recent interest in the linking of culture and psychology, as well as the conceptual obstacles that have stood on the way of re-introducing complexity of human psychological functions—higher cultural forms—to psychological research practices. The avoidance of complex and dynamic phenomena (affective processes in feeling, religious sentiments that take the form of values, and of the high varieties of cultural forms displayed all over the World) has limited psychology's knowledge creation. In the past two decades, with the emergence of cultural psychology at the intersection of developmental, educational, and social psychologies and their linking with cultural anthropology, sociology, and history, we have observed a renewed effort to build an interdisciplinary synthesis of ideas. This takes place in the wider social context of the globalizing world. Psychology needs culture to make sense of the human lives.

**Keywords:** cultural psychology, causality, quantity, quality, affect, globalization

This Handbook is a milestone in the effort to re-unite two large domains of knowledge—one covered by the generic term *psychology*, and the other by the equally general term *culture*. When two giants meet, one never knows what might happen—it can become a battle or the two can amiably join their forces and live happily ever after. The latter “happy end” of a fairy tale is far from the realities of the history of the social sciences.

In the case of this Handbook, we have evidence of a multisided effort to develop the connections between culture and psychology. The time may be ripe—discourse about that unity has re-emerged since the 1980s, and cultural psychology has become consolidated since the mid-1990s around its core journal *Culture & Psychology* (published by Sage/London). The present Handbook reflects that tradition, while extending it toward new interdisciplinary horizons. The contributors— from all over the World—enthusiastically take on the task to

bring culture into psychology. Such enthusiasm is needed—as revolutions, both in science and in societies, need it. Innovation in any science is impossible without the efforts of the scientists to explore the not yet known lands of the ideas that may seem nonsensical from the point of view of accepted knowledge yet tease the mind.

The complexity of the task of bringing culture into psychology as a science has been considerable. It has been historically blocked by a number of social agents (representing rivaling ideologies) who saw in this a damage to psychology as natural science (*see* Valsiner, 2012, Chapters 5–9). As a result, psychology has suffered from its self-generated image of being an “objective science”—of deeply subjective and culturally organized phenomena. Such historical myopia can be understood as a need for the discipline to compete in the representational beauty contest of the sciences. Yet it cannot win that contest—remaining such a frivolous competitor whose claims

to “objectivity” are easily falsified by yet another innovation in the social or psychological domain.

### ***Psychology’s “Blind Spot”: Personal Will As a Cultural Phenomenon***

Historical myopia of a discipline has dire consequences. Psychology of the last century turned out to be mute when basic human life phenomena—famines, wars, epidemics, religious piety and prejudice, political negotiations, and migration—have been concerned. It has refrained from the study of higher—volitional—psychological functions, while concentrating on the lower, simpler ones. Thus, psychology of affect has many ways to deal with basic emotion categories that are expressed similarly all around the world—yet has not made new breakthroughs in understanding the generalized feelings that lead to desirous actions and generalized values. The intentional affective actions were actively investigated until the beginning of the twentieth century in psychology but rarely later. It is the semiotic and narrative focus of our contemporary cultural psychology that restores our focus onto these humanly important phenomena. The most important cultural invention of the human psyche is the simple claim, “I want <X>!”—and it is precisely the least studied and understood theme in contemporary psychology. Although there is increasing interest, in cultural psychology, on the “I” part (e.g., Dialogical Self Theories), the “want” part of this simple meaning construction is rarely analyzed. The notable exception—Heider, (1958, 1983)—is an example of a synthesis of different European philosophical and psychological traditions. Psychology has been fearful of the willful human being and has instead presented the human psyche as an object influenced by a myriad of “factors” from all directions—biological, social, economic, even unconscious—rather than by the volition that could break out from all these confines and develop in new directions.

### ***Why Another Effort to Link Psychology With Culture?***

Given this complex history, bringing culture back into psychology is also a very multifaceted effort in today’s intellectual environment. Yet the realities of social life guide us toward it—in a world where people travel voraciously and their messages travel instantly, the know-how of how “the others” function is both necessary for life and profitable for businesses.

There can be very many different vantage points from where culture could enter into psychology in the twenty-first century. First, of course, there are the realistic connections with neighboring disciplines—cultural anthropology (Holland, 2010; Obeyesekere, 2005, 2010; Skinner, Pach, & Holland, 1998; Rasmussen, 2011), and sociology (Kharlamov, 2012)—from where such efforts could find their start. Yet in the last decade we also can observe the move inside of the vast field of psychology. Psychology itself is a heterogeneous discipline—within which we can observe a number of moves toward embracing the notion of culture. Although it began from the educational and developmental concerns of the 1980s that mostly used the ideas of Vygotsky as the center of their new efforts, by 2010s the effort also includes social psychology—both in Europe and the United States—where the generic label “social” becomes frequently taken over by “cultural.”

Second, it is the rapid movement—of messages and people—that renders the former images of homogeneous classes that dominated cross-cultural psychology either moot or problematic. The tradition of comparing societies (i.e., countries, re-labeled as “cultures”—e.g., of “the Mexicans” or “the Germans”)—which has been accepted practice in cross-cultural psychology—loses its epistemological value. Empirical comparisons of the averages of samples “from different cultures” (i.e., countries) can bring out interesting starting data for further analysis by cultural psychology.

All this is supported by real-life social changes. It is as if the globalizing movement of people across country boundaries brings “cultural foreigners” to be next-door neighbors. The issue of making sense of their ways of living becomes of interest for the already established colonists of the given place. It is hard to remain content with the prototypical notions of “being American” when one sees a collective Islamic prayer unfolding in the middle of a major U.S. airport. The world is now different from the last century—we are in close contact with “cultural others,” and all our social-psychological adaptations to this innovation acquire a cultural accent. Contemporary social psychology picks up the need to study such social events that carry complex cultural accents. It is supported by the demand of both the lay publics in different countries and their socio-political organizations to understand and administer the “cultural others” yet retain their own dominant centrality.

## The Third Effort for Psychology in its History: How Can it Succeed?

This effort—uniting culture and psychology—that has been taking place from the 1990s to the present time is actually the third one<sup>1</sup> in the history of psychology. We can observe, in the recent two decades, multiple efforts to bring culture into the science in general. Likewise, psychology begins to enter into cultural arenas in many new ways that Little Albert,<sup>2</sup> Ioni,<sup>3</sup> or Sultan,<sup>4</sup> or even the dogs of Professor Pavlov could never have thought about. A number of our contributions to this Handbook—those of Christophe Boesch (2012), Alfredo Gonzalez-Ruibal (2012) and Zachary Beckstead (2012)—give the readers a glimpse of new pathways for future development of cultural psychology.

Of course, psychology's historical inroads can be seen to have delayed such return to culture. The issue has been ideological in the history of the science of psychology—how to treat complex, meaningful, intentional, and dynamic psychological phenomena? These phenomena were actively addressed in the context of emerging psychology in Germany by philosophers in the first seven decades of the nineteenth century—yet all these contributions were lost as they were guided out of the history of psychology as it was re-written after the 1870s. According to most of the history textbook views, psychology as science was born in 1879. That origin myth dates back to Boring's work on re-writing the history of psychology (Boring, 1929) that selected *as science* only some part of the wide intellectual enterprise of psychology of the nineteenth century.

Psychology as a science was born in the German language environment—first in the 1730s (Christian Wolff's *Psicologia empirica* in 1732 and *Psicologia rationalis* in 1734), followed by the anti-Wolff denial of psychology's place among other sciences by Immanuel Kant. The birth of psychology as part of educational curriculae dates to years 1806 and later—when Johann Friedrich Herbart started his first university course in psychology (Jahoda, 2008; Teo, 2007). Yet in the early nineteenth-century psychology was the realm for discourse by philosophers and theologians, with natural scientists playing a secondary role. This power relation reversed in the 1860s in favor of the natural sciences—particularly physiology. This led to the “elementaristic revolution” in psychology that started from Wilhelm Wundt's establishing his laboratory of Experimental Psychology in

Leipzig in 1879. It was followed in North America by the avalanche of the “behaviorist” ideology (Watson, 1913), which has been slow to end. The intermediate birth of “cognitive science” in the 1950s from the behaviorist roots was a half-restoration of the focus on higher psychological functions. Hence, the cultural psychology movement that started in the 1980s constitutes another effort in that direction.

### *The Obstacles to Innovation*

As psychology is non-neutral in its context of social existence, it is not surprising that its progress is constantly organized by different promoting fashions (e.g., the need to look “socially relevant”) in unison with a multitude of conceptual obstacles. The latter are often the targets of discourse in cultural psychology that cannot avoid addressing them. Their relevance, of course, transcends the work in the realms of cultural psychology and would illuminate other fields of psychology.

### DECISION ABOUT WHERE NOT TO LOOK: AXIOMATIC DISMISSAL OF COMPLEXITY

Many of the habits of psychology, in their insistence on the study of elementary phenomena (Toomela & Valsiner, 2010), have led to avoiding the complexities of the human psychological functioning. This happens in a number of ways: by **imperative to quantify** those phenomena that are of “scientific interest” and by **developing theories inductively**—moving toward generalization from the thus selectively quantified evidence. This all happens with the belief in the work of **elementaristic causality** (factor X causes Y; e.g., “intelligence” *causes* success in problem solving; or “culture” *causes* “girls being shy”; see Toomela, 2012, in this Handbook). In contrast, cultural psychology leaves such causal attributions behind. Culture here emerges as a generic term to capture the complexity of human lives—rather than narrowly concentrating on their behavior. We are back to the study of psychological dynamics in all of its complexity (Valsiner, 2009a), yet we are still at a loss about how to do that. The lead from the “second cybernetics” of the 1960s (Maruyama, 1963) and the use of qualitative mathematical models (Rudolph, 2006a, 2006b, 2006c, 2008a, 2008b, 2009; Rudolph & Valsiner, 2008; Tsuda, 2001) instead of statistical inference can be a way to overcome the obstacles of unwarranted assumptions.

**THE TERMINOLOGICAL DIFFICULTY—*CULTURE* IS POLYSEMIC**

*Culture* is in some sense a magic word—positive in connotations but hard to pinpoint in any science that attempts to use it as its core term. Its importance is accentuated by our contemporary fashionable common language terms (multiculturalism, cultural roots, cultural practices, etc.)—hence the perceived value of the term. Yet much of “normal science” of psychology continues to produce hyperempirical work using methods that do not consider substantive innovation, even after having learned to insert the word *culture* into politically correct locations in its various texts. In this sense, the fate of culture in contemporary psychology continues to be that of up-and-coming novice who tries to get its powerful parents to accommodate to its needs.

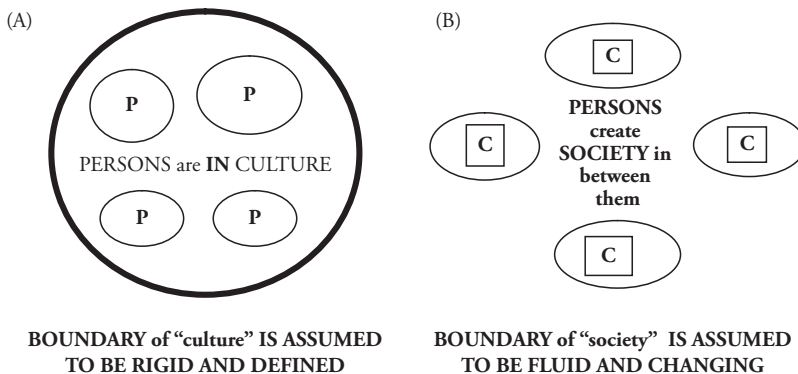

Cultural psychology is being sculpted in a variety of versions—all unified by the use of the word *culture* (Boesch, 1991; Cole, 1996, Shweder, 1990). That may be where its unity ends, giving rise to a varied set of perspectives that only partially link with one another. This may be confusing for those who try to present cultural psychology as a monolithic discipline—but it is certainly good for the development of new perspectives. Heterogeneity of a discipline breeds innovation—whereas homogenization kills it. History of psychology gives us many examples of originally innovative perspectives turning into established “theories or systems”—and becoming followed through sets

of imperatives rather than creating innovations. Psychology has suffered from too many consensual fixations of the “right” methods in the last half-century (Toomela, 2007a), rendering its innovative potentials mute. Cultural psychology as a new direction entails an effort to un-mute the discipline. It is helped by the appeal—and uncertainty—of the label *culture*.

*Culture As a “Container” as Opposed to a “Tool”*

The readers in this Handbook will encounter two opposite directions in handling of the notion of culture—that of a container of a homogeneous class (Fig. I.1A), and that of a unique organizer of person–environment relations (Fig. I.1B). These two uses have little or nothing in common, once more indicating the vagueness of the use of culture in our present-day social sciences.

Of course the proliferation of the notion of culture in the social sciences is no issue of science only. Reasons for that increasing popularity of a vague label are to be found beyond the boundaries of science—in the “culture stress” experienced by local communities resulting from in-migration of “others” and temporary (or not so temporary) outmigration of “our own” (Appadurai, 2006). Our globalizing world is also open to various projections of oneself to the (far-away) others. Politicians start to pretend they can say something in a foreign language in public, whereas production capacities move from their “First World” locations to the so-called “developing countries.”

**Figure I.1** Two meanings of *culture* in psychology. (A) *Culture* as a container (P = person). (B) *Culture* (C) as a tool within person.

## THE HERO MYTHOLOGY—REPLACING INNOVATION BY FINISHED IDEAS

Psychologists like to tell stories—beautiful stories—about famous people of their kind who had clever ideas that are still guiding our contemporary thinking. Of course, it is in the communication process between a science and the society that the making of such “hero myths” operates in creating *cultural connectors* (Aubin, 1997, p. 300). The popularity of “being X-ian” is a token in the public legitimization of a particular perspective (e.g., “Vygotskian” is “promising,” “behavioral” is “past its prime”)—independently of the particular ideas used within these perspectives to make sense of some phenomenon. Freud, Skinner, Piaget, and Vygotsky are often put on the pedestal for having revealed the great secrets of the psyche. Telling such stories is dangerous for the ideas of precisely those persons who are being honored. On the theoretical side, glory stories of various “giants” such as Vygotsky, Bakhtin, Gadamer, Levinas, and others are likely to promote the mentality of following previously expressed ideas, rather than developing new ones. Rather than innovate historically solid intellectual perspectives—the makers of which tried, but still did not solve their problems—we seem to enjoy turning these “classic thinkers” into some gurus and follow them ardently. Taking a theoretical perspective becomes transformed into a membership of a fan club of one or another of such guru figures—leading to a variety of intra- and intergroup relationship issues of such groups of followers. The main function of theories—being intellectual general tools for understanding—easily gets lost. Social scientists seem to enjoy the game of social positioning. We can still observe recurrent claims of “being X-ian” (“Vygotskian,” “Bakhtinian,” “Freudian,” “Habermasian,” “Levinasian,” etc.). I consider such claims misleading, because the best way to follow a thinker is to develop the ideas further—rather than declare one’s membership in a virtual community. But mere membership in a community is no solution to problems that the members of the community try to solve. The scientific community is a resource for providing new solutions—rather than a club, the membership of which is determined by loyalty to old ones.

### Vagueness in Science and its Functions

We know that culture’s journey into psychology has already been in the making for more than two

centuries (Jahoda, 1993, 2011). Such slow movement results from projection of social values into the term—*culture is not a neutral term*. It is suspect—and appealing—at the same time. Its appealing label feeds into the advancement of various streams of thought in the social sciences (Rohner, 1984; Sinha, 1996), and the constructive openness in using it as an intellectual catalyst in psychology continues.

Although it is well-known (Valsiner, 2001, 2004a) that the term *culture* is vague, as it has been proven indefinable, yet its functional role in public discourse has been growing steadily. Vagueness of a concept need not be an obstacle in scientific knowledge-building (many terms in many sciences are) and are kept vague, so as to enhance their generative potential (Löwy, 1992). As Löwy has explained:

The long-term survival of imprecise terms points to an important heuristic role. Adopting an over-precise definition may jeopardize a promising study, while maintaining a poorly defined concept may propel fruitful research. Imprecise terms may also facilitate the study of phenomena that share some, yet poorly defined, characteristics, and that may help link distinct disciplinary approaches. The fluidity of terms at times of conceptual change makes retrospective discovery accounts especially problematic. Discoverers tend to attribute a later, fixed meaning and imprecise, fluid terms current at the time of the discovery. (Löwy, 1990, p. 89)

The fate of *culture* in psychology and anthropology fits Löwy’s point well. Since the 1990s, we have seen the acceptance of the term by psychologists, who pride themselves in its vagueness and make it useful in various ways. In contrast, cultural anthropologists can be seen refusing to use it at all! *Culture* as a term becomes useless in anthropology, whereas it is becoming useful in psychology!

### Psychology Is Becoming Global

Globalization in a science—like in economics and society—is an ambiguous process. It brings with it emergence of new opportunities together with the demise of old (and “safe”) practices. The immediate result of globalization is the increase of “sudden contacts” between varied persons of different backgrounds—with all that such contact implies (Moghaddam, 2006). If “culture” is viewed in terms of a “container” (Fig. 1.1A) that implies selective “border controls,” segregation of immigrants into “we <>they” categories, and emphasis

on acculturation (Rudmin, 2010). If, in contrast, “culture” under globalization is seen as a tool (Fig. I.1B) it is the issue of relating to one’s next-door neighbor—with both positive (mutual learning and support from one another) and negative (frictions and open conflicts over trivial local issues) that come into our focus of observation.

Science also has to learn to tolerate its often less affluent but better educated neighbor. Any casual reading of leading science journals, which may be published in North America or Europe, reveals the enormous mixture of the home countries of the scientists. People from all continents collaborate in the solving of crucial scientific problems. Not surprisingly, together with the move toward international economic interdependence comes internationalization of sciences. Like other sciences psychology is no longer dominated by few (North American or European) models of “doing science” in that area. Instead, creative solutions to complex problems emerge from the “developing world,” where the whole range of the variety of cultural phenomena guarantees the potential richness of psychology.

### ***Cultural Psychology: Its Indigenous Roots***

Of course different areas of psychology are differentially open to such internationalization—cultural psychology in its recent new upsurge is thus a “developing science.” Looking back, much has changed since mid-1990s (Valsiner, 1995, 2001, 2004, 2009a, 2009b), mostly in the context within which the discourses of re-entering talk about culture into psychology have been framed. Cultural psychology has been the witness—an active one—of the transformations that go on in all of psychology as it is globalizing (Valsiner, 2009a, 2009b). Nevertheless, within psychology, cultural psychology remains “indigenous”—emphasizing the phenomena, rather than data, as these are central for science.

*Indigenous* is not a pejorative word. We are all indigenous as unique human beings, social units, and societies—coming to sudden contact with others of the same kind, and discovering that it is “the other” who is indigenous, not ourselves. Different ways of actions follow: changing the other (by missionary or military conquests) or using the other for production (by importing slaves, or allowing “guest workers” temporarily into “our country” to alleviate labor shortages), or for consumption (creating consumer demands for our products—arms or

hamburgers—in their places). In all of these adaptations to such contacts, the diversity of both human cultural and biological forms is being negotiated (Kashima, 2007; Moghaddam, 2006).

### **The Gains—and Their Pains—in Cultural Psychology**

The last two decades of the twentieth century were productive for cultural psychology. Following the lead of the originators of the rebirth of the cultural direction (Richard Shweder, Michael Cole, James Wertsch and Barbara Rogoff in North America, and Ernest Boesch, Lutz Eckensberger, Serge Moscovici, Ivana Markova and Ivan Ivic in Europe), a number of younger-generation researchers started to look at human phenomena intertwined with their everyday contexts. By the twenty-first century, many new research directions have become emphasized—ruptures as central for new developments (Hale, 2008; Zittoun, 2004, 2006, 2007, 2010), actuations as a new way to unite actions and meanings (Rosa, 2007), generalized significant symbols (Gillespie, 2006) as well as search for the self through looking at the other (Bastos & Rabinovich, 2009; Simão & Valsiner, 2007) and finding that other in the contexts of social interdependence (Chaudhary, 2004, 2007; Menon, 2002; Tuli & Chaudhary, 2010). At the same time, we see continuous interest in the cultural nature of subjectivity (Boesch, 2005, 2008; Cornejo, 2007; Sullivan, 2007) and the unpredictability of environments (Abbey, 2007; Golden & Maysseless, 2008). The topic of multivoicedness of the self as it relates with the world has emerged as a productive theme (Bertau, 2008; Joerchel, 2007; Salgado & Gonçalves, 2007; Sullivan, 2007), including the move to consider the opposites of polyphony (“intensified nothingness,” Mladenov, 1997). This is embedded in the multiplicity of discourse strategies (Castro & Batel, 2008) in institutional contexts (Phillips, 2007). Affective lives are situated in social contexts but by persons themselves as they relate to social institutions.

### ***Old Disputes in New Form: Immediacy and Mediation***

It never ceases to amaze me how old disputes re-emerge in terminologically new ways. When in the 1950s psychologists were disputing the immediacy of perception (à la James Gibson) in contrast to the constructive nature of the perceptual act (à la Jerome Bruner and Leo Postman, 1950—not to forget

Ansbacher, 1937 for the origins), then 50 years later, we find a similar dispute in cultural psychology around the issues of *enactivism*, focusing on the immediate nature of cultural actions—and *mediation*—that centers on the distancing from (yet with) the immediate action (Baerveldt & Verheggen, 1999, 2012; Kreppner, 1999; Christopher & Bickhard, 2007; Crisswell, 2009; Verheggen & Baerveldt, 2007). Furthermore, the immediacy dispute is built around the John Dewey-inspired look at human development as seamless linking of person and context (Rogoff, 1982, 1993, 2003). The question of boundaries between person and environment has been actively disputed in the last two decades. Of course, human beings live within the boundary—circumscribed by their skin. Futuristic film-makers, such as David Kroonenberg, have recently experimented with images that make the skin transferrable and let objects enter and exit through the skin in surprising—and horrifying—ways.

The roots of this new focus on immediacy are in the resurgence of the centrality of the body in theorizing about human beings and its abstracted corollary in terms of the processes of *embodiment* of the mental processes (Varela, Thompson, & Ross, 1991). Refocusing on the body—under the philosophy of fighting against “mind-body dualisms”—leads to the elimination of the mind. And with the elimination of the mind goes the focus on mediation.

#### IMMEDIACY IN ITS ENACTIVIST FORM

The enactivist position has been put forth succinctly:

Enactivism avoids the notion of “mediation” and problematizes the representational or semiotic status of social and cultural objects in general. Representation is a sophisticated social act and in that sense it is tautological to add the adjective “social.” Moreover, this specification becomes misleading when “social” is understood in terms of sharedness, even when the notion of sharedness is systemic rather than aggregate one. (Verheggen and Baerveldt, 2007, p. 22)

Of course, the enactivist move against ideas of mediation triggers a counteroffensive (Chryssides et al., 2009) defending the role of social representation processes precisely as acts of social construction. The focus on social representation can be dialectical (Marková, 2003, 2012), and the act of representing can itself be embodied. It seems that

it is the latter to which the enactivist viewpoint adheres.

#### CONSTRUCTION OF SIGNS AND THEIR USE— ALTERNATIVE TO IMMEDIACY

In contrast to the enactivist orientation, the semiotic meditational direction (Boesch, 2005, 2008, 2012; Lonner & Hayes, 2007; Valsiner, 2007) accepts the notion of mediation as an axiomatic given and concentrates on the construction of *what kind of mediating systems* can be discovered in human everyday activities and in the domains of feeling and thinking. The focus on cultural tools—or symbolic resources (Zittoun, 2006, 2007, 2012)—necessarily prioritizes the meditational view in cultural psychology. This is further supported by the work to bring Charles S. Peirce’s semiotics to cultural psychology (Innis, 2005, 2012; Rosa, 2007; Sonesson, 2010). Yet bringing in the philosophy of Peirce is a kind of “Trojan horse” for cultural psychology—if on the manifest level such importation allows for new look at the multitude of signs that organize human lives. Such appealing closeness to reality is supported by Peirce’s abstractions as a mathematician.

#### THE UNRESOLVED PROBLEM: UNITS OF ANALYSIS

The difficulty of returning to the psychological complexity in the context of cultural psychology is in the rest of psychology accepting the notion of analysis units as the atomistic concept of divisibility of the complexity to simplicity. Yet that tradition cannot work if complexity *as it exists*—rather than as it could be eliminated—is on the agenda for researchers (Matusov, 2007).

The root metaphor of the question of units in psychology has been the contrast between water (H<sub>2</sub>O) and its components (oxygen and hydrogen), used in making the point of the primacy of the Gestalt over its constituents widely in the late nineteenth- through early twentieth-century thought. The properties of water are not reducible to those of either hydrogen or oxygen—water may put out a fire, whereas the constituents of it burn or enhance burning. Hence the whole, a water molecule, is more than a mere “sum” of its parts. Furthermore, it is universal—the chemical structure of water remains the same, independent of whatever biological system (e.g., human body, cellular structure of a plant) or geological formation (e.g., an ocean, or in a water bottle) in which it exists. Vygotsky expressed

the general idea of what a unit of analysis needs to be like in psychology:

Psychology, as it desires to study complex wholes ... needs to change the methods of analysis into elements by the analytic method that reveals the parts of the unit [literally: breaks the whole into linked units—*metod ... analiza, ... razchleniyushhego na edinitsy*]. It has to find the further undividable, surviving features that are characteristic of the given whole as a unity—*units within which in mutually opposing ways these features are represented* [Russian: *edinitsy, v kotorykh v protivopolozhnom vide predstavleny eti svoistva*].<sup>5</sup>

(Vygotsky, 1999, p. 13)

Vygotsky's notion of units fits into the general structure, emphasizing the unity of parts and focusing on their relationship.

However, it is easy to see how Vygotsky's dialectical units—into opposing parts of the whole—go beyond the water analogy. The whole (water)—parts (oxygen, hydrogen) and relations—are fixed as long as water remains water. In reality of human development, the wholes are open to transformation. Together with charting out the pathways to synthesis, inherent in that unit is the constraining of options—the structure of the unit rules out some possible courses for emergence.

Vygotsky found that holistic unit in word meaning, as that meaning includes a variety of mutually opposite and contradicting versions of “personal sense” (*smysl*). Through the dynamic oppositions (contradictions) between subunits (of “personal sense”) of the meaning (*znachenie*), the latter develops. Thus, we have a hierarchical unit where the transformation of the *znachenie* at the higher level of organization depends on the dialectical syntheses emerging in the contradictory relationships between varied *smysls* at the lower level. And conversely, the emerged new form of *znachenie* establishes constraints on the interplay of *smysls* at the lower level. The *loci* of developmental transformations are in the relations between different levels of the hierarchical order, not at any one level.

#### TENSION BETWEEN MACRO-SOCIAL AND MICRO-SOCIAL LEVELS: HIERARCHICAL RELATIONSHIPS

Ratner's (2008, 2012) call for a macrocultural psychology fills the void at the boundary of psychology and sociology. Although doing that it faces a new challenge—that of the political nature

of all social discourses about the phenomena, as well as about the social sciences that study these phenomena. This challenge is most visible in the field—in the deeply politically embedded activities of NGOs in their relations with local government agencies, community structures, and personal goals (Bourdier, 2008). Culture in the field is a politically contested, non-neutral complex used by all disputing sides for their objectives (Wikan, 2002). Possibly precisely because of such multiplicity of vested interests, the process of “Westernization” can be replaced by a notion of parallel development of societies in contact. As Kagitçibasi (2005, p. 267) has commented:

... as societies modernize (with increased urbanization, education, affluence etc.), they do not necessarily demonstrate a shift toward western individualism. A more complex transformation is seen in family patterns of modernizing societies with cultures of relatedness. The emerging pattern shares important characteristics with both individualism and collectivism while, as the synthesis of the two, it is significantly different from each.

Thus the crucial issue in cultural psychology is to handle phenomena of synthesis. So far the field is as far from a productive solution for that problem as Wundt, Krueger, and Vygotsky were about a century ago. Psychology lacks the formal language that made chemistry back in the nineteenth century capable of solving the synthesis problem theoretically.

#### VARIED PERSPECTIVES: CONTESTED BY “INDIGENOUS” PSYCHOLOGIES

The meta-theoretical decision to build hierarchical models of relationships means a new return to the question of parts-whole relationships. The parts belonging to a whole are necessarily operating at a level subservient to that of a whole, and we have a minimal hierarchical system. That system is guaranteed by the central role of the agent—the acting, feeling, and thinking human being who is *always within* a context *while moving beyond the very same context* by one's goal-oriented actions. As Tania Zittoun has explained it:

... there is no such thing as a context-free competence or skill. However, the setting is not everything; every activity is also undertaken by a person, actively making sense of the situation, of its whereabouts, its goals and resemblances with other

situations met by her—these processes are in large part not conscious.  
(Zittoun, 2008, p. 439)

Thus, by the very act of modifying the setting, the person (actor) creates a hierarchical relationship that sets oneself above the setting, yet in ways that remain bounded with the setting (“bounded indeterminacy,” Valsiner, 1997). This hierarchy can be hidden from self-reflexivity and can occur at the intuitive level of *Umwelts*. From a generic idea, “either X or Y” (person OR context), we move to “X into Y into X into Y . . .”—a mutually recursive feed-forward process.

There is much to learn from the indigenous movement in contemporary psychology (Chakkarath, 2005, 2012; Choi, Han, & Kim, 2007; Li, 2007; Krishnan & Manoj, 2008). The productive use of the indigenous psychology movement for the conceptual texture of cultural psychology becomes available after the “colonizing” (treating “the other” society as a data source) and “independence” (the “other society” claiming the value of their indigenous concepts) is overcome. Instead of mere equality claims of the “others” concepts, the science of psychology can overcome its Euro-centric historical orientation by making some of these concepts the core terms (and treating their Euro-centric analogues as their derivatives). As Durghanand Sinha has noted:

Long before WHO defined health in positive terms as a state of complete physical, mental and social well-being, the Indian conceptualization was completely holistic as reflected in Susrut’s definition: *prasannamendriyamanah swastha* (or health is state of delight or a feeling of spiritual, physical and mental well-being). The aspect of *sama* or avoidance of extremes and having various bodily processes and elements in the *right quantity* (neither too little nor too much), that is, of maintaining proper balance, has been constantly emphasized . . . well-being is not equated with fulfillment of needs and production of material wealth through the control and exploitation of nature. The capacity to develop and maintain harmonious relationship with the environment is considered vital.  
(Sinha, 1996, p. 95)

Of course no governmental organization (WHO, UN, or any other) has a privilege in defining scientific terms. A science cannot start from a local definition of a socio-political kind—it would reduce its generalizability and would let a social institution

direct the knowledge construction along its political orientations.

### ***Self-Reflexivity of Psychology: Advantages of the “Cultural Look”***

Psychology’s theory construction site is itself culturally organized. It includes sensitizing concepts (social representations)—meanings that give direction to empirical efforts of researchers (Joffe & Staerklé, 2007, p. 413). A sensitizing concept may block the advancement of a direction of research for long time—as the history around developmental logics (Valsiner, 2008b) shows. Although the core notion of “taking” may guide Western psychological theories to accept the rationality of benefit maximization axiom that leads to the “independent self” notion as normative, the Indian focus on “giving” (Krishnan & Manoj, 2008) sets the stage for different versions of “interdependent self” theories. The generic social representation accepted in the occidental worlds—such as Aristotelian two-valent logic—makes the emergence of multitrajectory holistic (yet structured) concepts much more complicated than in many cases of indigenous meaning systems. Existing meta-level social representations guide the directions of theory construction in the sciences.

For example, Western psychologies have had difficulty accepting the notion of development as it entails synthetic emergence of generalized, abstracted phenomena. The focus has been on “what was” (memory, history) or on “what we now think that was” (Galasinska, 2003; Goldberg, Borat and Schwartz, 2006; Mori, 2008; Wagoner, 2008, 2011) and rarely has considered “what is not yet—but is about to become.” What is “being measured” is assumed to be “out there” in its essentialist form (fixed quality) and in different amounts (quantities). Once the quality is immutably fixed, it cannot transform into new forms—hence, the difficulty of developmental thinking in occidental psychologies. It is only at present that questions of processes by which the movement toward the future occurs begin to be analyzed (Järvinen, 2004; Sato et al., 2007). Cultural psychology cannot deal with behavior as something “out there” that can be observed. Instead, we can observe *meaningful conduct* of goal-oriented organisms (not only humans—Sokol-Chang, 2009) who are in the process of creating one’s actual life trajectories out of a diversity of possibilities (Sato et al., 2007, 2012). That process may be poorly captured by the use of real numbers (Valsiner & Rudolph, 2008), and hence careful qualitative

analyses of particular versions of human conduct are the empirical core of cultural psychologies.

### The Range of the Handbook—And Its “Missing Pages”

Obviously a handbook of 51 chapters is a huge corpus of ideas and seems to be fully comprehensive. Unfortunately we did not succeed in including all the expected and desired relevant authors in the Handbook, for various reasons—mostly linked with workloads and travel. Thus, the voices of traditional experimental social psychology (of Shinobu Kitayama and Hazel Markus), and its adamant critiques (Richard Shweder), psychoanalytic cultural anthropology (Gananath Obeyesekere, Sudhir Kakar), sociology of complex societies (Veena Das, Rama Chan Tripathi), socio-cultural semiotic perspectives (Alberto Rosa), and the cultural psychology of work processes (Yrjö Engeström) did not materialize by the time the Handbook project was to be finished. The following entails a brief synopsis of some of these.

### Social Psychology of Cultural Self—The Stanford Tradition

The “Stanford tradition” emanating from the work of Hazel Markus since 1980s and proliferating in North American social psychology is an outgrowth from the contextualist orientation in personality psychology of the 1970s. Markus’ work starts from an empirical emphasis on the schematic self-descriptions. She gives new theoretical life to William James’ notion of *possible future selves* that is conceptualized in terms of subjective approach/withdrawal tendencies of a person who is facing possible futures (Markus & Nurius, 1986). Furthermore, the emphasis on “possible selves” constitutes a return to Gordon Allport’s idea of hierarchical organization of personality and tentatively explains the role of the personally constructed “possible selves” in the regulation of personality development (e.g., Markus & Wurf, 1987). Although proceeding from self-personological roots, Markus creates a contrast between different collective cultures in terms of the opposition of independence versus interdependence notions that organize the selves (Markus & Kitayama, 1991). In years since, Kitayama has developed the notion of interdependent self into a major research program in experimental social psychology. The normal state of the self is interdependent—interdependence is merely a special condition of interdependence.

### Gananath Obeyesekere’s Cultural World of Person in Context

*Culture* for Obeyesekere consists of internalized ideas in the minds of persons, mediated by consciousness. Because consciousness is primarily personally constructed, the “sharing” of culture between persons can only be episodic and partial (see Obeyesekere, 1977—demon possession is a personal-psychological phenomenon that is not shared with others, yet can be exorcised by cultural rules). Furthermore, specific sophisticated readings of cultural texts by constructive persons can bring into being forms of conduct that seemingly deviate from cultural meanings yet are incorporated into those by special conditions (e.g., the making of “Buddhist eggs”; see Obeyesekere, 1968, p. 30). He has shown how constructed discourses—such as the stories of Maori cannibalism—proliferate (Obeyesekere, 2005).

### CULTURALLY REFORMED PSYCHOANALYSIS

Obeyesekere has been working within a psychoanalytic paradigm, enriching it with his hermeneutic stance, and diligently trying to reformulate its conceptual structure on the basis of empirical evidence from the Sinhalese cultural contexts (Obeyesekere, 1963, 1968, 1975, 1976, 1977, 1981, 1984, 1990). He has also taken a look at encounters between societies (Obeyesekere, 1993) that reveal the “work of culture,” as it

... is the process whereby symbolic forms existing on the cultural level get created and recreated through the minds of people. It deals with the formation and transformation of symbolic forms, but is not a transformation without a subject as in conventional structural analysis ...

(Obeyesekere, 1990, p. xix)

The work of culture is a developmentally progressive process in its main scope (even if it may include moments of temporary “regressions” in its course—e.g., a person’s dissociation of the existing personality organization and being in turmoil for long periods of time (Obeyesekere, 1987, p. 104). The key idea is **cultural constraints set up conditions under which personal symbolic action takes place**—be this the construction of women’s pregnancy cravings in Sri Lanka (Obeyesekere, 1963, 1985) or sorcery for retribution (Obeyesekere, 1975). On the other hand, each person acts in one’s unique ways, has unique personal history, and hence any “standard ritual” (e.g., that of exorcism

of “demon dominance,” Obeyesekere, 1977, or in Christian traditions, Obeyesekere, 2010) needs to accommodate a variety of specific conditions that may be characteristic of a particular person.

#### OVERDETERMINATION BY MEANING

Perhaps the most central innovation of the psychoanalytic thought that Obeyesekere introduces (and that moves him irreversibly away from psychoanalytic explanations of the occidental orthodox kind) is the move from overdetermination of motive (as emphasized by Freud and reflected in dream analysis) to overdetermination of meaning (Obeyesekere, 1990, p. 56). All events in human life occur in polysemic contexts, being framed by a variety of cultural meanings, operating simultaneously at different levels of symbolic remove from deep motivations. Some of the cultural meanings are closer to the motivations (events) that originally triggered the personal symbolization process, which utilized culturally available means. However, in human development, some levels of symbolization may lose all of their connection with the initial “triggering event” and acquire symbolic life of their own in the personality of an individual. Furthermore, Obeyesekere’s theoretical transposition of the notion of overdetermination to the symbolic level is an important idea:

... “[S]ymbolic remove” is based on the psychoanalytic idea that symbols in principle, if not always in practice, show infinite substitutionability. Related to this idea is another principle of the work of culture that psychoanalysis has not, and could not, consider seriously since it would threaten the isomorphism between symbol and symptom. And that is the principle of disconnection of the symbol from the sources of motivation. Substitution implies that symbol X related to motive Y can be replaced by symbols A, B, or C ... n. A, B, C are all “isomorphic replacements” of X, related to motive Y in identical or similar manner. “Disconnection” questions the postulated isomorphism and suggests that A,B,C, ... n might exhibit degrees of symbolic remove from Y and might eventually lose its connection with Y ... Admittedly, total disconnection is rare, but one can make a reasonable case that the more the symbol is removed from the sources of motivation the more it gets the attribute of arbitrariness, thus approximating the Saussurean idea of the arbitrary relation between signifier and signified.

(Obeyesekere, 1990, p. 58)

Obeyesekere adds this constructive-disjunctive (of the symbol from the motive) dimension to the culture-work idea, thus liberating the psychoanalytic perspective from its expression-interpreting fate.

#### *Richard Shweder—The Voice of Culture for Psychology*

Starting from an anthropological background, Richard Shweder’s voice in psychology over the recent two decades has undoubtedly pointed to the need to consider culture in psychology as a primary constituting factor of the self (Shweder, 1984, 1991; Shweder & Much, 1987; Shweder & Sullivan, 1990, 1993). The cultural richness of India has certainly fascinated Europeans in very many ways, but it is rarely that occidental science has attempted to provide in-depth analyses of the cultural constructions in the Hindu world. Shweder’s approach recognizes the heterogeneity and culture-inclusiveness of moral reasoning of human beings (Shweder, 1995; Shweder & Much, 1987; Shweder, Mahapatra, & Miller, 1987). Shweder returns to the emphasis of culturally constituted person as an agent in both subjective and collective domains:

... to imaginatively conceive of subject-dependent objects (intentional worlds) and object-dependent subjects (intentional persons) interpenetrating each other’s identities or setting the conditions for each other’s existence and development, while jointly undergoing change through social interaction ... (Shweder, 1990, p. 25)

The personal minds (object-dependent persons) construct mental and affective order out of chaos of everyday events—hence, an illusory view of reality is constructed by persons but on the basis of the culture. Shweder has been a consistent critic of psychology’s “culture myopia” (taking the role of “the grand confusionist” by his own designation), pointing out that psychology—even its cross-cultural version—has ignored culture as the central player in the domain of human *psyche*.

#### **A SINGLE EXAMPLE MATTERS: HOW MR. BABAJI IS IMPORTANT FOR PSYCHOLOGY**

Shweder’s specific work on the organization of the self in Hindu collective-cultural contexts takes the form of elaboration of specific personal-cultural transformations of socially shared knowledge. Everyday conversations surrounding the developing person are filled with cultural suggestions for how

to interpret the nature of experience in accordance with social representations (Markova, 2003, 2011).

Shweder encountered specific collective-cultural organization of moral discourse in his efforts to apply Kohlbergian moral dilemmas in Hindu contexts in Orissa. His elaborate dispute with the informant Babaji (Shweder & Much, 1987, pp. 235–244) revealed how a Western collective-culturally shared “moral dilemma” (stealing/not stealing a drug under life-threatening illness of one’s wife and drug-owner’s refusal to provide it by special arrangements) can be translated into a completely different personal-cultural issue (i.e., sinning vs. not sinning via stealing for one’s wife, even if the latter’s life is in jeopardy). By way of specific combination of collective-cultural meanings of “sin,” “wife” (as “belonging to” the husband), “multiple lives,” and “inevitability of death,” a set of alternative personal-culturally allowable scenarios for the action of the person in a dilemma situation is being constructed (*see also* Menon, 2003, on Hindu moral discourses). Cultural-psychological investigations are necessarily of unique events—yet of those that happen within a hierarchy of social contexts. Instead of situating cultural psychology on the socio-political landscape (Ratner, 2008, 2012), it is the macro-social organization of society that becomes analyzed in micro-social activity contexts. Here the traditions of micro-sociology of culture give cultural psychology a lead—generalization from a carefully studied single specimen can be sufficient.

### ***Qualitative Methodology As the Root for All Methods in Psychology***

A liberation movement is happening in psychology—an effort to topple the socially normative fixed role of the quantitative methods as having the monopoly of being “scientific.” Yet making the qualitative and quantitative methods look like they oppose each other as two rivals is an unproductive stance—which is even not overcome by the “cocktail” metaphor of giving preference to “mixed methods.”

In reality, quantity is a derivate of quality. As Ho et al. (2007) have demonstrated, contemporary social sciences that treat qualitative and quantitative methods as if these were opposing methodologies are introducing a false dichotomy. Research questions in psychology—as long as psychology is not hyperformalized by mathematical ideas—are asked in philosophical terms, hence qualitatively. Echoing

the concerns by many scholars over the twentieth century (e.g., Baldwin, 1930; Michell, 1999, 2003, 2005; Rudolph, 2006a, 2006b), they point out:

Quantification is neither a necessary nor sufficient condition for science. No-one questions the scientific status of biology without quantification . . . . The price of quantification is a ‘loss’ of information, as when rich qualitative data are reduced to sets of numbers, such as frequency counts, means, and variances. Quantitative data have to be translated into qualitative statements if their meanings and implications are to be spelled out, communicated to and received by the researcher’s audience.

(Ho et al., 2007, p. 380)

Qualitative perspectives are clearly on the ascent in contemporary psychology at large (Diriwächter & Valsiner, 2006, 2008; Gelo, Braakman, & Benetka, 2008; Mey & Mruck, 2005, 2007; Michell, 2004). This is more easily fitted to cultural psychology—where the molar level units of analysis resist quantification anyway (e.g., Toomela, 2008b, pp. 64–65, on psychology’s production of meaningless numbers). To ask the question “how much of [X= “love”, “hatred” . . . .]?” presumes the *unitary quality* of that X and its nature together with *homogeneity* of the presumed substance (X), which makes it possible to apply quantitative measurement units to it. Hence the assumption of quantifiability rules out from the outset the possibility of transformation of quality by separating the latter from whatever numbers are attached to the phenomena in the act of “being measured.”

### **UNITY OF QUALITY AND QUANTITY**

All quantitative approaches constitute a subclass of qualitative ones but not vice versa. Psychology treats numbers as if they are objective in contrast to mathematics. For example, the difference of 0 (zero) and 1 (one) and 2 (two) in case of psychology’s assumption of interval or ratio scale treats each of these numbers as equally meaningful. Yet they are not; the concept of 0 (zero) is in its quality different from 1 or 2. Zero indicates a dialogue:

Zero means both all (excessive) or none (void). The dialogical process includes the middle, which gets excluded in the dichotomies.

(Tripathi & Leviatan, 2003, p. 85)>

Thus, psychology’s—not only cultural psychologies’—core conceptual problem is not merely “dualisms” of all kinds but of the understanding of the

dualities (or multiplicities) inherent in what seems to be a unitary point to which a number can be easily assigned (Wagoner & Valsiner, 2005).

The issue—treating *science* of psychology as an *act of assigning numbers* to qualitative phenomena (to get data) has been discussed critically by Rudolph (2006a, 2006b, 2006c, 2009) as well as Toomela (2007b, 2008a). The social consensus of number assignment guarantees no science—hence much of psychology’s data analytic practices are of the kind of cultural artifacts that may belong to a museum rather than contribute to advancement of knowledge. The cultural nature of the meaning of “statistical significance” has been shown to be one of such widespread artifacts (Ziliak & McCloskey, 2008).

More importantly, the crucial conceptual mishap in psychology is the reduction of the notion of abstract formal models of mathematics to the use of only one kind of numbers—real numbers. At the same time, many cultural-psychological phenomena are better fitted with models using imaginary numbers (Valsiner & Rudolph, 2008) and topological models (Rudolph, 2008a, 2008b, 2009). Such number systems may be better fitted for dealing with the phenomena of uncertainty of living (Abbey, 2004, 2007, 2011; Golden & Mayseless, 2008) and with dynamic boundaries-making (and unmaking) in human social lives (Madureira, 2007a, 2007b, 2011; Tsoulakas, 2007). Tsoukalas (2007) has brought the issue of religiosities—differentiating doctrinal and imagistic types—back to our focus of attention. Specific cultural practices of communication—turned into institutionalized framework through activities like *prayer* (del Rio & Alvarez, 2007), asking for forgiveness (Brinkmann, 2010; Phillips, 2007), apologizing, and many others may lead the way toward cultural psychology of religious sentiments.

### *From Oppositional Terms to Unity of Opposites*

Psychology has usually adhered to exclusive separation of opposites along the lines of Aristotelian-Boolean two-valued logic. Consider the basic opposition of “individualist” versus “collectivist” cultures—a staple organizer of knowledge in cross-cultural psychology. Societies on the Globe are divided into either “individualist” or “collectivist” and contrasted with each other.

Matsumoto (2003) has specified the location where tension can be located in human cultural

functioning—between the consensual reflection about one’s group membership (e.g., “as an X [i.e., “an American”] I am Y [“individualistic”], not Z [“collectivistic”]) and the circumstances for action (“while an X in general—in situation S, I am Z”). Because each person is context-bound, no statement about one’s cultural label (“individualist” vs. “collectivist”) can characterize the negotiation between the opposites and the situation demands. The tension is thus granted by the social community (*see* Mead, 2001/1931, on the role of community in U.S. society). By the regular cross-cultural psychology nomenclature, the United States is considered to be “individualistic,” yet if one looks at the level of person–community relations, it looks very “collectivistic.” That person is therefore necessarily analyzable as a dynamic structure of multiple parts—such as Autonomous-Related Self (Kagitçibasi, 1996, 2005; Tuli & Chaudhary, 2010) or in terms of dialogical self (Hermans, 2001, 2002; Hermans & Dimaggio, 2007; Salgado & Gonçalves, 2007).

It is here—at the unity of various parts within the whole—that cultural-psychological processes make stability out of instability; parents operate at the intersection of various cultural models (Keller, Demuth, & Yovsi, 2008), and kindergarten teachers evoke danger scenarios for children in the middle of mundane everyday activities (Golden & Mayseless, 2008). The *cultural-psychological worlds are relational worlds*, yet that recognition leads us to inquire into what *relational* could mean.

### RELATIONSHIPS AS BOUNDARIES

Cultural tools both set up boundaries—by way of classification—and set the stage for transforming them (Boesch, 2008). As Boesch sets up these two functions of culture—classification and transformation—we can expand these from two different functions into one. Although classification (“this belongs to A”) creates the distinction with the rest (non-A), it also sets up the boundary {A || non-A}. The act of classifying is simultaneously boundary-setting, and boundary is the trigger for its overcoming, by way of transformation {A |is becoming| non-A}. As such, classification and transformation are two mutually linked processes. Boundaries of gender (Madureira, 2007a, 2007b, 2011) and body (Ingold, 2004) turn out to be both solidly protected and quasi-permeable. Human social life entails constant boundary construction (Joffe & Staerklé, 2007) and transformation—social classes create their boundaries in urban globalizing worlds (Tevik, 2006) together

with opening up the possibility of transcending these boundaries. By creating boundaries, we create objects, which are simultaneously physical and cultural entities.

### CULTURAL OBJECTS

Objects are not just material “things” that exist in and of themselves but distinguished contrasts between a figure and the ground. Thus, a black point on a white surface is an object, based on a relationship of the figure and the ground. Human cultural histories are filled with hyper-rich construction of such objects through abundant use of signs. We create our lives through ornaments, which seem to us to carry decorative purposes, yet these decorations abound and can be found in unexpected locations (Valsiner, 2008). By our constructive actions we turn things into objects.

We live among objects—and relate to them:

The words “object,” *objectus*, *objet*, *Gegenstand*, *ogetto*, *voorwerp* all share the root meaning of a throwing before, a putting against or opposite, an opposing. In the English verb “to object” the oppositional, even accusatory sense of the word is still vivid. In an extended sense, objects throw themselves in front of us, smite the senses, thrust themselves into our consciousness. They are neither subtle nor evanescent nor hidden. Neither effort nor ingenuity nor instruments are required to detect them. They do not need to be discovered or investigated; they possess self-evidence of a slap in the face.

(Daston, 2000, p. 2)

It is not surprising that cultural psychology becomes increasingly interested in the study of meaningful objects. Cultural objects are everywhere—in our private domains of homes (including the homes themselves) and in public (in the streets, town squares, etc.). They are both stationary (temples, monuments, etc.) and moving (buses, trains, airplanes, etc.). As Bastos (2008) pointed out, these objects can be seen as “tattoos on the collective soul,” and they bring into cultural psychology the methodological credo of visual anthropology. The kind of meaning-making in the creation of such (moving or stationary) wholes is of hybrid nature, including indexical, iconic, and symbolic signs (to follow C. S. Peirce’s basic typology). Cultural psychologists of the semiotic orientation have usually detected varied versions of encoded versions in their descriptions of objects, whereas the jeepney example forces us to look for principles by which different sign

types become coordinated in the making of a holistic cultural order (Diriwächter & Valsiner, 2008).

Last—but not least—the increasing interest in objects in cultural psychology leads to its new relationship with another discipline—that of archeology. Empirical evidence from the structure of objects used by human beings in the past in various social contexts becomes functional for understanding the present and the future (González-Ruibal, 2005, 2006, 2011). It is in this historical focus—of objects-in-their context (in case of archaeology) and meanings-in-their context (in case of cultural psychology)—that a new interdisciplinary synthesis of knowledge is likely to emerge in the future.

### Preview of the Handbook

The 12 sections of the Handbook are merely an orientation device for the reader to orient oneself in the large heterogeneous field of cultural psychology. The chapters in the historical section (I) situate both the previous efforts to unite culture and psychology (Diriwächter, 2012; Jahoda, 2012) as well as provide an insight into the role of Vygotsky (van der Veer, 2011). Different other chapters in other parts of the Handbook (Magnus & Kull, 2012 on the role of von Uexküll; Tarasti, 2012, on various philosophical tendencies that underlie the semiotic perspectives in cultural psychology) show how the scientific minds of various backgrounds have been looking for solutions to similar problems. History of the social sciences is a rich ground for finding out how different theoretical efforts emerged—yet failed to reach solutions to the problems.

The key message from our turn to history is the need to rejuvenate the theoretical schemes of psychology by touching on similar solutions attempted in other sciences. Semiotics (Innis, 2010, 2012; Magnus & Kull, 2012; Tarasti, 2012) stands out as a new and very promising peer for psychology. This is complemented by bringing the science of archeology into contact with psychology (Gonzalez-Ruibal, 2012).

Cultural psychology benefits from conceptualizing the notion of positioning—a geographic metaphor that allows for elaboration of the multiplicity of psychological phenomena (Harré, 2012; Bento et al., 2012). When the notion of positioning is linked with that of social representations (Aveling et al., 2010) we gain a multifaceted dynamic view into the human lives as these move through various social settings. Obviously such positions are themselves embedded in the macro-social settings, as Ratner

(2008, 2012) reminds us. Through the synthesis of positioning theory, social representation theory (Marková, 2003, 2012), and the macro-cultural look, cultural psychology can arrive at a hierarchy of “niches” of socially embedded and personally constructed phenomena. All these are united through the use of semiotic tools at all levels of that social hierarchy (Innis, 2012; Salvatore, 2012; Sonesson, 2010; Tarasti, 2012).

Yet at the beginning of all efforts to unite culture and psychology is the act—a purposeful, meaningful, future-oriented movement by a willful person (Boesch, 2011; Eckensberger, 2011). Action theory is unabashedly focused on the symbolic (*see also* Bruner, 1986; Salvatore, 2011). Although the semiotically organized ACTING PERSON–SOCIAL POSITIONING–SOCIAL REPRESENTATION–MACRO-CULTURAL ORDER hierarchy could be considered the vertical axis of cultural psychology, it is important to pay attention to its horizontal counterpart. The latter entails the transitions between different culturally structured contexts within which human beings act, position themselves, and become involved in macro-social activities. The home leads, through an entrance, to the street, the city square, to the road that leaves the city for the rural countryside. Airplanes take us 10 kilometers above the ground, where our positioning ourselves is surrounded by white clouds and thinking of the past that we left behind while taking off and the future that awaits us in the airport where we are about to land. Kharlamov (2012) brings to cultural psychology the notion of moving between different spaces—and the role of constant meaning construction “on line” as such movement takes place. This resonates well with the focus on migration as human main *modus operandi*—from micro-migration (movement between home and workplace, home and school), temporary work-related migration (sailors at sea, guest workers in foreign lands), immigration, and establishment of oneself in a far away place. By the twenty-first century, the latter includes extra-terrestrial spaces—as long as the ideas of “colonizing the Moon” (or Mars) are entertained as potential future projects. In all these migrations—real or imaginary, temporary or permanent—we can observe the unity of the self and the other (Bento et al., 2012; Simão, 2012). The human being needs to relate to the other to be oneself and develop further while being oneself. An important part in that is creating stories—both about oneself and about the other. In this respect, the developing qualitative research practice

using narratives (Brockmeier, 2011) or focusing on the micro-level discourse phenomena (Murakami, 2011) is a notable direction for future development of culture within psychological research. Into the human propensity of narrating—all over the life-course—enter different semiotic resources (Eco, 2009; Zittoun, 2007, 2012) and we consolidate our selves around the images of fictional characters from novels, movies, or revered historical figures. The connections of psychological data and different literary constructions are being explored in contemporary cultural psychology (Brinkmann, 2006, 2007, 2009; Johansen, 2010; Moghaddam, 2004). The creative writers may have had better insights into the complexities of the human psyche than North American college undergraduates diligently putting pencil marks onto the myriads of Likert scales.

It is for the reason of providing resources that culture in psychology needs to consider the history of human beings (Carretero & Bermudez, 2012; Winston & Winston, 201=2). That history entails the construction of meaning about one’s social and economic status as well as that of the others. “Being poor” may look different from various definitions of social positioning, as can objective state of economic status (Bastos & Rabinovich, 2009, 2012). So does the construction of the notion of race (Winston & Winston, 2012). Behind all these socially constructed human phenomena are very real biological bodies of *Homo sapiens*. Historically oriented cultural psychology needs to look at the phylogensis of cultural means. The Handbook provides a glimpse into our thinking about the newest developments in the studies of primate cultures (C. Boesch, 2012) and gives the readers a glimpse into the biosemiotic look at the animal world (Magnus & Kull, 2012). Theoretically, contemporary cultural psychology shares the ground with epigenetic thinking in biology (Tavory et al., 2012).

Human beings move around—as tourists, pilgrims, traders, warriors, or vagabonds. In such movements, they enhance their horizons of “the Other”—persons, customs, habits, and economic opportunities. Understanding people-in-movement is a crucial task for cultural psychology (Gillespie et al., 2012; Kharlamov, 2012). The hybrid trajectory of self-willed movement—the pilgrimage—is a cultural phenomenon that dynamically unites the otherwise static rural–urban, religious–secular, and nomadic–sedentary oppositions. The pilgrim’s path is not geographic but psychological (Beckstead, 2012).

Complex psychological functions of social kind are covered in Part X of the Handbook. Perhaps the most crucial issue is the way in which duties and rights (Moghaddam et al., 2012) are linked with the construction of values (Branco, 2012). In a counterweight to the Euro-American discourse on such higher processes, Nsamenang (2012) has provided a contextualized perspective from the vantage point of African societies.

The basic tenet of cultural psychology—in contrast to cross-cultural psychology—is the inclusion of the social institutions in which people participate in the study of the cultural ways of living (*see* Valsiner, 2007, on two ways of knowledge creation). Our Handbook looks at a number of social practices—those in the macro-structure of a school (Daniels, 2012; Marsico & Iannaccone, 2012, Marsico, Komatsu & Iannaccone, 2012) The educational contexts can—and do—change; our Handbook covers the ways in which interventions have been observed (Downing-Wilson et al., 2012; Lopez et al., 2012).

All human beings who participate in the activities of social institutions are acting on the basis of their affective relations with the immediate social worlds. Chaudhary (2012) demonstrates how the normative stance for such relations is the strategic coalition-making in family networks—filled with affective construction of dramas. The centrality of play (van Oers, 2012) in human lives guarantees that within any social group there is constant differentiation of forms of new action. The peer group sets the range of social constraints that enable further innovative collective action (Li, 2012).

The crucial area for re-integration of culture and psychology is the creation of new methodology (Part XII). It needs to transcend the elementaristic logic of the General Linear Model by allowing for recognition of cyclical nature of causal processes, focus on constant construction of variability (which leads to idiographic science; Molenaar, 2004), and accepting the multilinearity and multifinality of the psychological processes (Sato et al., 2012). Ambivalence—rather than its absence—is the normal state of affairs in psychological phenomena (Abbey, 2012). That ambivalence is being temporarily overcome through the use of cultural tools by persons (Boesch, 2011; Eckensberger, 2011; Innis, 2011). New methods are emerging from this general line of thinking—collective techniques of looking at reconstructive memory (Wagoner, 2012) and the look at life trajectories in-the-making (Sato et al., 2012).

Encountering the rich material in this Handbook is a multilinear experience for the reader—a worthwhile effort, so as to make sense of where psychology so far has failed and to get some ideas of better future for the human sciences of the future. It is our hope that this Handbook becomes a rich resource for future generations of thinkers who want to see culture in the psyche and let psychology as a science enter the social realities of cultural organization.

## Notes

1. The first two having been the times of *Völkerspsychologie*, 1860–1920, and the efforts of the “culture and personality” school in cultural anthropology in the 1950s.
2. The boy who was trained by John B. Watson, one of the originators of behaviorism
3. The infant chimpanzee who was raised by Ladygina-Kohts (2002, original in 1935 ) in the classic study of chimpanzee development in human environments
4. Wolfgang Köhler’s best known research participant on the Tenerife.
5. It is important to note that the intricate link with the dialectical dynamicity of the units—which is present in the Russian original— is lost in English translation, which briefly stated only the main point in a summarizing fashion: “*Psychology, which aims at a study of complex holistic systems, must replace the method of analysis into elements with the method of analysis into units*” (Vygotsky, 1986, p. 5). Yet it remains unclear in the English translation what kinds of units are to be constructed—those that entail oppositional relationships between parts—while in the Russian original it is made evident.

# Culture and Psychology: Words and Ideas in History

Gustav Jahoda

## Abstract

This chapter provides an historical overview of the links of culture and psychology from antiquity to the present time. The roots of interest in culture are traced to the social practices of travel—exploration, trade, conquest, and administration—that lead to experiencing other human beings as living by very different practices. Psychology emerged in the eighteenth and nineteenth century European thought that carried various cultural prejudices into its mainstream. This took place in the context of basic philosophical tension between *nature* and *nurture* as causal streams resulting in cultural differences. Over most of the period nurture predominated, with a sharp reversal during the nineteenth century when *race* came to the fore. Yet it was after the middle of that century that the terminology began to change and *culture*—the name, not the concept—entered the vocabulary. Cultural psychology of today is in a position to see mind and culture as mutually constituted.

**Keywords:** history, culture, *Völkerpsychologie*, mind, exploration, customs

Like some Freudian terms, *culture* has now become part of our everyday vocabulary. As such, it is usually coupled with a range of adjectives to indicate some undefined properties of a category, such as “adolescent culture,” “consumer culture,” “literary culture,” “tabloid culture,” “visual culture,” and so on. Such ordinary usage is regarded as unproblematic, whereas the social sciences have agonized over the meaning of *culture* for more than half a century and continue to do so. In 1952, Kroeber and Kluckhohn published their well-known monograph that listed some 160 proposed definitions. For reasons that will be explained later, no definition will be offered here, but the history of the word will be outlined.

The original source of the term was *cultivation*<sup>1</sup>, as in “agriculture,” although already in Roman times Cicero used the expressions *cultura animi* for the training of the mind and *cultura mentis* in a figurative sense to refer to philosophy. But for centuries

it meant producing or developing something, such as “the culture of barley” or “the culture of the arts,” and it is still applied in this sense, as in the phrase “the culture of bacteria.” In English, the first use of “Culture” in the figurative sense of improvement or refinement by education and training dates back to the early sixteenth century. More than three further centuries had to elapse before it was employed in more or less its current quasi-technical sense by Tylor ([1871]1958), whose approach will be more fully discussed later. Initially *culture* was mainly used in the singular to denote a property of humankind in general, and it was not until the 1930s that a clear distinction came to be drawn between “culture-in-general” and “a culture” as one of many different cultures.

So far this may seem rather straightforward, but in fact matters are more complicated. Tylor’s definition began with the phrase “Culture or Civilization . . .,” indicating his view, then widely held, that these

terms were synonyms<sup>2</sup>. There are further complications because, as shown by Elias (1982), there are national differences in the meanings of these terms. In France, *civilisation* was seen as a universal feature of the (superior) West, encompassing a cluster of features including economic, political, technological, social, and moral ones. In Germany, for historical reasons, civilization that transcends national boundaries was conceived as something external and even threatening to their *Kultur*, which embodied their particular national values. In more recent times, these distinctions have become somewhat blurred without being altogether eliminated.<sup>3</sup> It will be clear, therefore, that the term *culture* is of relatively recent origin and that there are variations over time and place in the manner it is understood.

### Psychology: Its Historical Roots

Let me now turn briefly to *psychology*, a term that goes back to the end of the seventeenth century. There was and remains a general consensus that it refers to the study of the (mainly human) mind. In the present—historical—context, it will be interpreted more broadly as psychological features attributed to (usually other) peoples.

At this point the reader might well begin to doubt whether the implicit promise of the title of this chapter is really capable of being fulfilled, as it entails a retrospective application of the concepts of “psychology” and “culture.” There seems to be no fundamental difficulty with regard to psychology, as long as one thinks of it as concerned with the mind, which in turn is a key aspect of human nature. Ideas about human nature not only go back to the beginning of recorded history but exist in some form in all known human societies, and they are being studied now under the heading of “indigenous psychologies.”<sup>4</sup> For earlier periods, long before the advent of specializations, one can draw freely on the writings of a wide range of thinkers, including philosophers, physicians, naturalists, travelers and, later, anthropologists and sociologists. Such usage is sanctioned by the practice of most conventional histories of psychology. For despite of the fact that the term *psychology* dates back only to the sixteenth century, authors usually have no compunction in tracing origins back to antiquity.

By contrast, there appear at first sight to be strong objections to the retrospective use of the elusive term *culture*, which has undergone radical changes over time. Let me try to show that, quite

apart from the cumbersomeness of a constantly changing vocabulary, there is a case for using the term *culture* as a kind of rough-and-ready shorthand for past ideas. The argument rests on the fact that the absence of a term does not preclude the presence of concepts, otherwise articulated, which at least broadly correspond to, or overlap with, what we understand today by *culture*. These include expressions like “customs” or “the genius of a people.” Such notions again go back to antiquity and gradually came to be more clearly formulated, so that by the eighteenth century prominent thinkers put forward ideas dealing with the relationship between salient features of peoples or societies and their psychological characteristics.

An example of past usage will help to illustrate this, and I have chosen for this purpose Michel de Montaigne’s famous essay “On cannibals” written in the sixteenth century:

... il n’y a rien de barbare et de sauvage en cette nation ... sinon que chacun appelle barbarie ce qui n’est pas de son usage; comme de vray il semble que nous n’avons autre mire de la verité et de la raison que l’exemple et idée des opinions et usances du pais ou nous sommes.

(Montaigne [1580] 1954, p. 33)

In the above, reproduced in the original archaic French, Montaigne is saying that everyone calls “barbarism” whatever does not correspond to their own customs; and he states that we have no other criterion of truth and reason than the example of the opinions and customs of the country in which we find ourselves. Now these “opinions and customs” are important aspects of what we mean by *culture*. The view that Montaigne can be regarded as having been concerned with culture is widely shared, and a number of commentators have described him as one of the first “cultural relativists”—that is, taking the view that each culture should be judged only in terms of its own standards. Corresponding notions, such as Voltaire’s “*moeurs et esprit*” or Hume’s “moral causes” of differences between peoples, were widespread in the eighteenth century. This, of course, should not occasion any surprise. A term like *culture* is a kind of construct that groups together a set of phenomena and what makes up the set will largely be a function of implicit or explicit theoretical assumptions. Past thinkers made different assumptions and applied different labels, yet they were concerned with similar phenomena. Even today the boundaries between what is and what is not to be

treated as *culture* remain fuzzy, with considerable divergences of views. Thus I would submit that it is defensible to employ the term *culture* diachronically to designate a certain commonality of—admittedly somewhat vague—meanings.

### Antiquity and Middle Ages<sup>5</sup> *The Greeks*

The origins of most aspects of western thought can be traced back to figures from ancient Greece, and the present theme is no exception. Among them, one of the most prominent was of course Aristotle (384–322 BC), whose teachings retained their authority for more than one-and-a-half millennia. Mainly in *de Anima* (but also in other works), he laid the foundations of a theoretical psychology. Here only a few relevant comments can be singled out. Aristotle often disagreed with his teacher Plato (c.428–c.348), but when it came to the external factors (chiefly climatic and geographical) influencing peoples' psychologies, they followed much the same lines:

Some regions are unsuitable or unfavourable, probably owing to the prevailing winds and the heat of the sun; others because of the water or even the food that comes from the soil and which not only provides better or poorer nourishment, but also can have no lesser consequences on the souls.

(*Plato*, *Politeia* II)

This is not to say that Plato placed major emphasis on such influences, because he took the view that willingness to learn, strength of memory, and a keen mind can be produced by education and appropriate laws.

Aristotle went into rather more details:

Namely the peoples of the cold regions and those in Europe have a courageous character, but are behind in intelligence and skill; they also prefer to be free but lack an organized state and are incapable of dominating their neighbours. Asian peoples, by contrast, are intelligent and artistically gifted but inactive, and therefore they live in subjection and as servants. The Greek people lives so to speak in the middle between them and therefore partakes of both these characters. For it is courageous and intelligent. Hence it is free, has the best state, and is able to dominate everything . . . .

(*Aristotle*, *Politeia* VII)

The views of these philosophers were entirely speculative, no doubt drawing on ideas that were

prevalent in their time. On the other hand, Thucydides (c. 460–c. 400 BC) and Herodotus (c. 485–c. 425 BC) were historians whose work was at least partly based on observations. The former's *History of the Peloponnesian war* was a masterly account of Greek history but not only that. Thucydides wanted to explain that history in terms of what he regarded as fundamental human nature and sought to analyze the motivations of the actors and as such was described by Collingwood ([1946] 1961, p. 142) as the founder of psychohistory. In undertaking this analysis, he did not ignore the effect of external circumstances as these interacted with the common human nature. The same principle was applied by his contemporary Hippocrates (c. 460–c. 377 B.C.) the "father of medicine." According to him, one has to consider a series of factors to arrive at a correct judgment about illnesses: general human nature, the particular constitution of the individual, the climate in general and its specific manifestation, and regional influences.

Although Thucydides was able to personally observe aspects of the war, he did not have much to say about other peoples. Herodotus, on the other hand, traveled widely and collected extensive ethnographic data in Egypt, Babylonia, India, Persia, and Scythia (the region north of the Black Sea). The list of topics he covered is a long one, including: race, looks, intelligence, virtues and vices, language, occupations and skills, food, sexuality, various rites (e.g., naming and funerals), sciences, arts, religion, history, notable personalities, geography, and climate. In addition to direct observation, he also questioned local people. Well aware of the dangers of what we now call "ethnocentrism," he was rarely judgmental. His view is epitomized in the following passage:

... if someone were to assign to every person in the world the task of selecting the best of all customs, each one, after thorough consideration, would choose those of this own people, so strongly do humans believe that their own customs are the best ones. Therefore only a madman would treat such things as a laughing matter. There are many weighty proofs which confirm that all people have these strong attachments to their own customs, but let me describe this particularly interesting one: during his reign, Darius summoned the Hellenes at his court and ask them how much money they would accept for eating the bodies of their dead fathers. They answered that they would not do this for any amount of money. Later, Darius summoned some Indians called Kallatai, who do eat their dead parents. In the

presence of the Hellenes . . . he asked the Indians how much money they would accept to burn the bodies of their dead fathers. They responded with an outcry, ordering him to shut his mouth lest he offend the gods. Well then, that is how people think, and so it seems to me that Pindar was right when he said in his poetry that custom is king of all.

(*Herodotus* [c. 440 BC], 2008, Book III, p. 38)

Herodotus also related the story of the Egyptian king Psymmetichos (seventh century BC), who wanted to find out experimentally who the first people were. For this purpose he obtained two newborn children and handed them to shepherds, with strict instructions that not a single word must be spoken in their presence. One day, after 2 years, the children called “bekos.” They repeated this when brought before the king, who instituted enquiries from which he learned that “bekos” was the Phrygian word for “bread.” Hence, he concluded that they were the most ancient people.<sup>6</sup>

This brief sketch has concentrated on a just a few outstanding figures, and many more contributed. Even so, it will be clear that the outlook of some of the intellectual elite was wide-ranging and, in some respects, remarkably modern.

### **The Romans**

A great deal of their learning was transmitted to the Romans from the Greeks, and their brilliant innovations were mainly in technology. A huge compendium of all then existing knowledge, from Astronomy to Zoology, was assembled by Pliny the Elder (pp. 24–79). It includes sections on humans and quasi-humans, the latter becoming important later. In Julius Caesar’s account of the Gallic war, he discussed not merely the characters of different tribes but described how cultural change can come about:

Among them the most courageous are the Belgers, because they live most remote from the civilization (*cultu atque humanitate*) of the Roman province; and also because traders bringing luxury goods, which could weaken their character, seldom reach them.

(*De bello Gallico*, I,1,3)

Other writers, like Tacitus, made similar comments. Generally, however, much of their thought on the topic was derived from the Greeks.

### **The Middle Ages**

These lasted from the fall of the Roman Empire to the Renaissance, roughly the millennium from

500 to 1500. It has rightly been called the “Age of Faith”—gone were the bold speculations of the Greeks, and horizons narrowed. A great deal was written on what might be called “Christian psychology” by St. Augustine or Thomas Aquinas, but not without merit it was essentially the study of the soul.<sup>7</sup> Contact with the world outside Europe was limited, except for Muslim countries, which were seen as the enemy. The world beyond was perceived as being peopled by Pliny’s “monstrous races” (cf. Friedman, J.B. (1981). The typical description cited below is from the fabled Sir John Mandeville’s travel reports:

And in those isles there are many manner of folk of divers conditions. In one of them is a manner of folk of great stature, as they were giants, horrible and foul to the sight; and they have but one eye, and that is in the midst of their forehead. They eat raw flesh and raw fish. In another isle are foul men of figure without heads, and they have eyes in either shoulder one, and their mouths are shaped round like a horseshoe, y-midst their breasts. In another isle are men without heads; and their eyes and their mouths are behind their shoulders.

(*Letts* ([1346?] 1953, Vol.1, pp. 141, 142)

The existence of the “monstrous races,” including creatures that were half-human and half-goat, was believed by Albertus Magnus (1200–1280), one of the great scholars of the Middle Ages. For him a marginal case on the boundary between animal and human was the pygmy, of whom he probably heard from Greek sources. His main criteria were psychological ones: pygmies have memory and are able to compare memory images, but they lack abstract concepts. Albertus likened them to feeble-minded humans possessing only the shadow of reason. Hence, he concluded, they are incapable of *civitas*—what we would call culture.

An earlier saint and scholar, Isidore of Seville (c. 560–c. 636) had put forward a climatic theory of psychological characteristics:

In accordance with diversity of climate, the appearance of men and their colour and bodily size vary and diversities of mind appear. Thence we see that the Romans are dignified, the Greeks unstable, the Africans crafty, the Gauls fierce by nature . . .

(cited in *Slotkin*, 1965, p. 5)

Climatic theories of various kinds persisted until the nineteenth century and were not confined to Christian Europe. Regarding Europeans, the

Muslim writer Masudi (?1–956) noted, “The farther they are to the north the more stupid, gross, and brutish they are” (cited in Lewis, 1994, p. 139). In the year 1068, Said Ibn Ahmad, from Toledo in Spain, wrote a treatise on the types of cultures. He divided them into two groups: those who contribute to science and learning, including Arabs, Egyptians, Greeks, Romans and Jews and those he considered to be progressively more stupid and ignorant with increasing distance from the sun, including people living in the north; Chinese and Turks were treated as marginal.

The most remarkable of the Muslim Arab scholars was Ibn Khaldun (1332–1406) who wrote a treatise on the history and theory of social and political change, which he regarded as cyclical. Many of his ideas have an astonishingly modern ring, such as his view that stability depends on “group feeling”; again, here are his comments on culture:

Culture is not an independent substance, but a property . . . of another substance which is man. Hence the natural character of culture must have reference to what is natural to man, i.e. to his nature and is what differentiates him from the rest of the animal world.

(Mahdi, 1971, p. 173)

Significantly, the subtitle of his opus is *A Study in the Philosophic Foundation of the Science of Culture*. Although it is not clear what Arabic word was glossed as *culture*, there can be little doubt that it must be close to our concept, probably more so than any of the notions discussed so far.

## From the Renaissance to the Enlightenment *Renaissance*

In Christian Europe the fantastic image of the outside world was slow to change even after the dawn of the voyages of exploration. These began with Marco Polo who visited India and the Far East at the end of the thirteenth century. During the fifteenth century, the Portuguese explored the West Coast of Africa, later getting to the Cape of Good Hope shortly before Columbus reached America. The following century saw the conquest of Mexico and Peru by the Spaniards, who also found New Guinea.

It was a new breed of men, created by the Renaissance cult of the individual, who embarked on these hazardous voyages of exploration. The all-embracing theological shell had cracked, opening

the way for a renewed interest in the cultures of Greece and Rome, which in turn liberated minds. Renaissance travelers eagerly sought personal fame as well as proclaiming the goal of converting the pagans. One can clearly discern the ethnocentric anchoring of the concern with exotic peoples. At the same time there was a search for a perspective whereby one might locate “the Others” in time and space for the purpose of systematic comparison, and with a view to gaining a better understanding of one’s own individuality and society (Rowe, 1965).

The period was also characterized by an immense—albeit somewhat diffuse—curiosity, manifesting itself in a passion for collecting a wide range of natural objects and artifacts, as well as by receptivity to new ideas. The travel literature resulting from these voyages therefore found an avid public. Although the first-hand accounts by travelers were often sober and factual, it did not follow that belief in the fabulous had disappeared. Popular travel books embroidered the tales—describing, for example, the inhabitants of the New World as “blue in colour and with square heads.” One of the most successful of these collections, the *Cosmographia* by Sebastian Muenster (1544), presented an indiscriminate mixture of the old “monstrous races” and the newly discovered “savages.” Yet despite the persistence of fables, the Renaissance saw an unprecedented expansion of the European intellectual horizon in terms of both the physical and human worlds.

With a vast expansion of travel, exploration, and colonization, the material available for comparative studies grew proportionately. From the beginning of that period, advice to travelers came to be published. The advice included general admonitions of a vague kind (e.g., to mark down things observed) and moral warnings about dallying with women. Other works listed various kinds of customs and institutions that should be recorded and also mentioned the need to note the psychological dispositions of the people as well as their moral character, qualities, and abilities. Varen’s (1650) *Geographica generalis* achieved a wide circulation among travelers. The topics it covered, reproduced below (from Malefijt, 1974, p. 45), are by no means outdated:

1. Stature, shape, skin color, food habits
2. Occupations and arts
3. Virtues, vices, learning, wit [in the sense of intelligence]
4. Marriage, birth, burial, name giving

5. Speech and language
6. State and government
7. Religion
8. Cities and renowned places
9. History
10. Famous men, inventions, and innovations

It would, of course, be anachronistic to suppose that the authors of such guides were thinking in terms of anything like culture and psychology, as these categories were then nonexistent. All they show is an interest in a range of topics we include under these rubrics.

Among the travel literature, one of the most remarkable works, dealing with Japan, will be briefly outlined. The first substantive contact with Europe began with Portuguese missionary activity in the sixteenth century, and from this stemmed the first coherent account of Japanese culture. The Jesuit Father Louis Frois (1532–1597) wrote a slender volume entitled *Treatise on the Contradictions and Differences in Customs* (Frois, [1585] 1998). In the preface, he wrote: “Many of their customs are so strange and distant from ours that seems almost unbelievable that there could be so many oppositions [between us and] people who are so civilized [*une grande police*], have such a lively spirit and natural wisdom” (p. 13). Evidently the good Father was favorably disposed toward the Japanese, although he could hardly have approved of some of the customs he described. A few examples of oppositions from several of his categories are cited below.

#### PERSONS AND THEIR CLOTHES

With us, there are many men and women with brownish spots on the skin; this is very rare with Japanese, *even though they are White*. (Author’s emphasis added)

With us, wearing painted clothes would be regarded as mad or ridiculous; the Japanese do it customarily.

#### OF WOMEN, THEIR PERSONS AND THEIR MANNERS

In Europe, the honor and the supreme good of young women are the modesty and the inviolate cloister of their purity; the women of Japan set little store by virginal purity, and losing it neither dishonors them nor prevents them from marrying.

With us it is rare that women know how to write; an honorable woman in Japan would be held in low esteem if she did not know how to do it.

#### OF CHILDREN AND THEIR MANNERS

With us, a child of 4 years does not yet know how to eat properly; those in Japan eat by themselves with chopsticks from the age of 3 years.

With us it is customary to whip and chastise boys; in Japan it is very rare to act in this manner, and this applies even to reprimands.

#### THE JAPANESE MANNER OF EATING AND DRINKING

We drink with only one hand; the Japanese always do with two.

We like dishes cooked with milk, cheese, butter, or bone marrow; the Japanese abominate all that, which smells very bad to their nose.

Altogether Frois listed more than 400 binary oppositions, throughout his tone remains neutral and objective. Differences capture attention and interest, as already shown by Herodotus when writing about the “peculiar customs” of the Egyptians. For example, he noted that Egyptian priests have shaven heads, whereas in other nations they have long hair.

#### THE SIXTEENTH AND SEVENTEENTH CENTURIES

The existence of a wide diversity of peoples having been established, the general question arose as to the nature of the differences. The most commonly postulated cause remained the climate, viewed in broad sense,<sup>8</sup> although there were some dissenters. Jean Bodin (1530–1596) tried to classify peoples in terms of north and south but was troubled by the fact that people in the same latitudes can differ. Nevertheless, as already noted, such ideas persisted. About the same time, a *social* interpretation of differences gained ground—namely, in the variety of *customs*. It was Montaigne, already cited, who most eloquently described the power of custom:

... the principal effect of the force of custom is to seize and grip us so firmly, that we are scarcely able to escape from its grasp, and to gain possession of ourselves sufficiently to discuss and reason out its commands. In truth, since we imbibe them with our mother’s milk, and the world shows the same face to our infant eyes, we seem to be born to follow the same path; and the common ideas that we find around us, and infused into our souls with the seed of our fathers, appear to be general and natural.

(Cited in *Slotkin*, 1965, pp. 56–57)<sup>9</sup>

In his famous essay “On Cannibals” and elsewhere, Montaigne applied this to what we would call “cultural differences”

The different customs I find in one nation after another please me by their very diversity ... I am ashamed when I see my countrymen steeped in that silly prejudice which makes them fight shy of any customs that differ from their own ...  
(p. 55)

This insight was repeatedly voiced throughout the sixteenth and seventeenth centuries. Here are some examples:

It is good to know something of the customs of different people in order to judge more sanely of our own.  
(Descartes, p. 104)

But there is another force, that ravishes away the minds of men, and makes them addicted to certain affections. Namely, that spirit which being appropriate to every region, infuseth into men, as soon as they are borne, the habits and affections of their owne country.  
(Barclay, p. 106)

Custom is our nature. ... What are our natural principles but principles of custom? In children they are those which they have received from the habits of their fathers ... A different custom will cause different natural principles. This is seen in experience; and if there are some natural principles ineradicable by custom, there are also some customs opposed to nature, ineradicable by nature, or by a second custom.  
(Pascal, p. 120)

It is interesting that Pascal struggled with the problem of the relationship between, in our terms, “nature versus culture,” an issue that has not gone away. This is because culture is now often seen as an evolutionary product (e.g., Auger, 2000). The general tendency to refer to *custom* in the sense of our *culture* long continued. Even at the end of the nineteenth century, Bagehot (1872) employed the phrase “the cake of custom” to refer to cultural traditions. Apart from *custom*, there is one other kind of expression, rare at that time but becoming more frequent subsequently: Harrington explained national differences in terms of “The *Genius of the Nations*” (Slotkin 1965, p. 130).

So far nearly all the ideas that have been reviewed have been impressionistic and speculative, but during the second half of the seventeenth century, that

began to change. It was the age of the scientific revolution and John Locke (1632–1704), friend of Isaac Newton, was an empiricist who stressed the need for observation. His views on the environmental determination of people’s characteristics were much the same as those of Descartes. Other developments at that time contributed to the formation of a fresh perspective. Ludwig Seckendorf (1626–1692) and William Petty (1623–1687) elaborated a system of social statistics dealing with births and deaths, showing that human life is subject to order and regularity and could be studied quantitatively.

### *The Enlightenment*

In the eighteenth century, the authority of the churches became undermined by Newton’s demonstration that the physical universe is lawful. This prompted the question whether one might not envisage causal laws of mind and society. Montesquieu was one of the first to attempt the formulation of such laws that would account for differences between societies (1689–1755):

I have first of all considered mankind, and concluded that its infinite variety of laws and customs did not uniquely arise from arbitrary fancy. I have postulated the principles, and have seen how particular cases fit them neatly.  
(Montesquieu, [1748] 1964, p. 529)

In the same work (p. 641), he also proposed that various influences, including “the examples of things past,” create “a general spirit [*esprit général*]” that corresponds fairly closely to what we mean by *culture*. The underlying assumption, then widely shared, was that human nature remains constant and that differences result from varying historical circumstances. It was an optimistic age, based on the belief in inevitable progress driven by reason. Its effects were regarded as cumulative. A typical statement is that by Adam Ferguson (1723–1816). He begins by listing the commonalities between animals and humans, and then goes on:

Yet one property by which man is distinguished has been sometimes overlooked ... In other classes of animals, the individual advances from infancy to age or maturity; and he attains, in the compass of a single life, to all the perfection his nature can reach; but in the human kind, the species has a progress as well as the individual; they build in every age on the foundations formerly laid; and, in a succession of years, tend to perfection in the application of their faculties, to which the aid of long experience is

required, and to which many generations must have combined their endeavours.

(Ferguson, [1767] 1966, pp. 4–5)

Apart from the vocabulary used, this seems a fair description of what is now referred to as “cultural transmission.”

In France Louis-Francois Jauffret (1770–1850) founded the *Société des Observateurs de l'Homme* in 1799. Its object was to study human nature, including ethnic differences and their causes, the history of various peoples, and their customs and migrations, as well as child development from infancy onward. The membership consisted of a galaxy of illustrious names in France, and a number of empirical studies were performed. One of the most ambitious ones took advantage of an opportunity to study “savages” at first hand. Napoleon approved the project of an expedition to Australasia, and the *Société* commissioned Joseph-Marie Degérando (1772–1842) to prepare a kind of handbook of methods for this purpose,<sup>10</sup> entitled “Considerations on the Methods to Follow in the Observation of Savage Peoples” (Degerando, [1800] 1969). This is one of the most remarkable documents in the history of social science, which reflects and advances the knowledge then available. After two centuries, many of its recommendations are still valid. They will be briefly summarized, employing modern terminology.

At the outset, Degerando warns against a number of possible pitfalls in research, such as inadequate sampling and communication errors. One should not judge people in other cultures by ethnocentric standards. It is best to become a participant observer and learn the indigenous language. One should consider the effects of the presence of an observer.

The psychological topics he suggests reflect the then prevailing “sensationist” theory of Condillac. The first illustrative category will be described in some detail, whereas for the others, just headings will be listed.

### SENSATIONS

The first thing to be observed is the sensations of savage people, examining in detail their varieties and focusing on the following four questions:

1. What are the senses among them that are most exercised, active, and finely discriminating?
2. What are the conditions that might have led to the more marked development of a particular sense modality?

3. What is the extent of development of each of their senses compared with what one encounters normally among ourselves?

4. What is the type of sensation in which they find most pleasure?

There follow some comments on ways to estimate the degree of development of a particular sense modality, including the threshold as well as speed and accuracy of sensory judgment responses. An example given is the skill in estimating distances. Observers should seek to establish whether innate factors as well as practice contribute to the frequently noted perfection of savage senses.<sup>11</sup> They will also find out if blindness and deafness are more or less common than among Europeans, the effects of such handicaps, and the modes of adaptation.

Other topics include abstract concepts; association of ideas; opinions and judgments; attention; memory; imbecility; education; and child development. It will be noted that nearly all these topics have subsequently become topics of cross-cultural research.

### AGAINST ENLIGHTENMENT THOUGHT

The idea of a social science based on the model of physics was strongly opposed by Giambattista Vico (1668–1744). In *The New Science* ([1725] 1948), he wrote:

... the world of civil society has certainly been made by men, and its principles are therefore to be found within the modifications of our own human mind. Whoever reflects on this cannot but marvel that the philosophers have bent all their energies to the study of the world of nature, which, since God made it, he alone knows; and that they should have neglected the world of nations, or civil world, which, since men had made it, men could come to know ...  
(p. 331)

The philosophers of the Enlightenment saw human history as progressive pan-human stages based on modes of subsistence: from hunting to pastoral to agricultural and finally to commercial. Vico's stages were essentially psychological in character and referred to “a world of nations,” and his concept of a nation appears to have been very much the same as what we mean by *culture*. For him the language, morals, customs, myths, and rituals of a “nation” constituted a complex unity of interdependent parts.

Unlike Vico, Johann Gottfried Herder (1744–1803) was in his youth an ardent disciple of the

Enlightenment but later came to question most of its ideas and values and moved much closer to the position of Vico (although without knowing Vico's work). In opposition to the then prevalent view of the immutability of human nature, Herder stressed its variability, conditioned by historical and environmental factors.

In one of his main works on *The Origin of Language* (1772), he discusses its broader functions. Language, according to him, serves not merely as a means of communication but also as a mode of transmitting the ideas and feelings of past generations. Thus what Herder calls "tradition" is not just a static bundle of beliefs and customs but a *process* in which past and present are fused and that gives a group of people their sense of identity. This clearly anticipates later ideas of the transmission of culture through the generations.

The key term Herder applies to such a group—or better, organic community—is *Volk*. A *Volk* is characterized by a shared language and historical tradition that shape the mentality [*Volksgeist*] of its members, not into any permanent mold but in constant movement of growth and development—or decay. A *Volk* may or may not coincide with a nation-state—it certainly need not do so. This concept is in fact very close to what we mean nowadays by a *culture*, and Herder's somewhat flowery description of the way in which, from infancy onward, not merely collective ideas but also feelings and images are conveyed is essentially an account of socialization into a particular culture.

The diversity of human languages and cultures was, for Herder, a positive value, something "good" and "natural." In contrast to most philosophers of the Enlightenment' who established scales of "progress" whereby to evaluate different societies as "high" or "low," "barbaric," or "polished," Herder was a relativist who considered that each culture must be approached, and valued, on its own terms:

Thus nations change according to place, time and their inner character; each carries within itself the measure of its perfection, incommensurable with others.

(Herder [1785] 1969, vol.4, p. 362)

Herder was also unusual in that he did not share the then quasi-universal assumption of a *general* European superiority and disapproved of the European practices to "subjugate, cheat, and plunder." Thereby he went directly against the spirit of nationalism and colonization that was dawning toward the end of his life.

## *The Nineteenth Century*

### THE FIRST HALF OF THE NINETEENTH CENTURY

This was a period of transition. With the rise of biology, human differences came to be increasingly attributed to "race," and environmental factors tended to recede into the background. Yet most of the figures to be discussed here bucked this trend. One was Wilhelm von Humboldt (1767–1835), who was influenced by some of Herder's ideas but did not believe in cultural relativity, being convinced of "the governing principle of universal humanity." Humboldt's dominant interest is epitomized in the title of his most important work, *On the Diversity of Human Language Construction and Its Influence on the Mental Development of the Human Species* ([1836] 1999). He held that language is the main glue that holds human cultures together, and he had a great deal to say on the relationship between language and thought.<sup>12</sup> Moreover, he maintained that social processes are an essential prerequisite for adequate cognitive functioning.

The nature of mental processes was the main focus of the work of Johann Friedrich Herbart (1776–1841), best known for his writings on educational and mathematical psychology. Of course, it is not possible here to go into details of his complex theories, but some basic features have to be briefly indicated. He envisaged an intra-individual system whereby different *Vorstellungen* (ideas and/or feelings, or presentations) interact, either combining or opposing each other. They can rise above and/or push each other below the threshold of consciousness. Subsequently he put forward the proposal that the forces in society analogously reflect the individual system, which is similar to Benedict's (1932) contention that culture is individual psychology writ large.<sup>13</sup> Herbart also recommended that psychologists should study people from outside Europe:

... how many of us concerned with psychology have been to New Zealand? How many of us have occasion to observe the savages in their home setting? (1825/1890, vol.6, p. 16)

Herbart could therefore be regarded as one of the ancestors of cross-cultural psychology, and he furnished the theoretical underpinning for Lazarus and Steinthal's *Völkerpsychologie* (Diriwächter, 2011). One of their main aims was to clarify the concept of the *Volksgeist* (spirit of the people), a concept whose meaning is at least loosely related to that of *culture*.

Theodor Waitz (1821–1864), prominent follower of Herbart, devoted himself to the cause of “psychic unity” (a phrase he coined) as against the biological race scientists. Like James Pritchard (1786–1848) in Britain, he was faced with the problem that given the (then) stark contrasts between human groups, the claim that they all had one common mind appeared counterintuitive. Hence they accumulated a mass of ethnographic material in an effort to make their case, and Waitz wrote:

However great the difference between their mental *culture* and ours, we may, if time and opportunity are favourable, learn to understand all their actions, and we are thus justified in assuming in the human species, only difference in *culture*.

(Waitz [1859] 1863, p. 274, emphases added)

It might be tempting to conclude from the ending of this passage that Waitz used the term *culture* in its modern sense, but that would be a mistake, as the earlier mention of “mental culture” indicates. The sense is that of “cultivation,” and some peoples are said to be insufficiently “cultivated.”

Yet around mid-century, a monumental work was published by Gustav Klemm (1802–1867) under the title “General Culture-History of Humanity” (Klemm 1843–1852),<sup>2</sup> which at times does appear to employ the term *Cultur* in something like its modern sense.<sup>14</sup> The work is historical and does not deal with psychology, but it is mentioned here because it inspired what is widely regarded as the classical definition of culture by Tylor, usually cited as follows:

Culture or Civilization, taken in its wide ethnographic sense, is that complex whole which includes knowledge, belief, art, morals, law, custom, and any other capabilities acquired by man as a member of society.

(Tylor [1871] 1958, p. 1)

From this, one might infer that his definition was purely anthropological, but the next sentence shows that he did not ignore psychological aspects: “The condition of culture among the various societies of mankind . . . is a subject apt for the study of laws of human thought and action” (emphasis added). It will be noted that he treated *culture* and *civilization* as synonyms, an issue to be pursued below.

#### ADOLF BASTIAN

Another German figure of that period, very much concerned with psychology, was Adolf Bastian

(1826–1905). In his student days he attended lectures by Lazarus, one of the founders of *Völkerpsychologie*, for whom he had a high regard. Among the aforementioned eighteenth- and nineteenth-century writers, he was the first to have personally collected ethnographic material in various parts of the world, including Australia, New Zealand, North and South America, China, and India. Unlike other travelers who mainly reported about the geography of the places they visited and the physical characteristics of the peoples and their artifacts, Bastian was mainly interested in their psychological features. He obtained information on religious beliefs and practices, myths, legal and political forms, customs, and so on.

In his travels, he found that peoples all over the world had a great deal in common as well as differing in many ways. He therefore postulated the existence of what he called “elementary ideas” that are universally shared. He sometimes wrote in a manner suggesting that by “ideas” he also meant “thought processes.” The differences between peoples are said to result partly from the development of their particular languages which, according to Bastian, afford valuable insights into national characters and partly from environmental and historical factors. The ultimate objective was to arrive at a comparative psychology:

A comparative psychology can only be established on the basis of ethnology, which traces in the various ethnic groups [*Volkskreisen*] the genetic development of mental products [*Gedankenschöpfungen*] and explains their local colouring in terms of geographical or historical contexts.

(Bastian, 1868, p. XI)

How far does Bastian’s notion of “elementary” or “folk ideas” correspond to a modern concept of culture? Here we have to remind ourselves that far from there being a generally agreed definition of culture, there are numerous varied ones. Among them is that of “a symbolic meaning system,” and this to some extent resembled what Bastian had in mind. It should also be said that Bastian’s was essentially a *collective* psychology, located midway between psychology and anthropology and as such had a good deal in common with Wundt’s *Völkerpsychologie*.

#### CULTURE AND PSYCHOLOGY IN THE CIRCLE OF WUNDT

*Völkerpsychologie* was located outside the mainstream of experimental psychology pioneered by

Fechner and Ebbinghaus. Not everybody was happy with experimental psychology, which to some seemed rather dry and mechanical, failing to do justice to the subtleties and complexities of human life. The most articulate critic was Wilhelm Dilthey (1833–1911). Like Bastian, he had met Lazarus and had even worked with him for a time. But his initial enthusiasm for *Völkerpsychologie* was later tempered by reservations related to the speculative nature and diffuseness of the enterprise. He turned toward the scientific side, became a pupil of Helmholtz, and attended lectures on physiology.

After obtaining a chair in philosophy, he became increasingly preoccupied with problems of psychology, philosophy, and history, which he came to see as connected. Regarding psychology, he proposed that there are two distinct approaches to the subject: one is empiricist, concerned with hypothesis-testing and aiming at *causal explanations*, the other rests on lived experience and aims at *understanding*—a contrast analogous to that drawn by Vico. While accepting the legitimacy of the former, Dilthey described it as formal and atomistic, ignoring the fact that the self has a functional unity that eludes any approach that concentrates exclusively on its constituent parts.

Dilthey himself focused on *Erlebnis* or “lived experience,” and his two key concepts are *Verstehen* (a kind of understanding<sup>15</sup>) and *Bedeutung* (or “meaning”).

Both of these operate within particular culture-historical contexts. In this connection he took over from Hegel the notion of “objective spirit,”<sup>16</sup> employing it in a manner that corresponds closely to what we refer to as *culture*:

I understand objective spirit to be the various forms in which the common ground that exists is objectified in the world of the senses. In this objective spirit, the past is a continuing presence for us. Its domain extends from the style of life and the forms of economic interaction to the system of ends which society has formed: to morality, law, the state, religion, art, science, and philosophy.

(Dilthey, [1894] 1977, p. 126)

One could also gloss this as a reference to intersubjectively shared meaning systems. At any rate, the broad congruence between “objective spirit” and what we know as culture is supported by the way in which Dilthey characterizes what we would call the acquisition of culture:

From earliest childhood our self receives its nourishment from this world of objective spirit. It is also the medium in which the *Verstehen* of other

persons and their expressions of life comes about. . . . Before he learns to speak, the child is already completely immersed in the medium of common contexts. . . . In this way, the individual becomes oriented in the world of objective spirit.  
(Dilthey, [1894] 1977, pp. 126–127)

It may be noted that Dilthey’s ideas were one of the sources from which almost a century later the so-called “cultural studies” movement emerged.

Karl Lamprecht (1856–1915) was an unorthodox historian who thought that history was not bound to remain merely descriptive but could become scientific and thereby attain objective truth. Like many of his contemporaries, he adopted an evolutionary framework, taking the view that humanity went through a set of distinct stages that were lawful. It should therefore be possible to arrive at universal historical laws. For Lamprecht, historical phases and events are essentially of a psychic nature, so that any stage is characterized by a *collective* psychic state. This he regarded as a kind of diapason, pervading all mental states, and thereby also all activities, in any given period.

The auxiliary science that would enable historians to arrive at these sequences was the then emerging social psychology. Furthermore, he devised and sought to apply an empirical method for identifying the sequence of distinct evolutionary stages.<sup>17</sup> Lamprecht proposed a schema detailing the social-psychological factors operative in the course of history, which will be summarized. He divided them first into natural and cultural ones. The natural comprised such influences as climate, soil, flora, and fauna. The cultural is further subdivided into material (e.g., economy, nutrition, population, and, oddly, custom) and ideal (e.g., opinion, language, myth and religion, and art). Altogether it is a rather strange mixture, yet nonetheless somewhat distantly reminiscent of Berry’s (1976) scheme. One could also mention the French *Annales* school of historians that began during the interwar period. At the outset, one of their principal tenets was that each historical period features a particular kind of mentality. So not only was Lamprecht directly focusing on culture but his ideas had certain resonances in the twentieth century.

### Some Debates in Germany

To grasp the issues at stake, it is necessary to explain first that in German, a distinction had long been drawn between scholarly or humane and scientific disciplines. The former were known as *Geisteswissenschaften* (literally “disciplines of

the spirit”) and the latter as *Naturwissenschaften* (what we would call “natural sciences”).<sup>18</sup> This dichotomy became the subject of a great debate. Its ostensible aim was the purely scholarly one of conceptual clarification, but the fact that it was conducted mainly by exponents of the *Geisteswissenschaften* indicates that it was the status of the *Geisteswissenschaften* that was chiefly at stake. Although the debate as such was not about psychology, psychology was nevertheless to be found at the heart of the controversy. The reason, no doubt, is the hybrid character of psychology that spans the divide separating the sciences from the humanities and social studies.

In 1880, philologist Hermann Paul published a book in which he argued that the opposite of *Natur* is not *Geist* (mind or spirit) but *Kultur* and proposed the expression *Kulturwissenschaften*. The characteristic mark of *Kultur*, he maintained, lies in the involvement of psychic factors.<sup>19</sup> The new label was adopted by the philosopher Heinrich Rickert (1848–1936), who defined *Kultur* as “the totality of objects to which generally recognized values are attached” (Rickert, 1910, p. 27). Thus the basic difference between *Natur* and *Kultur* is that the former, unlike the latter, is value-free. This broad issue also concerned Wundt, whose rather variable positions will be outlined next.

### **Wundt on Kultur**

It is difficult to examine Wundt’s ideas regarding *culture* without the context of his *Völkerpsychologie*, to which they are closely related. Because *Völkerpsychologie* is dealt with in detail by Diriwächter (2011), all that can be done here is to provide a sketch of his usages.

In his earliest relevant publication, Wundt (1863) employed the term in the then most prevalent sense—namely, the higher forms of human intellect and creativity. In his later work, he generally takes it that the essence of *Kultur* consists of three elements—namely, language, myth, and *Sitte*, a term denoting both “custom” and “morals.” In the *Methodenlehre* (1883), he refers to *Kulturvölker* as meaning “civilized peoples.” In a later edition of his *Logik*, Wundt (1908) makes a passing comment anticipating the view that culture is not merely a random assembly of features but possesses some unity and coherence:

Cuvier<sup>20</sup> maintained that one can reconstruct from a single bone the typical form of the whole vertebrate to whom it belongs; similarly, each single part of a

culture provides an approximate mirror image of all the remaining parts.

(Wundt, 1908, vol.3, p. 434)>

A more detailed treatment is to be found in Volume 7 of the *Völkerpsychologie* dealing with Society (Wundt, 1917). This contains a critical discussion of the dichotomy of *Natur-* versus *Kulturvölker* (the term *Naturvolk* is roughly equivalent to our “savages”). This distinction had usually been drawn on the basis of the absence of history and an organized state, but Wundt points out that these criteria are too vague for any clear division to be possible. There is no *Naturvolk* without elements of *Kultur*, consisting of the above-mentioned language, myth, and *Sitte*, and there are different levels of culture among these peoples. Hence the dichotomy is becoming redundant:

[It is for this reason] that the concept of *Kultur* in its actual extension to the peoples of the earth has become ever broader, while the concept of *Naturvolk* is gradually disappearing.

(Wundt, 1917, p. 121)

From this passage one might suppose that Wundt had begun to think of *culture* in much the same way as we do today. But one is rapidly disabused of this by an immediately subsequent—and rather confused—discussion of the concept of “culture-minimum.” In this he reverted to a usage of *Kultur* as more or less synonymous with *Zivilisation*.

The same theme is taken up in the tenth and final volume of his *Völkerpsychologie*, entitled “Culture and History” (Wundt, 1920). There he states that the absolute lower limit of *Kultur* is set by the possession of language, which presupposes at least a modicum of mental life. The question of origins is a futile one, and it is more profitable to ask what cultural products and events have been critical for cultural development. Wundt reviews various turning points, like the invention of the plough or the printing press, but raises various objections to such simple schemes—particularly that they leave out qualitative aspects of cultural values. These are implicit in the concept of *Zivilisation*, which is felt to be something that has been actively achieved, whereas culture is merely the outcome of historical processes—a rather curious distinction. This means that civilization leads to a sense of superiority and of a mission both to civilize and dominate more backward peoples.

Wundt regarded this as a valuable feature of civilization, because it contained a purposive element that is absent from *culture*.

Shortly afterward, there occurred a radical shift in the meaning attributed to *Kultur*:

*Kultur* is national. It is confined to a particular national community [*Volksgemeinschaft*] which constitutes a coherent unity in terms of language, custom, and intellectual cultivation [*geistige Bildung*]; but it lacks the tendency to go beyond these limits by spreading the acquired cultural achievements more widely . . .

(Wundt, 1920, pp. 20–21)

Here Wundt suddenly identifies *culture* with something very much like Herder's *Volksgeist*, seemingly unaware of the change. He concludes that the notions of *Kultur* and *Zivilisation* are complementary: *Kultur* is bound to nationality, whereas *Zivilisation* embodies an ideal of humanity as a unity under the leadership of the advanced nations (*Kulturvölker*).

The next section, entitled "Animal antecedents of cultural man," reverts again to a wider concept of *Kultur*, applying to humans in general. However far one goes, he maintains, what one finds universally among all those who have the physical characteristics of humans are language, myth, and *Sitte*:

As these three labels designate only the major directions in which human life is distinguished from that of other organic beings, and although each of these directions comprises very different forms, so all these factors and their influences on men may be subsumed under the collective name of *Kultur*, so that in view of this *Völkerpsychologie* and *Kulturpsychologie* are equivalent concepts.

(Wundt, 1920, p. 57)

In the end, therefore, Wundt overcame his misgivings and accepted that what he had been doing could be described as "cultural psychology," because he seemed to have arrived at a conception of culture-in-general that is close to our own. The path that led him to this position was not a straight one. For a long time, Wundt swiveled between several different and mutually exclusive notions of *Kultur*, varying according to context, as well as between an objective stance and one that uncritically accepted the then prevailing ethos.

Wundt rarely drew a sufficiently explicit distinction between "human-culture-in-general" and the varied cultures of different peoples; nor did he seek to

relate these, respectively, to general *Völkerpsychologie* and to what he regarded as its applied aspect, which he called "ethnic characterology"—that is, dealing with the psychological characteristics of particular peoples. There is no indication that any echoes of the radical rethinking of the category *culture* by Franz Boas (discussed below) ever reached Wundt.

Before going on to Boas, it is necessary to return briefly to Tylor, whose classical definition of culture was cited on p. 34. As already mentioned, in his time the favored explanation of human differences was simply in terms of "race." This opinion was not shared by Tylor, who was an inheritor of the Enlightenment tradition of a basically unchanging universal human nature.<sup>21</sup> Under the influence of environmental factors, its manifestations underwent progressive changes, occurring at varying rates among different peoples. Thus he was a social (rather than Darwinian) evolutionist, and the approach to the study of evolutionary stages was the "comparative method." For example, ancient Swiss lake habitations were very similar to those of nineteenth-century Maoris, and this was taken to show that the same evolutionary trajectory was being followed, although the Maoris were well behind.

### *Franz Boas*

Both racial and social-evolutionary theories came to be rejected by Franz Boas (1858–1942). He was the main creator of a fresh concept of culture and came to dominate American anthropology during the 1920s. He was born and educated in Germany, where he began by studying chemistry and physics but later turned to biology and geography. He also became interested in psychophysics and attended lectures by Wundt. In 1882 he went to Berlin in preparation for a geographical expedition to Baffin Island, and in Berlin he came to know Bastian. A year later he departed on the expedition, intending originally to compare the objectively studied environment with the knowledge of it held by the Inuit inhabitants. As a result of his close acquaintance with the Inuit (e.g., he hunted with them) Boas came to understand that their knowledge was not just a reflection of the environment but discovered that there was a *tertium quid* that intervened—namely, their culture. This was a turning point in his career, and back in Germany he applied for his *Habilitation*,<sup>22</sup> and the members of the commission included Dilthey and Helmholz. Subsequently Boas emigrated to the United States, where he embarked on fieldwork with the Indians

of the Northwest Pacific Coast and in 1899 became the first professor of anthropology at Columbia University in New York.

In his theorizing about culture, Boas was greatly influenced by his German background, from Herder onward. Although he initially shared Tylor's social evolutionism, he later abandoned it. He pointed out that similarity does not necessarily imply an identical cause, showing how the same outcome could result from combinations of quite diverse historical, environmental, and psychological factors. He also objected to specific traits or complexes being torn out of their particular cultural context and lumped together indiscriminately. He showed that biological traits (i.e., "race"), language, and culture were not intrinsically linked to each other and had to be studied using different methods.

Generally, Boas was instrumental in changing the intellectual climate toward thinking about *cultures* in the plural as entities that had a certain unity based on history, environment, and psychology. His enduring concern with psychology is clear from the title of one of his major works—namely, *The Mind of Primitive Man* (Boas, 1911); it is also implicit in an early definition of *culture* he proposed:

Culture embraces all the manifestations of social habits of a community, the reactions of the individuals as affected by the habits of the groups in which he lives, and the products of human activities as determined by these habits.

(Boas, 1930, p. 79)

Boas and his students, including Ruth Benedict and Margaret Mead, shaped the character of American anthropology for many years and led to its being called "*Cultural anthropology*" as distinct from British "*Social anthropology*," but that came later.

### ***The Problem of "Convergence," Rivers, and Bartlett***

The issue of how disparate cultures came to display similarities, which were often striking, was extensively debated during the first two decades of the twentieth century. Tylor and other social evolutionists had attributed them to universal human nature; an alternative interpretation, putting the major emphasis on transmission through culture contact, was put forward in Germany. It is neither necessary nor possible to enter here into the details of the debate, except to say that the sharp opposition between the two sides gave way to a question

of relative emphasis. What is relevant here is the fact that these anthropological discussions usually involved psychological ideas and speculations. For example, Goldenweiser (1910) referred to "the mechanism and psychology of borrowing behavior" (p. 285) and proposed that "the phenomena of diffusion [are] replete with psychological problems" (p. 287). In a similar manner, Boas (1910, pp. 375–376) proclaimed, "the necessity of looking for the common psychological features, not in outward similarities of ethnic phenomena, but in the similarity of psychological processes in so far as these can be observed or inferred." Although these were American comments, in Britain, Rivers took part in the debate.

William Halse Rivers (1864–1922) was an experimental psychologist at Cambridge when his anthropological colleague Alfred Haddon invited him to take part in the Cambridge Anthropological Expedition to Torres Strait in 1898. It was the first systematic cross-cultural research, although confined to sensory processes;<sup>23</sup> Rivers had little to say about culture at that time. He was then still a social evolutionist, but that changed when he became actively involved in anthropological fieldwork. In his very substantial book on Melanesia (Rivers, 1914), he discussed at length the impact of culture contact, especially through migrations, on cultural changes. In an essay on "The Contact of Peoples," Rivers wrote "... it becomes a matter of urgent necessity to understand the process of blending [of cultures]" (Rivers, [1913] 1926, p. 299). He always stressed the importance of including a psychological approach, and in an address on "The Ethnological Analysis of Culture" to the British Association for the Advancement of Science, he argued:

Side by side with ethnological analysis, there must go the attempt to fathom the modes of thought of different peoples, to understand their ways of regarding and classifying the facts of the universe. It is only by the combination of ethnological and psychological analysis that we shall make any real advance.

(Rivers, [1911] 1926, p. 132)

Rivers returned to Cambridge in 1908, and a year later Frederic Bartlett (1886–1969) became his student, whom he inspired to pursue research concerned with the effects of culture contact. In his Fellowship Dissertation, Bartlett (1916) declared his intention of studying the process of *conventionalization*, whereby new elements are incorporated in

cultures as a consequence of contact; and he refers in this connection to a passage by Rivers on “the blending of cultures.” He stressed that the manner in which he used the term *conventionalization* implies the existence of social intercourse, the passing of representations between individuals within a community.

It is in this context that Bartlett carried out his experiments on “repeated” and “serial” reproductions, also reported later in his classic volume on *Remembering* (Bartlett, 1932). In 1923 he published his *Psychology and Primitive Culture* in which he sought to analyze the social-psychological processes of culture change resulting from contact and borrowing. When expounding the principles underlying cultural transmission, Bartlett made extensive use of anthropological illustrations, largely drawn from North America and Boas in particular. The psychological theory underlying his analysis was that of McDougall (1908). Although it is evident in hindsight that the work suffered from considerable flaws, it constituted the first systematic attempt to interpret anthropological data in psychological terms; he also recommended the method of serial reproduction as a promising tool for the experimental study of cultural transmission.<sup>24</sup> In his later writings, the theme of culture recurs frequently, but he made little further empirical or theoretical contributions.

### The Interwar Years: 1929s and 1930s

During the 1920s and 1930s, British psychologists generally displayed hardly any interest in culture, and British social anthropologists turned away from psychology. This was because their main inspiration had become Durkheim, who focused on “collective representations” and did not believe that what he understood by “psychology” was relevant for the study of societies. Yet, in fact, he and his followers deduced a kind of social psychology from social (we would say *cultural*) facts. For example, Marcel Mauss, in his classic essay on *The Gift*, used ethnographic material to deduce psychological principles involved in social exchanges that he regarded as universals. Similarly, Lucien Lévy-Bruhl (1857–1939) attributed a “pre-logic” to “primitive peoples,” yet without describing them as childlike. Following Lévy-Bruhl, the early Piaget went even further when painting a picture of what he took “primitive society” to be:

In a society where generations place all their influence on each other, conditions necessary for the

elimination of childhood mentality cannot appear. There is no discussion, no exchange of points of view. . . . There are thus only personalities who do not know themselves and a group which is everything. In such a situation nothing is created by individuals, and nothing extends beyond the level of childhood thought.

(Piaget, [1928] 1995, p. 207)<sup>25</sup>

All such writings were about what we would now regard as culture, but in France this term was very seldom used until fairly recently. That was a matter of linguistic usage, but for quite different reasons some British anthropologists became somewhat disparaging about the notion of *culture* during the interwar years. Radcliffe-Brown dismissed it as “a vague abstraction” (Radcliffe-Brown, [1940] 1952, p. 190). Yet anthropologists could not really do without some kind of psychology, and so they made up their own. Radcliffe-Brown used the concept of “sentiments,” and Malinowski (who *did* use the concept of *culture*) elaborated a “theory of needs” whose aim was to provide a basis for analyzing human behavior in any culture (cf. Piddington, 1957). Generally, they had scant use for the then prevailing academic psychology.

Matters were very different in America, where for Boas culture had been a key issue, and he had always been keenly interested in psychology; and Boasians dominated the anthropological scene during that period. Two of his most prominent students were Ruth Benedict (1887–1948) and Margaret Mead (1901–1978), both very much concerned with the relationship between culture and psychology. Benedict’s famous *Patterns of Culture* ([1934] 1946) was partly inspired by Gestalt psychology, and the emphasis she placed on psychological features is clearly seen in the following passage:

Within each culture there come into being characteristic purposes not necessarily shared by other types of societies . . . Taken up by a well-integrated culture, the most ill-assorted acts become characteristic of its peculiar goals, often by the most unlikely metamorphoses. The form that these acts take we can understand only by understanding first *the emotional and intellectual mainsprings of that society*.

([1934] 1946, p. 42; emphasis added)

Mead took courses in psychology before becoming a student of Boas at Columbia University. The task Boas set her was to research the way in which the personality reacts to culture and she did that in

several cultures in the South Pacific. As the titles of her famous trilogy (shown below) indicate, psychological aspects of culture were salient for her:

Mead, M (1928). *Coming of Age in Samoa; A Psychological Study of Primitive Youth for Western Civilization*

Mead, M (1930). *Growing Up in New Guinea; A Comparative Study of Primitive Education*

Mead, M (1935). *Sex and Temperament in Three Primitive Societies*

All three books were aimed to persuade western readers that culture is more important than biology in shaping personality and behavior. An admittedly impressionistic scan indicates that Benedict and Mead were almost the only anthropologists occasionally mentioned in early post-war psychology texts. Yet in two interwar handbooks of social psychology (Murchison, 1935; Murphy et al., 1937) *culture* had figured prominently. Several noted anthropologists contributed to the former, and the latter included the following warning:

... the concept of culture ... has awakened us to an immensely important fact regarding the limits of social psychology. It must be recognized that nearly all the experimental work in social psychology ... has value and is definitely meaningful only in relation to the particular culture in which the investigation was carried on.

(Murphy et al., 1937, p. 7)

These wise words were later forgotten, or at least not acted upon, and that remains true even today for most of experimental social psychology.<sup>26</sup> Yet there was a period when *culture* was taken seriously,<sup>27</sup> and it is an intriguing question why that concept subsequently suffered an eclipse in psychology. Farr (1996) suggests that it resulted from the rise of behaviorism and that may well be part of the answer: both the handbooks mentioned above were in varying degrees inspired by Darwinian evolutionism rather than behaviorism. Yet that cannot be the whole answer since Floyd Allport ([1933] 1969), archpriest of behaviorist social psychology, did discuss the notion of *culture* in several passages. He argued against cultural determinism and regarded the culture-versus-nature dichotomy as misleading.<sup>28</sup> For Allport, culture consisted of *habits* that, although learned from the social environment, are “organically grounded” (p. 508). He did not specify against whom his arguments were directed, but it was probably the Boasian anthropologists.

The year of the outbreak of World War II saw the beginning of what came to be known as the culture-and-personality school. Its main exponent was Abram Kardiner (1939), an unorthodox psychoanalyst, who collaborated with several anthropologists. This school sought to link subsistence type, child training mode, and belief systems. It was later described by Bruner as “a magnificent failure.” Yet it generated during the post-war years the field of “psychological anthropology,” which continues to flourish.

Later still, more than half a century after the pioneering work of Rivers, “cross-cultural” psychology emerged, to be followed by “cultural psychology.” But that is another story.

## Concluding Overview and Future Directions

The broad overview that has been presented here is unavoidably rather sketchy. Nonetheless, it should be sufficient to support the claim made in the introduction that despite varying terminology, there shines through an ever-present interest in other people’s “customs”—to use the most common term of the past. Differences held a fascination, and there was a good deal of speculation about their causes, climate being the prime candidate; it was not until the Enlightenment that such causes as ecology and modes of subsistence were proposed, in a manner not unlike that still prevailing.

A related issue sometimes raised was that of nature-versus-nurture as the cause of differences. Over most of the period, nurture predominated, with a sharp reversal during the nineteenth century when “race” came to the fore. Yet it was after the middle of that century that the terminology began to change and *culture*—the name, not the concept—entered the vocabulary. For quite some time confusion prevailed, even in so acute a mind as that of Wundt: no clear distinction was made between culture as a universal and the multitude of cultures over the globe.

From earliest times, the notion of custom was indissolubly linked with psychological aspects. For differences in customs entailed differences in beliefs and behaviors, and these features were often noted and even emphasized as early as Herodotus more than two millennia ago. As some writers on culture such as Cole (1983) and Shweder (1990) have it, culture and mind are really different facets of the same phenomenon.

## Notes

1. In modern French/English dictionaries, the first translation given for *culture* is generally still “cultivation.”
2. For example, the German title of Freud’s book first published in 1930 was *Das Unbehagen der Kultur* (The uneasiness of culture); the English translation was “Civilization and its discontents.”
3. For a discussion of current usages in the context of culture and psychology, see cf. Krewer & Jahoda (1993).
4. In anthropology, they are called “ethnopsychologists.”
5. For some of the material in this section, I am indebted to Chakkarath (2003).
6. Much the same proposal, although more sophisticated, was put forward by the *Société des Observateurs de l’Homme* in late eighteenth century.
7. For a detailed account, see cf. Peters (1962).
8. The north–south divide continued to be regarded as a key factor, but the values attributed to them varied according to the writers own geographic position. For Europeans, north was good, for Muslims, it was bad.
9. All the following quotations, where only page numbers are indicated, are derived from Slotkin.
10. The expedition, which included a majority of natural scientists, was dogged by ill fortune from the start. Although it produced some interesting findings, this was at a heavy cost: one-third of the personnel (including the leader) died on the voyage.
11. Until the cross-cultural work of Rivers (1901), it was widely believed that “savages” had more acute senses.
12. Humboldt’s views greatly influenced the *Völkerpsychologie* of Lazarus and Steinthal.
13. “Cultures from this point of view are individual psychology thrown large upon the screen, given gigantic proportions and a long time span.” (Benedict, 1932, p. 24).
14. For a detailed analysis, see cf. Kroeber and Kluckhohn (1952).
15. It is a particular kind of comprehension specifically related to human behavior.
16. In his rather indigestible *Philosophy of Spirit*, Hegel assumed the existence of spiritual facts that cannot be described as subjective states of individual persons but that have an independent, objective existence.
17. For an account of this method, see cf. Jahoda (1991).
18. There is no exact equivalent to *Wissenschaft* in English; the word is usually, and misleadingly, translated as “science.”
19. Because “psychic factors” are also present in animals, Paul argued that one has to recognize the category of animal culture and therefore include the study of animal behavior among the *Kulturwissenschaften*. At the time that was regarded as absurd, but the existence of “animal culture” is now accepted.
20. Georges Cuvier (1769–1832) was a distinguished French naturalist.
21. This is not strictly true: In his later years, Tylor became persuaded that race differences in the complexity of the convolutions of the brain set limits to the progress of some races.
22. *Habilitation* is an examination by thesis that entitles the candidate to consideration for a chair.
23. Some years later, the German anthropologist Richard Thurnwald (1913) carried out some psychological studies in the Solomon Islands. He explicitly referred to cultural factors in cognition (p. 4).

24. This claim has more recently been renewed by Kashima (2000).

25. For a more detailed discussion, see cf. Jahoda (2000).

26. For a complaint about the neglect of culture, see cf. Jahoda (1988).

27. It must be said, however, that during the 1930s the topic of “culture” was greatly outweighed by that of “race differences.” This literature has been surveyed by Richards (1997).

28. “It seems almost as though the individual becomes a product of the ‘group’ or of ‘society,’ rather than of his own biological ancestry. Viewing human development in this light, certain social scientists have proposed that all this range of modifications of the original tendencies should be set apart from these tendencies themselves as a separate category, to which the name ‘culture’ or ‘civilization’ should be applied. Thus arises the notion of *culture* as something entirely distinct from, and even antithetical to, *human nature*.” ([Allport [1933] 1969, pp. 507–508).

**Abstract**

*Völkerpsychologie* is, so to speak, the grandfather of cultural psychology who has been left sitting in the corner, full of nostalgia, while yearning for and dreaming of the old days when ambitions and spirits surrounding his existence ran high and dedicated disciples tried to use his knowledge to explain complex mental phenomena. However, it is not the case, as many would like us to believe, that *Völkerpsychologie* needs to remain an outdated model that has no connection with the present. Many of its problems stem from language barriers, lack of cultural-historical understanding, and the absence of any considerable synthesis that would present it as a unified theoretical model ready to be applied in today's research. *Völkerpsychologie*, like cultural psychology, is still a work in progress, albeit one that has been left to fend for itself without anyone seriously considering its continuation or integration.

**Keywords:** Völkerpsychologie, culture, history of psychology, Wundt, folk psychology

“*Die Personen vergehen, aber die Völker bestehen*”  
—Wilhelm Wundt, 1914, p. 4

It is almost hard to believe that less than 100 years ago, the name *Völkerpsychologie* was once widely used, becoming a part of the vocabulary of the educated German public, psychoanalysts, and ethnographers alike (see Jahoda, 1993). But since then, much has changed. Nowadays, *Völkerpsychologie* has sunk into the abyss of time, and through this chapter I hope to spark some readers' interest in the rich theoretical literature, certainly beneficial to the study of culture and psychology, that is gathering dust in the archives of libraries throughout the world.

Giving an adequate translation of the term *Völkerpsychologie* is virtually impossible. Its broad use and distinct “German-ness” makes it especially difficult for non-Germans to grasp. At its core, *Völkerpsychologie* relies heavily on ethnology and

focuses on the psychological aspects of ethnicity. However, in the strictest sense, *Völkerpsychologie* is to be translated into “peoples' psychology” or *folk psychology*, and it was to present an alternative to “person psychology” or “individual psychology.” It is clear that readers who are familiar with *Völkerpsychologie* would be quick to raise objections with the aforementioned translation. For example, Danziger (1980, p. 303) called folk psychology an “absurd mistranslation” of the discipline. To be sure, folk psychology is not ideal, as it brings with it a lot of connotations. However, as *Webster's Dictionary* (1987) defines folk as either “a group of kindred tribes forming a nation” or “the great proportion of the members of a people that determines the group character and that tends to preserve its

characteristic form of civilization and its customs, arts and crafts, legends, traditions, and superstitions from generation to generation,” it may well be the closest translation to the original word.<sup>1</sup> Further, the term *folk psychology* was used as the translation of *Völkerpsychologie* by E.L. Schaub, who translated (with the cooperation of the author) Wundt's *Elemente der Völkerpsychologie*. Thus, in an effort to remain true to the original intentions, the German term will be applied throughout this chapter.

### Language, *Weltanschauung*, and the Origins of *Völkerpsychologie*

There may be little doubt that *Völkerpsychologie* finds its roots in German idealism and can be especially said to have been influenced to some degree by the philosophies of Hegel,<sup>2</sup> Herder, and, notably, Herbart (Jahoda, 1993; see also Danziger, 1983; Eckardt, 1997; Krueger, 1915; Schneider & Müller, 1993; Volkelt, 1922; Wundt, 1877). Nonetheless, it is Wilhelm von Humboldt (1767–1835) who is generally credited to have laid the immediate groundwork for *Völkerpsychologie*<sup>3</sup> (Krueger, 1915; Volkelt, 1922). Humboldt, a philologist, philosopher, statesman, and one of the founding fathers of the University of Berlin (1810), has also been described as one of the founding fathers of neo-humanism (Knoll & Siebert, 1967). This is largely because of his idea that education (*Bildung*) operates on two levels: first, that the goal of humans is education on the individual level and second, that education serves the purpose of broader humanity—namely, to reach an ideal.

It is important to recognize that *Bildung* does not necessarily mean education in the scholarly sense but includes the education we gain from all aspects of life. According to Humboldt, the education of the individual occurs through historical experience. Here the need for synthesis occurs when the broader masses pass down ideas to the individual. The connection between individuals occurs through understanding, which in turn occurs through language. Hence, language assumes a central position when we try to understand and analyze humans. It may not be surprising, then, to learn that language was to become one of the main themes in *Völkerpsychologie*.

However, language is not a complete product; rather it is a process that contains a historical character (Steinthal, 1860). This character is “shaped” through the individual, the *I*, who speaks it. But the individual is also limited to that understanding for which language allows. The *geistige* (spiritual/mental) attachment to language occurs through the respective

language community. Through this language community, a self-awareness begins to emerge, one in which we come to realize that we are not isolated individuals, rather we are *I*s who are located in a language community relative to a *YOU*.

Language is one of the primal strengths of humans. According to Humboldt, every language contains its unique form, based on a particular *Weltanschauung*. That is, our outlook on the world is built in language because those who share a language develop a similar subjectivity. By being born into a language community, humans are immediately exposed to a particular relationship with their world. Because of language, this relationship is to a large extent mental (Volkelt, 1922). In other words, language can be seen as the creating force as well as the tools of higher mental processes.

For Humboldt, language was a lively process, one that never rests and thus cannot be truly captured by any signs. Hence, for him the true definition of language could only be a developmental (*genetische*) one (Krueger, 1915, p. 7). Through vocalisms, the internal language form could be discovered; it develops through the interaction of objectivity and fantasy with momentary moods. It is precisely the feeling-factor (*Gefühlsfaktor*) that enhances the subjective occurrences in the listener. Although language receives its final definitions within the individual, the continuity of language forms is only guaranteed through life within society, and thus the entire objectivity of human thought rests therein. This would be precisely the point on which the pioneers of *Völkerpsychologie* would touch base.

### *The Zeitgeist: A New Psychology Discipline in the Making*

Somewhat comparable to the Greek city-states of antiquity, Germany had developed a national culture in the late eighteenth century but was split into numerous independent states. Since the days of Johann Gottfried Herder (1744–1803) at the latest, German philosophers had come into contact with the idea that social relations are not only grounded in power, but also involve cultural communities (i.e., *das Volk*). The notion of nationalism, albeit certainly a preoccupation of the upper classes, found increasing (although nowhere near overwhelming) support. This was well-reflected in the political arena prior to 1866, when there was a general political struggle for and against nationalism between liberals and conservatives (see Eckardt,

1997). It is precisely through this political climate that we see *Völkerpsychologie* emerge.

In 1860, Moritz Lazarus (1824–1903), a professor of psychology in Bern, and his brother-in-law, Hajim Steinthal (1823–1899), a philologist from the University of Berlin (for a biographical review, see Eckardt, 1997), began the task of developing the new academic discipline of *Völkerpsychologie*. As with any fresh start, getting an ambitious program underway was no easy undertaking. The term *Völkerpsychologie* was, of course, not chosen for the purposes of attracting fame or to announce that something new had been discovered; rather, it was to draw attention to an area that had only recently been approached and still needed further development (Steinthal, 1891, p. 11).

The central aims of *Völkerpsychologie* were to investigate the psychological aspects of groups of people living in communities bound by common language, myths, and customs. In the midst of international unrests and conflicts between neighboring countries, it seemed that the time was right for a psychological discipline that would account for the national character of people to better understand their ways of thinking. After all, the German-oriented states and the young republic of France had not been the best of neighbors, and their frequent disputes had led to much bloodshed.

The trend for a nationalistic-oriented psychology is nicely captured in a letter that Lazarus wrote to his friend Paul Heyse on November 29, 1870 (during the Franco-Prussian War):

*France is a beacon in the midst of chaos. I personally do not yet have the courage to dissect this issue with my folk-psychological (völkerpsychologisches) scalpel . . . , but my thoughts of course are all around that topic, and I can already say today: the big, though futile, displays of strength of the French, which will cost us and them much bloody work, will only serve to make us stronger, and them for the future more cautious, hopefully also better, and will uphold, foremost, the dignity which seemed to have come to an end with Sedan and the pitiful republic.*  
(as quoted in Schneider & Müller, 1993, p. 94)

It certainly seems that the national feeling was a driving force in Lazarus's approach to *Völkerpsychologie*. After the Franco-Prussian War of 1870/71, under the leadership of Wilhelm I and Otto von Bismarck, the German people saw unification come true, as Germany was finally united and declared an Empire in the Hall of Mirrors in Versailles on January 18, 1871 (see Noble et al., 1994), thereby reigning

in what became known as the "Second Reich" of Germany. Although the unification was marked by authoritarian aristocracy, the German identification as separate peoples, *das Deutsche Volk*, caught on. German preoccupation was to lay with honor and dedication to their community<sup>4</sup> or folk (*Volk*), and with that general notion of distinctness among different "tribes," the focus of psychology needed to expand to include the study of that *uniqueness* of different *Völker*, social classes, or ethnic groups. That is, the study of psychology was also to include the products of collective mental processes of peoples identified as a unified body (e.g., the Germans), distinctly separate from others (e.g., the French). Individual psychology was limited to the focus of the capabilities of one person. However, the person was always part of relationships with the masses (e.g., family, community, society, etc.). Hence, the need arose to expand the investigation to include collective capabilities of peoples living together and how a person "evolved" within that "togetherness."

### ***Völkerpsychologie: The Individual As Part of the Volk***

Much debate of early *Völkerpsychologie* surrounded the notion of individual versus collective spirit (*Geist*) and soul (*Seele*). The underlying question was whether it was possible to study collective mental phenomena. Such a study was indeed seen as possible as society dominates over its individual members. Lazarus and Steinthal (1860) defined the *Volksgeist* (or collective spirit) as "the inner activity, according to content as well as form, which each individual has in common with the *Volk*; or: that which each individual has in common in terms of inner activity" (p. 29). The *Volksgeist* was to be governed by the same principles as the individual spirit; however, the collective was much more complex and extended (see Jahoda, 1993). In any case, the *Volksgeist* could be objectively studied by examining intrapsychic events: thoughts, sentiments, and dispositions that were objectified through books, art, and other products of cognitive processes (Eckardt, 1997; Jahoda, 1993).

For Lazarus and Steinthal (1860), psychology represented a third science, placed between natural science and history (p. 16). Psychology differs from natural science because it makes the human spirit the object of investigation, something materialists would undoubtedly see as a mere appendix to physiology. However, psychology does look for underlying laws that govern psychical processes. Because humans are ever-changing, their mental capacity

needs to be seen as being in a constant, never-ending, dynamic state of “becoming.” With the experiences we gain, we grow, and as a result our *Volk* becomes different over time. Therefore, psychology needs to account for the dynamics of society, the historical forces, and the complex web of social structures in which individuals find themselves.

Both Lazarus and Steinthal repeatedly warned their readers of the incomplete picture given when examining humans only from an individualistic perspective, without regard to their place within human society (e.g., Lazarus, 1862, 1865; Lazarus & Steinthal, 1860; Steinthal, 1887). They proposed that one should study the spirit of people as part of a community or society. Similarly to Humboldt and Herbart, Lazarus and Steinthal reasoned that no man has become what he is because of himself; rather, man has become what he is through being part of a larger community. It was Lazarus and Steinthal’s (1860) belief that humans cannot be raised in solitude, and that those few who have been raised in the forest, absent from civilization and other companions, resembled humans merely through their physical similarities (p. 3). Humans are social beings, and to understand them, we must examine them from a *Volk* perspective; we must understand the influences society has on them and how humans develop within the social structures and through the social tools (e.g., language) that have been passed down from one generation to the next. Hence, of primary importance for *Völkerpsychologie* was determining the relationship between the whole and the individual (p. 31).

Moreover, Lazarus and Steinthal (1860, p. 5) warned their readers not to separate society and the individual so that one looks at the individual, then society, and then puts one into the context of the other. Instead of retroactively attributing certain social influences to the individual, the object of investigation was to be the dynamic processes of the two that intermingle in complex ways. *Gesellschaft* (society) cannot be broken down into smaller circles, such as families, without realizing that they are constantly connected to a *Gemeinschaft* (community). Psychology would always be one-sided if it were merely to examine the person without context. Or as Lazarus (1862) put it:

We cannot emphasize the following enough, society does not consist of individuals as such, rather it is within and from society that individuals exist.  
(p. 419)

For Lazarus, the individual receives his/her properties through being linked within society, through

being parts of the whole, through being a participant and representative of societal values. Only the collective idea or spirit of the *Volk* brings meaning to the individual. After all, ideas do not emerge from nowhere; rather, they transform from previous ideas that have been passed down through communal efforts. Thus, our “individuality” is integrated in our community.

In fact, identification with the *Gemeinschaft* is what gives *Volk* its meaning. We, as a *Volk*, share similar dangers, faith, happiness, and identities. According to Lazarus and Steinthal (1860, p. 35), membership in a race is based on objective criteria (e.g., skin color, but also bone structure, etc.); however, membership in a *Volk* is based on inherently subjective standards. We identify and choose to be a member of a *Volk*, and the *Volk* recognizes us as a part of them. This notion of belonging is a bidirectional, dynamic process (*Wechselseitigkeit*). In this sense, *Völkerpsychologie* positioned itself alongside individualistic psychology so that it became its necessary extension. The myriad of questions posed by psychology can only be answered by the combined efforts of both *Völkerpsychologie* and individual psychology.

### Lazarus and Steinthal’s Program for *Völkerpsychologie*

For Steinthal (1887, p. 248), the myriad of questions psychology poses could be addressed by a research program sorted into the following three categories:

I. General Psychology: The study of mechanisms of thoughts/imagination (*Vorstellungen*), feelings (*Gefühle*), and drives (*Triebe*).

II. *Völkerpsychologie*: The study of the collective “mental” (*geistige*) life. [This implies the coexistence of members of society living together. *Völkerpsychologie* can be divided into] (a) synthetic *Völkerpsychologie* [see Lazarus, 1865], which deals with the general requirements of collective mental life, and (b) the use of these requirements within ethnology, pre-history, and history. It needs to be added that whereas (a) results in a self-standing theoretical construct, (b) only exists implicitly.

III. Individual Psychology [the reader may want to note that Steinthal lists this at the end]: The study of the individual, which can only be examined within the historical context of a given culture. Individual psychology, in a synthetic form,

is incorporated within the previous two categories, but its application appears in biographies.

The task for *Völkerpsychologie* was to objectify collective mental life to be able to study it. That is, wherever people are living together, the result of their “togetherness” is that subjective processes manifest in objective content, which in turn becomes the norm and organ of the former. Lazarus (1865, p. 41) takes language to exemplify this idea. When several individuals operate under similar motives and conditions, thereby sharing a common understanding, the subjective activity of talking results in an objective language. This language then represents objective content for the subsequent speech acts of the individuals. It provides laws for thoughts and further represents the organ that is open for further development through ensuing speech acts by all members of society. What has been born through the actions of individuals in relation to others (or the self) becomes a mental content that rises beyond the individual. It becomes generality vis-à-vis the actions of the individual. In short, we are molded by the “organ,” which in turn is molded by us.

For Lazarus and Steinthal (1860), the objectification of collective mental life—that is, the core program of *Völkerpsychologie*—was broad and could be found in language, myths, religion, customs, art, science, law, culture, and, most notably, history. It was especially the historical aspect that was important for the emerging discipline of *Völkerpsychologie* because it attempted to understand the history of humanity and its peoples (*Völker*) through which psychical laws were revealed (Lazarus, 1865, p. 2). We needed to understand the historical forces that underlie collective life; hence, analysis of history combined with the synthesis of *Völkerpsychologie* would result in the discovery of the very nature of collective mental life (*Volksgeist*). Only through such a program would we be able to understand such constructs as individual personality because only in and through the community does the person become a “mental/spirited” being (*geistiges Wesen*). As Steinthal (1891) would later say, “The spirit (*Geist*), before it becomes individual and personal, is in reality a collective spirit, a spirit of the entirety (*Gesamtheit*), an objective spirit, and it is that which forms the object of *Völkerpsychologie*” (p. 12). It should be made clear that none of the advocates of *Völkerpsychologie* saw the spirit (*Geist*) as a mystical substance; rather, it should be understood similarly to how we interpret the concept of mind. It goes without saying that such concepts remain,

then and now, inherently controversial and difficult to define.

#### THE SPIRIT OF EARLY VÖLKERPSYCHOLOGIE AND THE JOURNALS THAT MADE IT FAMOUS

Lazarus and Steinthal’s central aim was to achieve a synthesis of the humanities and social sciences in regards to the study of the *Volksgeist*—to study the collective mind through the combined forces and the strengths that each academic discipline could bring to the table. This spirit is nicely captured through Lazarus and Steinthal’s (1860, p. 1) opening statement in the first volume of *Zeitschrift für Völkerpsychologie und Sprachwissenschaft* (*Journal of Völkerpsychologie and Speech Science*), where they invited all researchers to participate:

*We are not only asking those men who are working in the field of psychology, rather we are asking anyone who is investigating the historical appearances of language, religion, art, literature, science (Wissenschaft), customs, law, the societal-, home-, and state- constitutions; in short, we are asking everyone who is researching the historical life of ‘civilizations/cultures’ (Völker) in any of its manifold aspects, so that the discovered facts out of the most inner workings of the ‘mind’ (Geist) can be explained, hence, revealing their psychological causes.*

What ensued over the next 30 years of the journal’s existence was an accumulation of 200 original works that, perhaps not surprisingly, had little to do with its contemporary psychology that was building up along the lines of natural sciences. However, Eckardt’s (1997, p. 72) claim that under the numerous reviews published in the first 20 volumes of *Zeitschrift für Völkerpsychologie und Sprachwissenschaft*, not a single one addressed the pioneering breakthroughs of Fechner, Helmholtz, Wundt, Ebbinghaus, and other experimental psychologists may be somewhat misleading.<sup>5</sup> Nonetheless, the great majority of the journal’s articles (67 of 200) focused on issues surrounding linguistics (*Sprachwissenschaft*), followed by religion and mythology (26 articles).

Many of the controversies surrounding early *Völkerpsychologie* (see Eckardt, 1997; Jahoda, 1993) are comparable to what Valsiner describes as “ideological taboos” (2001) or “theories as identity markers” (2004). Indeed, the topic of culture has again become very fashionable, and today’s institutional taboos may well be much more rigid in regard to methodology than in the heydays of *Völkerpsychologie* when the spirit of the great pioneers ran high while

they embarked on their quest to discover the collective manifestations of the inner workings of the human mind. This is not to say that German academia was not riddled by politics (which has been discussed in detail by Ash, 1995); rather, it is to point out that at the very least not much has changed in regard to trying to enforce proper etiquette for psychology research methodology along with the political maneuvers that would help establish ideological supremacy for one's own approach at the expense of others.

Volume 20<sup>6</sup> of *Zeitschrift für Völkerpsychologie und Sprachwissenschaft* brought the first epoch to a close. The grand synthesis had not yet occurred, and *Völkerpsychologie* was far from being guided by a unified systemic approach, free of controversy (thus, no different than the general state of psychology today). The predominantly philological approach of the journal had not helped much to shed light on the *Volksgeist*, and a fresh start was needed. This new start was announced on the first five pages of Volume 20, when Weinhold (1890) announced a new scientific (*Wissenschaft*) discipline—namely, that of *Volkskunde*. The literal translation of *Volkskunde* is folklore; however, in his opening as well as closing statements, Weinhold was careful to distinguish between those folklorists who merely collected folk-traditions as if it were a fashionable sport<sup>7</sup> and those who took the matter seriously—that is, from a scientific (*wissenschaftlichen*) perspective. To the latter belonged those people who were familiar with “history and linguistics, with anthropology and psychology, with the history of jurisprudence, with history of national economics, of natural history, literature, and art” (pp. 1–2). When done correctly, *Volkskunde* was to become a national and historical science with the aim of examining a *Volk* in all its life expressions (*Lebensäusserungen*). First, the new discipline would have to research a particular *Volk*, and only then could one make comparisons and conclusions, which should eventually merge with anthropology. After all, anthropology and *Volkskunde* had the same scientific end-goals.

Weinhold (pp. 2–4) went on to say that body and mind, or material and spirit, would present the two main halves of the new field. The first half would explore the physical appearances of a *Volk*. It would need to penetrate the historical conditions of a *Volk*, the gradual development, its relationships, and its geographical distributions. In short, the terrain upon which the *Volk* lived needed to be historically explored. The next step required that the lives

of members of a *Volk* were to be made the object of investigation; in terms of how morals and customs left their mark. In this regard, birth, the selection of names (baptism), childhood, education, love, marriage, aging, and dying would all represent points of interest. Weinhold believed that these morals and customs had developed over a long period of time and could be traceable through people's folklore. A related section would be the material that provides the basis for physical life. To this area belong the different methods and conditions through which we take our nutrition, including living conditions, clothing, and technical material (*see also* Weinhold, 1891).

The second area of *Volkskunde*, the mental/spiritual one, would first need to address religious conceptions and customs. To this area belonged all belief systems, and especially the beliefs in those *Gestalts* that are anchored in the fantasy and feelings of a *Volk*, developed over time, that have been brought forward to consciousness from the days when demonic forces ruled over man and earth. Certainly fairy tales and sagas would prove to be a rich source of those “dark” ages but also poetry (especially those poesies that could no longer be traced to a particular person and that have not been taken over by other *Völker*), songs (especially children's songs), melodies, dances, legends, riddles, and, from all this, most importantly language would provide an immense treasure chest for gaining access to the historical mental roots of a *Volk*. In this respect it needs to be mentioned that language was important from the psychical perspective—that is, not in terms of grammar (which was to be left to linguists) but rather in terms of how sentences, sounds, and words found their origins (Weinhold, 1891, p. 7). Of particular interest would be the study of words<sup>8</sup> and how their meanings emerged over time—how certain semiotic mediations were conveyed through statues, and later through live talk (i.e., speeches).

Similarly to Lazarus and Steinthal's opening remarks in the *Zeitschrift für Völkerpsychologie und Sprachwissenschaft* back in 1860, we again find a remarkable enthusiastic spirit in Weinhold's (1891) call for participation in this transformed program when he writes, “[W]e wish that the cultural researchers in the Netherlands, in the Scandinavian lands, in England and America will join us in our brotherly ranks” (p. 10). With the new aims in mind, the *Zeitschrift für Völkerpsychologie und Sprachwissenschaft* got transformed into the *Zeitschrift des Vereins für Volkskunde* (*Journal of the Volkskunde Association*),

with Weinhold replacing the aging Steinthal as editor in 1891. It is an often overlooked fact that the former journal did not end after 20 volumes *per se*; rather, it merely took on a new title to capture its new approach but retained the earlier title as a sub-heading for several more years.<sup>9</sup>

The 26 volumes of *Zeitschrift des Vereins für Volkskunde* are filled with in-depth analysis of topics from around the world, such as fairy tales (e.g., by the Grimm brothers), *Volk* riddles (e.g., “The Riddle of the Fish in the Water” by Robert Petsch), *Volk* customs (e.g., “The Use of the Death-Crown in Germany” by Otto Lauffer), rhymes, songs, sagas, poetry, mysticism, biographies, religious practices (e.g., “The Journey of the Soul into the Afterlife” by Julius von Negelein), gender studies (e.g., “The Woman in Islam” by Martin Hartmann) ... in short, the diversity in contents by far surpasses those volumes edited by Lazarus and Steinthal from 1860 to 1890. The choice to refocus the attention of the discipline away from linguistics and instead toward the study from the *Volk* about the *Volk* in a manner that includes folklore, but is not itself folklore, provided a means to broaden the perspective from which to investigate collective mental processes.

To alleviate the confusion about the differences between *Völkerpsychologie* and scientific *Volkskunde*, Steinthal (1891, p. 17) captured the fundamental difference by emphasizing that it is not that each of them takes a different slice from mental occurrences; rather it's in the *way* the two disciplines look at them. If it is done in a more synthetic way, then it is called *Völkerpsychologie*; if it is done more analytically, then we count it as *Volkskunde*, or history. In any case, *Volkskunde* would always be a psychological discipline, as the spirit (*Geist*) of any person, no matter how distinguished he/she is, always rests within the *Volk*. However, despite its ambitions, no systematic synthesis of materials can be found within the editions of *Zeitschrift des Vereins für Volkskunde*. It seems that this was left to be done by a later generation of researchers.

### **Wilhelm Wundt's Völkerpsychologie**

Wilhelm Wundt<sup>10</sup> (e.g., 1888, 1911, 1917) had been an avid reader of Lazarus and Steinthal's publications on *Völkerpsychologie*, and he agreed that the discipline was a necessary extension of the individualistic approach.

Just like it's the objective of psychology to describe the actuality of individual consciousness, thereby

putting its elements and developmental stages in an explicatory relationship, so too is there a need to make as the object of psychological investigation the analogous genetical and causal investigations of those actualities which pertain to the products of higher developmental relationships of human society, namely the folk-communities (*Völkergemeinschaft*). (Wundt, 1888, p. 2)

The simple, elementary mental processes could be studied via internal perception (*innere Wahrnehmung*). This should not be mistaken for introspection, however. In fact, Wundt was opposed to the form of introspection (*Selbstbeobachtung*) that J.S. Mill or Edward Titchener would much later advocate (Danziger, 1980). For Wundt, as for many other psychologists of those days, introspection was closer to retrospection, or the observation of an unreliable memory image. Instead, Wundt proposed that the processes we want to observe can be produced via experimental presentation of respective stimuli (Diriwächter, 2009). These experimental situations, however, were limited in their scope and did not allow for the examination of the higher processes of thought. Experimental internal perception was usually limited to examine simple relationships as they occurred but not higher mental processes.

To understand higher psychological processes, only historical comparisons, the observation of our mind's creations (*Beobachtung der Geisteserzeugnisse*), could be looked at. It was these products that Wundt saw as central to *Völkerpsychologie*. The simple psychological experiences were to be studied experimentally, whereas the products of the higher processes (which could be seen as having properties of “objects of nature”) preceded the folk-psychological analysis. With Wundt, *Völkerpsychologie* was to fill the voids of the limited applicable experimental analyses by examining under a historical-genetic approach complex mental functions, thereby determining both the social dimensions of the mind and the psychic processes.

However, for Wundt (1888), the broad conception of what academic fields should belong to *Völkerpsychologie* made it vulnerable to attacks. Wundt was especially opposed to integrating history *per se* (a core component of *Völkerpsychologie* for Lazarus and Steinthal) on the grounds that (1) history is already integrated in the subdisciplines (e.g., language, myth, art, etc.) of *Völkerpsychologie*, and (2) there is a great risk of making causal inference

on historical grounds without accounting for natural and cultural factors (Wundt, 1888, pp. 3–7). In other words, there is the risk of psychologizing history, something that was certainly not the objective of *Völkerpsychologie*. Instead, Wundt proposed that *Völkerpsychologie* should be divided into the following main areas: language, myth, customs, and morals.

What these areas have in common is that they originate in communal life. They are further related because they have an historical context. The roots of this assumption can be found already in the works of Johann Georg Hamann (1730–1788) and Johann Gottfried von Herder (1744–1803), who tried to supplement Immanuel Kant's philosophy of pure reason with a philosophy of language, culture, and history (Nerlich & Clarke, 1998, p. 181). Aside from language, it was especially historical development (not to be confused with history as a discipline) that was central to Wundt's *Völkerpsychologie* in that it gave direct insight into the products of creative synthesis of many individuals.

#### WUNDT'S VÖLKERPSYCHOLOGIE AS A SOCIAL-DEVELOPMENTAL PERSPECTIVE

For Wundt (1888, 1911, 1912, 1917), *Völkerpsychologie* was, in essence, a social-developmental discipline: social because it predominantly moves within societal dimensions; and developmental because it also needs to examine the different steps of mental development in humans (true psychogenesis), from underdeveloped to higher cultures (it goes without saying that the supremacy of one culture over another is in the eye of the beholder).

Examining the products of higher mental processes brings with it a myriad of methodological problems, most notably that products of mental processes are subject to interpretations. It is important to note that this applies not only to *Völkerpsychologie* but also to any division of psychology. However, it is especially the broad perspective of *Völkerpsychologie* that has raised the eyebrows of the critical investigator. For example, unlike his predecessors (i.e., Lazarus and Steinthal), Wundt (1912) attempted a form of *völkerpsychologische* synthesis in his *Elemente der Völkerpsychologie*, where he traced the roots of modern man by emphasizing a seemingly universal primitive man (*Urmensch*). The connection can be traced through various developmental stages: (1) primitive man, (2) the totemic era, (3) the ages of heroes and gods, and (4) the development of

humanity. Examining the different levels of mental development in which humans continuously find themselves is the way of true psychogenesis (Wundt, 1912, p. 4).

In this sense, the continuous progression from one level to the next, including the in-between stages that connect the stages to more complex, higher cultures, makes *Völkerpsychologie* in its true nature a developmental discipline. Each stage has its own unique characteristics that mark the achievements of the group under examination. For example, whereas primitive man is said to be closest to nature, comparable to wild animals, the man of the totemic era is already distinguished by a realization of the possession of a soul. In fact, the totem itself is the manifestation of a soul, either the soul of an ancestor or the soul of a protective being, often in the shape of an animal. In this regard, Wundt (1912, pp. 114–115) carefully noted that the difference between primitive and totem is not necessarily indicative of a lesser and greater development, as humans in both stages are best adapted for their level of development.

Each stage is marked by distinctive characteristics, directly relating to the products of higher level mental processing. More specifically, the products relate to the elements of our psyche, not in an atomistic sense, but rather in an elementaristic sense as pertaining to the units of *processes*. These elementaristic processes, however, make sense only when looked at in relation to the whole. Thus, taking context into account also becomes an absolute necessity.

Nonetheless, Wundt's general claim that he was investigating the historicity of the psyche was somewhat problematic. In his *Elemente der Völkerpsychologie*, it was not always clear whether he was indeed adhering to that claim. That is, what is investigated is not the historicity of the psyche in and of itself but the development of the mental objectifications of psychical activity during the course of history. As Eckardt (1997) points out:

Although the reconstruction of cultural development implies an aspect of historicity in the psyche, it still has to be distinguished if the historical changes of the psyche or the psychological parameters of historical development are the objects of investigation. In other words, the historicity of the psyche is not to be mistaken for psychologizing the historical.  
(p. 104)

The problem of psychologizing history may well be rooted in Wundt's determination to separate

psychology into a lower and higher discipline—an obstacle that Wundt's successors would later overcome (see Diriwächter & Valsiner, 2008). To find general laws about the fundamental psychical functions based on the objectification of complex psychic processes seemed to be a methodological impossibility. The main problem was the jump from one level to the other (i.e., from higher to lower). That is, Wundt was forced to leap constantly from the products of interaction to intra-individual processes, whereby the crucial mediating process never really went beyond general theoretical postulates (Danziger, 1983).

#### CREATIVE SYNTHESIS: FROM ELEMENTARY PROCESSES TO WHOLENESS

*Under the principle of creative synthesis I understand the fact that psychical elements, through their causally related bi-directional processes (Wechselwirkungen) as well as the resulting consequences thereof, create connections which may be psychologically explained through their components, but at the same time those connections contain new characteristics which are not contained in the elements.*

—Wundt, 1894, p. 112

Wundt felt that creative synthesis was the necessary link between the lower mental processes (i.e., sensory perceptions) and the higher processes that give our life meaning. The higher ones were the foundation of *Völkerpsychologie*. However, it needed to be understood that *Völkerpsychologie* was not really a self-standing discipline; rather, it was intimately connected to the lower processes—that is, those connected to physiology (Wundt, 1917), albeit this connection was never truly shown.

Sensations, according to Wundt, are the product of isolated abstractions. They become the end result of psychological analysis when components of a totality can no longer be reduced—that is, they are the elements that precede consciousness/awareness. Nevertheless, although such elementary processes can be temporarily examined in isolation, it needs to be reiterated that they too are constantly connected with other components that lead up to the wholeness of experiences. Although it may well be possible to further abstractly differentiate aspects of the elements (sensations), it comes at a cost: the destruction of the experiential totality. A psychology that takes these elements as the starting point of analysis, from which they build up to create the immediate experience, will always find it impossible

to show the complex state of affairs (*Tatbestände*) from these elements alone (Sander, 1922, p. 57).

It may be helpful to use one of Wundt's (1894, p. 113) own examples on how this worked. When looking at our sensations, every conscious perception (*Wahrnehmung*) can be divided (*zerlegt*) into elementary sensations (the reader may want to note the deductive approach). However, our experience is never just the sum of these sensations (in the additive sense). Instead, through the connections of these sensations something new is created, with unique characteristics that were not contained in the sensations alone. Therefore, although we can abstract elements from a phenomenon, attempting to put these elements together again will not result in the original phenomenon. For example, through numerous light-shades/impressions (*Lichteindrücke*) we create spatial forms (*räumliche Gestalt*). No matter how nativistic our philosophical orientation is, this conscious perception is something creative as opposed to the sum of all the light-shades/impressions, which is the substratum (*Substrat*) of the perceptive act. Wundt saw this principle as valid for all psychical relationships; it guides mental development from the first to the last step.

#### TRANSFORMATION IN CREATIVE SYNTHESIS: ELEVATION TO THE CULTURAL LEVEL?

Volkelt (1922, p. 88) points out that for Wundt, synthesis had a double meaning. First, synthesis is the inverse of psychological analysis—that is, it is a task in which psychologists take the abstracted products of their analysis and place them together again. It must be noted that the object of synthesis (the totality) is the starting point of analysis, and abstracted components need to be reintegrated into the original totality. In other words, synthesis is the inversibility of psychological analysis, a task in which psychologists are capable of reproducing the abstract elements in a synthesized whole. This is where Wundt's primary concern about grasping the person in his/her entirety becomes clear.

The second meaning of synthesis, according to Wundt, is that it is a real genetic process of melding originally unrelated elements. As mentioned above, when we are looking at an object, we may say that it consists of certain elements (i.e., the light-shades/impressions reflected on our retina). However, we do not perceive this object in terms of its elements; rather, it is the object in its totality on which we reflect. The genetic process of melding unrelated elements goes unnoticed, and

our psychological processes thus begin at the level of synthesis. Nevertheless, although unnoticed, the finalized synthesis has undergone a genetic process.

The finalized synthesis is precisely the point that some of Wundt's closest students (e.g., Krueger, 1915, 1922; Sander, 1922; Volkelt, 1922) picked up on when they transformed the Leipzig School into one that took *Ganzheitspsychologie* (or holistic psychology) as its guiding principle (see Diriwächter, 2008 for a discussion on the doctrine and main tenets of *Ganzheitspsychologie*). For them, Wundt's notion of creative synthesis was not a true synthesis but rather only another form of aggregation based on the researcher's manipulations of elements. Hence, it did not tell us much about the true experience of the psyche's totality. Instead, there is a necessity to incorporate qualitative elements that circumscribe the psyche in its entirety by leaving the realm of the synthesized aggregates to the sphere of holistic measurement. Any attempt to incorporate the products of elementary processes into a totality (*Ganzheit*) requires the person to leave the method of summation of properties and acquire the process of qualitative description of the experienced phenomenon from the perspective of the totality. When all is said and done, we are interested in explaining the entirety of experience and not merely its isolated products. In that sense, analysis of the psyche should be a top-down process and not vice versa.

If we give up the genetic elemental synthesis (the melding of unrelated elements) and replace it with the genetic totality (*Ganzheits*) transformation, then the creative character of development is no longer hindered: each higher totality is in relationship to the totalities out of which it emerged—a creative novelty. The person's development does not progress from scattered elements to a synthesized whole; rather, it progresses from one totality/whole to another (Volkelt, 1962, p. 27). For Wundt's successors at Leipzig, creative synthesis did not mean that scattered elements connected to form a new whole but, rather, that an old synthesis was restructured. Synthesis does not replace the aggregate structure; rather, a different synthesis replaces previous ones. Elements were not of much use because in isolation they had no meaning, and thus for Wundt's students the notion of cumulating elementary processes needed to be dropped and replaced with the principle of psychical totality.

#### THE CASE OF SYNTHESIS TRANSFORMATION, THOUGHTS, AND LANGUAGE: AN EXAMPLE

That Wundt unknowingly anticipated and stood at the threshold of *Ganzheitspsychologie* (see Diriwächter, 2009) becomes especially evident in his dealings with the higher totalities within a self-contained discipline: *Völkerpsychologie*. Of these higher totalities, language was given particular attention to be able to trace mental development (or synthesis transformation), and Wundt devoted two volumes of his *Völkerpsychologie* (volumes I & II) for this task. For example, Wundt (1912, pp. 436–458) divided language into two domains:

1. Outer phenomena: this domain consisted of a person's actual produced or perceived utterances. The outer phenomena can be described as the organized system of sounds of language. However, this aspect is just the expression of much deeper cognitive processes:

2. Inner phenomena: this domain entailed the cognitive processes that underlie the outer phenomena. These processes organize the person's thoughts. They allow for analysis of the phenomena encountered and to put mental images into words that are then presented in the form of organized utterances. Or, in the case of a listener, to comprehend a speaker's utterances by extracting meaning from the perceived sound units (see below). In short: The cognitive processes constitute the inner mental domain of speech.

Sentence production, according to Wundt (1912, pp. 436–458), begins with a *Gesamtvorstellung* (a unified idea that entails the whole mental configuration) that one wishes to express. The analytic function of apperception prepares us to express our *Gesamtvorstellung* by analyzing it into components and structure that retains the relationship between the components and the whole. Let's say that I marvel at how green the grass is today and wish to share this perception. What I first need to do is to dissect this unified idea (the grass is green) into component parts, which at the most basic level consist of a subject (grass) and predicate (green). Thus, the basic structural division consists of two fundamental ideas that can be represented through a simple tree diagram (see Figure 2.1 below).

These basic ideas receive their corresponding symbols (i.e., words) with the addition of function words such as “the” and “is,” which are required in a particular language for full sentence creation. The result is that through an analytic process, I was

able to describe the transformation of an inexpressible, organized whole (the *Gesamtvorstellung*) into an expressible sequential structure of symbols (the words) that manifested themselves by means of a sentence (the media of language), whereby in the present case above I have shared verbally two fundamental ideas (grass and green). Naturally, the more complex our *Gesamtvorstellung* is, the more expanded our analysis must become, which in turn results in more complex tree diagrams. In each case, we are examining the results of a creative synthesis—the meanings that have become united as a *Gesamtvorstellung* and are now deconstructed via the tools (e.g., words) that our system of language has provided.

In the case of comprehending a person's *Gesamtvorstellung*, the above process now needs to be reversed. That is, a listener (the receiver of a communicative event of meaning exchange) is confronted with a transmission of sequential components (such as “green” or “grass”) that now need to be synthesized into a whole (a creative act). In principle, this proceeds via a reversed tree diagram (see Fig. 2.1 below) by which particular components (e.g., words and grammar) are linked and melded (one after the other) as they arrive in the listener's mind. The words and grammatical structure of the transmitted sentence are merely the tools through which the listener can try to reconstruct the speaker's *Gesamtvorstellung*. Beyond that, the words (the parts) are of no particular relevance. Thus, as Wundt pointed out, we usually retain the meaning (inner phenomena) long after we have forgotten the specific words (outer phenomena) that the person spoke to convey that meaning.

### ***Völkerpsychologie* and Culture**

The investigation of language (as well as myth and customs) comprised the core of *Völkerpsychologie*, as these were seen as universal phenomena across all human civilizations and thus made humans distinguishable from other organic beings. Although

**Figure 2.1** Tree diagram depicting the dissection of a unified idea into its most basic components.

Wundt would not have phrased it so, one could say that these labels rest on the foundation of creative synthesis transformations.

That such ideas are not far removed from a discipline called cultural psychology should not be surprising. In his tenth (and final) volume of *Völkerpsychologie*, titled *Kultur und Geschichte* (culture and history), Wundt (1920), to the best of my knowledge, brings *Völkerpsychologie* for the first time close to cultural psychology:

As these three labels [language, myth, customs] only describe three main directions, according to which human “mental” life (*Seelenleben*) differs from all organic beings, and while each of these directions encompasses various appearances, we can say that these factors and their development in relation to humans are joined under the general term of culture, so that in this regard *Völkerpsychologie* and the psychology of culture (*Psychologie der Kultur*) are equivalent terms/concepts (*Begriffe*).

(p. 57)

However, as Jahoda (1993) emphasizes, culture (in the German sense of *Kultur*) did not always have the same meaning for Wundt. According to Jahoda, culture was sometimes “the expression of the higher forms of human intellect and creativity; it meant art science, knowledge and high-level skills, sophistication and *savoir-faire*” (p. 185). At other times, the label *culture* was more or less used synonymously with the term *civilization* or *nationality* (the later especially after World War I). Hence, a clear definition of culture was not always apparent in Wundt's writings (a problem that also occurs in present-day studies on culture and psychology).

Nonetheless, what present-day readers of Wundt's *Völkerpsychologie* can benefit from is the wide breath of scope with which he approached the subject. Although many things he wrote are arguably outdated and in some cases flawed,<sup>11</sup> he nevertheless demonstrates a remarkable talent for inquisition, curiosity, and, above all, skills with which to relate and integrate information that was previously left nearly exclusively to the domain of anthropology or ethnology, thereby broadening the scope of psychology beyond the laboratory setting.

However, taking the notion of creative synthesis transformation as the basis to approach the discipline of *Völkerpsychologie*, one could arguably make the discipline more focused and proceed to study culture as Wundt's successor, Felix Krueger (1953,

pp. 321–323), suggested by applying the following principles:

1. The highest level of totality (e.g., culture) weighs most on its sub-totalities (e.g., the individual).

2. Just like life in general, communal (*Gemeinschaft*) and cultural life is hierarchically organized.

3. The emphasis is on experience, most notably the centrality of feeling and the structural orientation, as well as the complexity of whole, which is dynamic and all-encompassing.

These principles have finally been addressed in more recent cultural-psychological publications (e.g., Valsiner, 2000; Valsiner & van der Veer, 2000). Communal life has internal roots and borders that embed it within its environment. In this regard, the focus shifts from the products of peoples (as in Wundt's *Völkerpsychologie*) to their experiences as a complex phenomenological whole. For Krueger (1953), social life was grounded in tension among the group, its environment, and the individual will. In fact, this tension (in the form of opposites) increases as a *Volk* progresses and develops. Reaching higher levels of totality (e.g., from primitive to civilized cultures) is tied to pain and must be gained by some sort of force (e.g., hard labor or battle). And naturally, true to the doctrine of any *Völkerpsychologie*, it is futile to study individuals independently from a group; rather, the group membership is the basis for the individual. Collective experiences are embedded not in the individual but in the totality of the group, of which the individual is but a mere subtotality.

### **Future Directions: The Place for *Völkerpsychologie* in Today's Cultural Psychology?**

Although rare, attempts have been made to conduct *völkerpsychologische* analysis from Krueger's (1953) perspective. For example, Dürckheim-Montmartin (1934) examined the structural forces of community life with Krueger's theory guiding his analysis. Consistent with the notion of no parts without the whole, Dürckheim-Montmartin reiterates that true membership of a group implies spontaneous action in accordance with the collective will, whereby the individual does not feel forced but, rather, pledges himself/herself to act. The phenomena experienced by the collective people (*Völk*) are most clearly distinguishable when the *Volk* remains rather homogeneous—that is, united in

times of stress—and rejects outsiders. Thus, despite the holistic emphasis on heterogeneity, it is best to start such studies on the *völkerpsychologische* level in peoples who exhibit a great degree of unique characteristics that are not found in other communities (similarly to the aims of *Völkskunde*).

Through the fusion of *Völkerpsychologie* with new ideas, the horizon may open to allow for investigations that were previously not methodologically possible on the level of *Völkerpsychologie* alone. The criticism of Eckardt (1997) that Wundt's proclaimed unified historical-genetic approach to investigating psychological phenomena was more a “psychologizing” of history than a historicizing of the psyche would have to be re-examined in light of the experiential factors that could be deduced from a new *Völkerpsychologie* that is grounded not in the past but in the present. This would be possible because we are now aware of other approaches that are grounded in the feelings and structures that are experienced in the totality of a phenomenon as it occurs.

John Greenwood (1999) once added to the criticism of Wundt by stating that although Wundt did recognize the possibility and potential of forms of social and/or cultural psychology (the investigation of psychological processes that are grounded in cultures or social groups) distinct from individual psychology (the investigation of psychological processes that operate independently of cultures and social groups), his own work lacked concrete details. That is, although he felt that there was a need for bringing individual psychology and *Völkerpsychologie* into organic relation theoretically as methodological procedures, he did not recognize that a similar need existed with regard to the concrete facts and processes with which these psychologies were supposed to deal. This criticism, of course, would also need to re-examine the new form of *Völkerpsychologie* because newer approaches do not necessarily make that dual distinction, as Wundt's *Völkerpsychologie* and physiological psychology did.

Moreover, Greenwood (2003) even went so far as to make the controversial suggestion that perhaps there may be a space for experimental procedures in Wundt's *Völkerpsychologie*, something that has not previously been deemed possible. However, in this regard we should be very careful not to fall into the linear causality model (as is so often applied in mainstream social sciences today). I can only imagine that Wundt would be shaking his head in disbelief if social sciences came forth presenting research under

the heading of *Völkerpsychologie* in which claims are made that “A caused B.” Instead, alternative models of causality would need to be applied, such as catalyzed systemic causality models (Valsiner, 2000, pp. 74–76; see also 2004) that would not only be able to capture the essence of Wundt’s *Völkerpsychologie* but would be closer to real-life events. It is clear that in such an approach, the catalyzed system necessarily needs to include the historical nature of the *Volksgeist*, something that completely removes the model from present-day mainstream linear approaches to ones that turn the causality issue into one of emergent or synthesis causality. After all, we must remember that theories are not supposed to take on the role of a *set mental* (and *socio-ideological*) position; rather, they are the tools that help us look at phenomena (see Valsiner, 2004).

Holzner (1961) proposed several specialized subdivisions of *Völkerpsychologie* that are abstracted from a general *Völkerpsychologie*. In that regard, *Völkerpsychologie* would consist of a *völkerpsychologische* description of cultural content, a sociological analysis of the totality of society, and disciplines that specifically focused on studying social stratifications, the totality of communal life, socialization, and personality. In the past, these studies would predominantly require a comparative analysis, but with the framework of modern cultural psychology, they could become experiential to include phenomenology of the higher levels of totality on topics like feelings and emotions, thereby utilizing the rich methodological knowledge that has been introduced by various cultural psychology researchers (for a general overview, see Valsiner, 2000).

Finally, Wundt’s *Völkerpsychologie* has done little to integrate the actual developmental processes, and such an approach would be a desirable addition to *Völkerpsychologie* as a part of today’s cultural psychology. After all, development implies processes that engulf the entire person or persons, and this form of totality needs to be accounted for. One can now only hope that the present-day generation of cultural psychologists will dare to step into the footsteps left behind by the early giants of *Völkerpsychologie* and complete the ambitious project that, until now, has been left dormant but ready for a re-awakening.

## Notes

1. Other translations of the term *Völkerpsychologie*, such as cultural psychology, could be equally misleading as none really grasps the spectrum of this discipline. *Völkerpsychologie* was more

than cultural psychology, as culture (in the German sense of *Kultur*) was merely incorporated into the approach (see also Jahoda, 1993), although Wundt does compare *Völkerpsychologie* and the “psychology of culture” at one point (see below). Nevertheless, *Völkerpsychologie* was to focus on all aspects of people living together, not just culture *per se*.

2. Although not without criticism (see Schneider & Müller, 1993).

3. However, according to Thurnwald (1924, p. 32), it was Wilhelm Humboldt’s 2-year-younger brother, Alexander von Humboldt, who coined the term *Völkerpsychologie*. Thus, it remains unclear who was the first to have coined that term. Jahoda (1993, p. 145) followed up claims that Humboldt was the first and found that these claims rest on mere assertions.

4. This idea was nicely captured by Wundt (1915) as Germany’s Second Reich was soon to near its end when, shortly after the outbreak of World War I, he advocated German idealism and a social state in which the duty of citizens was to live for the community and not for themselves.

5. For example, Achelis (1889) published an article in honor of Gustav Theodor Fechner (1801–1887) and in it addresses several of Fechner’s important points in his system of psychology. Thus, the scholars of *Völkerpsychologie* were aware of the theories in experimental sciences but may have not necessarily been on the “cutting edge,” and certainly did little to incorporate it into *Völkerpsychologie* theory. The three articles that Eckardt (1997, p. 71) highlights as specifically psychology-related are to be classified as a form of philosophic-psychological essays. The authors were Lazarus (1868) and Meyer (1878, 1880). The reader may wish to note that the latter reference has been cited wrongly in Eckardt’s text (he provides the same year and issue number for both of Meyer’s publications) and is given in the corrected form in the references below.

6. This volume also contains a complete name and topic index, stretching over all 20 volumes of *Zeitschrift für Völkerpsychologie und Sprachwissenschaft*.

7. He made it a point to emphasize those people who belonged to the folklore guild, which held an international congress from July 29 to August 3, 1891 in Paris, France.

8. Weinhold (1891) believed that the lower a person’s education, the fewer words are needed for talk.

9. The title *Zeitschrift für Völkerpsychologie und Sprachwissenschaft* continued to be displayed under the title *Zeitschrift des Vereins für Volkskunde* until the new editor, Karl Weinhold, passed away in 1901. In 1902, when Johannes Bolte became Weinhold’s successor, the old title of *Zeitschrift für Völkerpsychologie und Sprachwissenschaft* finally became history. The new journal would continue until the midst of World War I, by then under a new editor, Fritz Boehm, when the lack of personnel in the printing factory and money problems would force it out of existence.

10. A biographical account can be found in Rieber and Robinson (2001).

11. For example, in his approach, Wundt faced considerable difficulties in explaining the intermediate steps of cultural development. In his *Elemente der Völkerpsychologie* (1912), despite his emphasis on context, Wundt is often accused of reconstructing the cultural development of humans (e.g., Eckardt, 1997; Werner, 1953). First of all, the way Wundt breaks down the development of humans into elements leads to the assumption of an *Urmensch*, which by its nature is the same for all humans. The development is then similar for all of mankind, given the environmental conditions. Werner (1953), for example, opposes

this by noting that if two human cultures are superficially similar today, it does not guarantee that they are not of different origins and of different functional relevance. Further, the interpretations of the *völkpsychologische* elements are tainted by our own developmental stage (which is arguably operating out of a different world than the world it is analyzing).

This has proven to be a fundamental problem for *völkpsychologische* analysis: capturing and determining cultural units or cultural layers that are so formed that all the outer manifestations of these cultural layers are carried by the distinct mental uniqueness of a higher unit. (Werner, 1953, p. 11)

This issue, however, will always remain a problem for psychology. No matter how well we design an experiment, no matter how objective we try to be, the results are always subject to the interpretations of those who are investigating the matter.

## Cultural-Historical Psychology: Contributions of Lev Vygotsky

René van der Veer

### Abstract

A brief outline of Vygotsky's major ideas is presented with only cursory reference to their historical background. Drawing on psychological and linguistic research, Vygotsky developed a theory of the development of mind. Central is the idea that the child's naturally given mental processes become transformed by the acquisition of speech and meanings. Through speech the child acquires a worldview that reflects reality in a more adequate way. The driving force in creating new meanings for the child is education in school. Given that meanings and schools differ in different cultures, children and adults living in different cultures will think along different lines. Attention is paid to the argument that Vygotsky overemphasized the role of speech to the detriment of the child's concrete operations with reality.

**Keywords:** Cultural-historical psychology, history of psychology, speech, concept formation, lower and higher mental functions, social interaction, cross-cultural research

Cultural-historical psychology is connected with the name of Lev Vygotsky and originated in the 1920s in what was then the Soviet Union. The definitive account of Vygotsky's conception cannot yet be provided—given the inaccessibility of a substantial part of his writings (Van der Veer, 1997)—but enough is known to give a fairly accurate picture of what he was up to. However, the understanding of Vygotsky's ideas is made more difficult by the fact that they originated a long time ago and in a different culture. Theories often reflect the social context and historical period in which they were written, and Vygotsky's theories formed no exception. No social scientist in his time and country could permit himself to ignore the socio-political events taking place, nor could he fully escape the pressure of social demands. This makes it essential for an understanding of Vygotsky's theories and their social embeddedness to provide a brief account of that rather remote period in a country that no longer exists.

### Social History

Born in a Jewish family in Belarus in 1896, which then formed part of the Russian empire, Vygotsky<sup>1</sup> could not avoid participating in and witnessing the social turmoil his country went through in the early twentieth century (Van der Veer & Valsiner, 1991). This included several pogroms against the Jews, the October Revolution in 1917, the Civil War from 1917 to 1923 (with foreign intervention), the collectivizing of farming in the late 1920s and early 1930s with resulting famines and millions of death, and widespread political terror during the reign of both Lenin and Stalin (Conquest, 1986). Practically from the beginning of the new state in 1917, the authorities began curtailing the freedom of speech and scientific research. Some unwelcome investigators were exiled or arrested, and others were fired or criticized in public (Chamberlain, 2006). Researchers reacted by complying or trying to avoid sensitive subjects; only a few openly

resisted the new official ideology to the extent that this remained possible (Van der Veer, 2000). As the new official doctrine was loosely based on Marx's ideas about class struggle and Engels' ideas about the origin and nature of man, the social sciences and humanities were most vulnerable for criticism from above. As a result, the researchers within these domains attempted to develop a Marxist psychology, a Marxist sociology, a Marxist anthropology, and so on. Vygotsky was one of the younger generation of psychologists who tried to develop this new Marxist psychology and one who, in the process, developed close ties with high officials, such as the minister of education Lunacharsky and Lenin's wife Krupskaya. One might think, then, that his writings would be full of obligatory terms and references as shibboleths of the right worldview and, more generally, that he did not sincerely believe in the ideas he advanced, like so many of his generation. This, however, does not seem to have been the case. Vygotsky's work is relatively free of the standard criticism of class enemies and bourgeois mentality, and one gets the impression, while reading his private notebooks and letters, that he truly believed in the possibility of a Marxist reform of psychology and society at large. Also, in his attempts to develop his own new version of a Marxist psychology, he steered his own course—for example, relying heavily on contemporary linguistic studies—which in the end made him suspicious for ideological hardliners. In the final years of his brief life, Vygotsky suffered criticism and harassment from the Soviet authorities, and no one knows what would have been his fate had he not died from tuberculosis at the age of 38 years (Van der Veer, 2000).

### **Basic Ideas**

Vygotsky developed his ideas over a period of about 10 years, and given this relatively short period, one would expect to find a reasonably consistent oeuvre without major revisions. In Vygotsky's case, this expectation is not vindicated, however. Characteristic of Vygotsky is that he was constantly lecturing and writing—he published several hundreds of books and articles in one decade—and revising his ideas in the process. That implies that while reading one of Vygotsky's publications, one always has to take into account when it was written or published. However, in what follows, I will avoid that problem by presenting mostly concepts and ideas that Vygotsky still adhered to by the end of his life.

### **Functions**

One of Vygotsky's principal claims is that human consciousness is a unique phenomenon in the animal world and develops in ontogeny. It is unique in that it is based on the use of cultural means, which become internalized by the individual (Vygotsky, 1997c; Vygotsky & Luria, 1994). Vygotsky was primarily thinking of the unusual power of words as cultural means to transform our mental activities. Drawing on the work of the linguists Jakobson (1923), Potebnya (1926), and, ultimately von Humboldt, he emphasized the capacity of words to influence both the other and the self (Bertau, 2009). Words can be used to urge another person to do something, but they can also be used to steer one's own behavior. Words can be used to make a plan for the day, to form an intention, and to memorize a list of objects. Because such use of words does not develop overnight, children and adults may differ substantially in their way of mental functioning, in their consciousness.

Take the phenomenon of memorization. It is obvious that animals have memory, just like it is clear that preverbal infants learn to recognize their mother, but Vygotsky argued that this is a type of memory that is qualitatively different from typically human, verbal memory. Using words, we humans may make a list of errands, we can think of categories of objects to be bought (vegetables, meat, dairy, etc.), we can describe pictures or music in words (which may help to recognize and remember pieces of music or art), and so on and so forth. Vygotsky preferred to call the first type of memory—that of infants and animals—“natural memory” and the second type “cultural memory,” and, more in general, he distinguished natural from cultural mental functions. Cultural functions always involve the use of cultural means such as words, and natural functions do not. Vygotsky posited that cultural functions are much more powerful than natural ones and, consequently, also spoke of higher and lower functions. In this conviction, he may have been strengthened by his own feats as a memory artist. Using various classic tricks, he showed his own students how one can memorize long lists of words or numbers and thus increase one's memory capacity immensely. Subsequent researchers (e.g., Cole & Gajdamaschko, 2007) have tried to soften the natural-cultural dichotomy on several grounds, but there is no doubt that the distinction itself is a valid one.

## Origins

Inasmuch as words are first learned and used in social interaction, we can conclude with Vygotsky that higher mental functions have a social origin. Vygotsky accepted Janet's view that in human history, words were originally commands (i.e., *ego* instructs or urges *alter* to do something). However, it belongs to the peculiar nature of spoken words that we also hear them and that we may instruct ourselves. Speaking to ourselves, we wander through the day and, in a way, human "consciousness is, as it were, social contact with oneself" (Vygotsky, 1925/1997, p. 78). Vygotsky argued:

We are conscious of ourselves because we are conscious of others and by the same method as we are conscious of others, because we are the same vis-à-vis ourselves as others vis-à-vis us. I am conscious of myself only to the extent that I am another to myself . . . the social moment in consciousness is primary in time as well as in fact. The individual aspect is constructed as a derived and secondary aspect based on the social aspect and exactly according to its model.  
(1925/1997, p. 77)

It is not difficult to see this statement as a further elaboration of the *dualis* concept developed by von Humboldt, who emphasized the social nature of speech and its importance for the understanding of the self:

Language, however, develops only socially [*gesellschaftlich*] and man only understands himself because he tentatively tested the intelligibility of his words on others.  
(quoted in Bertau, 2009, p. 61)

So, in this view we know ourselves only through the medium of social speech, via the shared meanings of existing language and becoming conscious of oneself is formulating one's experiences in words acquired through others. That implies that our most intimate, private, and personal feelings—to the extent that they can be verbalized—are nevertheless very social and that becoming an individual or personality does not imply becoming less social. As Vygotsky put it in his book on the psychology of art, "We should not say that feeling becomes social but rather that it becomes personal . . . without ceasing to be social" (Vygotsky, 1925/1986, p. 314). In this way, Vygotsky also undermined facile individual–society dichotomies: society is within the individual and our uttermost individuality consists of

a combination of socially acquired features, ideas, skills, et cetera.

Incidentally, Vygotsky's emphasis on the social nature of mind may seem Marxist, and in Vygotsky's case, it was certainly also inspired by Marx's writings, but it should be said that the social emphasis was shared by several non-Marxist thinkers of the time as well. In 1939, for example, the sociologist Norbert Elias wrote in a remarkable essay on "the society of individuals":

[E]ven the nature and form of his solitude, even what he feels to be his 'inner life', is stamped by the history of his relationships . . . one must start from the structure of relations *between* individuals in order to understand the 'psyche' of the individual person.  
(Elias, 1935, pp. 33, 37)

Indeed, this is not far from a statement made by Vygotsky's collaborator Luria (1979, p. 43), who wrote that "we needed, as it were, to step outside the organism to discover the sources of the specifically human forms of psychological activity." Our most intimate core, our private ideas and feelings have their origin in human interaction and make use of (are molded by) the available cultural means in a specific society.

## Means

There are different usages of the word "social" in the above passages that should be distinguished. Of course, one can say that human babies are social in the sense that they depend on others and seek the presence of others. In this regard, human babies do not differ from the young of other primates. Or, one can say with Elias that to understand an individual one needs to look at the history of his or her relationships. But Vygotsky was aiming at something more specific. What Vygotsky had in mind was the slow change of learning, memory, vision, hearing, and so forth into *human* learning, *human* memory, and so on. This takes place by the acquisition of cultural means transmitted and/or acquired in a social context. In this sense, the mental faculties of a child of, say, 7 years may not have become fully socialized or *culturalized*.

According to Vygotsky, the understanding and acquisition of cultural means goes through several stages in ontogeny, and the first cultural means often have a concrete, material nature. At first, the young child will disregard cultural means even when they are made available; then the child will use the material means in a purely formal way, without

understanding them and without improvement of the performance. Subsequently, the child will make use of the material means and profit from them. And, finally, the child will internalize the cultural means and no longer need material support. One of Vygotsky's favorite examples was that of counting, which for children still depends on the concrete availability of body parts such as fingers and toes but which most adults can do without this dependence. Another of his examples was that of memorizing an intention such as the purchasing of some present. Children may need to rely on such material means as a knot tied in a handkerchief to remind them of their intention. Adults, however, may tie a mental knot by vividly connecting the image of some situation or person with the intention to buy the present. This switch from external to internal means is not always fully complete for a specific function—adults may still use the stratagem of tying knots in handkerchiefs—and neither can one say that it is always generally present in adults, perhaps, but Vygotsky argued that it is characteristic of human mental development. And one might add that the fact that we have gone through this development is what makes it so difficult for humans to fully grasp the bovine or porcine wordless worldview. In any case, the above examples give an idea of Vygotsky's concept of the gradual acquisition of cultural means in social interaction to steer one's own behavior.

### Words

Speech itself was the subject matter of Vygotsky's final chapter in his posthumous book *Thinking and Speech* (1934). His discussion of private or inner speech and its relation to social speech, on the one hand, and thinking, on the other, was partially inspired by the reading of his contemporary, Jean Piaget. Piaget (1923; 1924) first described the phenomenon of children who, during play, speak for themselves in a way that is often not intelligible to other children. Piaget hypothesized that such speech is unintelligible, because young children are unable to take the other's point of view—that is, children up to age 7 or 8 years do not realize that the other child does not have the same knowledge, tastes, or feelings as they themselves. In a word, they are egocentric. Only gradually will children learn to replace their egocentric speech with social speech. Piaget's background philosophy was that children are originally autistic, and their autistic thought and speech is gradually suppressed and replaced by more

open, social variants under the influence of peers and adults.

Vygotsky (1932) criticized Piaget's contention and performed several little experiments to refute his views. Vygotsky noted, for example, that egocentric speech was absent or greatly reduced when the child was alone or surrounded by deaf children. This suggests that egocentric speech is meant by the child as social communication. Vygotsky also observed that the incidence of egocentric speech rose when the child was confronted with unexpected problems. This suggests, in his view, that egocentric speech has some function in the solution of problems. Finally, Vygotsky noticed that egocentric speech becomes *less* intelligible as children grow older, which is not consistent with Piaget's idea that egocentrism gradually disappears. From these results, Vygotsky drew the conclusion that so-called "egocentric speech": (1) originates in normal, communicative speech and branches off at a later stage; (2) has as its function to steer the child's behavior when the need arises; and (3) becomes less and less intelligible for the outsider until it has become proper private or inner speech. According to Vygotsky, then, egocentric speech is an intermediary stage between normal, communicative speech and inner speech. Like communicative speech, it is audible, and like inner speech, it serves to guide the child's thinking (Van der Veer, 2007).

Of course, it is very difficult to describe and analyze the nature and function of inner speech given its intimate nature, and Vygotsky's reasoning here was necessarily largely hypothetical. He began (following Jakubinsky, 1923/1988, pp. 27–43) with positing that inner speech must be shorter because one need not spell out details that are known to the speaker but not to the listener. In inner speech, speaker and listener coincide, which means one can be much less explicit. With Paulhan (1928), Vygotsky added that inner speech is dominated by personal connotations—that is, in inner speech subjects may, on the basis of their private experiences, attach private meanings to words that do not coincide with their lexical meanings. The word "sun," for example, may acquire strongly negative connotations for a person with delicate skin, whereas for others it may be an entirely pleasant word. In sum, the chances are that inner speech made audible would not be entirely intelligible to other people given its abbreviated nature and its personal connotations and jargon. In itself that is a comforting thought, but more important is to see

how Vygotsky attempted to trace our inner voice from social dialogues. As stated above, in his view, verbal thinking begins with social speech (i.e., *ego* utters things meant to be heard by *alter*) but after a series of transformations becomes utterly private and presumably unintelligible to the social other. Again, then, thoroughly private mental processes originate in social interaction. In a recent investigation, Werani (2010) investigated whether Vygotsky was right in suggesting that inner speech may have a function in problem solving. Using thinking aloud protocols, she was able to show that overt speech was connected with the complexity of the task and the quality of the solution. It may be inferred that this holds for inner speech as well (cf. Lloyd & Fernyhough, 1999; Zivin, 1979).

### **Systems**

If Vygotsky was right in his claim that mental faculties such as memory and perception gradually become dominated or transformed by the acquisition of verbal meanings and concepts, then it follows that mental processes are mutually connected in a system that in adults is dominated by verbal thinking. With several contemporaries (e.g., Charlotte Bühler), Vygotsky believed that in children mental functioning may be dominated temporarily by other functions such as perception or memory—that is, children behave led by what they perceive or remember, without thinking too much—but that in adults thinking has the dominating role. In one of his later writings, Vygotsky developed this notion of the systemic structure of mind. His basic claim was, in his own words:

It is not so much the functions that change ... what is changed and modified are rather the relationships, the links between the functions. New constellations emerge that were unknown in the preceding stage. That is why intra-functional change is often not essential in the transition from one stage to another. It is inter-functional changes, the changes of inter-functional connections and the inter-functional structure that matter. The development of such new flexible relationships between functions we will call a *psychological system*.  
(Vygotsky, 1997b, p. 92)

One of Vygotsky's examples was that of perception. In adults, perception is dominated by knowledge. We see what we expect to see, and it is almost impossible to find what Wundt called the "immediate experience" (i.e., the sensational experience that

supposedly precedes the verbal understanding and designation of the experience). In other words, as adults we live in a conceptual world and it is very hard or impossible to regress to the preverbal world of the newborn and once again experience a meaningless universe. With the acquisition of words, the child's phenomenal world begins to change; the child learns to classify things, animals, and persons in several more or less coherent groups. Vygotsky posited that the most fundamental changes in the child's understanding of the world take place in adolescence when children develop full-fledged scientific concepts. Younger children do interpret the world in intelligent ways, but their conceptual grasp is inadequate compared to that of trained adults. (It is here that Vygotsky's research into concept formation discussed below becomes relevant.) Conversely, in diseases such as schizophrenia, Vygotsky (1997b, p. 103) claimed, the subject loses his ability to use adequate concepts.

It is not just perception that becomes, so to speak, intellectualized. The same holds true for memory and feelings. Vygotsky believed that our feelings become trained to gradually fit into a historically determined cultural system. When and to what extent we feel jealous is determined by our culture, Vygotsky argued. And the appreciation of music and wine is framed in elaborate systems of technical terms that co-constitute the experience. Thus, what in children may be primary experiences become refined aesthetic feelings in the adult through the introduction of complex conceptual systems. In a sense, then, mental functions that originally operated in isolation become connected through language.

### **Brains**

It is, of course, tempting to speculate about the cerebral substrate of a system of mental functions. Vygotsky believed that brain systems are not pre-given but that connections between different zones of the brain develop in ontogeny. When the images of two different objects are evoked in tandem and become connected for the subject, then this presumably means that new connections are formed between the loci where these images and their names are stored. In other words, the neural network of meanings and images is constantly being revised as the person grows older. Also, the social other may stimulate the connection between different cortical centers of the subject through instruction and so on. To Vygotsky this once more showed that social

interaction is crucial for cognitive development: cortical centers that were originally unconnected now form a cortical network thanks to outside interference. The functional plasticity of the brain permits the dynamic systemic structure of mind.

The idea of a flexible systemic brain structure also allows us to understand cases of compensation in patients with brain lesions. Subjects may, for example, lose the ability to name an object they perceive—that is, the visual image of the object no longer triggers its name. However, when allowed to touch the object, they may regain its name. That finding seems to imply that in a complex system of cortical centers responsible for the storage of the sound, image, touch, and name of the object, some connections may be lost but may be compensated for by others. A better understanding of the exact nature of such interfunctional systems may allow us to devise means of compensation for brain patients. It was Luria, Vygotsky's former collaborator, who developed this approach into the new discipline of neuropsychology.

Ultimately, for Vygotsky the most important implication of the system notion was that of the possibility of deliberate control. The well-trained adult is capable of using his thinking to improve his memory feats, for example. As thinking is nothing other than the use of cultural means such as words to solve problems, this is equivalent to stating once more that we may use cultural means to enhance memory performance. That is to say, by making deliberate use of cultural signs, we can lift our perception, memory, and attention to new levels. Ultimately, we may even be capable of fully dominating our passions by framing them in culturally accepted meanings. As we reasoned before, the attention of children is dominated by factors outside their control. Similarly, children are the slaves of their passions. Adults, however, are ideally capable of steering their own behavior; they are less spontaneous, they can ignore external or internal stimuli, they can choose to conceal their feelings, and they can become capable of deception. Thus, with Spinoza, Vygotsky (1997b, p. 103) believed that man, through his intellect, has gained power over his affects and other mental processes.

### **Concepts**

Vygotsky's evidence for conceptual change in childhood and adolescence rested on several of his own investigations, which he described in *Thinking and Speech* (1934). Subjects of different age groups

were told the name of an object and asked to find another object of the same name in a group of objects differing on various dimensions (color, size, etc.). They found that younger children's approach to that task was qualitatively different from that of adults. The attempts at classification by children were inconsistent, based on concrete features, and often unsuccessful. The last preconceptual stage is reached in pre-adolescence when children classify the objects on the basis of what Vygotsky called "pseudo-concepts." Children might gather all objects of the same form but be unable to state their joint property in an adequate way. Thus, they might select all triangles because "they look the same" but be unable to state the abstract concept "triangle" and its defining properties. Superficially, they seemed to experience the world as adults do, and nothing prevented successful communication between children and adults, but deeper probing learned that children of that age conceptualize the world differently from adults.

A recent replication in South Africa, using Vygotsky's original material and experimental setup, has verified Vygotsky's assertion that true conceptual thinking only becomes possible in adolescence (Towsey, 2009; Towsey & Macdonald, 2009). In their meaning-making efforts, children are guided by the culturally determined meanings available in the words around them, but they reach the (adult) stage of full-fledged scientific concepts only after a lengthy process of development.

### **Teachers**

It is education that plays a fundamental role in children's growing ability to make use of scientific concepts. Inspired by Piaget, Vygotsky made a distinction between everyday concepts and scientific concepts. Everyday concepts are based on concrete and sometimes irrelevant features of phenomena and do not form part of a coherent conceptual system. Scientific concepts reflect essential, abstract properties of phenomena and are logically connected to other, related concepts. Such scientific economic concepts as supply, demand, scarcity, turnover, and profit, for example, form part of the interconnected system of concepts called economic theory. Characteristic of scientific concepts is that they are explicitly and systematically introduced in an educational setting and that students are trained to define them, to state their interrelationships, and so on. In other words, students make conscious and deliberate use of these concepts, realizing their

interconnectedness. Vygotsky posited that the mastering of such scientific concepts in school carries over to everyday life and that children's everyday concepts become transformed by them. Thus, the child's original concept of a worker as someone who goes to work (with concrete images of clothing, factories, etc.) will become enriched by the idea that a worker is someone who sells his labor to an employer in accordance with the system of economic concepts mentioned above. Everyday concepts, on the other hand, give bone and flesh to scientific concepts. They provide the rich concrete details that scientific concepts lack and are tied to the child's concrete reality. Vygotsky, thus, posited that everyday and scientific concepts mutually enrich each other but nevertheless emphasized the leading role of scientific concepts in creating new and deeper understanding of reality. As often, he discussed some empirical investigations that corroborated his view, but these left much to be desired in terms of research methodology (Van der Veer & Valsiner, 1991).

### Zones

The leading role of school or, more generally, instruction in stimulating children's mental development was emphasized by Vygotsky time and again. In the final years of his life, he lectured about education as supposedly creating a new zone of mental development. His basic idea was very simple. Some tasks children can solve themselves, independently. Others are only within their reach when they receive assistance or scaffolding from more capable peers or adults. Using the hints and prompts of parents or teachers, they then reach above their present abilities. The interesting thing to note is that children cannot utilize all the hints they receive; some assistance is so beyond their present abilities that they fail to profit from it. But there is a twilight zone between their present darkness of ignorance and their future brightness of understanding, and just as the daybreak announces a new day, that twilight zone announces the child's understanding in the near future. What the child can do today with support, she can do tomorrow independently. In other words, we may use the children's assisted performance to predict their future independent performance. Vygotsky clearly suggested that parents and teachers, by giving hints and prompts, were of paramount importance in calling into life (rather than laying bare) new levels of the child's understanding, but in this context he provided no empirical backing

for that suggestion. Also, he suggested that children differ in their ability to profit from assistance and that the difference between their independent and assisted performance has differential prognostic value. More than standard cognitive tests, assisted performance would give us an indication of the children's potential, their independent performance in the near future. This suggestion has long been ignored, but the recent dynamic assessment movement—also inspired by Feuerstein, who independently reached similar conclusions—is exploring its potential (cf. Van der Veer, 2007).

### Cultures

If higher cognitive processes are determined by the acquisition of cultural means, if instruction plays a fundamental role in creating new zones of cognitive development, then it follows that higher thought differs between cultures. The lower, natural mental functions will be shared because they belong to the human make-up, but the higher, cultural functions should differ because they depend on different cultural means from sometimes radically different cultures. This was a conclusion that was unusual for that time: contemporaries were inclined to attribute the different mentality of 'savages' to their different bodily constitution or animal-like nature (Jahoda, 1999). Vygotsky followed another line of reasoning:

We have no reason to assume that the human brain underwent an essential biological evolution in the course of human history. We have no reason to assume that the brain of primitive man differed from our brain, was an inferior brain, or had a biological structure different from ours. All biological investigations lead us to assume that biologically speaking the most primitive man we know deserves the full title of man.

(Vygotsky, 1997b, p. 97)

Thus, Vygotsky denied that there could be any relevant biological differences between contemporary persons of different races or cultures. However, if we cannot attribute the existing differences in mentality to nature, then they must be attributed to nurture, to the way human children are raised in various societies, and to the cultural means these children master. But do we find any deep differences in cognitive functioning between cultures? This is largely an empirical matter, and Vygotsky and his associates were among the first investigators who tried to answer this question through

scientific investigation. Alexander Luria, Vygotsky's closest collaborator, found important cognitive differences in the Islamic population of Kazakhstan in the early 1930s. Previous investigators had found various minorities in Central Asia to score low on intelligence tests, and in an effort to explain the differences medical anthropologists had measured the size of their skulls (cf. Van der Veer, 2007). Luria took another approach: after due preparation and with the help of interpreters, he offered Kazakh subjects intellectual riddles and carefully discussed the proposed solutions with the subjects—challenging them for better arguments, expressing dissent, and so forth—in a manner not unlike that used by Piaget in his clinical interviews with children. He found that his subjects failed to solve several cognitive tasks in the manner that he found to be superior and that was common in most adult Western subjects. Thus, asked to group together three of four objects, subjects failed to sort them according to their function or to abstract properties. For example, when asked which object did not belong in the series “glass, saucepan, spectacles, and bottle,” the subjects could not reach a solution. They did not say that three of the objects were vessels (function) nor that three others were made of glass (abstract property). Instead, they imagined concrete situations in which these objects would fit together despite Luria's suggestions that other solutions were possible. Luria concluded that “different psychological processes determined their manner of grouping which hinged on concrete, situational thinking rather than on abstract operations which entail the generalizing function of language” (Luria, 1976, p. 77). Similar results were reached with other cognitive tasks such as hypothetical reasoning: the subjects reacted to the tasks in ways that differed from those of Western subjects and relied on their concrete, everyday experience. Thus, when subjects were told that all bears on Nova Zembla were white and that Jaan was a bear on Nova Zembla, they refused to draw any conclusions about Jaan's skin color because they had never been on Nova Zembla.

On the basis of such results, Luria and Vygotsky were inclined to speak of different *levels* of cognitive functioning—that is, they reasoned that the non-Western subjects had not yet reached the Western level of abstract reasoning. In their view, the Islamic culture to which the subjects belonged did not offer the necessary cultural means to solve the tasks presented, and therefore, the subjects could not manifest the required hypothetical scientific thinking.

In Vygotsky and Luria's view, it takes the Western school instruction to develop truly scientific abstract reasoning in children, and Luria provided data to prove that the subjects' capacity for abstract thought was directly linked to the number of years of schooling received. Given the right education, they might make “a leap of centuries” (Luria, 1976, p. 164). Now, as then, these conclusions are viewed as debatable. It is contentious to compare cultures on a developmental scale. It is risky to draw general conclusions about subjects' general ability to reason abstractly on the basis of their failure or refusal to solve the presented tasks. It is doubtful whether Western school is essential in creating abstract abilities. Be that as it may, Vygotsky's and Luria's findings have been verified time and again, and now, as then, it is unlikely that the differences found are caused by genetic differences. The exact nature of the differences in higher reasoning is still subject of considerable debate, whether it be cognitive differences or moral reasoning à la Kohlberg.

## Conclusions

In the early 1930s, Vygotsky advanced a set of ideas that was quite unlike that of contemporaries such as Karl and Charlotte Bühler, Kurt Koffka, Kurt Lewin, Jean Piaget, Wilhelm Stern, and Heinz Werner. He posited a peculiar theory about the merging of *natural* and *cultural* lines in child development. The cultural line was based on the acquisition of cultural means that transformed the child's functioning. Applying the socially acquired cultural means to the self, the child becomes conscious of his or her mental functioning. The mastering of cultural means takes years and is only finished in adolescence. At first, higher mental functioning needs the support of concrete material actions and objects but gradually the child becomes able to operate on the purely mental level. The most important cultural means is speech, with its variants social, egocentric, and inner speech. The inclusion of speech into mental functioning implies that the inter-relationships between different mental functions become changed and form a dynamic system. On the level of the cortex, this probably means that different cortical centers become connected and disconnected depending on life experiences. A primary role in intellectual development is played by education, which teaches children a logically connected worldview. Children can profit from education when it falls in their zone of proximal development. To the extent that cultures offer different cultural

means inside or outside education, subjects from different cultures will display different modes of thinking. Children from different cultures may have the same intellectual potential, but they do end up thinking in fundamentally different ways.

### Future Directions

In the 1920s and 1930s, Vygotsky's ideas were virtually unknown in the West and thus met with no criticism there. In fact, it is very difficult to find any mention of his person or work (Van der Veer, 2007). In the Soviet Union this was different: in the late 1920s and early 1930s, his work first met with criticism, which was continued after his death in 1934. The first criticisms were largely ideological and can be left aside in this context (Van der Veer, 2000). However, shortly after his death several of his closest collaborators—notably Aleksey Leontiev (1935, 1937) and Pyotr Gal'perin (1935)—began to voice criticism that needs to be taken seriously. Gal'perin, among other things, argued that the distinction between natural and cultural mental processes as made by Vygotsky leads to the unfortunate consequence that children age, say, 7 years may be said to function naturally, outside culture. He pleaded to trace the origin of mediated actions to the “child's first cry”—that is, he believed that the role of cultural, semiotic means should be studied already in the child's proto-language. Second, Gal'perin argued that Vygotsky laid too much emphasis on verbal consciousness and ignored the child's concrete operations in the real world. Vygotsky's claim that education is the driving force of development, Gal'perin deemed “idealistic,” because it suggested that the child's ideas are changed by those of his teacher (the social other) without intervention of the real world. Leontiev elaborated this criticism and gradually developed it to create his so-called “activity theory.” In his view, the subject matter of psychology was “activity as a relationship to reality, to the objects of this reality” (Leontiev, 1935, p. 68). Acknowledging the central role of speech, Leontiev nevertheless claimed that speaking with others, or social interaction in general, could not be the driving force behind changes in ego's consciousness. In his view:

The social nature of the child's mind thus does not reside in the fact that he interacts with others but in the fact that his activity (his relationship to nature) is objectively and socially mediated.

(Leontiev, 1935, p. 74)

Thus, Leontiev shifted the emphasis from speech to concrete operations, with reality mediated by speech. Undoubtedly, this move was motivated by his wish to stay closer to orthodox Marxist thought with its emphasis on the role of concrete labor in the development of human consciousness. Whether Leontiev's view substantially differed from Vygotsky's stance and, if so, whether it constituted an improvement has since been the subject of considerable debate.

### *The Dialogue that Could Not Be*

It is very interesting to note that what Leontiev and Gal'perin wished Vygotsky to do—to shift the emphasis from speech to concrete actions—was to some extent realized in practice by Vygotsky's contemporary Jean Piaget, albeit in his own original way. Just like Vygotsky, the young Piaget attached fundamental importance to language and social interaction, but gradually he began put more emphasis on the importance of the child's concrete operations. It would have been highly interesting to see what happened had these two great scientists been able to communicate and criticize each other's ideas in this respect. What is more, I think it would still be beneficial to confront the two theories more substantially than has been the case to date. I offer just a few examples from an introductory book on Piaget to show what kind of topics might be worth discussing.

the child's ability to profit from training depends on his initial developmental level”... [only] those at a transitional level showed considerable progress ... the child can profit from external information ... only when his cognitive structure is sufficiently prepared ... / ... Interest and learning are best facilitated if the experience presented to the child bears some relevance to what he already knows, but is at the same time sufficiently novel to present incongruities and conflicts ... the child's interest is aroused when an experience is moderately novel.

(Ginsburg & Opper, 1979, pp. 217–219, 226)

This statement seems to deal exactly with the situation that Vygotsky described in discussing his concept of the zone of proximal development. The question to ask might be to what extent the “hints and prompts” discussed by Vygotsky differ from the Piagetian type of education that hoped to create incongruities and conflicts in the child's mind in a transitional stage.

Ginsburg and Opper also offer the following observation:

Adults often believe that once a child has learned the linguistic label for an object, he has available the underlying concept. But Piaget has shown that this is often not the case ... only after a period of cognitive development does the child use these words and understand them in the same way as the more mature person.

(Ginsburg & Opper, 1979, pp. 223)

Is this not the same conclusion that Vygotsky reached in his own research on concept formation? If not, what are the differences? Finally, Ginsburg and Opper formulated what can be called a law of internalization:

First the child physically sorts or otherwise manipulates objects ... later, he can sort the objects solely on a mental level.

(Ginsburg & Opper, 1979, p. 225)

Again, one might ask whether this is fundamentally different from what Vygotsky discussed when describing the internalization of cultural means.

I offer these examples for contemplation, not to argue that Vygotsky and Piaget basically thought along similar lines. But I do believe that many researchers who quote Vygotsky to make some point might just as well have quoted Piaget, who now for them seems outdated, perhaps. A thorough confrontation of both theories by impassionate researchers would be quite beneficial, I believe, for the progress of psychological science. It is high time that we make some fundamental steps in our understanding of the development of the human mind. The replication and criticism of Vygotsky's many research projects against the background of other fundamental theories may contribute to this cause.

## Notes

1. He was born as Lev Simkhovich Vygotsky but changed his patronymic and surname for reasons that have not been fully clarified.

# The Role of Indigenous Psychologies in the Building of Basic Cultural Psychology

Pradeep Chakkarath

## Abstract

In this chapter, the author traces some of the common historical roots and features of indigenous psychology and cultural psychology. He then considers the extent to which the mainstream historiography of psychology's encounter with culture conveys a misleading impression and why correcting this impression is of general importance for a science that deals with human development and functioning in varying socio-historical and cultural environments. Examples from Indian psychology are used to illustrate the potential of indigenous psychology to add to our scientific knowledge. Finally, conclusions are drawn about how and whether indigenous psychological knowledge and methodologies can help the cause of cultural psychology, what can be learned about the research skills that different research environments demand, and what kinds of inequalities hinder a more fruitful exchange of knowledge within the psychological community.

**Keywords:** indigenous psychology, cultural psychology, historiography, ethnocentrism, Indian theories about self-concepts, hybridity, third space

The current psychological literature on the relationship between culture and the human psyche differentiates between subdisciplines and/or approaches on the basis of their historical lines of development, their basic theoretical assumptions, and the research methods they consider appropriate for the investigation of the psychological role of culture. Although their historical lines of development can be traced back quite far into the history of thought, when it comes to the historical impact of the approaches and their scientific merits and the number of scholars representing these fields, the following subdisciplines and/or approaches may be named the most influential:

a. **psychological anthropology**, a research tradition that introduced psychological theories and methods into cross-cultural scientific field work and

had an impact on psychology's cultural turn in the twentieth century (Jahoda, 1982; 1992)

b. **cross-cultural psychology**, which emerged from psychological anthropology and has always been inclined toward mainstream psychology's nomothetic/quantitative approach and an experimental paradigm in which culture is treated like just another quasi-independent variable (Berry et al., 2011)

c. **Soviet Russian cultural historical psychology**, which helped uncover the role of the contextual dependence of human psychological development and the complex process of the cultural mediation of meaning through social interaction (Vygotsky, 1930/1978; Wertsch, 1985)

d. **cultural psychology**, which (in its current form) owes much of its interdisciplinary character, its focus on the "meaning making process" in

human action and experience, to the Soviet school and is also characterized by its corresponding preference for qualitative and interpretative methods (e.g., Boesch, 1991, 1996; Bruner, 1987, 1991; Chakkarath & Straub, in press; Cole, 1996; Lonner & Hayes, 2007; Ratner, 2002; Shweder, 1990; Valsiner, 2009)

e. **indigenous psychology**, which shares many perspectives with cultural psychology, but (in its current form) resulted from the dissatisfaction with the historically and politically rooted dominance of certain other psychological disciplines (including cultural psychology) and the frequently insufficient expertise of their representatives when pursuing their goals in other cultural contexts than their own (e.g., Chakkarath, in press; Ho, 1998; Kim & Berry, 1993; Kim, Yang, & Hwang, 2006).

Taken together, these fields are frequently and collectively referred to as “culture-sensitive,” “culture-inclusive,” or “culture-informed” psychology. Although they consider themselves culture-sensitive, they nonetheless vary as regards the extent to which they agree or disagree that (1) psychology should follow the nomothetic paradigm of the natural sciences and (2) the established methodological standards and procedures of natural scientific psychology will enable us to deal with the psychological role of cultural phenomena. It is also the extent of agreement or disagreement with these positions that determines whether the positions mentioned above consider themselves to be more a subdiscipline or an alternative, new conception of mainstream psychology—that is, a new paradigm for doing psychological research and analysis.

In the following, I will focus on the latest of the culture-inclusive approaches to psychology: indigenous psychology. I will try to characterize its self-understanding and to evaluate its potential to refine the approach of cultural psychology, the discipline it is most closely related to. In doing so, I will first sketch the historical development of indigenous psychology and its historical relationship to cultural and cross-cultural psychology. I am not beginning this chapter with a historical sketch merely to follow academic convention but, rather, to show that even the historiography of psychology, including culture-informed psychology, reveals shortcomings that are interesting for our understanding of the importance of perspectives from indigenous psychology. That will also help to show why the relationship between indigenous and cross-cultural psychology is so distant while

indigenous and cultural psychology bear a strong family resemblance. In the next step, I will present some of the main features and goals of indigenous psychology as they are portrayed by prominent representatives of the field. There, I will also take the opportunity to critically comment on that portrayal and to add to it. Drawing on examples from Indian psychology (and contrasting them with stereotypical views that are deeply embedded in Western accounts of the “Asian” and the “Indian psyche”), I will then try to illustrate the impact indigenous psychological theories can have on various aspects of human development and why this should have the attention of psychology in general. Finally, in the same line, I will summarize the potential of an indigenous approach to improve and refine the foundations and state of the art of cultural psychology.

### **Cross-Cultural, Cultural, and Indigenous Psychology: A Historical Sketch** *A Critical View of the Mainstream Historiography of Psychology*

The mainstream historiography of psychology, particularly as written by Western historiographers, portrays psychology as a comparatively young scientific discipline rooted in the scientific enthusiasm of eighteenth century’s European Enlightenment and institutionalized at Western universities in the late nineteenth century. This narrow, Eurocentric, and misleading but dominant historical view stems from a characterization of psychology not based on its broad range of research topics and questions but primarily on its quantitatively oriented research methods. These methods were devised by early scholars of the field in accordance with Descartes’, Newton’s, and Boyle’s models of rigorous science as exemplified by then modern astronomy, physics, and chemistry. Thus, observation, experiments, and the quantitative processing of data were regarded as the *via regia* to discover the universal natural, rationally understandable laws governing the human psyche. The year in which Wilhelm Wundt established the first “Institute for Experimental Psychology” at the University of Leipzig, 1879, is commonly marked as the founding year of psychology as a science. However, Wundt himself had a far less reductionist idea of psychology in mind. Rather, he proposed a culture-inclusive and multimethodological psychology that he called “dual psychology” and that was meant to do justice to the investigation of man as a natural as well as a cultural being. Thus, his conception represents the

variety of topics and approaches that were to be found even in the nineteenth-century beginnings of psychology far more appropriately than common historiography does (Wundt, 1900–1920). For the history of the more recent culture-sensitive subdisciplines and approaches to psychology, it is particularly significant that nineteenth-century psychology (along with philology, philosophy, anthropology, sociology, religious studies, and others) was among the very first institutionalized disciplines to apply a culturalistic perspective to the social sciences (Jahoda, 2011). The same perspective showed up in Wundt's conception of a culture-integrative psychology to which he dedicated the 10 volumes of his *Folk Psychology (Völkerpsychologie)*. Within that framework, Wundt, one of the founders of physiological and experimental psychology, declared that in addition to investigating the elementary mental processes using natural scientific methods, psychology also needed to investigate the higher or more complex processes and products of the mind like language, religion, myths, art, and social practices. Because these higher mental processes are historically shaped, creative, and dynamic phenomena that cannot be brought under control in a laboratory, psychology, according to Wundt, needed to avail itself of knowledge and methods from the social sciences and the humanities as well (Diriwächter, 2011). Terminologically and intellectually, Wundt's conception of folk psychology reflected an influential tradition of social scientific thought that found its well-documented expression even earlier in the *Journal of Folk Psychology and Linguistics (Zeitschrift für Völkerpsychologie und Sprachwissenschaft)* founded by Moritz Lazarus and Heymann Steinthal in 1860. The journal served as an interdisciplinary panel for psychologists, linguists, anthropologists, ethnologists, and historians, all with a common interest in the investigation of different languages, myths, institutions, diffusion processes, thinking and communication styles, differences in education and learning, personal and interpersonal perception as well as in the dynamic and reciprocal effects within all these domains. Thus, this early conception of a culture-inclusive psychology embraced topics and perspectives that could be traced back to scholars as different as Johann Gottfried von Herder and Wilhelm von Humboldt. These scholars themselves can be seen in a line of thought that arose as a critical assessment of the adequacy of the Newtonian paradigm for the field of the social sciences.

One of the leading proponents of that criticism was Giambattista Vico. At the beginning of the eighteenth century, Vico (1725/1968) laid the ground for a social scientific theory that did not conceive of human beings as simply mechanically functioning entities, as proposed within the mathematical framework of the natural sciences. Vico stressed that the human realm is not ruled exclusively by foreseeable regularities but much more by circumstance, coincidence, opportunity, chance, and a wide range of complex psychological phenomena like love, hatred, courage, fear, indecision, capriciousness, heedlessness, and fantasy. This complexity cannot be described and understood in terms of modern physics or any other kind of methodological monism, especially if one considers that nature, society, individual, and psyche are interdependent and in constant flux. Because humans are capable of giving meaning to things, events, themselves, and the historical dimensions of the world and their existence, they need to be understood in their own terms and by using methods that allow us to analyze the processes and structures of the individual as well as the collective production of meaning.

As this short recapitulation of an influential line of thought in the history of social science and psychology shows, it is not as clear as many historiographers of psychology suggest why the natural science paradigm became so powerful in twentieth-century psychology. They propose that culture as a psychological topic was not taken seriously before the twentieth century, before psychological instruments were used in anthropology, before the Russian school of Vygotsky investigated the influence of socio-cultural aspects on human development, and before cross-cultural psychology—the nomothetic approach to culture-inclusive psychology—was formally acknowledged as a subdiscipline of psychology. However, highly sophisticated theorizing about the cultural nature of man has existed for centuries. If we only identified as beginnings those that follow natural science models, we would be ignoring previous theorizing and the quality thereof. This momentous decision, however, could remain incomprehensible if the factors leading to the self-understanding of our discipline and the cultural narrations about its development are not investigated using a cultural and indigenous psychological approach. To my knowledge, such an analysis of the mainstream historiography of psychology has never been conducted. However, it would help us understand why important contributions to the changed

and much more diverse field that now makes up what we call “psychology” were overlooked and did not find the recognition they deserve. In the following, I will provide a short example of early contributions to our field of research that foreshadowed many of the topics, theories, and methodologies at the core of approaches like cultural and indigenous psychology.

### ***Missionaries as Forerunners of Cultural and Indigenous Psychology***

When the Age of Discovery began in the late fifteenth century and European overseas expansion led to the rise of colonial empires in remote parts of the world, there was an increase in reports and reflections on non-European cultures, expedited by the introduction of Gutenberg’s printing press. Interestingly, at a time when Christian mission was closely linked to European imperialism, the main progress in the attempt to methodically investigate foreign cultures and their members was achieved by sixteenth-century missionaries. Perhaps the most impressive account in this regard was given by the Franciscan Bernardino de Sahagún in Mexico.

Sahagún studied at the University of Salamanca, the birthplace of modern Western linguistics and philology. He was therefore very much aware of the complex problems involved in spreading the word of the Gospel among the natives who only spoke Nahuatl and were unable to understand Spanish, Latin, or any other European language. So Sahagún, who was to stay two-thirds of his long life in Mexico, trained some of the natives in Spanish and field observation, had them interview indigenous experts, and took the data collected as well as data from his own observations as a starting point for the construction of questionnaires written in Nahuatl. He selected three groups of Nahuatl experts from three different regions, who studied the data collected and confirmed that the testimonies Sahagún had gathered were authentic and not biased by Christian or Spanish attitudes or points of view. He sorted the information into three categories or main themes: information related to gods, religious beliefs, and religious practice; information related to the “human sphere”; and information related to “facts of nature.” It took Sahagún decades to complete his project of documenting the indigenous perspectives on religion, history, aspects of social life (e.g., characterizations of good and bad qualities in parents as well as children, the respondents’ perceptions of others—for example,

neighboring peoples and European foreigners), and information about the geophysical environment, including flora and fauna. The product was his *Historia general de las cosas de Nueva España*, later known as *Florentine Codex*, a bilingual opus written in Nahuatl and Spanish, supplemented by hundreds of ethnographic illustrations and various comments by Sahagún himself (Leon-Portilla, 2002).

Sahagún was not the only missionary who refined social scientific fieldwork in the sixteenth century. Many examples can also be taken from the Jesuits’ approach to intercultural perspective-taking. In China, for example, they further developed their accommodation method: They acquired profound general and intellectual knowledge of the host society, dressed, behaved, and talked like the members of the various Chinese societal groups—especially the literate elite because they were the ones most interested in the Western scientific knowledge that the Jesuits were able to offer and that served as a common ground of understanding on which the missionary work could be built. The Jesuits applied psychological assumptions in the field of intercultural communication. Instead of simply trying to convey Christian concepts and beliefs to the Chinese, they tried to find out what field of knowledge their Chinese interaction partners were especially interested in, what they had already contributed to that field, and what kind of Western knowledge could serve as a valuable contribution to the Chinese body of knowledge. Thus, they first tried to identify culture-specific intellectual interests that promised a successful intercultural exchange and then took that exchange as a starting point for further exchange on various levels and topics, including religion and philosophy. One famous example of this method was Jesuit missionary Matteo Ricci’s “Treatise on Mnemonic Arts,” which he wrote to teach Western memorization techniques to the Chinese. Ricci, who had studied the Chinese and their languages for more than a decade before writing his book, chose this topic cognizant of the importance of memorizing vast amounts of text from the Chinese classics when preparing to apply for a position in Chinese civil service administration. At least in Ricci’s case, the Chinese nobility and literati welcomed his efforts and—as he had expected—became interested in learning more about Western and Christian thinking in general.

Like Sahagún, many of these missionaries developed outstanding approaches to methodically investigating a foreign culture to understand

how people from that culture view and understand the world. They learned the languages of the cultures they were staying in fluently, became familiar with the natives' oral and written traditions, and employed the method of long-term interactive and non-interactive observation in manifold ways. Although these missionaries' main goal was always to promote their faith and to persuade the natives to convert to Christianity, the methods they used to achieve this goal were culture-sensitive and rooted in the methodological, hermeneutical, and psychological question about how beliefs, worldviews, and concepts can be translated into the meaning systems of a foreign culture without naively tapping into the pitfalls of ethnocentrism. Thus, these missionaries became forerunners of cultural anthropology, ethnolinguistics, and cultural psychology. In so far as they were interested in the indigenous cultures and mindsets of their members, they were also pursuing one of the main goals of indigenous psychology: acknowledging that scientific theories have a certain cultural and historical range and that in many cases they may not provide the concepts, the methodological equipment, or the intercultural competence to adequately deal with the foreign and the others.

Not surprisingly, the Catholic Church criticized many of the missionary field workers for their attempts to combine Catholic tenets with elements of the indigenous (e.g., Nahua or Confucian) belief systems. Sahagún's work, for example, was not published until the early nineteenth century. The Spanish inquisition prevented the publication, because—willingly or unwillingly—it attested to a remarkably high level of civilization of the Nahua people and their culture, even before their conversion to Christianity. Moreover, because Sahagún's emic approach had allowed the indigenous people to convey their own views, the 12 volumes of the Florentine Codex contained depictions of the Spanish that were not altogether favorable. After publication, it contributed to that century's culturalist perspectives in the social sciences but was mainly ignored by the historiography of the social sciences, including the historiography of psychology, even of culture-inclusive psychology.

### ***Historiography and Scientific Importance of an Indigenous Psychological Perspective***

Western historiographies convey a number of assumptions about culture-sensitive psychology, including the following:

- Compared to Western psychological thinking and research, as it was laid down in the nineteenth century within the framework of the laboratory-based experimental and nomothetic paradigm, all previous thinking and research of a psychological nature is prescientific.

- The academic institutionalization of culture-sensitive psychology became possible as soon as psychology conceived of culture as one more independent variable within an experimental or quasi-experimental research design. Because that—at least as a broader movement—did not take place before the twentieth century, all earlier approaches to the psychological investigation of the relationship between culture and humans were, scientifically speaking, inadequate and unsuitable.

- The history of psychology is a success story of scientific progress. Within this linear understanding of progress, it seems that culture-sensitive psychology developed from prescientific speculation during the Early Modern Age, to naïve conceptions of “folk psychology” in the nineteenth century, to the testing and measuring procedures within psychological anthropology at the turn of the twentieth century, and finally to cross-cultural psychology, the nomothetic approach of culture-informed psychology.

- Against this background, cultural psychology then appears to be a new and critical endeavor that, just a couple of decades ago, resulted from dissatisfaction with cross-cultural psychology's ways of dealing with the topic of culture.

- Finally, indigenous psychology appears to be the latest of the branches of culture-sensitive psychology and seems to have its beginnings within the academic post-Colonial protest movement against imperialistically imposed (culture-insensitive) guidelines and standards of the best way to do culture-informed psychology.

As the few examples given above have shown, and as I tried to show in more detail elsewhere (Chakkarath, 2003), this historiographical account is unconvincing. Essential features of both cultural and indigenous psychology can be traced back at least to the culture-informed scientific fieldwork performed in the sixteenth century, shortly after Europe's discovery of distant cultures in the West and the East. Thus, achievements by researchers like Sahagún and Ricci took place far before the scientific revolution and far before the culturalization of the social sciences in the nineteenth century. Scholars like Vico, Herder,

and Humboldt emphasized early that humans, because they are social, cultural, and self-conscious beings who give meaning to their lives, actions, and beliefs, cannot be scientifically investigated within the experimental and mathematical-statistical paradigm of modern physics. Against this history of ideas, nomothetic approaches to the investigation of the cultural dimension of the human psyche do not appear to be a plausible consequence of consecutive linear steps toward cross-cultural psychology. Rather, nineteenth-century psychology can be seen as an interruption of a scientific tradition that foreshadowed core positions and methodological convictions held by cultural and indigenous psychology until today.

With regard to the psychological aspects of historiography and what is usually called “scientific progress,” there are some interesting lessons to be learned that can be related to important theories of the philosophy of science and moreover to Wundt’s idea of a dual psychology. Like Herbert Butterfield (1949), Michael Polanyi, and Stephen Toulmin (1961) before him, it was especially Thomas Kuhn (1970) who tried to explain scientific progress—that is, the success of certain paradigms over others—by drawing upon concepts taken from cognitive and social psychology. His model of paradigmatic change makes use of Butterfield’s theory about “mental transpositions” that take place when scientists—primarily in times of considerable and rapid social change—put on new “thinking-caps” that help them to assess various phenomena in a new way so that they can still be interpreted and understood although the contextual conditions and familiar frameworks of thinking might be changing. Kuhn uses the term *gestalt switch* to describe the change within the cognitive process that supports the paradigmatic change. We could also call it a change within the scientist’s mindset.

If we take this psychological view on the history and the historiography of psychology seriously, it becomes obvious that this perspective is an essential aspect of what Wundt called the “higher” mental faculties and processes of our mind, which he—in line with Vico, Herder, Humboldt, Lazarus, Steinthal, and others—wanted to be investigated so that we would understand the inter-relationship between onto- and phylogenesis and between the individual psyche and the social and cultural conditions of its functioning and development. Moreover, this perspective demands a culture-sensitive approach to investigation because different socio-cultural and

historical contexts might foster different paths of individual and social development, including the development of scientific thinking. These differences could include the concept of development, which is not necessarily as tightly linked to the concept of science as it is in the dominating Western traditions of thought. Concepts like these might function as thinking caps, which might be useful in a certain regard but might also be a hindrance to a sounder understanding of the psychological meaning of culture in the world of meaning-making humans (Bruner, 1987; 1991). It might also prevent us from identifying and acknowledging valuable contributions to our discipline because having a certain mindset prevents us, for example, from expecting contributions to culture-sensitive science from missionaries and within the early times of Western colonialism. Moreover, the evaluation of the quality of these contributions—especially within a culture-specific understanding of development and progress—might be guided by presentist judgments (i.e., by measuring achievements of the past against our current understanding of proper science). This is not only true in diachronic perspective—that is, the genesis of science over time in its own culture as well as in other cultures—but also in synchronic perspective (e.g., with regard to judgments about different current approaches within a given culture as well as across cultures). Here, we also have to face one of the most problematic impediments when dealing with the psychological investigation of culture: culturally and historically embedded stereotypes about “us” and the “others,” and the dense bundle of stereotypes known as ethnocentrism (Chakkarath, 2010c).

It should be clear that the psychological investigation of these aspects in a culture-sensitive way can profit considerably from conceiving of certain traditions of doing psychology as indigenous traditions. Of course, that includes Western psychology and all its subdisciplines as well and is not challenged by Western psychology’s claim that it is oriented toward universalism because (1) the frequent reiteration of its claim of universal validity might be one of its many indigenous features, and (2) even most non-Western conceptions of psychology that we know of share the very same claim. A closer look at some of the key features of current indigenous psychology as well as some examples from Indian psychology, which I will present in the next section of this chapter, will help illustrate these points.

As a first result, we should keep in mind that only a proper historiography of psychology can help us understand the development of cultural and indigenous psychology (Pickren, 2009), and that, at the same time, it is an indigenous psychological perspective that can help us develop that kind of historiography. It is also an indigenous psychological perspective that helps to arrive at a sounder and *culturally informed* understanding of psychology as a cultural construction (Marsella, 2009) and its role in shaping the cultural and mental frameworks of our thoughts, feelings, and behavior.

### **Indigenous Psychology** *The Recent Development of Indigenous Psychology*

*Indigenous psychology* is a term that characterizes the latest approach within culturally informed or culture-sensitive psychology that aims to deal more appropriately with the relationship between culture and the human psyche. Although frequently the beginning of indigenous psychology is associated with the books and articles that first started using the term in the 1970s, as we saw in the historical sketch given above, key elements of the approach can be traced back much further, at least to the theoretical and methodological attempts of certain sixteenth-century missionaries to make learning about the perspectives of members of indigenous cultures an essential part of empirical social scientific work by letting those members speak for themselves. Within the more recent discussions about the status quo of psychology, however, one notices that, at least in Europe, many of the debates within so-called “critical psychology”—especially as initiated by the German psychologist Klaus Holzkamp in the mid-1960s—concerned topics and questions broached by cultural but also by indigenous psychologists. A strong critic of behaviorism, Holzkamp drew upon the theoretical foundations of the Russian socio-historical school of psychology and analyzed phenomena like perception, cognition, and motivation as historically and culturally shaped concepts of meaning. Moreover, his critical psychology also focused on aspects of power and power differences in relationships and society as well as their effect not only on the psycho-social well-being of individuals and groups but also on the success of certain psychological theories. As for the latter, critical psychology took up many elements of Thomas Kuhn’s analyses of the mechanisms behind what is considered scientific progress. Although cultural psychologists and

indigenous psychologists share many of critical psychology’s point of views, the topic of power and how it has been exercised in spreading Western psychology all over the world plays a much more important role in the indigenous psychology literature. Thus, it is not surprising that indigenous psychology, at least in this regard, echoes the main themes of postcolonial studies, which frequently reflect on the lasting psychological effects of colonialism, including the role of science as one of colonialism’s most effective instruments. Within the latest discussions of indigenous psychology, the question of power with respect to various levels of human relationships is a crucial one. Critical psychology and cultural psychology have been focusing more closely on intracultural aspects of unequal power distribution—for example, debates about appropriate scientific approaches (and the dominance of quantitative methods) or gender-related issues. Indigenous psychology adds a focus to the intercultural, international, and global effects of power (e.g., the role and effects of colonialism, Eurocentrism, and scientific hegemony).

Apart from this specific point of view, indigenous psychologists and cultural psychologists often cite the same intellectual sources. Thus, the contributions of Jerome Bruner and Ernst Boesch, the founders of twentieth-century cultural psychology, also play a prominent role in indigenous psychology. This is especially true for their criticism of mainstream psychology’s attempt to decontextualize human behavior, thought, and feelings, an effort that lost sight of human beings as intentionally acting individuals who are deeply embedded in a complex web of culturally mediated meanings from birth on. According to this picture, humans are bound to this web and at the same time take part in weaving and modifying the web. Although these webs are the scaffolds of what we call culture and are therefore universal, the structures themselves are different and even vary within a given society and its subgroups. They also vary between people from different regions and environments and between people with different socio-cultural histories, worldviews, and value and belief systems. As we saw above, these contributions to the European history of science were quite early and elaborate but were superseded by the paradigm of natural science as it was promoted by biological and psychological behaviorism.

Along the lines drawn by critical psychologists and cultural psychologists and dating back at least to Vico, scholars from non-European and non-American countries, many of whom had become

acquainted with Western psychology during a period of colonialization, began evaluating the adequacy of Western psychological theories and procedures for their indigenous populations. One of the first attempts to contrast a specific national psychology with mainstream (especially U.S. American) psychology was Berry's (1974) portrait of a "Canadian psychology." A few years later, Rieber (1977) used the term *indigenous psychology* to describe early nineteenth-century attempts to develop an American psychology that would fit the genuine socio-historical and intellectual context of the United States. Interestingly, however, most assessments in this direction came from countries that were not usually represented in the samples of mainstream psychology: the so-called "WEIRD" samples of Western, Educated, Industrialized, Rich, and Democratic societies (Henrich, Heine, & Norenzayan, 2010). Sinha (1969, 1984, 1986) documented the necessity of indigenizing Western psychology to fit the people and their specific cultural environments in India; Doi (1973) and Azuma (1986) followed suit in Japan, Diaz-Guerrero (1977) in Mexico, Enriquez (1977, 1978, 1990, 1993) in the Philippines, Ho (1982, 1998) in China and other East-Asian countries, Yang (1986, 2000) in Taiwan, and Kim (Kim & Berry, 1993, Kim, 2001; Kim, Yang, & Hwang, 2006) in the Republic of Korea. Moreover, *Indigenous Psychologies* was also the title of a frequently cited collection of essays documenting the early attention that the approach received at the interface of anthropology and psychology (Heelas & Lock, 1981).

Of the earlier publications mentioned above, some not only request modifications of Western approaches to make them fit non-Western contexts and subjects, but they also doubt the general scientific value of some core Western concepts when it comes to merely understanding psychological phenomena in certain cultures. The probably best-known example of this challenge to Western psychology is Takeo Doi's (1973) criticism of Western attachment theory and his assumption that the Japanese concept of *amae* represents a culture-specific form of interpersonal behavior and related personal feelings that can only be understood within the semantics of the Japanese language. He offered various approximate translations (e.g., "indulgent dependency" or "craving for affection") that are meant to describe the unique relationship between Japanese mothers and their children and that he sums up as "personal freedom within safety and dependence,"

emphasizing that the Western notion of autonomy, which is understood to contrast with dependence, is not applicable to the specific make-up of the Japanese psyche. Within the *amae* relationship, the mother exercises a maximum of indulgence and care that, according to Doi, serves as the basis for the child's efforts to become an autonomous person in the Japanese sense. According to Western attachment theory, an overprotective mother hinders her child's autonomy development and is therefore evaluated as problematic. However, the Japanese mother experiences herself as warranting her child's positive development, which makes her feel fulfilled and happy. Doi thus questions Western attachment theory's characterizations and categorizations of secure as opposed to insecure types of children and mother-child relationships. He then uses his analyses to develop a more general theory on the indigenous specifics of the Japanese understanding of individuality, autonomy, responsibility, freedom, and self, thereby showing the broader relevance of *amae* for a deeper psychological understanding of the Japanese culture and its members.

Some of the main aspects of Doi's theory, especially his insistence on the strictly indigenous and unique nature of self-development in Japan, have been criticized (e.g., Yamaguchi & Ariizumi, 2006). Nonetheless, his assessment that the range of Western attachment theory is culturally restricted was also welcomed within Western psychology (Rothbaum & Morelli, 2005) and psycho-analysis (e.g., Johnson, 1993) and thus serves as one of only a few examples of the success of a non-Western theory in Western psychology. Like Doi, other researchers, including cross-cultural, cultural, and indigenous psychologists, identified concepts they believed to be culture-specific—that is, indigenous (for a list of researchers, countries, and examples, see Kim, Yang, & Hwang, 2006). Similarly, the fields of cultural psychiatry and counseling have identified indigenous features of mental illness and therapy as well as different attitudes toward the "abnormal" in different cultures (Gielen, Fish, & Draguns, 2004; Pedersen, Draguns, Lonner, & Trimble, 2002) that are of interest for indigenous psychological perspectives. Taken together, the sum of examples and the perspectives taken by some authors might create the impression that indigenous psychology advocates a strong cultural relativism that shows up when, for example, the term *indigenous psychology* is replaced by *indigenous psychologies*. However, as we will see, this may only be true for a minority

of psychologists, even for a minority of those who would call themselves indigenous psychologists. All in all, one can state that indigenous psychology is currently undergoing a phase of self-discovery as can be seen in the special issue of *Applied Psychology: An International Review* (1999) as well as in the variety of topics and methodological approaches documented in the *Asian Journal of Social Psychology*, the journal of the *Asian Association of Social Psychology (AASP)*, which was founded in 1995. A special issue published in 2000 documents the historical, philosophical, and methodological debates that have continued since then (e.g., see Greenfield, 2000; Jing & Fu, 2001; Kim, 2001; Kim, Park, & Park 2000; Moghaddam, 1987; Shams, 2002; Shweder, 2000; Sinha, 1998; Triandis, 2000; Yang, 2000; see also the additional special issues on indigenous psychologies of *Australian Psychologist*, 2000, *Asian Journal of Psychology*, 2005, *The Psychologist*, 2005, and the *International Journal of Psychology*, 2005 and 2006). The manifold spectrum of the field is also well-documented in two books edited by Kim and Berry (1993) and Kim, Yang, and Hwang (2006). Although both publications show that the movement is represented by psychologists from many corners of the world, they also show the striking number of Asian psychologists among its prominent spokespeople. For example, the increasing role of indigenous psychology in India is tellingly documented in the so-called “Pondicherry Manifesto of Indian Psychology” (2002). Signed by 160 Indian psychologists in 2002 (among them some of the most prominent Indian researchers), the manifesto characterizes psychology in India as a “western transplant, unable to connect with the Indian ethos and concurrent community conditions (...) by and large imitative and replicative of western studies, lacking in originality and unable to cover or break any new ground” (p. 168). Also, the first International Conference of Indigenous and Cultural Psychology was held in Asia (Indonesia) in 2010. On that occasion, the *Asian Association of Indigenous and Cultural Psychology* was launched and the publication of the *Asian Journal of Indigenous and Cultural Psychology* announced.

### ***On the Current State of Indigenous Psychology***

As mentioned above, the first book entitled *Indigenous Psychologies* (Heelas & Lock, 1981) was published in the early 1980s and combined perspectives from cultural anthropology and psychology.

Whereas that book focused on the “anthropology of the self,” a later book edited by Enriquez (1990) presented the first collection of international essays addressing a larger number of more genuinely psychological topics (with a clear emphasis, however, on “Filipino psychology”), thus documenting the broad spectrum of a field that the title of the book identified as *Indigenous Psychology*. Three years later, Kim and Berry (1993) published a volume with a title focusing again on numerous *Indigenous Psychologies*. Their book gained more recognition, probably in part because the selection of topics as well as the higher number of authors from different countries showed that the movement had already gained momentum. In the introduction to that book, the editors suggested that we conceive of indigenous psychologies “as the scientific study of human behavior (or the mind) that is native, that is not transported from other regions, and that is designed for its people” (Kim & Berry, 1993, p. 2). Although this definition gives us a glimpse of the direction of impact the investigation of indigenous psychologies might have on mainstream psychology’s claim of universal validity, it also raises questions about the character and aims of indigenous psychologies. First, it is almost impossible to verify whether a tradition of psychological study was solely developed within a given region and only for the people of that region. From what we know about the history of science, we may assume that scientific knowledge—as almost any cultural achievement—has been spread across regions and cultures since the beginning of scientific thinking. We may also assume that one of the reasons why the diffusion of psychological knowledge across cultural boundaries was frequently successful is that various cultures found at least some of the foreign psychological theories applicable to themselves. So it seems more plausible that in many cases we are dealing with indigenous psychologies that resulted from import and *indigenization*. We need to remember that, for most of history, human societies did not develop psychologies solely for themselves and that many societies were willing and quite flexible in integrating foreign knowledge into an already existing indigenous body of knowledge. The readiness of European regions to import U.S. American psychology since the early twentieth century is a very prominent example of the continuity of this development. However, a process in which indigenous psychologies were designed hermetically within a specific region and only for that region’s people,

and then exported into the regional and cultural contexts of other people, would have to be considered an imposition. A prominent example of this kind of process—at least if we take the critical assessment by many Asian, African, and Latin American psychologists seriously—is the export of psychology during European imperialism and colonization (Holdstock, 2000; Howitt & Owusu-Bempah, 1994; Moghaddam, 1987; Paranjpe, 2002). Moreover, with regard to the validity and reach of psychological theories, the definition of indigenous psychologies as given above suggests a certain relativist position that, according to some researchers in this field, actually became quite influential.

A third collection of essays (*Indigenous and Cultural Psychology*) edited by Kim, Yang, and Hwang (2006) documents the development of indigenous psychology since then and its state of the art in the early twenty-first century. In part, the title signals how the issues mentioned above entered the discussion about the character and goals of the discipline. Instead of highlighting several indigenous psychologies, the title advocates one indigenous psychology—that is, it focuses more on one overarching conceptual and scientific approach than on multiple traditions of psychological thinking. In addition, the title (as does the whole book) emphasizes indigenous psychology's familial relationship to cultural psychology.

In light of the debates mentioned above and by extending and modifying Kim and Berry's (1993, pp. 3–4) list of six aspects of indigenous psychology, Kim, Yang, and Hwang (2006) provided a list of 10 aspects that, against the background of discussions I have portrayed so far, reflect how the discipline is striving for a clearer scientific profile. I paraphrase:

1. Indigenous psychology emphasizes the need to investigate psychological phenomena in their specific ecological, historical, and socio-cultural contexts.

2. It does not, as the term might suggest and as many of the leading cultural and psychological anthropologists of the twentieth century did, concentrate on the investigation of so-called “exotic” people in distant regions of the world. Rather, it aims to investigate all cultural and ethnic groups. Of course, this includes the WEIRD samples, but it recognizes them as only one very specific sample that neither reflects the variety

of groups in developed Western societies nor the plethora of cultures and subcultures distributed across the world.

3. Indigenous psychology advocates the use of multiple methods and various research designs and does not consider an exclusively quantitative research design appropriate for dealing with a variety of cultural environments and subjects.

4. Indigenous psychology considers a close cooperation between “insiders” and “outsiders”—that is, the conflation of internal and external views, a sine qua non for the development of integrative theories about the relationship between culture and individuals.

5. Psychologists within mainstream Western psychology have been testing the hypotheses that are based on Western samples using new samples in foreign cultures. Thus, they have mainly been testing the ethnocentrically biased, ready-made psychological theories formulated by the specific sample of psychologists they belong to. Indigenous psychology acknowledges that individuals in all cultures have a complex and developed, practical and episodic, understanding of themselves. However, most of them are not trained academically to identify and describe the structures and processes that are the grounds for the development of such understandings. It is therefore the task of indigenous psychology to translate and arrange the indigenous subjects' knowledge in a way that allows for accurate psychological testing.

6. Indigenous psychology pushes for the integration of various perspectives without advocating various psychologies. In other words, it is not to be equated with cultural relativism but rather with a culture-informed and genuinely integrative psychological approach. At the same time, facing the claim that there may be many examples of indigenous concepts that do not have an equivalent translation in other languages, indigenous psychology aims to verify the psychological relevance of these concepts. In this regard, it has two complementary goals: to identify truly indigenous psychological phenomena and, at the same time, to more thoroughly test psychological theories that claim universal validity.

7. Although there are attempts to stress the relevance of philosophies, religions, and other worldviews within indigenous psychology, indigenous psychology should not be equated with a thought tradition of a specific culture. To prove

that any given thought tradition has psychological relevance, its hypotheses need to be translated into psychological concepts and empirically tested.

8. Humans are culturally shaped agents of their culture who themselves stabilize as well as change it. They are the subjects as well as the objects of psychological research who not only possess insight into their inner and outer worlds but also send and receive communications about their and others' insights. To deal with this complexity adequately, researchers must integrate the perspectives taken by all individuals participating in the interactions under investigation, including their own scientific perspective.

9. Indigenous psychology supports an interdisciplinary approach to the investigation of culture. It should be clear that, by definition, any culture-informed psychology should take advantage of knowledge provided by other scientific disciplines (e.g., sociology, anthropology, philosophy, philology, the science of religion, history).

10. Finally, according to indigenous psychology, indigenization from without can be as useful and necessary as indigenization from within. "Indigenization from without" refers to the importation of already existing psychological theories and methods into another culture and the process of their adaptation to the cultural and environmental specificities of the other culture. "Indigenization from within" refers to the development of theories and methods within a certain culture, based on indigenous knowledge; of course, this "internal" knowledge can also be exported to refine general psychological knowledge.

This characterization of indigenous psychology contains key features emphasized by most researchers within the field. However, although certain features are highlighted, others are not mentioned at all or downplayed, thus reflecting a certain ambivalence toward particular issues that reflects the differing views held by different researchers.

For example, as I mentioned before, the list attempts to avoid the impression that indigenous psychology advocates cultural relativism, which might be the reason why the term indigenous psychology is favored over the term indigenous psychologies. However, without going in depth into the fields of the philosophy of science and epistemology, let us simply note that in one way or another, the position

of cultural relativism has been held by or attributed to many different prominent social scientists (e.g., Franz Boas, Margaret Mead, Ruth Benedict, Clifford Geertz, Kenneth Gergen, Richard Shweder) and has played and still plays an important role as a heuristic and critical tool in cultural anthropology as well as other cultural sciences. It is not an unscientific position, but one that characterizes specific traditions and schools, cultures of scientific thinking, so to speak. As such, from a scientific point of view, it is nothing to worry about (contrary to the reservations of prominent cross-cultural psychologists like Poortinga, 1999, and Triandis, 2000) but, rather, something we need to deal with scientifically (Geertz, 1984). Moreover, if we take the approach called indigenous psychology seriously, we should be open to the possibility that we may find psychological phenomena that can only be found in certain cultures and contexts or that function differently across cultures—that is, play a different role for different people who are embedded in different webs of meaning. We would then call these phenomena indigenous. If, however, indigenous psychology is not open to that perspective and considers itself an approach that is exclusively interested in universals, then it becomes a mere complimentary science to mainstream psychology and I am not sure if that would fit its self-understanding.

The list given above also shows an ambivalent attitude toward the role of religions and other worldviews. On the one hand, it emphasizes that we should not hasten to view historically developed worldviews or any other traditions of thought that somehow address psychological issues as relevant for indigenous psychology. On the other hand, many examples of so-called "indigenous concepts" presented in various studies are embedded in the context of religions or other worldviews, which are also frequently used to explain certain aspects of human thought and behavior. Although it is certainly true that we need to prove empirically the psychological relevance of these kinds of theories, it is also true that before doing so we need to render more precisely the theories in question and also evaluate whether there are indigenous theories of psychological relevance. Therefore, indigenous psychology should consider as one of its tasks and competencies the identification and accurate presentation of indigenous theories that have hitherto been ignored by mainstream psychology. In this regard, it is also important to note that the relevance of these kinds of indigenous theories should not depend solely on

their successful translation into the nomenclature of previously existing theories but on the evaluation of the role they play within the theory of origin. In addition, if indigenous psychology shares the cultural psychologist's conviction that we need to investigate psychological phenomena in their specific ecological, historical, and socio-cultural contexts, then it should acknowledge that these contexts are often co-constructed, structured, and considerably influenced by religions and other worldviews.

Against the background of the socio-historical aspects of psychology and their importance as outlined in the first section of this chapter, let us add a final comment: Indigenous psychology should consider the analysis of psychology's development to be one of its main tasks, especially with regard to indigenous and national but also global aspects. Some researchers highlight the effects of colonialism and the colonialists' psychology on the people living in former colonies and also note that the recent emergence of indigenous psychology is related to post-Colonial reassessments of the socio-cultural impact of Western science in general (Bhatia, 2002; Marsella, 2009; Moghaddam, 1987; Smith, 1999). Others tend to deal with these issues at the periphery of their work or even largely ignore them. However, ignorance toward these aspects will fail to do justice to the goal of properly understanding all aspects involved in human psychological development. Therefore, these issues should not be left to historians, sociologists, and politicians but should be of utmost importance to psychologists, especially to psychologists interested in indigenous perspectives.

I will return to this characterization of indigenous psychology in the last part of the chapter, but now, following this portrayal, I believe it is necessary to raise the question concerning the extent to which the aims of indigenous psychology listed above differ from those of cultural psychology. As we saw above in the historical sketch of early culture-sensitive field research, both the indigenous psychology approach and the cultural psychology approach can be traced back to the same historical beginnings. It would go beyond the scope of this chapter to list the main characteristics of cultural psychology, but I will say this: I cannot help getting the impression that most of the foundational work outlining cultural psychology's program and self-understanding proposes a very similar view of humans as culturally shaped shapers as well as very similar perspectives on how to proceed methodologically when investigating the human psyche in a culturally informed way (Ratner,

2002; Straub, 2006). Because the question of what cultural psychology can learn from the indigenous approach is at the center of this chapter, it needs to be addressed. However, before I attempt to propose an answer, I think it would be appropriate to at least give an exemplary sketch of an indigenous psychological perspective on a key topic of psychology in general, to show how it helps to decrease stereotypical and ethnocentric perceptions of the "other" that are deeply embedded in our cultures, including the sciences, and to show how it might help refine our understanding of the inseparable relationship between culture and humans, an endeavor that cultural and indigenous psychology share.

### ***Psychology of the Indian Self: Eurocentric and Indigenous Views***

#### **STEREOTYPES IN THE WESTERN VIEW**

##### **OF ASIA AND INDIA**

There is a long and influential Western tradition of viewing the regions and peoples living to the east of Europe, the formerly so-called "Orient" and the "Orientals" (Said, 1978/2003)—especially "Asia" and the "Asians"—as distinctively different from "Europe" and the "Europeans" (Chakkarath, 2010a). The interest of culture-inclusive psychology in the comparison of "East" and "West" is still salient in many research designs and publications of cross-cultural and cultural psychology (Ward, 2007) and was also the focus of earlier influential contributions by Western sociology or cultural and psychological anthropology. For example, Max Weber's seminal studies on world religions and their meaning for cultural and economic development was to a considerable extent a comparison of Western and Eastern rationality and had a profound influence on Western scientific assessments of Asian culture and psyche. Ruth Benedict's *The Chrysanthemum and the Sword* may have been criticized by many for its "national character" approach and overly simple (and somewhat demeaning) dichotomous comparison of the Japanese "shame culture" with the Western "guilt culture," but it nonetheless established patterns of comparison that still have a palpable impact on cross-cultural comparisons of "Easterners" and "Westerners" (cf. Chakkarath, 2010c).

In culture-inclusive psychological research, the focus of interest is frequently on "self" and "cognition" (i.e., two central domains of psychological research in general). These topics, especially with regard to self-concepts, have been investigated for several decades now, ever since Hofstede based his

individualism–collectivism differentiation on an impressively large data pool from more than 40 countries (Hofstede, 1980). This differentiation has also been discussed among European scholars since antiquity and regained prominence with the individual-centered view of man propagated by thinkers of the European Renaissance. It also shows up in Triandis' (2001) differentiation between *ideocentric* and *allocentric* tendencies and Markus and Kitayama's (1991) well-established distinction between the *independent* and *interdependent* self. These and similar theories frequently draw upon the broader differentiation between Westerners and Easterners and also make use of additional dichotomous constructs like individual orientation versus group orientation, autonomy versus relatedness, separation versus connectedness, high versus low self-monitoring, high versus low context dependence, stability versus instability, and so forth. Theories about the underlying cognitive basis of intercultural varying self-other perceptions and thinking styles also place their bipolar concepts in the framework of the geographical East–West dichotomy. Well-known examples are Nisbett's *The Geography of Thought*, in which Western and Chinese cognitive styles are contrasted (2003) or Peng's studies on differences between U.S. Americans and East Asians in perception, interpretation, and reasoning (Peng & Nisbett, 1999). Against this background, I have chosen the analysis of the self to illustrate how an indigenous perspective might increase our culture sensitivity in developing psychological theories and research. The example I am going to present as an indigenous psychological discourse is taken from India and focuses on the academic debate between Hindu and Buddhist scholars about the nature of the self. I will start with a few remarks about some influential stereotypes in the European tradition of portraying India and the Indian self before I contrast these views with indigenous Indian accounts of the self.

In many of the theories mentioned above, the attributes of a stable, independent, autonomous, rational, and responsible self are usually related to Westerners, whereas attributes deficient in these qualities are usually related to Easterners. This line of thought can also be found with regard to many European scholars' view of India, which itself can easily be traced back to European antiquity where the earliest written accounts of India and its people by "Westerners" can be found in the works of Greek and Roman authors (e.g., Ctesias' *Indica* and

Herodotus' *Histories* from the fifth century BC or Pliny's *Natural History* from the first century AD). According to most of these authors, India is a land of miracles and wonders, an image that has survived for millennia and that became the basis of India portraits, especially in the age of Romanticism. Although this portrait is not necessarily pejorative, in many cases it was accompanied by assumptions about the almost complete "otherness" of Indians as compared to other peoples of the world. For example, until the Middle Ages, even "monsters" (i.e., creatures [like dog-headed men] that bridge the gap between animals and humans without belonging to either of the two groups were said to abound in India, reiterating a topos deeply embedded in European views about the East; see Jahoda, 1999). Accordingly, many European travelers like Ludovico di Varthema, who visited the country in the sixteenth century, interpreted sculptures of Indian deities as images of monsters. Even in the Age of Enlightenment and under the perspectives of philosophical rationalism and empiricism, historically developed stereotypical ideas about India were not completely abandoned (Chakkarath, 2010c). Hegel was only one of many leading European scholars of the eighteenth and nineteenth centuries who declared these alleged intellectual deficits to be psychological deficits and related them to societal deficits,—an enduring thinking pattern that Gergen (1994) identified as a "deficit discourse." Although Hegel's verdict on the intellectual achievements of Asian cultures was broadly general, he found some gradual differences between different Asian civilizations, especially between China and India. In comparing the Chinese and the Indian cultures, he claimed that the failure of Indian thinkers to come up with the idea of a stable and autonomous self was to blame for their failure to build modern, clearly defined, stable, autonomous, and reliable nation-states like those in Europe or that in China. Instead, the almost complete lack of proper scientific thinking and the boundless and erratic style of Indian self-theories resulted in declaring the subject–object difference an illusion so that neither a concept of individuality or personality nor a historical consciousness or a conceptualization of individuals as historical persons could arise. Hegel's account of the psychological nature of the Indian self is a diagnosis of deficits, and as for many scholars after him, including some twentieth-century social scientists (e.g., Weber and Benedict), it is especially these deficits that allow

one to differentiate between Westerners and most Easterners, including Indians.

In the following, let us try to take an indigenous psychological perspective on the Indian self and see the extent to which it confirms or disputes core aspects of the Western assessments exemplified above. To also show the character and quality of academic discourse within indigenous Indian analyses of the self, I will first present some key features of Hindu traditions of thought and then contrast them with assessments by Buddhist psychology.

#### INDIGENOUS VIEWS OF SELF AND IDENTITY: HINDU AND BUDDHIST PERSPECTIVES

Hindu beliefs play different roles in the everyday lives of different Indians—depending especially on the region they live in, their social class, caste, gender, and education—but there are central tenets that most Hindus share (for a more detailed description, see Chakkarath, 2005; in press). One is the belief in *brahman* (“eternal universal soul”), the all-encompassing life force that embodies all aspects of existence and that is reflected in *atman* (“individual self”), the life force that makes any living being part of *brahman*. It is a core conviction of Hindu believers that not understanding the relationship between *brahman* and *atman* is deeply problematic because ignorance of the true nature of this relationship results in suffering. Suffering is the underlying principle of all existence, and human beings are equipped with a cognitive system that is the main source of human suffering. However, they can be trained to cope with life’s miseries and even to overcome them.

The problem of suffering arises especially from the nature of the individual self and the psychological processes that cause its development. In other words, it is mainly caused by processes within the human psyche: The individual develops the conviction that he is a unique and separate entity, in principle unrelated to the rest of the world, which he sees as the “other” sphere of life. Thus, the individual constructs an opposition between himself and the world instead of recognizing that all beings and things and phenomena of the world, including himself, are reflections of one and the same—that is, *brahman*. This ignorance is the source of egoism (i.e., unawareness of the interrelatedness and interdependence of all existing things) and results in selfish behavior, driven by uninhibited emotions, greed, the need for a diversified and adventurous life, and so forth. Because these kinds of desires

and needs constitute the root of failure, disappointment, frustration, aggression, shame, and many other negative states, it follows that the psychological processes that lead to this fateful condition of selfishness need to be analyzed, understood, and controlled. Otherwise—and this is another central conviction in the Hindu belief system—the selfish actions and behavior will result in a cycle of endless death and rebirth (*samsara*). The driving force behind the process of *samsara* is believed to be the accumulated sum total of the individual’s good and bad deeds that Hindus relate to the universal law of karma. The function of the *karma* concept can be illustrated as follows:

*Karma* can be conceived of as similar to the law of gravity that, metaphorically speaking, “weighs” and “judges” the qualities of matter and decides its velocity, direction, and place in the universe as well as its function within the larger cosmic order. A fundamental assumption of this theory is that, like matter, psychological phenomena, too, are subject to natural laws. The natural law of *karma* is believed to evaluate one’s moral behavior as “good” if one lives according to the cosmic law of being (*dharmā*). Because *dharmā* is understood as the representation of a just world that attributes a precisely defined place and function to everyone and everything, each Hindu must follow certain rules and fulfill specific duties, recognizing that selfishness will only harm that order. This code of conduct that constitutes the Hindu way of life involves doing what is right for the individual, the family, the caste (*jati*), the society, and the cosmic order. The rules of conduct were laid down in various *dharmā shastras*, compilations of laws that help one to give practical meaning to the theoretical aspects mentioned above and thus show that, from a Hindu point of view, there is no real difference between the religious and the social spheres. This becomes even clearer in the conviction that not only one’s membership in a particular caste, but even the biological, physical, psychological, and social conditions of one’s life (whether one ends up being a plant, an animal, a demon, or a human being, a member of a higher or a lower caste, male or female, attractive or unattractive, ambitious or unambitious, more or less intelligent) are decisively influenced by one’s conduct in one’s previous life. Thus, the whole belief system is metaphysically legitimized, which makes it possible for anyone to perceive social reality as just and fair, an assessment that has helped stabilize the Hindu society and the caste system for thousands of years.

Here, we should note that contrary to many Western thinkers' stereotypical assessments of the Indian self, the metaphysically induced, psychological pressure put on the Hindu to take care of his psyche actually results in stability, not diffusion. One can easily recognize the importance of a stable self within the Hindu self-theory in the idea of rebirth: According to the *atman* concept, there are core aspects of the individual self that remain stable and unchanged through all rebirths. Thus, a person's (immortal) core identity is composed of a kind of matrix into which the sum total of his *karma* is entered from birth to birth. This core identity ensures that much of the responsibility for the current life as well as for the preceding existences can be attributed to the individual himself. In addition, we should note that following a rigid normative system of rules and fulfilling one's spiritual as well as social duties does not result in world renunciation (as, for example, has been claimed by the classical Western sociology of religion, following Max Weber and Louis Dumont) but in commitment to worldly things that need to be taken care of for the sake of societal and universal order as well as for individual satisfaction. This aspect is also emphasized in the socially institutionalized Hindu model of ideal human development (*ashramadharma*), a four-stage life-span model that aims to help (mainly male) members of society attain the central material, psychological, and spiritual goals that not only reflect the Hindu value system but also Hindu psychology's assessment of human needs and desires (see Chakkarath, 2005; in press). The consecutive goals encompass the acquirement of knowledge (including knowledge about one's ritual and social duties); the accumulation of material wealth; the satisfaction of genuine human desires, such as the desire for sexuality, conjugal love, art, filial affection, fine clothes, savory food and other luxuries; and finally spiritual development and release from *samsara*. The model also suggests at what stage in life one should pursue the different goals and makes clear that human development, including cognitive development, does not end with old age because spiritual goals can be achieved more easily when the need for material and sensual satisfaction have calmed. Moreover, the model makes clear that possessing specific psychological capabilities are especially necessary to pass through the life stages successfully—namely, knowledge and the readiness to learn, concentration and truthfulness, honesty, reason, patience, forgiveness, self-control, control of

the senses and the emotions (e.g., absence of anger). The model also helps one to train these capabilities: According to the Yoga system, the best known system of Indian-applied psychology, these capabilities correspond to those that constitute the moral prerequisite of *moksha*.

Buddhist analyses of the self are partially based on the Hindu diagnosis that psychological problems are caused by cognitive processes. However, although the Buddhist scholars have maintained various elements of the Hindu framework (e.g., the idea of suffering as the fundamental principle of all being, the concept of *karma* as well as the belief in *samsara* and *karma*-dependent rebirth), there are crucial differences. From early on, Buddhism argued against the idea of an immortal core self (*atman*) that provides personal identity through all transmigrations. Similarly to the Hindu self-theory, the Buddhist theory of the non-self (*anatman*) is closely related to psychological theories of cognition.

The Buddhist theory of cognition and self is based on a detailed analysis of the psychophysical condition of humans, which is believed to be empirically examinable by anyone through systematic and regularly executed meditation exercises, which play an important role in the Buddhist way of life. With respect to contents as well as abstraction and systematization level, these analyses rank among the most important psychological contributions of Asian science. Again, I can only describe the analyses here very briefly, so what follows is merely a sketch (for a more detailed description, see Lamotte, 1988).

At the core of the analyses is the view that a person or one's "I consciousness" is collectively constituted by the five "aggregates" (*skandha*):

1. physical form (*rupa*), which includes the four elements: earth (solidity), water (liquidity), fire (temperature), and wind (expansion)
2. sensations and feelings (*vedana*): unpleasant, pleasant, or neutral sensations that stem from contact between the six internal sensory organs (eyes, nose, ears, tongue, body, and mind) and the corresponding external objects (appearance, smell, sound, taste, touch, and mental object)
3. perceptions (*sanna*): the perception of appearance, smell, sound, taste, physical form, and spirit
4. volitional formations (*sankhara*), from which the six expressions of will emerge, which

can be directed toward all of the sensations and perceptions specified above

5. consciousness (*vinna*), consisting of consciousness of the six sensory organs and the external objects assigned to them.

Humans are thus described as an aggregate of different mutually causal factors that are in constant flux and temporary. The 6 internal sense bases (organs) and their 6 external sense bases (objects) are called the 12 sense bases and, combined with the 6 forms of consciousness, they are called the 18 elements (*dhātu*). When the physical factors are taken into consideration, every mental procedure can be described as an entirely specific combination of these elements among themselves and with the perception and will phenomena they cause. The key result of this Buddhist analysis is that by means of this thus restructured and constantly changing causal structure, the illusion of a “self” that witnesses all these events is created that does not correspond to anything in reality because this self is also only the result of a process that is constantly beginning and ending. Thus, the notion of a personal soul or a lasting identity, for example, of the baby growing to become an adult or even the dead person is refuted. On the one hand, reconstructing (i.e., interpreting) such convictions as the result of psycho-physical causal relationships provides a way of explaining the development of an individualistic self-concept. In addition, we also see why a key factor of human suffering is seen in this view of self. In the causal nexus mentioned above, it causes selfish attitudes and resultant actions, which lead to negative *karma*, which results in rebirth yet again.

The question concerning what can be understood by “rebirth” if there is no “soul” with lasting identity is the most-discussed philosophical question of Buddhist philosophy and metaphysics. The perhaps most descriptive and most concise answer, which will have to suffice here, is a parable from the non-canonical text *Milindapanha*, in which an Indian Buddhist monk explains the theory to one of the Greek governors installed in Northern India by Alexander the Great in fourth century BC: Rebirth without a soul is like the flame of an oil wick, which was ignited with the flame of another oil wick; the second flame is not identical to the first but was created as a function of the first and continues on when the first is extinguished. Although we can admit that there is some causal nexus between the first and the second flame, we do not have plausible arguments

to defend the idea that both flames are identical. Buddhism declares the Hindu belief in a stable, unchanging, and even immortal self an expression of psychologically deeply rooted human selfishness: It is out of ignorance, fear, weakness, and desire that man develops the idea of *atman* to find consolation. Considering itself partially a critical reform movement, from early on, Buddhism aimed to destroy the psychological roots of these kinds of metaphysical beliefs and thus also developed a perspective on the psychology of psychology and psychologists.

Although the various schools of Hindu and Buddhist thinking forbid us to make overly general statements about the two traditions, nonetheless, the basic differences in the conceptualizations of the self may have some explanatory power with regard to differences in certain attitudes favored within Hindu and Buddhist conceptualizations of the relationship between the self and the “other” (Chakkarath, 2010). Although it is not my intention to say that in practice Hindus do not show compassion for the misery of others, it is still interesting to see that, at least on a theoretical level, the development of compassion plays a conspicuously more important role in Buddhism. As we have seen, it is a Hindu conviction that each individual forges his own destiny and that it is the destiny of an ignorant and selfish individual to be punished with new suffering in another life. This view, together with the Hindu understanding of unchanging personal identity through all rebirths, is the basis for the idea that, on the whole, *samsara* provides cosmic and societal justice. The orthodox Buddhist theory, however, holds that there is no identity between the producer of bad *karma* and the being that results from it (for Vasubandhu’s classic arguments, see Duerlinger, 2006). This means that in the end, the one who is accumulating bad *karma* is causing suffering for another being. In other words, the producer of bad karma is responsible for the creation and suffering of an existence that itself is innocent. Therefore, at least in theory, the *karma*-related guilt that a Buddhist feels is different from the guilt experienced by a Hindu. It follows that a Buddhist believer should show compassion for everything that suffers because everything that suffers is suffering innocently. Of course, the concept of the non-self (*anatman*) serves as an argument for Buddhism’s rejection of the Hindu caste system. Against the background of the Buddhist self-theory, membership to a certain caste cannot be justified by personal guilt. On the contrary, according to the

Buddhist point of view, the caste system does not reflect justice but adds to injustice and the miserable situation of the lowest castes and the outcasts. For Hindus, however, their caste is an important aspect of their belief system and their socialization context. It is the cornerstone of Hindu identity that is constituted within the manifold and intertwined aspects of the Hindu worldview, psychological analysis of cognitions and the self, conceptualizations of the other, and a model of ideal development that along with the caste system provides the framework to socially institutionalize this “identity web.”

Descriptions of Hindu and Buddhist analyses of psychological phenomena can hardly be adequate when they are removed from the general philosophical and spiritual framework in which they were developed. For most of the time since psychology was established as a modern Western science at Western universities and then implanted in universities around the world, these philosophical and spiritual elements made it easy for modern psychologists, including modern Indian psychologists, to disregard India’s and other cultures’ indigenous theories as mere pre-scientific speculation (Chakkarath, 2010b). Another indicator of the “unscientific” character of these theories was the assumed lack of an empirical method, which would assure that these theories meet the standards of modern Western psychology. However, at least in the case of the indigenous theories and debates presented above, one should be aware that the analyses of the interrelationship between cognition and self as well as the development of coping and regulation strategies were carried out by employing the probably most elaborate techniques of introspection known in the history of psychology. Interestingly, introspective methods of a different kind were considered useful in the beginning of modern Western psychology. Although Wundt did not consider them a reliable method, on certain occasions in his laboratory in Leipzig, subjects were asked to give verbal protocols of their inner experiences. More advanced introspective methods were used regularly by researchers from the Würzburg school (e.g., Bühler, Külpe, and Marbe), who trained their subjects’ introspective skills before asking them to report about their inner experiences during certain problem-solving tasks. Binet used similar methods in France, as did Titchener in the United States. James M. Baldwin, in his *The Story of the Mind* (1898), even called introspection the most important source of psychological data. Nonetheless, attempts to advance

introspective methods as a basic research procedure were short-lived in Western psychology. In fact, Watson, the father of behaviorism, even called them an alien and “un-American” import from Germany, thus contributing a little anecdote to the question concerning whether behaviorism would consider itself an indigenous psychology (Costall, 2006).

In contrast, in India and other Asian countries, more elaborate techniques of introspection and training of respective skills have been employed and refined for more than 2,500 years and are commonly referred to as “meditation.” Especially Buddhist scholars have provided extensive, highly detailed, and very precise theories and descriptions of meditation practices that not only serve the observation and analysis of psychological processes and mental states but are also employed to achieve those changes in behavioral and psychological traits said to decrease suffering and increase well-being (Conze, 2002; Lutz, Dunne, & Davidson, 2007). Of course, this twofold function of meditation practice can also be found in non-Buddhist traditions of psychology—for example, in the Hindu systems of Patanjali’s *Yoga* and *Siddhi Yoga* or in the Hindu medical system of *Ayurveda*. The systematic procedures that can be found in all these traditions have often been compared to the systematic steps taken in medicine: Identification of disease via detection of symptoms, diagnosis of causes, prognosis, treatment, and prescription. From a psychological point of view, we can hardly challenge the scientific nature of these highly systematic procedures. On the contrary, we should recognize that they aimed at a synthesis of careful observation, scholarly exchange about the adequacy of the observation and the observation techniques (over the millennia), theory development based on the analysis of the phenomena observed, and application of the resulting knowledge—for example, in therapy (Rosch, 1997). Although there is little reason to doubt the scientific nature of many aspects of Hindu and Buddhist psychology (Paranjpe, 1998), we have good reason to acknowledge that the indigenous psychological traditions, which could only be presented fragmentarily above, applied psychological knowledge within an integrative view of the psychophysical and social aspects of life, an aim that is not unfamiliar to Western psychology.

### **What Can Cultural Psychology Learn from Indigenous Psychology?**

We began this chapter with a critical look at the mainstream historiography of psychology and

its culture-sensitive branches. We saw that when a view of the genesis of so-called “Western” (especially European and U.S. American) culture-sensitive psychology tries to avoid stereotypical narrations about linear development and steady scientific progress, a very different picture of psychology’s history results than that conveyed in mainstream Western historiography. For example, we saw that high-quality culture-sensitive field research, which foreshadowed central positions of cultural and indigenous psychology, was carried out long before the Newtonian paradigm of laboratory- and experiment-based modern natural science was introduced. A certain group of psychologists adopted that monistic and nomothetic paradigm, whereas others suggested alternative approaches. Although these alternative approaches were rooted in some of the best traditions of European intellectuality and scientific research and had considerable impact on other cultural sciences, in psychology, they were typically ignored for most of the twentieth century. In this historiographic description, which does not show a continuous linear development but a variety of paths and interruptions, things are much more difficult to explain, and questions arise that are more difficult to answer. Of course, the explanations and answers cannot be given in a single chapter, but hopefully it has become clear that the answers need to include the psychological factors that Wundt and other forerunners of cultural and indigenous psychology identified as “higher” or more complex processes and products of the mind. When these scholars propagated an interdisciplinary and multimethodical approach for the psychological investigation of domains like history, religion, art, science, myths, social institutions, and interactions, they held core positions of current cultural and indigenous psychology. The issue concerning how certain psychological traits on the cultural and individual level are reflected, socio-culturally fostered, and intergenerationally transmitted is crucial for understanding the interplay of the various factors in various cultural domains that influences human psychological development and socialization. Of course, in this context, from a traditional cultural psychological point of view, the history of psychology might appear as only one discipline among innumerable scientific disciplines in which investigators could be interested. From an indigenous psychological perspective, however, the genesis of specific traditions of doing psychology comes into focus for several reasons that result from indigenous

psychology’s self-understanding and goals that were described in the second section of this chapter.

First, indigenous psychology can be seen as an approach that adds to our psychological knowledge by investigating various indigenous psychologies—that is, traditions of psychologically relevant thought and research. Second, this investigation itself profits from the expertise of the indigenous researchers involved. Third, the beginnings of recent indigenous psychology are rooted in historical, political, and sociological discussions about Western psychology’s international hegemony that was established in the era of Colonialism. Therefore, it is natural for indigenous psychology to deal with questions about the indigenous character of Western psychology, the question of indigenization from within and without, and the effects of an imposed psychology on people who experience it as unfamiliar to the ecological, historical, and socio-cultural environments in which they and their ancestors have lived. Of course, this is felt especially strongly if essential aspects of these environments still have the influence they have had for hundreds and thousands of years (e.g., the philosophical and psychological foundations of the Indian caste system). Such socio-historical dimensions and the relationship between simultaneously existing (e.g., imported and indigenous) conceptions of psychology can both be investigated much more thoroughly if we apply an indigenous psychological perspective.

Apart from what can be learned about the higher mental processes from investigating the manifold paths that scientific thinking can take, a less ethnocentric account of psychological theories and applications that can be found across cultures might provide even more accurate and fairer historiographies. It might also provide psychological knowledge from which other indigenous traditions, including Western traditions, can profit. For example, as the illustrations taken from Indian psychology have shown, a life-span perspective on development, and the insight that cognitive development does not end after schooling or with early adulthood, might appear to be a revolutionary perspective only within the paths taken by the European psychology of cognition and aging. In other traditions, this perspective might have been there for millennia and might have affected human psychological development in ways all psychologists are interested in. The same holds true for Buddhist scholars’ analysis of identity and their theory that self and personality are in a constant flux that depends on changing contexts

and interactions that simultaneously influence cognitive, emotional, and volitional processes within the individual. In the elaborate analyses of Indian psychology, there are many findings and ideas that foreshadowed modern Western perspectives on the topic of self and identity. This includes more recent theories in Western personality research—for example, the concept of identity configurations (i.e., the modes in which individuals integrate the manifold [e.g., worldly and religious] aspects of their self–other perceptions into a meaningful whole) (Schachter, 2004, 2005). Because indigenous psychological perspectives can help detect these contributions and inform the scientific community about the findings, there might be a lot to learn, not only from our own culture’s past but also from going beyond the ethnocentric boundaries of our own cultures. There we might find the roots of theories that we usually find exclusively in historiographies of Western psychology and other social sciences and celebrate as the milestones of these disciplines.

As the examples of psychological research on self-concepts have shown, socio-historically grown stereotypes and the resulting ethnocentric perspectives still have an impact on how we conceive of “the others” and is one of the main reasons we conceive of them as others at all. Interestingly, even cross-cultural psychology, which largely favors the nomothetic paradigm of the natural sciences and emphasizes the scientific need to identify psychological *universals*, has come up with countless theories that focus on cross-cultural *differences*. Hofstede’s culture dimensions, probably the most influential theory in cross-cultural psychological research and upon which a lot of cross-cultural research is based, is a prime example. The same holds true for many theories developed by cultural psychologists. Taken together, many aspects of the frequently cited theories in so-called “culture-sensitive psychology” remind one of stereotypical assessments that are deeply embedded in Western traditions of thinking about the “others” and can be traced back to antiquity. From a psychological point of view, it is not astonishing that these stereotypes also show up in the theories proposed by some indigenous psychologists. In the long run, stereotypes (especially when they successfully enter the frameworks of our scientific thinking or are already part of frameworks that are imported from other traditions) can make us believe in the accuracy and the heuristic value of the stereotypes ourselves. One example illustrating the complex problems that need to be solved here is

the question concerning the scientific value of religions and worldviews for indigenous psychology. As we have seen, people hesitate to acknowledge the value of psychological theories that can be found in religious, philosophical, or any kind of ideological frameworks. This skepticism is typical within post-Enlightenment Western science, although there were once intellectual Western traditions that aimed at reconciling our interest in spiritual goals with our interest in scientific goals. This integrative concept of knowledge can still be found in living intellectual traditions—for example, in Hindu, Buddhist, and Confucian schools of thought. Lately, it has even been rediscovered in Western psychology, where investigating the concept of “wisdom” has gained some interest (e.g., Baltes & Staudinger, 1993; Richerson & Boyd, 2005). If indigenous psychologists are hesitant to acknowledge the scientific value of these thinking traditions for their own work, then they may of course have good reasons for it. However, they might also be influenced by ethnocentric conceptions of science that are not necessarily part of the indigenous psychologies that, according to a prominent definition discussed in the second section, were once designed for the indigenous populations. In other words, indigenous psychologists should always ask themselves whether their discipline and their own mindset really provide the openness for new perspectives that is required if they want to take the investigation of any indigenous phenomena seriously and not simply stumble into the pitfalls of stereotypes and ethnocentrism themselves. Parenthetically, labeling certain non-Western traditions as “Hindu,” “Buddhist,” or “Confucian” also contributes to a stereotypical differentiation between “real” science (e.g., “Western” psychology) and “worldviews.” Moreover, it has successfully distracted us from the question whether “Western” science is also a worldview or at least unreflectedly transports stereotypes that, for example, can be traced back to Christian traditions of thinking (Altman & Rogoff, 1991). It is interesting, anyway, that one of the most influential concepts in culture-informed psychology, the concept of individualism, is frequently traced back to Christian—especially Protestant—roots. Nonetheless, no one would seriously propose renaming “Western psychology” as “Protestant psychology.” However, from an indigenous psychological perspective, it makes perfect sense to instead call any tradition of psychological theorizing and research indigenous. Although considerations like these are not completely new to

cultural psychologists, the indigenous psychological approach and the methodological reflections it requires could help to improve cultural psychology's methodological awareness, too. This includes what can be learned about the very specific role of indigenous psychologists studying natives in indigenous contexts outside the Western world, which is nonetheless, to a certain extent, represented in these contexts—for example, by the indigenous psychologists themselves. By borrowing well-known concepts from post-Colonial studies (Bhabha, 1994), we may say that the hybridity of these research contexts, as well as the hybridity of the psychologists dealing with it, puts them in a “third space” and shows that for them there is much more involved than for most of their colleagues in Western parts of the world.

In addition to the points already mentioned, I want to emphasize that the psychological relevance of indigenous traditions of thought, including psychological theories, does not solely depend on the question whether they meet specific standards of scientific truth. Many of the thoughts presented in the examples from so-called “Hindu and Buddhist psychology” can be understood as answers to questions that are very familiar to Western psychology, too: What factors influence human development and to what extent are individuals and societies able to influence them? What role do culture and worldviews play with regard to developmental paths, developmental tasks, educational goals, socialization and internalization processes, cognitive styles, attribution styles, evaluation of the “normal” and the “abnormal,” and intervention strategies? The answers usually have an impact on the social and the individual level. On the social level, for example, they find expression in social institutions and formalized social interactions; on the individual level, they are reflected in many individuals' subjective theories about selfhood, the others, relationships, proper attitudes, life goals, suitable coping strategies, and so forth. Therefore, indigenous theories play a crucial role in culture-specific features of the socialization context and thus assist us in guiding our thorough investigation of the complex developmental niche. In part, they can be compared to the impact that Freud's seminal theories had on so many levels and so many domains in Western societies and sciences, although the value of Freud's work as a *scientific* theory has never been unchallenged.

Because indigenous psychology not only strives to develop theories and approaches through indigenization but also aims to identify psychologically

relevant theories that already exist in indigenous traditions of thought, it often has to deal with the religions and other worldviews in which these theories are embedded. Although even some indigenous psychologists are hesitant to occupy themselves with worldviews, we should be reminded that, for example, religion was a central topic in the beginnings of modern psychology, and many of the founders of the discipline were also founders of the psychology of religion. Although the investigation of these topics continued to play an important role in neighboring disciplines like anthropology and sociology, they almost disappeared in mainstream psychology. Interestingly, there is also little interest in the culture-inclusive branches of psychology, including cultural psychology (*see*, for example, Tarakeshwar, Stanton, & Pargament, 2003; for rare cultural psychological approaches to the study of religion, *see* Belzen, 2010; Chakkarath, 2007; Sen & Wagner, 2009; Straub & Arnold, 2008). Therefore, the indigenous perspective on what is relevant for doing proper culture-sensitive psychology might draw cultural psychologists' attention to its neglect of these (and other) topics. We will only be able to provide the kind of “thick” description (Geertz, 1973) necessary for attaining a sounder understanding of the relationship between culture and psychology if we succeed in understanding which topics, domains, and phenomena are really *relevant* for achieving the goals of culture-informed psychology.

Although the psychological relevance of indigenous theories does not depend on the proof of their scientific validity, some theories might nonetheless meet the standards of valid scientific principles. As stated above, some indigenous theories might even add to our scientific insight and help modify or increase our inventory of theories. As I have indicated in the context of indigenous Indian psychology, indigenous theories can even make us reconsider the adequacy of our inventory of *methods*. The experience of doing research in contexts in which the subjects are less familiar with typical (and frequently standardized) testing or interview procedures has resulted in the indigenization of various methods commonly used in Western psychology. One example is the so-called “ladder rating” in which the standard two-dimensional, multiple-point rating scale is substituted by a tiny wooden ladder with multiple steps. Using this three-dimensional instrument, researchers ask illiterate Indian respondents to indicate the extent of their agreement with certain statements by placing their fingers on one

of the lower or higher steps of the ladder (Sinha, 1969). Apart from making such a simple modification to meet at least some of the necessities of the specific context, indigenous psychologists have also come up with more complex adaptations of research procedures to the indigenous people. For example, based on his experiences with qualitative field work in the regional and ethnic variety of the Philippines, Enriquez (1993) proposed to relate duration, place, and frequency of investigations as well as the size of the investigated groups and the selection of research staff to the habits of the investigated people. For some cases, “Filipino psychology” even recommends having the subjects interview the researchers before they are interviewed themselves because that would familiarize them with the unfamiliar procedure and result in less of a feeling of hierarchical asymmetry between the investigators and the respondents (Pe-Pua, 2006). Although these are examples of the indigenization of methods used in Western psychology, meditation techniques as described earlier can be considered indigenous methods. Usually, however, in Western psychological literature, meditation is emphasized as a coping strategy, a therapeutic procedure to reduce suffering and to increase well-being (e.g., Lutz, Dunne, & Davidson, 2007). Western psychologists largely ignore—and that is true for cultural psychologists as well—the fact that meditation is also a highly advanced introspective method that has always been the basic empirical procedure by which many results of indigenous Asian psychology were obtained. So, with regard to indigenous psychological methodology and methods, there are also things that can be learned or at least considered by cultural psychologists, too. Is it possible that Enriquez is right that outside the Philippines, we should also adapt our procedures much more frequently to the different groups that vary with regard to social origin, education, ethnicity, gender, and so forth? And is it possible that even most cultural psychologists do not really expect that there are non-Western traditions of methodical empirical research that could be valuable for the whole discipline? In other words, would it be useful to transplant non-Western indigenous concepts into Western psychology? It is worth mentioning that compared to their treatment in psychology, these kinds of questions are dealt with much more visibly in anthropology (Denzin, Lincoln, & Smith, 2008; Smith, 1999).

Finally, let me return to the question concerning the differences between indigenous and cultural psychology if there are any. Actually, it seems obvious

that both culture-sensitive perspectives have a lot in common and share some of their intellectual and historical roots. As we have seen, the main differences arise from the different socio-cultural and socio-political circumstances of both perspectives’ more recent development and the related different problems most indigenous psychologists have to deal with as compared to most cultural psychologists. Let me summarize these differences, this time with an emphasis on the unequal distribution of certain intercultural competencies.

The broader historical sketch given in the first section of this chapter and the description of indigenous psychology’s more recent development as portrayed in the second section give the impression that the theoretical and methodological foundations are to be found in German folk psychology (*Völkerpsychologie*), the Russian cultural historical school, critical psychology, and cultural psychology. Even if we think about earlier roots like the field studies conducted by some missionaries in the sixteenth century, the impression remains that even indigenous psychology owes its main assumptions to discourses within Western psychology (or psychologies). It is thus not surprising that indigenous psychology seems so similar to cultural psychology. However, this impression may have resulted from a mainstream historiography dominated by a Eurocentric assumption that outside of Europe, there were no important contributions to what we call “psychology” (in a Western sense). Thus, it is still a task for indigenous psychologists to come up with alternative indigenous historiographies of non-Western contributions.

The dominance of Western historiography as well as the need to relate indigenous psychological work to Western conceptions of psychology to be taken seriously in the international scientific community are symptoms of an ongoing asymmetry of power distribution in international psychology (Moghaddam, 1987). It becomes especially evident in the fact that even indigenous psychologists most frequently link their work to psychological theories of Western origin and research executed within the standard framework of Western psychology. Western discourses are mainly about Western authors as are the so-called “international discourses.” The dominant language of psychology is English, and therefore any findings from indigenous psychology, even potentially culture-specific concepts, need to be translated into English to be published in the leading journals. This situation is quite comfortable

for most Western psychologists, who often live in English-speaking countries, whereas indigenous psychologists from non-English-speaking countries have to adapt to psychology's dominating culture. They have to learn its language, read its psychological literature, take part in its debates (which are mainly about its authors), and so forth. At the same time, indigenous psychologists need to be equipped with the skills and knowledge required to conduct the kind of research that meets the standards of their own scientific perspectives (as described above): language skills, sufficient knowledge about the indigenous environments and the people, about indigenous authors and their literature, methodological versatility, and so forth.

The effects of this asymmetry of power and of intercultural competence can be summarized as follows: The intercultural competence and expertise that an indigenous psychologist needs to meet the standards of his discipline and to be heard are rarely met by Western psychologists. Not even the Western cultural psychologists read non-Western texts having psychological relevance in the sense described above. Their discourses are mainly influenced by Western—mainly Western European and U.S. American—intellectual traditions. This situation not only underscores why indigenous psychology is needed and could improve cultural psychology, it also appeals to all branches of culture-informed psychological research to inform themselves much more than they currently do.

## Conclusion

Having developed from similar traditions within the history of psychology, cultural and indigenous psychology share many common features and goals. Both favor the emic over the etic approach and both suggest multimethod research designs for the investigation of culture and the human mind. Moreover, both share the conviction that the higher cognitive processes and their inter-relatedness with environmental aspects as well as with the elementary cognitive processes need to be investigated in an integrative and interdisciplinary manner that reflects the human potential to give meaning to the world and ourselves in manifold ways and innumerable areas. Therefore, both disciplines investigate history, mythologies and other cultural narrations, art, social institutions, religions, world views, science, and so forth, to identify the psychological relevance of these topics for human development, thought, feeling, and behavior. However, although

cultural psychologists and indigenous psychologists share many scientific positions, all in all, they are differently positioned. Because cultural psychology's more recent development has been situated in a predominantly Western setting and accompanied by scientific debates that mainly reflect corresponding intellectual traditions, most psychologists who advocate the indigenous perspective work in non-Western environments with non-Western people who usually do not correspond to the WEIRD samples that provide the largest proportion of data collected to test Western psychological theories. Many of these indigenous psychologists are trained in Western psychology and equipped with the knowledge this training provides. Frequently, however, they experience dissatisfaction with this Western knowledge in non-Western research contexts. The criticism that has arisen from this situation is very similar to the critical assessments of Western science and its exercise of power that is brought forward within post-Colonial studies. The situation in which many indigenous psychologists are working can thus be described as a third space constituted by shared histories, overlapping contexts, and hybrid actors. It is especially this difference from which the specific expertise and the specific competencies arise from which cultural psychology can profit in many ways. This includes a greater knowledge of *all* topics and methods that might be relevant for psychological research (e.g., religions and other world-views, indigenous concepts pertaining to self and other, indigenous methods like meditative introspection) and, in addition, a more thorough reflection on the role of the psychologist as a culturalized figure within various and sometimes very different contexts. For the future development of both, psychologists from both fields should not just be satisfied with peaceful co-existence but intensify their peaceful collaboration. Both fields would fulfill the main purpose of all branches of culture-informed psychology: to collect as much psychologically relevant information as is needed to understand humans and culture.

## Future Directions

1. How can indigenous psychologists find a common definition of their discipline and their relationship to other culture-sensitive psychologies, including cultural psychology?
2. How can psychological methodologies profit from indigenous/indigenized methodologies and indigenous/indigenized methods?

3. What cultural psychological insight can be gained by investigating the specific situation that many indigenous psychologists are in and that we characterized as “third space,” in which hybrid researchers study indigenous (and occasionally hybrid) subjects?

4. What can be done to minimize the negative effects of politics and unequal power distribution in the field of international psychology?

5. To what extent can indigenous psychology refine our understanding of “psychological relevance?”

6. Do we need a historiography of psychology written from a cultural and indigenous psychological perspective, and how would it differ from conventional historiographies?

## Acknowledgment

This chapter was written during a fellowship at the Institute of Advanced Study at the University of Konstanz, part of the university’s “Cultural Foundations of Integration” Center of Excellence, established in the framework of the German Federal and State Initiative for Excellence. The author would like to thank Tamara Herz for proofreading the final draft of this paper.

# Cultural Anthropology

Susan J. Rasmussen

## Abstract

This overview of cultural anthropology begins with a brief discussion of historical, recent, and current trends in theory and method. Next, there is a critical analysis of two broad issues concerning the anthropological subject: namely, tensions between approaches and perspectives emphasizing the individual, practice, and agency, on the one hand, and those emphasizing collectivities, institutions, and structure, on the other; and tensions between shared universal themes, on the one hand, and local cultural variations, on the other. There follow illustrative examples from selected relevant topics, including enculturation, altered states, healing, the body and senses, and personhood. The chapter concludes with a brief sum-up and key questions for future directions in cultural anthropology.

**Keywords:** cultural anthropology, cultural theory, ethnography, psychological anthropology, enculturation, altered states, personhood

Anthropology, the study of humankind at the most comprehensive and holistic level, is a broad discipline that straddles the social sciences and the humanities and is comprised of several subfields or branches: social/cultural or simply, cultural anthropology; linguistic anthropology; archaeology; and physical or bio-anthropology. Some anthropologists also recognize an additional branch called applied anthropology, which involves the application of anthropological concepts, theories, and methods to public policy recommendations; whereas others locate this latter specialty within each of the traditional four branches. Central to social/cultural anthropology are several key concepts: culture, cultural relativism, holism, field research or fieldwork, ethnography, ethnology, comparison, translation, and concern with both shared (universal) themes and local diversity or variations in the expression of culture and the organization of society. This chapter will examine cultural anthropology; it will particularly focus on concepts and

issues concerning relationships between individuals, cultures, and collectivities as well as variations on universal themes.

Although in some respects, cultural anthropology's subject matter overlaps with its "sister" social sciences, sociology and psychology, its distinctiveness consists in its tendency toward more qualitative, micro-, small-scale, and intimate perspectives on cultural phenomena. Whereas most sociologists tend toward the study of groups and institutions as their subject or unit of analysis, and most psychologists focus on mental processes, most cultural anthropologists emphasize their holistic interconnections and work within a theoretical framework built on the *culture concept*.

## The Concept of Culture

Although the *culture concept*, in its classic and reformulated senses, constitutes the unifying paradigm for all subfields or branches of anthropology, cultural anthropology is that branch that focuses

most intently on contemporary (living) human cultural and social beliefs, knowledge, and practices through in-depth study of a single cultural setting, as well as comparative cross-cultural studies. Cultural anthropologists conduct ethnographic field research or “fieldwork,” which includes a method called participant-observation, involving intensive submersion in the everyday life of the community, and depending on the topic and setting of research, also additional techniques, such as guided conversations and more structured interviews, life histories, case studies, genealogies, censuses, and (in more complex settings) network analysis and snowball sampling. Ideally, anthropologists approach field research with an attitude called *cultural relativism*. Cultural relativism does not imply justifying practices that the researcher finds morally or ethically repugnant but, rather, involves refraining, in so far as possible, from judging cross-cultural practices solely from the standpoint of the researcher’s own cultural values and being aware of one’s own biases and their sources and effects on constructing ethnographic knowledge. In contemporary cultural relativism, there is particular effort made to refrain from ranking beliefs and practices across different cultural settings and in historical eras: ideally, the researcher analyzes social/cultural beliefs, knowledge, practices, and behavior in a variety of contexts: historical, political, social, psychological, and economic. On the other hand, some anthropologists today advocate “activist anthropology,” an approach involving greater engagement with political issues—for example, advocacy for indigenous peoples’ rights. There is much debate in the discipline concerning these issues (Bodley, 1975; Tsing 2005).

### ***History of Cultural Anthropology and the Culture Concept***

Until very recently, anthropology was primarily a western European science. Many concepts central to the discipline originated in philosophical concepts and political policies extending from classical Greece through the Renaissance, Enlightenment, and Scientific and Industrial Revolutions. Although there are increasing influences from scholars from post-colonial backgrounds today, anthropology nonetheless owes much in its origin and development to these historical legacies in Europe: for example, tensions between the “sacred” and “secular” worldviews of the Medieval Catholic Church and the secular views of the Renaissance and ensuing Age of Reason, with

the rise of science in western Europe between the sixteenth and eighteenth centuries, contributed to increasing interest in a human- and nature-centered universe. Discoveries by Charles Lyell, the geologist, suggested that the age of the Earth was much older than that proposed by the Church, and the evolutionary theory proposed by Charles Darwin, the naturalist, emphasized transformation, rather than immutability, of life forms and suggested long-term evolutionary interconnections. Much of this work was stimulated by European exploration and colonial domination, which promoted a growing interest in human physical and cultural variation and change. Eighteenth century philologists studied the history of languages, and, with the German Idealist philosophers, became interested in the connections between language, mind, and nation—for example, Kant’s distinction between noumena (things or objects directly perceived in the world) and phenomena (things or ideas indirectly experienced) as well as Hegel’s concept of *zeitgeist* or “spirit of the times or nation,” which associated culture, in its early conceptualization, with learning, language, individual psychological identity, and group affiliation. Naturalists pursued the connections among plant, animal, and human life. Many traveled on scientific exploratory expeditions beyond Europe.

### ***The Main Issues***

The problem for many theorists, in these contexts, was the following: how humans were similar, how they were different, why, and what shared universal themes and local variations implied. These conditions prompted the collection of data on this diversity—for example, flora, fauna, and folklore from the “folk” at home and from so-called “primitive” peoples abroad, for purposes of classification. Carolus von Linnaeus formulated botanical and zoological taxonomies, and the Romantic Nationalism movement encouraged the preservation of “quaint” customs from the rural peasants. Some early evolutionary anthropologists, such as Edward Tylor and James Frazer, interpreted exotic customs as “survivals” or remnants of past practices; ethnographic analogies were made between marginal practices assumed to derive from Europe’s past and the practices of non-Western peoples, in grand schemes of the origins of culture. This early version of the comparative method, which featured ethnocentric and racist ranking of cultures and societies in an effort to find the origins of civilization, differed from the relativistic cross-cultural comparison as practiced

by anthropologists today, whose purpose is not to rank or find origins but rather to yield insights into the range of human cultural and social behavior in terms of similarities and differences. At that time, anthropology was only beginning to emerge as an academic discipline at universities in Europe and the United States, and its branches or subfields of study had not yet become distinct; for example, biological or physical anthropology was not yet separate from cultural anthropology, and there was a conflation of physical characteristics with sociocultural phenomena—for example, a misguided equation made between physical attributes of so-called “race” and culture. In the first theoretical school called unilineal evolutionism in academic anthropology, which arose in the mid-to-late nineteenth century, peoples outside of Europe and their beliefs and practices, as representatives of earlier phases or stages of European institutions, beliefs, and practices, were thought to be capable of progress on the ladder of civilization but moving at different rates.

Additional processes—wider, wider demographic and economic changes in Europe from industrialization and bureaucratization in the nineteenth century—also encouraged the growth of the social sciences—for example, the rise of penal reform, and the disciplines of demography, sociology, and psychiatry (Foucault, 1978). Emile Durkheim (an early founder of anthropology and sociology) and his student Marcel Mauss were concerned with the perceived breakdown of reciprocity in European society in the wake of these changes. August Comte promoted positivist objective data collection. Karl Marx formulated his theory of alienation from the products of one’s labor is his critique of capitalism.

All these questions were initially addressed in a context of domination: increasing colonialism by European state powers beyond Europe and nationalist domination by these state governments over marginalized rural peoples, so-called “peasants” or “folk,” in Europe itself. There was the view that administrators and missionaries shared a civilizing mission, popularly called the “White Man’s Burden.” Many Victorian unilineal evolutionists at first worked at a distance from these remote locations, conducting armchair research; only a few of the early anthropologists conducted direct fieldwork.

#### IMPACTS ON CULTURE THEORIES

These conditions had several consequences for early theories of culture. First, in Darwinian circles, at least, culture tended to be equated with race—the

latter concept now recognized as a political device and an oversimplification, despite human physical variation. Second, for some time culture remained defined in the singular, in the Enlightenment sense of a civilization—that is, with implied greater or lesser degrees of cultivation—and having superior or inferior connotations, all based on very ethnocentric value judgments, with Europe believed to stand at the pinnacle or apex of development.

Beginning in the early twentieth century, anthropologists such as Franz Boas in the United States and Bronislaw Malinowski and A.R. Radcliffe-Brown in Britain spearheaded the newly diverging branch of (socio)cultural anthropology; they began to question the assumptions, theories, concepts, and methods of the nineteenth-century unilineal evolutionists and began to promote direct fieldwork and cultural relativism. Yet many, despite individual opposition to colonialism, continued to work for colonial administrations—for example, Evans-Pritchard (1940) among the Nuer in the then-Anglo-Egyptian Sudan. The concept of culture changed radically. The method of field research became mandatory for full professional status in cultural anthropology. Modern anthropology today owes a debt to these theorists, who reacted against previous Victorian anthropological paradigms of unilineal evolutionism—for example, “social Darwinism,” the distorted application of Charles Darwin’s evolutionary theory to human social practices. Franz Boas, a German-Jewish immigrant who had suffered from anti-Semitism, became interested in salvaging the cultures of the Native American Indians. Bronislaw Malinowski, a Polish aristocrat who became stranded in the Trobriand Islands off Australia upon the outbreak of World War I, similarly experienced marginal status himself, began undertaking intensive fieldwork and local language study, and became interested in the function, rather than the origin, of practices such as ritual and economics. Both these theorists rejected the heretofore prevalent “armchair scholarship,” racism, and speculative grand generalizations on the origins and sequences of human culture.

In the United States, Boas’s historical-particularism school of thought distinguished among culture, race, and language and advocated studying particular cultures and their histories directly, without ranking or proposing grand universal schemes of human origin or development. Boas and his colleagues and students also founded the subfield of culture and personality within cultural anthropology, which examined child-rearing customs across diverse cultures, emphasizing

learned cultural—rather than universal biological— influences on personality.

#### **ANTHROPOLOGIES ACROSS THE ATLANTIC**

Initially, ethnographies tended to describe entire cultures or communities comprehensively (Malinowski, 1926). Soon, however, cultural anthropologists began to focus intently on a specific problem or issue in anthropological theory, either drawing on their primary data from a single cultural/social setting in an ethnography or, in other cases, drawing on secondary data collected by several different researchers in several different cultural settings, in a cross-cultural comparison or ethnology. The ethnographies of Margaret Mead, a student of Franz Boas and Ruth Benedict and an early theorist in the “culture and personality” school, examined concepts of adolescence and gender in Polynesian societies (Mead, 1928, 1935), exploring how these differed from American psychologists’ concepts at that time. For example, Mead found that Samoan adolescents were permitted much more freedom and experienced less anxiety than their American counterparts, thereby suggesting, she argued, that the alleged stresses of adolescence were neither universal nor biologically based. Mead also studied gender constructs in three societies of New Guinea and argued that male and female roles were a result of nurture, rather than nature. Although some of Mead’s findings were later disputed by other anthropologists (Freeman, 1983; Gewertz, 1983), her work was nonetheless important in its early questioning of widely held assumptions of universals in life course and gendered experiences.

In Britain, the structural-functionalist school of thought similarly opposed unilineal evolutionism, eschewing history and origins and instead, somewhat like Durkheim in France, advocated synchronic analysis of the structure and function of institutions in terms of how they promote harmonious continuity of society. Later, students of Malinowski and Radcliffe-Brown developed increasingly complex theories of the connections between social structure and cultural knowledge or belief: E.E. Evans-Pritchard, in his works on the ecology, political system, and religion of the Nuer people of the then-Anglo-Egyptian Sudan, described how local religion was refracted in social life and how local philosophy was not child-like but, rather, was metaphorical (Evans-Pritchard, 1940, 1956). For example, when some Nuer say that “twins are birds,” they do not view them as equivalent but, rather, view human

twins as anomalous, and thus analogous, to birds in that both share qualities such as multiple births, and both are believed to mediate, in the sky, between humans and Kwoth, or Spirit. In France, Durkheim and his students also emphasized the importance of “social facts,” from direct observation, and developed the concept of the collective unconscious as an overarching belief of a group, much more than a sum total of individual viewpoints. Durkheimian sociology also analyzed symbolic classifications as reflecting society, not nature—for example, spirit pantheons often reflect human social divisions.

#### **Recent Trends in Modern Cultural Anthropology**

From these insights, there emerged several important new understandings of culture. This concept became defined more in the plural than in the singular and acquired more neutral connotations, as denoting the sum total of a group’s belief system. In the formulation of Clifford Geertz, founder of interpretive anthropology, culture is transmitted through learning and is widely shared (Geertz, 1973). In this formulation, the anthropologist “reads” a culture like a text—that is, as one would interpret and translate a poem or novel. Thus, the cultural anthropologist first interprets the local culture in the field in Geertz’s words, reads it “over the shoulders of the native,” and then “translates” this into terms understood by his/her audience at home. Thus culture is like a literary text. In Geertz’s textual approach, as in the pioneering Boasian schools of historical-particularism and culture and personality, the anthropologist seeks cultural relativism, but nonetheless still retains much authority as translator, and the culture concept, although more relativistic, tends to imply a monolithic homogeneity.

This more modern view of culture has been accompanied by important changes in anthropologists’ methods; “ethnography” has come to refer to several practices: fieldwork with participant-observation, the description of a cultural setting or community (usually focused on a specific issue or problem in anthropological theory), and the writing practice itself. Ethnology, more comparative work, draws more systematically on data from different settings to compare several distinct societies, to pursue cross-cultural comparisons of specified beliefs and practices. Notwithstanding their differences, both ethnography and ethnology are analytical, in the sense that they both engage wider issues and debates in anthropology. For example, the work

of Mary Douglas (1966) examined the meanings of purity, pollution, and ritual restrictions called “taboos” in both historical and cross-cultural terms. In her theory of anomaly, Douglas argued that food taboos’ meanings, for example, do not arise from strictly hygienic or ecological conditions in local consciousness (even if one of their functions may be hygienic or ecological) but, rather, have to do with symbolic classification of human cultural systems; many forbidden foods, such as pork in Islam and Orthodox Judaism, are not easily classified and therefore are anomalous. Here, meaning rather than origin, cause, or function is important in cultural classification, recalling in some respects Durkheimian sociology and also Levi-Straussian structuralism.

Since approximately the mid-twentieth century, in addition to Geertz’s comparative literature hermeneutic approach to culture as text, additional influences have derived from linguistics. French structuralism, brought by Claude Levi-Strauss (1963) to cultural anthropology, draws on principles and methods from linguistics: culture is seen as a system of communication, and meaning derives from contrast. In particular, Levi-Strauss analyzed the structure of myths and symbols to elicit meaning from binary oppositions, which revealed mythemes, or the smallest units of meaning in myth, which were analogous to the phonemic principle in linguistics. According to Levi-Strauss, this construction of meaning is a universal characteristic of all human mental logic, which finds expression in a variety of domains. Symbolic anthropologists and semioticians drew extensively on these ideas, applying them to ritual symbolism (V. Turner, 1967), kinship (D. Schneider, 1980), popular culture (Drummond, 1996), and advertising (Barthes, 1982).

Other trends have addressed ethnography. Until recently, much anthropological field research focused on small-scale and rural communities remote from the researcher’s own (home) community. In current reformulations of culture, which have responded to new cultural formations such as globalization, borderlands, and dynamic practices (such as science and technology), the concept of culture has expanded to include more complex settings, such as urban milieu and even virtual, online communities; accordingly, fieldwork may now take place in any community—rural or urban, locally or abroad—and sites of fieldwork for cultural anthropologists today are expanding to include such places as scientific laboratories (Rabinow, 2003) and virtual

communities, as well—for example, the Internet (Boellstorff, 2010).

There have also been changes in the writing of ethnographies, a practice following data collection in the field, in which the cultural anthropologist proceeds to analyze the data and write a description of a single cultural or community setting. This description, a literary genre using literary devices (Clifford & Marcus, 1986), has recently been the topic of much critical reflection in cultural anthropology. Classical or “realist” ethnographies—for example, those of Evans-Pritchard on the Nuer (1940, 1956) and of Malinowski on the Trobriand Islanders (1926, 1927)—tended to use rhetorical techniques similar to those used in a novel, which were previously considered objective, with only a single meaning determined by the author/researcher. More subjective reflections by the author/researcher, as well as his/her consultants and assistants in the field, initially were either omitted or appended in separate prefaces and afterwords (Evans-Pritchard, 1940; Marcus & Fischer, 1986). Recently, there have been efforts at greater experimentation in ethnographic writing projects—for example, including references to the personal experiences of the researcher, accounts of the circumstances of data collection, and recognition of local collaborators (Rabinow, 1977; Stoller, 1987, 1989; Gottlieb & Graham, 1994; Marcus, 2005).

Most recently, the concept of culture has been undergoing additional revisions, for several reasons. The mid-to-late twentieth century saw liberation movements among colonized peoples, ethnic minorities, and women, who have contributed much more to cultural anthropological theory. Anthropologists now come from diverse backgrounds. Postcolonial, post-structural, post-modern, and gender studies have conducted critiques of the old canons, in some cases rejecting all the major schools of anthropological thought. Feminist anthropologists (Rosaldo & Lamphere, 1974; Butler, 1999) have critiqued androcentric male bias in some earlier anthropological works. Other scholars—for example, Byron Good (1994) in medical anthropology—have proposed replacing *cultural belief* with *cultural knowledge* to render anthropological concepts of non-Western systems more commensurate with Western systems. Talal Asad (in Clifford & Marcus, 1986) conducted a critique of the Geertzian interpretive anthropological concept of cultural translation, arguing that the translation of culture is not the same as the translation of language. Asad has also written a critique

of the old structuralist binary opposition between “sacred” and “secular” in anthropological studies of religion and has questioned the assumption that secularism always produces greater liberty, drawing on examples from history, and arguing that there can be oppression in both religious and secular settings (Asad, 2003).

### ***Interdisciplinary Links***

In tandem with these trends, there have also occurred much cross-fertilization and interdisciplinary dialogue between the social sciences and humanities—particularly among anthropology, literary criticism, semiotics, and comparative literature. For example, the comparative literature scholar Edward Said (1978) in his work, *Orientalism*, critiqued some ethnographic portrayals of Middle Eastern peoples in an exaggerated exoticism (e.g., literary and historic portrayals of the Orient as sensual and the West as logical) and encouraged anthropologists to reflect more carefully on the history of their relationships with peoples glossed as “Other.” In his work “The Invention of Africa,” V.Y. Mudimbe (1988) explored the historical and social construction of the “idea” of Africa.

Additional influences have come from the Soviet Semioticians Mikhail Bakhtin and V.N. Volosinov, whose works written during Stalin’s reign and later translated into English critiqued authoritarian forms of literary analysis: these scholars proposed locating meaning not in the text but rather in the utterance, suggested that meanings are not monolithic but are multiple, and that meanings are dialogically constructed by not solely the author but also by the reader and other forces such as the histories readers of a text bring to the interpretation of a literary work. These critiques, as well as wider political and economic processes of globalization, mass media and communications, and transcultural or transnational processes, such as accelerating labor migration and refugee flight of vulnerable peoples and human rights concerns, have encouraged moving toward a concept of culture emphasizing more process and practice—of culture as an encounter, as negotiable, and as relational (Eriksen, 2003; Gupta & Ferguson, 1997) rather than textual or structural in the older, static sense of this concept. Arjun Appadurai (1996), for example, has proposed new terms for culture such as *ethnoscape* and *technoscape*. These terms have not, however, replaced the term *culture* in the mainstream disciplinary discourses. But they have brought greater

sensitivity to the need for specification in cultural analysis, and some anthropologists now tend to use “cultural” in the adjective form more often than as a noun to avoid the older totalizing, neatly bounded sense of this concept (Faubion, 2001; Rasmussen, 2008). However, locality remains important, albeit not as an isolated entity but more as a space of encounter. In these newer formulations, moreover, political-economy approaches emphasizing power and semiotic-expressive approaches emphasizing symbolism, once seen as oppositional, are often becoming intertwined (Rasmussen, 2001; Tsing, 2005). In these developments, a central concern has been with the units of analysis—that is, the anthropological subject.

### **The Anthropological Subject** ***Recurrent and Emerging Issues in the Study of Culture, Society, and the Individual***

Cultural anthropology, from its inception and throughout its transformations, has been concerned with what constitutes the human subject. As a science of *anthropos* (Rabinow, 2003), anthropology’s most basic, pervasive concern has been with relationships among individuals, institutions, and belief/knowledge systems. In this focus on individual/culture/collectivity connections, two broad issues have reverberated throughout the discipline. First, there have been tensions between theories and concepts emphasizing personal/individual agency and practice on the one hand and those emphasizing collective/institutional forces of structure and the group on the other. Second, there are debates over the extent of universals in human belief and practice, on the one hand, and the extent to which, and what explains, specific cultural differences in human belief and practice on the other. In this latter concern, studies have tended to emphasize either cultural universals (e.g., Levi-Strauss’s analysis of myths as manifesting a universal human mental logic) or cultural specifics (e.g., Mead’s ethnographic critique of T. Stanley Hall’s theory of a universal, biologically based experience of adolescence). The individual/collectivity issue, its roots pervasive in social theory, is addressed here first, in terms of the tendency of the theoretical pendulum to swing back and forth between these two poles of emphasis. Addressed next is the problem of universals versus local cultural variations, with a particular focus here on approaches in the sub-field of psychological anthropology within cultural anthropology.

Following discussions of these two theoretical issues pertaining to the individual in culture and society, there is a review of work relevant to these concerns: culture and personality and enculturation; altered states, including trance possession/mediumship and dreams and healing and medicoritual specialists; and concepts of body, senses, and person/self. These topics, although not representative of all issues or topics in cultural anthropology, have received much attention, have raised key questions, and have suggested future directions in the discipline.

### ***Collectivities and Individuals; Structure and Agency***

Structure and agency constitute two main shapers of outcomes. Most theories tend to emphasize individual practice or collective social action. In this trend, there have been approximately three main positions taken. First is the position involving doctrines that social/cultural life is largely determined by social structure and that individual agency or practice can be explained as mostly the outcome of structure or institutions; examples include French Structuralism of Claude Levi-Strauss, with its emphasis on universal mental logical structures; Durkheimian normative sociology and its influence in anthropology; the British social anthropological school of structural-functionalism (e.g., Radcliffe-Brown); and some Marxist theories.

The second position includes doctrines that reverse the above emphasis, stressing instead the capacity of individuals (individual agents) to construct and reconstruct their worlds, and the necessity of explanations in actors' terms. Examples include utilitarianism as formulated by John Locke, and the associated Economic Man liberal and neo-liberal economic theories of cost-benefit analysis; ethnomethodology and related game theory studies of Frederik Barth (e.g., the individual flexibly wearing different "hats" of identity); and the dramaturgical concept of social action analogous to theatrical performance of Erving Goffman, centering on the human actor's presentation of self and impression-management on a kind of stage. These share an emphasis on the immediate situation and individual calculations during social interaction, a philosophical school of thought holding that utility entails the greatest happiness of the greatest number of persons and in which the assumption is that individuals rationally pursue their own interests and this seeps down to benefit all in the long term. Here, society is

no more than an aggregation of individuals brought together in realization of individual goals. The focus is not on wider power structures, whether cultural/symbolic, social, or material.

The third major position on this issue includes doctrines that emphasize that these two processes and forces are complementary—that is, both structural influences on human action and individual agency are capable of changing social structure. In this view, there are moves toward emphasizing practice, process, and relations (e.g., post-structural and post-modern theorists such as Anthony Giddens and Pierre Bourdieu). In these works, a number of interesting formulations of alternatives to either extreme of emphasis have emerged; for example, Peter Berger and Steven Luckman in *The Construction of Social Reality* (1966) argued that society forms individuals, who create society in a continuous dialectic. Anthony Giddens (1984), in his concept of structuration, opposed the dualism of structure and agency out of hand, favoring a duality of structure in the sense that structure constitutes both the medium and the outcome of conduct it recursively organizes and structure constitutes rules and resources that do not exist outside actions but continuously impact its production and reproduction of action. Giddens also opposed analogies between social and physical structures (e.g., the British structural functional "machine" or "body" model of society). For Giddens, there is structure, but this is more fluid and negotiable. Even in these more nuanced approaches, the issue remains of not solely who we are but who we are in relation to ideas (cultural knowledge, or values), practice (agency), and structure (institutions).

One prominent concern, shown in the pervasive presence of the adjectives "structural" and "post-structural" in anthropology, has been with structure: what is it and from where does it derive? Also, how does one conceptualize the changing relationship between structure and agency? These concerns, still very much alive in cultural anthropology, can be traced back to the emergence of the social sciences as academic disciplines in the late nineteenth and early twentieth centuries. As founder of both anthropology and sociology, Emile Durkheim (1859, 1912) addressed the problem of social cohesion in so-called "poly-segmentary societies" that he considered based on mechanical solidarity, in contrast to the organic solidarity of modern societies with their division of labor (Parsons, 1965, p. 39). Parsons traces Durkheim's early opposition to utilitarian

and psychological explanations to other currents in French intellectual history—namely, Descartes, Rousseau, Saint-Simon, August Comte, and Fustel de Coulanges (Parsons, 1965, pp. 39–65). His deep concern was to mediate between British empiricism and utilitarianism and German idealism.

### THE ISSUE OF STRUCTURE

In his *Rules of the Explanation of Social Facts* (1895 [1958]), Durkheim critiques functional utilitarianism (Parsons, 1965) and, in my view, implicitly, also British structural-functionalism, by arguing there is more to interpreting social facts than social morphology; the utility of a social fact may lead to social insight, but it does not explain its origins. Function does not create the social fact; facts come from somewhere deeper. Prior forces must exist to produce the fact. Also, facts can exist without serving a purpose; they may have never been used or may have lost their utility—for example, because of this, causes of a social phenomenon and its function must be studied separately, and cause must be studied before its effects. Also confronted here is the issue of where social phenomena originate. Previously, Comte and Spencer asserted that society is a system derived from an individual psyche of humans set up to achieve certain goals. In their view, social theory is an extension of psychology. Durkheim disputes this argument: it is not individual wants and needs that dictate how humans act but social forces that transcend them; he asserted that it is not individual wants and needs that dictate how a human acts but, rather, social forces that transcend them. Only society remains to explain social life, as this pressures an individual to act and think in certain ways. This is accomplished through association. We are not merely the sum of our parts; in association, we act differently than we do as individuals. We become a separate entity that transcends our individuality. For example, this view would explain some unexpected election results as not resulting from the sum total of atomistic, individual opinions but instead from the work of structural facts (e.g., economic forces) and collective representations (e.g., cultural values) that transcend individuals' consciousness and actions—in other words, a collective conscious in a kind of crowd psychology à la Gustav Lamont. Society is a given reality, having exteriority from the point of view of its own members, but it also regulates or constrains their action. This view is very opposed to a utilitarian view, as expressed by the former British Prime Minister Margaret Thatcher in

her statement that “there is no society, only individuals and families.” For Durkheimians, by contrast, society is a system formed by association and a different reality with its own characteristics.

Yet Durkheim does not dismiss psychology completely; he believes it plays an important role in preparing for the study of social phenomena (Parsons, 1965). Indeed, Durkheim thought that the essential elements of culture and social structure are internalized as part of the individual personality. Nevertheless, an element of exteriority is involved in moral authority because, although internalized, the normative system must also objectively be part of a system extending beyond the individual (Baerveldt & Verheggen, 2011; Tavory, Jablonka, & Ginsburg, 2011, this volume). It is not subjective in the sense of a purely private individual, for it is also a cultural object in sense relevant to idealistic tradition. For example, the meaning of success cannot be established without understanding the interplay between the motivation of the actor and the normative claims impinging on him from his social environment, expressed in the distinction made by a student of Durkheim's, Marcel Mauss, between two types of personhood/self: *le moi* (me) and *la conception de la personne sociale* (concept of social person). For, at the same time, as Nsamenang (2011) points out in the present volume, the social environment of any given actor of reference is composed of other actors whose action must be also analyzed as interactional. Anomie, or normlessness, thus makes achieving goals meaningless from lack of clear criteria.

Durkheim later theorized on religion, symbolic systems, and collective representations (1912 [1954]) and emphasized a theory of culture in relation to that of society. Here religion is the primordial matrix, from which principal elements of culture emerged by the process of differentiation—specifically, in totemism, the origin of religion. The classification in cultural belief/knowledge that distinguishes between sacred and profane is similar to the distinction between moral obligations and expediency or utility. For Durkheim and those influenced by this theorist, such as Marcel Mauss (1936) and later, Mary Douglas (1966), the quality of sacredness does not reside in any intrinsic properties of the object treated as sacred but, rather, in its properties as a symbol and its position to other objects, seen by Durkheim as collective representations, which became defined in recent and contemporary cultural anthropology as symbolic systems (Turner, 1967). In this formulation, there is a close

integration between the religious system of representations and the structure of society itself, linked by the attitude of moral respect that Durkheim called “awe.” According to Durkheim, this integration is particularly close in primitive religion but also exists in others. Any cultural system must have a collective aspect, for symbolization that is wholly private is no longer cultural or even truly symbolic; this later influenced Clifford Geertz’s (1973) concept of culture as shared, public, and translatable.

In the wake of this legacy, several more nuanced approaches to this issue have tended to retreat somewhat from the normative traditions of the Durkheimians and the British structural-functionalists and place greater emphasis on agency and practice, although differing nonetheless from the older ethnomethodological and utilitarian emphases, by giving some nods to the power of structure.

For example, in his work *Outline of a Theory of Practice* (1977), Pierre Bourdieu addressed continental philosophy as much as anthropology. But Bourdieu drew on the Marxist concept of *habitus* and also emphasized practice to explore the question of human agency. In Bourdieu’s formulation, *habitus* consists of a system of durable, transposable dispositions, structured structures predisposed to function as principles of generation, and structuring of practices and representations that can be objectively regulated and regular without in any way being the product of obedience to rules. The term *disposition* signifies the special place the body occupies in *habitus*; dispositions are cultivated through interaction with a whole symbolically structural environment, and these cultivated dispositions become inscribed in body schema and in schemes of thought. For example, Bourdieu discusses the Kabyle sense of honor, emphasizing the dual location of honor in both the mind and the flesh. In Bourdieu’s conception of *habitus*, mastery of body is essentially successful in incorporation (literally, the taking into the body) of particular social meanings, inculcated through various bodily disciplines oriented to such mundane practices as standing, sitting, speaking, walking, and organization in space. In mastering the body, the child develops skills to act in and on the world. This is a dialectical process Bourdieu calls “the appropriating by the world of a body thus enabled to appropriate the world” (Bourdieu, 1977, p. 89). Thus the ideology or culture is not only in our head but also in our bodies (e.g., is embodied), and although there is some room for agency, structure tends to reproduce itself.

### *Shared Universal Themes, Local Cultural, and Personal Variations*

Another stream of thought in cultural anthropology, psychological anthropology (which arose from its ancestral school, culture, and personality) approaches the problem of the anthropological subject by focusing on individual mental aspects of humankind in learning the culture and weighs the relative power of shared universal common themes and local variations. The complex processes by which an individual acquires traits his or her society considers desirable—or undesirable—involve learning to experience the world in a particular way. Enculturation and socialization practices are one focus. These differ widely from culture to culture and are processes by which the individual learns knowledge, values, and skills required in a particular society. Because of this great variation, anthropologists have asked whether people who grow up in different societies learn to see the world differently. So completely does socialization shape our experience of the world that we come to see our own worldview as natural. Psychologically oriented cultural anthropologists have used cross-cultural studies as a basis for considering whether people universally perceive the world in the same way in some contexts, whether they think about it in same way, and whether concepts of person/self are universal.

The history of psychological anthropology has been marked by attempts to distinguish human universals from characteristics that are particular to specific, local populations of different cultural and community settings. One major focus in this debate has been Sigmund Freud’s concept of the Oedipal complex. Freud thought that all male children are subject to the Oedipal complex, in which they sexually desire the mother and resent the father. Bronislaw Malinowski (1927) suggested that the Oedipal complex is associated with patrilineal inheritance, but some other anthropologists see what they consider to be Oedipal patterns cross-culturally in myths and dreams.

The Oedipal complex takes its name from the story of the Greek hero Oedipus, who unknowingly killed his father and married his mother. Freud suggested that the Oedipal story expresses conflicts that are universal in the developmental cycle of males throughout the world. According to Freud, boys become sexually aroused by their mothers during intimate contact occasioned by maternal nurturing and, as a result, become envious of their fathers. Melford Spiro described the resulting conflict in the

boy's mind: "As result of his wish to possess exclusive love of the mother, boy moreover develops wish to kill father and to replace him in his relationship with mother (in mind of little boy, to kill means to eliminate, to banish, to get rid of)" (Spiro, 1982, p. 4). At the same time, the boy admires his father and seeks to emulate him.

Malinowski ([1927] 1955) rejected Freud's contention that the Oedipal complex is universal. Rather, he argued, the tension between father and son described by Freud results from European system of patrilineal inheritance, rather than from sexual competition for the mother. Because, under the patrilineal system, a boy inherits property and social status from his father, the boy feels resentment toward his potential benefactor, who has authority over him. At the same time, the father feels ambivalence toward his son, who will eventually assume control of his status and property as the father grows older and dies.

Among Trobriander Islanders, Malinowski noted, descent is matrilineal, which means a boy inherits status and property from his mother's brother rather than from his father. In the Trobriands, boys have warm, affectionate relationships with their fathers because they do not see them in authoritarian role (Malinowski, [1927] 1955, p. 31). By contrast, the relationship between the boy and his mother's brother is one of tension and conflict, as the boy will inherit his status and property through his mother's line, from the senior male, his maternal uncle. The maternal uncle is also in charge of disciplining the boy and feels ambivalent toward his heir, who will eventually displace him and take property away from his own son. According to Malinowski, it is competition over authority and status, rather than over sexual access to the mother, that is the source of anxiety between a boy and the man from whom will inherit his social position. Thus the Oedipal complex does not exist among matrilineal Trobriand Islanders.

Other anthropologists have more recently re-analyzed Malinowski's data to challenge his view that the Oedipal complex does not occur in matrilineal societies. For example, Annette Weiner (1976) found that fathers in the Trobriand Islands still maintain social, emotional, and economic ties with sons, despite the matrilineal emphasis, in gift-giving and other exchanges. Melford Spiro (1982) found that in their dreams, Trobriand subjects never dreamed of having sexual intercourse with their mothers but did have some sexual dreams about

their sisters, despite strong sexual taboos between siblings. Brother-sister incest is also a prominent theme in Trobriand myths. Melford Spiro argues that the brother-sister incest theme in these dreams and myths suggests that sexual attraction and hostility are deflected from their true objects, mother and father, and displaced onto less threatening subjects, sister and maternal uncle. Thus Oedipal complex is not absent among Trobrianders; rather, it emerges in disguised form as love for one's sister and hostility toward one's mother's brother (Spiro, 1982).

Whether the Oedipal complex is universal continues to be debated in anthropology. Freud suggested that unconscious conflicts are expressed in dreams of individuals and myths of societies. Allen Johnson and Douglass Price-Williams (1996) conducted a cross-cultural survey of myths and tales and concluded that the Oedipal complex is indeed universally represented in these societies, suggesting that mother-son attraction and father-son hostility is a theme in all societies (Womack, 2001, p. 186). This debate is not settled, however.

The foregoing debate raises wider issues, such as the relative influence of socialization and patterns of social organization on individual practices (Nsamenang, 2011, this volume). Recall that Franz Boas, as founding father of American anthropology, in the early twentieth century emphasized the importance of culture. This insight influenced a number of anthropologists who studied the relationships among culture, childrearing practices, and adult personality. The works of those anthropologists became known as the culture-and-personality school. Although contemporary anthropologists reject these researchers' overemphasis on uniformity within cultures and oversimplification of complex variables, the culture-and-personality school provided an important basis for development of psychological anthropology.

One topic within this school concerned defining "normal" and "deviant" behavior as shaped by socialization or enculturation. Ruth Benedict (1934) discussed how societies tolerate a range of behaviors considered normal and have means for dealing with behavior that violates the norm—sometimes providing a niche for those who do not conform to normative expectations; for example, some Native American Indians have very flexible concepts of gender roles in which biological men may become cultural females, formerly called "berdache" and now called "two spirits" (Whitehead in Ortner, 1981).

In some non-Western medicine, shamans or mediumistic healers treat a variety of disorders, both physical and psychological. Anthropologists (Harner, 1990; Kendall, 1989; Winkelmann, 2000) have noted that shamanic healing can be effective, in part because it treats underlying tensions in the group instead of isolating the individual. Shamans also treat illnesses through medico-ritual therapies, such as spirit possession (Rasmussen, 1995, 2001), that are similar to techniques used by Western psychotherapists.

#### **ALTERED STATES (SPIRIT POSSESSION/ MEDIUMSHIP/SHAMANISM; DREAMS) AND HEALING**

According to the widespread biomedical model, a human being is a physical entity, a thing existing apart from other such physical entities. These individualistic and Cartesian mind/body dualist views are reflected in the allopathic or biomedical model of healing, in which illness is treated as a failure of one's organs or of bodily mechanisms. For example, an illness may be diagnosed as a renal failure, a failure of kidneys to perform as they ordinarily do. Following from that diagnosis, treatment may be confined to repairing kidneys rather than treating the system that gave rise to failure of kidney to perform as expected. In fact, kidneys share a relationship with every other aspect of body, including the circulatory system, which delivers oxygen and other nutrients to kidneys, and lungs, which take in air and provide oxygen that every part of body requires (Womack, 2001, p. 183).

By contrast, shamans or mediumistic healers trace the origins of illness to disrupted social relationships. This is an alien concept in Western bio- or allopathic medicine, which until recently has tended to emphasize isolated, biological causes of disease. Recent research is suggesting that although the biomedical tradition is necessary for healing some diseases, it is an oversimplification in some contexts of healing. Medical conditions such as cancer, hypertension, and asthma may be related to the expression or repression of emotions, which is also related to socialization and cultural expectations about the appropriate way to behave in social groups. Underlying the biomedical model is the idea that individuals are discrete units that stand in opposition to a culturally coherent group. This view is at variance with some other models, which view humans as members of groups, fulfilling their destinies only through social interaction.

Cross-cultural studies of medico-ritual healing through altered states of consciousness—namely, trance—illustrate these dynamics vividly. According to the established biomedical allopathic medical model, recall that illness tends to be classified as either physical or mental (organic or non-organic). Deviance from the ideal is often regarded as an individual problem rather than as an affliction of the group as a collectivity. Most societies do not, however, distinguish so neatly between physical (organic) and mental (non-organic) illness, nor do they always draw a rigid boundary between intentional and unintentional deviance. Treatment is usually aimed at identifying problematic relationships within the group. In these societies, the source of the problem is often attributed to outside forces, either naturalistic, human/social (personalistic), or spiritual—for example, malevolent ghosts or shades (Foster, 1977). Traditional mediumistic healers, widely called shamans in anthropology, frame their diagnoses and treatments in symbolic terms. The use of symbols in medico-ritual treatments express complex ideas in dramatic forms and allow indirect expression of emotional and social issues, (Turner, 1967), such as the unequal treatment of co-wives (Rasmussen, 1995, 2001, 2006).

By attributing illness or nonconforming behavior to demons or spirits, the shaman can diffuse and defuse the powerful emotions generated by competing interests and conduct psychotherapeutic healing. The shaman uses symbols to treat a disorder within the social context. For example, he/she might diagnose an illness as the result of not pleasing an ancestor. In so doing, the healer brings to the surface tensions underlying the illness or deviant action of patient undergoing the medico-ritual and addresses wider social conflicts.

Anthropologists have noted that many indigenous healers use techniques similar to those used in Western psychotherapy. In the former, symbols are used to communicate, whereas in the latter, medical terminology is used. For example, a shaman may perform a ritual drama by symbolically journeying into the realm of spirits. This journey is usually accompanied by percussion music, which encourages the patient and/or the healer to enter an altered state of trance, and malevolent spirits are dramatized with gestures and/or obliquely referred to in song verses (Rasmussen, 1995). Levi-Strauss (1963) explained the effectiveness of a shamanic treatment of a difficult labor among the Cuna Indians of Panama, who guided a woman through a potentially fatal

childbirth through ritual use of symbols. The shaman made ritual figures, chanted invocations personifying the birthing woman's pains as important figures in local myth, and purified the birthing room by burning herbs. He changed the story of his journey to the realm of Muu, the female power responsible for forming the fetus. The shaman diagnosed the problem as Muu having exceeded her role and capturing the soul of the mother-to-be. Through the persuasiveness of these metaphoric chants, in which Muu is persuaded to release the woman's soul, and the shaman exhorted his spirit figures to help him rescue her soul, a successful childbirth occurs. These rituals, featuring spirit possession and mediumship, are often open to the public, and the audience may participate in the healing process through support for their person undergoing the healing. Whereas in Western psychotherapy the patient speaks, in this case the healer speaks (chants). Levi-Strauss analyzes the shaman's account of his journey into the abode of Muu as a description of the woman's body, and the patient understands this subconsciously and then relaxes, understands pain as not arbitrary but rather meaningful, and allows the birth to take place. Thus, in his symbolization, the shaman provides the sick woman with a language by means of which unexpressed, and otherwise inexplicable, psychic states can be immediately expressed (Levi-Strauss, 1963, p. 198).

Another important altered state or out-of-body experience is dreams, but these are given diverse interpretations in different social and cultural settings. Thus, although dreams are individually experienced, they are culturally informed (Lohmann, 2003, p. ix). Dreams are expressed in accordance with social values pertaining to communication, concepts of person, spirituality, and notions of public/private. Roles of dreams vary, from a casual topic of conversation, a psycho-analysis topic, to divine revelations, shamanic mediumistic journeys to heal, and political meetings. Dreams also allow many people to experience continued participation of ancestors in their daily lives, and this too may influence decision-making. Stewart and Strathern (in Lohmann, 2003, pp. 43–61) examine dreams phenomenologically in two Melanesian societies, the Hagen and the Duna; here, the dead come to visit the living in dreams and may warn of future problems or attacks.

The spiritual and emotional connection of dreams is widespread. Roger Ivar Lohmann (in Lohmann, 2003, pp. 189–211) presents a series of

first-person spirit encounter narratives from Asabano culture. Asabano understand dreams to allow travel in a spiritual dimension, such that a personal soul can leave the body and contact other spirits. The Asabano spiritual world is rich in indigenous tradition but also reflects rapid cultural change they have seen in recent decades. Dreamed spiritual encounters predispose people to perceive spirit beings in waking life and are a significant cause of religious convictions.

Despite the diverse ways cultures influence and extract meanings from dreams, everywhere at least some dreams are understood as a means of actually traveling across spatial, temporal, and spiritual dimensions (Lohmann, 2003). Common dream experiences are of person/self in motion, being and doing what one cannot in alert consciousness. Thus dreams are experiences of some kind of transportation and transformation of body and soul. There are many shamanic dream journeys reported in anthropology of religion and medical anthropology from different parts of the world. Thus there are rich variations on common themes in cultural understandings and practices surrounding transformations of body, senses, and person or "self."

### ***Concepts of Body, Senses, and Personhood/Self***

In anthropology, the body, senses, and personhood have been accorded central importance since approximately the nineteenth century. This interest developed along several lines. First, historically, anthropology has been more inclined to pose questions about the universal "essence" of humanity, as the context of European colonialism prompted early scholars to address problem of human universals of ontology (knowing; understanding) in relation to variations of social relationships. As a consequence, the ontological centrality of human embodiment became one focus in the quest of universals.

One early question raised concerned the range of social and cultural arrangements necessary for survival and reproduction of self and body. Several streams of study were important here: in nineteenth century unilineal evolutionism, there was a convergence of questions of universals in these theorists' quest for universals in human origins. Central here was the relationship between culture and nature. In this, the body played a part, as it offered one solution to the problem of cultural relativism and psychic unity of humankind. But opposed to this was another line of development that contributed

to anthropological study of the human body in nineteenth century social Darwinism during the Victorian period. There were three key ideas here: that human beings were essentially a part of nature, rather than outside it; in a distortion of Charles Darwin's theory of natural selection, there arose the theory of universality of the fittest and unequal ranking of cultures in terms of phases of progress to explain social change; and more recently, there have been studies in twentieth century physical anthropology of the expression of emotions in humans—for example, Konrad Lorenz on aggression.

Another question that directs anthropological attention to person/self and body has been, "What is it to be human?" In more recent structural and symbolic studies of the late twentieth century, theories such as Claude Levi-Strauss's proposed that humans are cultural because of meaning contrasts—specifically certain prohibitions (e.g., the incest taboo and purity and danger categories) (Levi-Strauss, 1963; Douglas, 1966). This focus on contradictions between body and soul, and instinct versus social solidarity, opposed civilization to nature and argued that categories of reality—for example, pure and impure, sacred and profane—reflected categories of culture, not nature.

Also relevant to these ideas was German romanticism of the nineteenth century, whose tripartite division of body (*Leib*), spirit (*Geist*), and soul (*Seele*) conveyed that idea that because humans are unfinished as biological creatures, not at home in nature, they require the protective canopy of institutions and culture. The point here is that the body is constructed by culture and society; the latter, with language, filter and buffer nature (Baerveldt & Verheggen, 2011, this volume).

Now, from these streams of thought, three fundamental propositions have remained influential in anthropology and sociology: human embodiment creates a set of constraints, but also the body has the potential to be elaborated on by socio-cultural development—that is, in Western philosophical and social theory, the body generally appears as a constraint and potential; there are contradictions between human sexuality and socio-cultural requirements; and these natural facts are experienced differently according to the classification system (e.g., gender constructs). This insight lead to the issue of body as a classificatory system. Mary Douglas (1966), for example, theorized that humans respond to disorder, such as risk, uncertainty, and contradictions; their principal response

was symbolic classification through the medium of the body itself; for example, the body becomes a central metaphor of political and social order (e.g., food taboos reflect the wider order).

The body has long been an important locus of discourse, not solely in biology and medicine but also in the human sciences, although in the latter it has often been denigrated. In the seventeenth century, rationalists believed that the sensuous body was an object to be distrusted because it led to subjective, rather than objective, perceptions. Also denigrated were the "lower senses"—that is, non-visual sense modalities. But later there were trends toward greater attention to the body and extra-visual modalities, as well, as a vital subject of cultural study. These trends arose from critiques of the rationalists—for example, Montaigne, Nietzsche, Husserl, and Heidegger.

Karl Marx suggested a dialectical relationship between the body and the social and natural worlds. For example, Marx recognized that it was only by attending to human engagement in sensuous practical (i.e., material) activity that he could understand "real, corporeal man." In other words, Marx insisted that the body is not just there but acts upon the world and is, in turn, acted upon by the world that they body has helped to create. Marx saw this dialectic as mediated most fundamentally by human labor. However, subsequent writers have explored this dialectic in terms of a much broader compass; for example, Michel Foucault (1978) traced the historical development of scientific discourse (i.e., conversations that represent and study and form policies) and institutions impinging on the body in practices seemingly as disparate as sexuality, psychoanalysis, medicine, and the penal system, as well as physical spaces such as architecture. Scientific study involves surveillance and control, not merely knowledge, of the body. This is Foucault's concept of the panoptic gaze, power at different levels in the system.

In more recent social theory, most views of the body analyze this as not merely a natural object but as one socially, historically, and politically constituted. This idea animates the most recent and current (i.e., mid-to-late twentieth and twenty-first century) work on the body. Erving Goffman has described how the body forms the implicit foundation for stigma. Feminist theorists such as Susan Bordo (1993) examine more general representations of bodies—particularly of women's bodies—within myriad discourses and institutions, such as

art, advertising, and popular romances, and ask how these shape both how women experience their bodies and how others treat them as embodied beings. Now, these writers insist that discourses and institutions impinge as powerfully as does (Marxian) labor process on how body is lived.

Also, another aspect of common ground shared by Marx and many of these writings is a dual concern with the ideological (symbolic and expressive) and material (political and economic) aspects, or, in Foucaultian terms, discourses and techniques of the lived body. But Marx's and Foucault's and many feminists' body studies almost always and often implicitly concern the Western (Euro-American) body.

Finally, also relevant in developing a theory of body was the traditional emphasis in social/cultural anthropology on comparison and the study of small-scale, non-industrial, and more recently, of more industrial large-scale societies. Scholars from Marcel Mauss's (1935) "Techniques of the Body" have found that cross-culturally, the body is an important surface in which marks of social status, family, position, ritual prohibitions, social affiliation, and religious condition are displayed (e.g., tattoos in Polynesian societies). Mauss catalogued cross-cultural variations in bodily techniques for all manner of activities, from swimming to sex, emphasizing how powerfully each society inscribes itself on the body of each of its members and how resistant the body can be to altering techniques it "knows." Although these processes are present everywhere, they are most obvious and directly expressed in smaller-scale societies. Mauss's point here was that these techniques are not consciously taught; rather, they are shaped by and express a *habitus*, a notion Mauss invented, but one that the French ethnographer and social theorist Pierre Bourdieu, as shown, later developed further.

The body has also become a popular focus in medical anthropology within both cultural and bio-anthropology, over the past several decades in particular, from concerns over AIDS and other pandemics. A seminal essay on the body in this area, "The Mindful Body" (1988), was authored by Nancy Scheper-Hughes and Margaret Lock. This is an attempt to deconstruct, uncover, and problematize and ultimately to encourage resistance to conventional Cartesian concepts of the body heretofore accepted by earlier anthropologists. Scheper-Hughes and Lock label the failure of medical anthropology to critically examine accepted conceptions of the

body as a "prolegomenon," suggesting that the lack of more critical analysis of the body could lead to anthropology's falling prey to biological fallacy and related assumptions that are paradigmatic to biomedicine (Scheper-Hughes & Lock, 1988, p. 6). This biological fallacy, the Cartesian mind-body split, has multiplied into a number of other binary relationships in Western societies, such as culture/nature; society/individual, spirit/matter, and so forth (Scheper-Hughes & Lock, 1988, p. 10). These authors write this essay specifically because they see body concepts as being quite significant to anthropologists for understanding culture and societies, on the one hand, and for increasing knowledge of the cultural sources and meanings of health and illness, on the other (*ibid.*, p. 8), and because they want to prescribe alternatives to accepted approaches and concepts.

These authors propose seeing the body as "physical and symbolic artifact, naturally and culturally produced" (*ibid.*, p. 7). They conceptualize three distinct but related body perspectives anthropology should take in its study: the individual body; the social body; and the body politic. They assume that most humans have a concept of individual body—that is, they phenomenally lived experience of the body-self, separated into other body-selves. They highlight alternative ways of looking at the individual body-self and accounting for relations between mind, body, culture, nature, and society (*ibid.*, p. 11). Recognizing different concepts (monistic, holistic, multiplistic) of body-self is key to any anthropological understanding of way societies diagnose and treat illness and the way they define health, the way they define selves as healthy and treat perceived individual and societal illnesses. These authors make a final suggestion that an exploration of body-image (body boundaries, distortions in body perceptions) is essential to the concept of individual body—for example, point out that a relationship between people's choice of symptoms and concepts of body image should be considered to come to a better understanding of social and cultural meanings of humanity and perceived threats to human health, well-being, and social integration (*ibid.*, pp. 17–18).

Turning to their concept of the social body, Lock and Scheper-Hughes discuss how the body is culturally and socially representative, stating that "Cultural constructions of and about the body are useful in sustaining particular views of society and social relations" (*ibid.*, p. 19). The body is used

representationally to devise and justify social values (e.g., as in symbolic equations involving left and right handedness). Links have been made between health or sickness of individual bodies and social bodies for centuries. These authors suggest that most common symbolic use of body has been to classify and humanize living spaces (*ibid.*, p. 21). Point to differences between ethnomedical and biomedical concepts of social relations in the healthy or sick body; for example, ethnomedical systems see social relations as inevitably linked to individual health and illness. They suggest that ethnomedical concepts seem to entail a unique kind of human autonomy (*ibid.*, p. 21) that industrialized modern world has lost. These societies do not appear to experience the same sort of body alienations (anorexia, bulimia, etc.) experienced in Western societies, which seems also to be linked to capitalism and its regimentation. They point very specifically also to the body as machine metaphor as one of the sources of body alienation in industrialized societies. Their overall sentiment is that in industrialized Western society, “the human shape of things and even the human shape of humans is in retreat” (*ibid.*, p. 23).

Expanding on the concept of social body, Scheper-Hughes and Lock use the concept of body politic to suggest that the relationship between social and individual bodies is more than metaphors and collective representations of natural and cultural (*ibid.*, p. 23). This relationship is ultimately about power, about social control of bodies. Societies do not control bodies only in times of crisis but often aggressively reproduce and socialize kinds of bodies they need or require to sustain themselves (*ibid.*, p. 25). Ways in which societies reproduce and socialize bodies are through body decoration and through constructing concepts of politically correct bodies. Although the politically correct body is often supposed to be healthy, it can actually mean grotesque distortions of human anatomy. The body politic has brutal ways of conforming individual bodies to requirement of socio-political establishment: medicine, criminal justice, psychiatry and various social sciences, and even torture. They further point out that, post-Malthus, the body-politic concept involves finding ways to control populations, involving control of sexuality, gender, and reproduction. These authors propose that an anthropology of the body involve a theory of emotions because emotions may provide a vital link, a bridge, between mind and body, individual, society, and body politic (*ibid.*, p. 29). Tracking emotional states

or altered states experienced in illness and healing is, as shown, another way anthropologists attempt to move beyond a restrictive, Cartesian viewpoint and re-explore notions of human agency in society.

Another trend, since around the 1970s, has been to question the classical supposition that rigorous research methods always result in objectively “true” observation. The concept of the sensuous body (i.e., focus on the senses in studies) emerged as a new site of cultural and political analysis. Initially, many works considered the body as a text that could be “read” hermeneutically and consequently tended to ignore context and multisensorial modalities. There have been calls for greater attention to not solely cataloguing local cultural concepts of body and senses into the ethnographic record but also incorporating them into anthropological theory. As Herzfeld (2001, Chapter 11) notes, sight and writing have been widely associated with power; anthropology is primarily verbal and textual, but much cultural and social life is more complex and involves additional, extravisual, and nontextual sense modalities.

In response to these problems, there are attempts to consider how knowledge and perceptions of legitimacy and truth in many societies devolve from not simply vision and text, but also from modalities of smell, touch, taste, and hearing. Classen (1997) describes how historically and culturally in Euro-American philosophies and cultures, theories tend to be based in perceptions of the body and senses that are inflected with gendered values. For example, the sense modality of sight has in the west often been considered associated with masculine values and the sense modality of touch with feminine values. In pre-modern Europe, women were seen as the imperfect result of an insufficient amount of heat during the process of conception and gestation. Sex differences in temperature were drawn from Aristotle, Galen and other ancient authorities and supported by contemporary scholarship and folklore. The innate coldness of women was considered by physicians and philosophers to be the cause of particular characteristics of the female body: storing food as fat, menstrual blood, milk, enabling them to carry and nourish children (Classen, 1997, p. 3). Because of this lack of heat rising up into their heads, women’s bodies were allegedly broad at the bottom and narrow at the top. By contrast, “hot” men had narrow hips and broad shoulders; baldness was a sign of burning up of the hair on their heads. Heat also caused men’s sexual organs to be external, whereas

insufficient heat obliged women's sexual organs to remain within the body (Classen, 1997, p. 3).

Among some other peoples, the thermal attributes of the body and the different senses are not conceived as hierarchically nor represented as rigidly in ranked or oppositional terms, as in the major European philosophical and scientific traditions, despite widespread cultural differentiation according to gender constructs—for example, the prevalent association in some cultures of written texts with scriptural scholarship. Rasmussen (2006) describes how, in Tuareg culture, visual and written texts are associated with Islamic scholarship and Qur'anic healing, which tends to be dominated by men, and touch in healing is more associated with female herbalists and other non-Qur'anic healers. All of these healers are respected and sought out by both women and men at different times; thus, here the sense modalities, although having associations, are not rigidly dichotomized by gender, nor are they hierarchically ranked. Although the Quranic healing by marabouts is often described as a science, nonetheless, non-Qur'anic healing is not denigrated or considered less reliable but as specialized in healing certain ailments—for example, stomachaches and women's reproductive and marital problems (Rasmussen, 2006). Although Tuareg also differentiate according to gender and make gendered thermal/humoral associations in their counteractive medical system, there is marked absence of a deficiency model here. There is also flexibility according to context. In local counteractive theories of balance and harmony, for example, hot and cold states of the body and diseases are caused for men and women alike by an imbalance of these forces (Rasmussen, 2006). Women should ideally be cool, and men ideally warm, but even these ideals should not become too pronounced or intensified; for example, a man can become too hot and fall ill. The goal is to find equilibrium between hot and cold; one should avoid an excess of either thermal states.

Recently, there have been analyses of how anthropological and ethnographic knowledge systems are constructed through extravisual sense modalities. Paul Stoller (1987, 1989) has described ethnographic insights from sound and taste. In his apprenticeship with a Songhai sorcerer/healer in Niger, he learned about ritual healing powers by tasting local herbs and listening to the healer's incantations and learned about social conflicts through the gustatory medium of food, when a co-wife of his field host prepared a bad sauce to express

her anger at her husband. He also described vividly how Songhai cosmology/philosophy and medico-rituals later inspired him to cope with his cancer treatments in the United States (Stoller, 2004). Rasmussen (1999) analyzed the role of aroma as channeling communication in Tuareg society and also analyzed its role in constructing ethnographic knowledge; among the Tuareg, for example, scents are used to diagnose non-organic (mental) illnesses, and many pleasant scents are associated with spirits. Perfume and incense are used as a medium to communicate among humans and between humans and spirits—for example, in medico-ritual healing. Their use is taken seriously and are not merely aesthetics, an alternative, or less credible, in contrast to aromatherapy in the United States. Islamic scholars use scents to diagnose mental states. Diviners place scented bark inside their mouth to aid their memory in healing and place perfumes in cowrie shells to their tutelary spirits in a special pact that enables the diviner in a dream to foretell the future and conduct psycho-social counseling. Certain scents, however, are also considered dangerous, and aroma in general can also be used to express anti-social feelings, conflicts, and struggles. For example, many Tuareg believe that a person can catch illness through the scent of someone who already has the illness, somewhat like Victorian contagion theories. The aromas of certain medicinal trees are believed to cause infertility in young women; that is a reason given by some Tuareg for the predominance of older women in the herbal healing profession. The nose and mouth are the principal orifices through which disease and more general pollution (from both physiological and social sources) enter the body; for example, smith/artisans can convey anger at nobles' not sharing food with them, even if food is out of sight, through smelling it. Thus one must hide food from smell and not solely from view. Also, local cultural values show great concern with protecting the body from what enters through the nose, as well as the mouth. In rural areas, most men wear a face-veil over the nose to protect from evil spirits and other malevolent powers, as well as to express respect and reserve, important values in the male gender role, particularly among nobles. Also, incense and perfume are believed to not just mask unpleasant odors but to actually dispel them, to repel evil spirits and disease; they work like a religious amulet. For example, incense is burned during weddings and passed around a circle of guests, who saturate their clothing with it. New mothers and babies also are protected

from jealousy by incense burning nearby along with a metal knife stuck in the sand of the tent floor and Islamic amulets placed around it. Thus in Tuareg culture, society, ritual, and healing and sociability, aroma is not solely a part of cosmetics and aesthetics but also acts powerfully in medico-ritual and pharmaceutical contexts (Rasmussen, 1999, 2006).

More broadly, the studies of these cultural uses of taste, the gustatory modality, and scent and the olfactory modality reveal magic, religion, and science as not so neatly opposed. Anthropologists should attempt to understand, represent, and take seriously other peoples' ways of constructing experience and knowledge, and the study of sense modalities and body and person/self contribute profound insights into these issues.

This demonstrates the need, recognized widely in anthropology, to take analysis of the body to another level. The focus here is on the cultural construction of what it means to be a person, or human—that is, identity and expectations concerning how the person or “self” acts in cultural and social settings and how different cultures elaborate on this identity. Despite their very different approaches to this topic (philosophical approaches tend to be more influenced by European Enlightenment concepts and Anthropological approaches attempt to elicit more culturally relative concepts), there has been some influence of philosophy on anthropological theories, and both anthropology and philosophy share questions regarding how the concept of person is defined and used in social interaction. Both anthropology and philosophy, as heirs to Classical and Enlightenment theories predominantly from Western European historical and political and intellectual milieu, are concerned with distinguishing between continuity over time that enables social agents to characterize an individual as a person and with an epistemological problem posed by differences between social attributes and self-knowledge. For example, in an early study, Marcel Mauss distinguished between *le moi* and *la conception sociale de la personne*; the former is the externally imposed cultural and social identity; the latter consists of one's self-definition or self-concept.

How is person/self relevant to the anthropological subject? Anthropology's primary concern is to examine comparatively and historically ideas about power, personhood, and agency, cultural ideas about how humans interact with each other in terms of self and social concepts of identity. For example, Evans-Pritchard (1940, 1956) described the case of a man

who had been missing for a long time from his Nuer community, for whom mortuary rituals were held, thereby defining his status as deceased. Even upon his return many years later, he remained defined as deceased and thus was no longer a full social person in the community of the living. In many cultures, there is no concept of what the English expression “self-made man” (or person) implies; rather, one's achievements cannot be isolated from the achievements of one's lineage or clan. Also, many cultural knowledge systems conceptualize components of personhood in distinctive ways: for example, in some communities in the Congo, a person's shadow is key to identity and cannot be stepped on or photographed without threatening one's identity (Jacobsen-Widding, in Jackson & Karp, 1990).

Historically, there have been at least three basic attempts to define personal identity in Western (i.e., Euro-American) philosophy since the Enlightenment that have influenced, to varying degrees, anthropology: (1) mental/idealist based; (2) material based; and (3) illusion, construct, or memory-based. First, those who define personal identity in mentalistic terms view our identity through time as a function of the continuity of our thoughts, beliefs, and feelings—for example, medieval religious theory of the soul as the seat of personal identity, where reason and will reside (e.g., St. Augustine) (later, Rene Descartes substituted mind for soul in this scheme). Next, those who explain personal identity in terms of the continuity of our bodies; according to this group, despite changes we undergo in growth and development, there is a basic physical unity of our identity that is responsible for our remaining the same person (e.g., Gilbert Ryle); this position opposes Cartesian and other older forms of dualism. Finally, some philosophers have argued that personal identity is just an illusion without an independent existence or substance. For example, Thomas Hume believed that all existence was a matter of perception. For John Locke, personal identity was seen as based on self-consciousness, in particular on the memories of past experiences. All these theories suggest a non-uniform (Western and other view of) notion of personal identity and self; even in our own culture, we can hardly sum up in one set of language terminology a unitary notion of self, because there has been historical change and internal cultural diversity even within that category commonly called “the West.” Thus the problem is how we know this: Which data do we examine? Useful are data from psycho-analysis;

popular lay folk notions; childrearing advice; and healing systems. Thus one may tentatively generalize, with some caution, contemporary “Western” (i.e., Euro-American) notions of personhood as generally (albeit with exceptions) more individualistic (Battaglia, 1995, Introduction) relative to some other cultural concepts of personhood. Yet neither Western nor non-Western concepts of personhood are unitary or static; everywhere, these concepts may change in relation to economics, history, politics, and social processes.

Thus, most recent and current studies of concepts of person/self attempt to elicit a fuller range of expression of person/self beliefs in different contexts, regardless of where these prevail. For example, according to Didier Kaphagawane (in Karp & Masolo, 1990), the work of early scholar Placide Tempels on Bantu philosophy tended to reproduce Enlightenment philosophical bias viewing a person as divided between mind or ideas and material body. Kaphagawane shows how, among the Bantu-speaking Chewa in Malawi, *munthu* denotes humans in certain situations but not others. *Munthu* refers to a person with social and morally valued qualities, not without them. Thus to state that someone is not a *munthu* does not imply he/she is not a human but, rather, that he/she lacks approved moral and social conduct. Thus personhood is not a stable category but is disputed and negotiated, and changes, even within a single community and during the same era.

In addition, most recent studies of personhood or concepts of person/self in anthropology have focused on factors that shape cross-cultural variations in definition of self/person. The question posed is, “Where do these concepts come from?” Based on her study of French-Portuguese bilingual speakers, Michele E.J. Koven (2000, p. 437) suggests that bilingualism allows people to express different kinds of selves in each language. Desjarlais (2000, p. 467) suggests that actions and diffuse understandings they effect are commonly rooted in relations of differential powers and authorities. Alice, a resident of a shelter, had represented herself as “happy on the street” until authorities (police, psychiatrists, social workers) started to treat her badly by forcing her to take medications, confining her in psychiatric hospitals, and requiring her to follow the edicts of psychiatric and legal institutions (Desjarlais, 2000, p. 468, quoted in Womack, 2001, p. 184). Whereas Alice had seen her life on the streets as an expression of her competence, authorities viewed Alice

as mentally ill and felt they were helping Alice by preventing her from engaging in what they saw as inappropriate social behavior.

## Future Directions in Cultural Anthropology

These highlights in cultural anthropological studies share a concern with representing culture and society as more fluid, dynamic, and relational and a vision of individuals and collectivities as mutually influential. As noted, there have recently been critiques of all the canons of anthropological thought (culture and personality, Durkheimian, structural-functionalism, interpretive, and French structuralism schools) for oversimplifying the variables involved in studying culture and society and also for overestimating the degree of conformity and continuity in culture and society. In all societies, values are often contradictory. Culture and society and the persons comprising them can no longer be reduced to clear-cut, essentialized entities, and their localities are no longer always literal, geographical, or neatly bounded.

Thus many cultural anthropologists now recognize the need to explore the following questions:

1. What are some emerging new spaces or localities of culture?
2. Why, alongside resistance, dissent, and personal practice and agency, does society nonetheless tend to reproduce itself?
3. What leads some persons to internalize the rules or habitus of learned dispositions more fully and others less fully?
4. In globalization, what are some forces of relocalization, and how can scholars in their analyses escape this binary opposition?
5. How can scholars in their analyses, similarly, escape circular arguments concerning individual/culture/collectivities and local/universal processes?
6. How can the culture concept be reformulated to encompass virtual aspects of human life?

# Cross-Cultural Psychology: Taking People, Contexts, and Situations Seriously

Heidi Keller

## Abstract

This chapter explores the role of culture for human psychology. First, the history of this relationship is briefly outlined. The early conceptualizations were characterized by a holistic understanding and methodological plurality. This wisdom, however, was ignored for much of twentieth century psychology, when different perspectives with different ideological underpinnings prevailed—notably, cross-cultural approaches, cultural approaches, and indigenous approaches. Recently the field has opened again, setting the stage for the development of integrative views. Different challenges for the future are formulated. The careful conceptualization and definition of culture for empirical studies, diverting from the practice of comparing the needs of citizens of different countries is a necessity. An integrated conception of culture and biology is an inevitable next step. The contents of cultural models need to be considered. Finally, a developmental perspective on psychological phenomena is crucial. Methodological openness and plurality of approaches is needed for the empirical realization. It is concluded that psychology in general needs to be culture-inclusive to overcome the sole representation of a minority of the human population.

**Keywords:** *Völkerpsychologie*, cultural, indigenous, socio-demographic characteristics, autonomy, relatedness, developmental tasks, evolutionary approaches, mixed methods

Cross-cultural psychology in its most general sense deals with the study of the relationships among culture and human behavior, emotion, and thought. The International Association for Cross-Cultural Psychology (founded in 1972) defines its scope in the constitution as follows:

“... further the advancement of knowledge about psychological functioning of humans in all human societies; develop and test theories about the relationships between culture and human behavior; test the generalizability of theories from all branches of psychology and related disciplines in all human societies . . . . encourage the development of valid measurement techniques and research methodology

in the study of human behavior . . . . encourage the incorporation of the knowledge and expertise gained by cross-cultural . . . psychology into the main body of psychology and develop and promote the application of psychological knowledge to social phenomena and problems in all countries. Last but not least IACCP wants to facilitate communication and cooperation among scholars who study the relationships between culture and human behavior and serve as a fertile ground for communication, discussion and social encounters in general.”

(<http://www.iaccp2010.com/>)

Cross-cultural psychology is understood here as one, nevertheless very important, branch of

psychology. The argument developed in this chapter, however, will be that psychology and culture mutually constitute each other and that all branches of psychology need to be culture-inclusive; Joan Miller made this claim in 1999 when she stated that psychology is and always has been cultural (Miller, 1999). Most of the psychological science is developed by Western scholars and is based on empirical findings from Western research participants. It is even worse because it is not only Western, but Western, Educated, Industrialized, Rich, (Democratic origin) (WEIRD), as Henrich, Heine, and Norenzayan (2010) have argued in a review paper. Thus, the majority population of this planet is not represented in psychological science. Before we look into the future, first we shall look back briefly to track the origins of thinking about the role of culture for psychology.

### **Culture in Psychology—Before Cross-Cultural Psychology**

The concern about the influence of culture on psychology goes back to Moritz (Moses) Lazarus (1824–1903). He applied the laws of the psychology of the individual to the nation and to mankind and established a new branch of research with his article, “Über den Begriff und die Möglichkeit einer Völkerpsychologie als Wissenschaft” (“About the term and possibility of folk psychology as a science”) (in Prutz’s “Deutsches Museum” [German Museum], 1851) in which he coined the term *Völkerpsychologie* (folk psychology; for more extensive discussions of the historical origins, see the chapters of Diriwächter and Johoda in this volume). Some years later, Lazarus, in collaboration with Heymann Steinthal (1823–1899), his friend and brother-in-law, established the *Zeitschrift für Völkerpsychologie und Sprachwissenschaft* (*Journal of Folk Psychology and Language Science*, vols. i–xx, Berlin, 1860–90; continued as the *Zeitschrift des Vereins für Volkskunde* [*Journal of the Association for Folk Science*]).

Lazarus and Steinthal developed the conception of *Volksgeist* (folk consciousness) as the structure of congruent, historically emerged values. They considered every person to be unique, and such uniqueness was expressed through its *Volksgeist*, the unchanging spirit of a people refined through history. *Völkerpsychologie* as a science, however, only became popular in psychology much later and mainly with reference to the 10-volume edition of Wilhelm Wundt, (1832–1920), who was also the

founder of modern psychology with the establishment of the first psychological experimental laboratory in Leipzig, Germany in 1879 (for a more detailed discussion, see the Chapters 1 and 2).

Based on Lazarus’ and Steinthal’s ideas, Wundt conceptualized *Völkerpsychologie* as complementary to the psychology of the individual with an emphasis on the historical and social dimensions of human behavior and experience. The target was the cultural-historical analysis of the *Volksgeist*, especially language, art, myth, and customs. He understood human psychology and psychological development as not determined merely by sensation but also by the meaningful influences of the individual’s spiritual and mental [*geistig*] environment—his culture. Wundt thus clearly stressed the cultural dimension of human psychological functioning and the importance to understand human behavior within the complexity of its historical and cultural embeddedness. He also made clear that the prevailing research methods adopted from natural sciences are not sufficient to study human psychological functioning adequately. As Edwin Boring (1950) concluded: “Wundt never held that the experimental method is adequate to the whole of psychology: the higher processes, he thought, must be got at by the study of the history of human nature, his *Völkerpsychologie*” (Boring, 1950, p. 328).

This holistic understanding of psychology and the necessity of different methods for the study of human psychological functioning, however, got lost afterward for most of the twentieth century and has only recently come at the verge of rebirth. This temporary amnesia can be certainly attributed to psychology’s struggle to belong to the pantheon of science that was understood for a long time as natural science and experimental methodology.

### **Different Perspectives on the Role of Culture for Psychology**

The loss—or rather the ignorance—of a holistic approach to human psychology in North American and European mainstream psychology has been embodied in different perspectives that were discussed in quite controversial terms in the following decades. These different views (characterized as *cross-cultural*, *cultural*, and *indigenous*) as well as their methodological implications will be briefly portrayed in the following as the prevalent perspectives in the past. Such brief characterizations by

necessity risk being stereotypical, and it should be stressed that there is considerable variation in each of the conceptions, as well as overlap among them. Nevertheless, the stereotypical portraits capture some of the reality of the field—for example, that some cross-cultural psychologists accuse cultural psychologists of being hermeneutically unscientific whereas some cultural psychologists accuse cross-cultural psychology of being positivistic and reductionistic. These debates somehow represent continuity of the nineteenth-century ideological struggles. In fact the stereotypical views are particularly pronounced in this area because they tap into the basic understanding of the model of man and personhood.

### ***Cross-Cultural Psychology***

Most of cross-cultural psychology—especially in its early days—can be characterized as conceiving of culture as outside of the individual, a bounded entity that can be treated as an antecedent or independent variable. The comparison of different index variables (cultures) should explain or predict differences in psychological phenomena. Much of the studies reporting differences on cognitive styles can be subsumed here (e.g., Witkin & Berry, 1975), demonstrating, for example, differential susceptibility to optical illusions depending on contextual/cultural (socialization) experiences. There has also been some recent research on information processing labeled as cultural psychology that seems to be conceptually similar to the cross-cultural research ideology. Comparing East Asians and Euro-Americans, Nisbett and colleagues (e.g., Masuda & Nisbett, 2001) have demonstrated that East Asians perceive and reason more holistically, whereas Euro-Americans perceive and reason more analytically. However, proponents of this research tradition do not understand themselves as cross-cultural in the aforementioned sense, but as using experimental methodology to prove the inter-relationship between culture and social systems.

Another branch of cross-cultural psychology manipulates culture as an independent variable to demonstrate its nonexistence. These studies are mainly aimed at confirming the universal nature of humans and psychological laws. This conception of absolutism (Berry, Poortinga, Segall, & Dasen, 2002) is based on the assumption that all psychological processes and the way they are expressed are universal. An example of this line of thinking is research on the conceptions of personality, especially the big Five-Factor Model (Costa & McCrae,

1992). The Five-Factor Model is conceptualized as a comprehensive taxonomy of personality traits, which are thought to describe consistent patterns of thoughts, feelings, and actions. Originally identified in the United States, it is repeatedly demonstrated that openness to experience, conscientiousness, extroversion, agreeableness, and neuroticism can be identified in a wide variety of cultures, suggesting that the personality trait structure is universal. Much effort is being awarded to methodological issues and sophisticated statistical procedures to prove this aim. This conclusion, however, remains nevertheless an illusion because the statistical absence of differences does not confirm that there are no differences. Evidence for other factors and other structures of personality from non-Western cultures, which have been presented as well, are often criticized from methodological points of view.

Another strand of research that follows this second approach is informed by biologically based assumptions about the universality of human functioning—for example, attachment research. It is argued that all infants are biologically predisposed to develop attachments to caregivers to survive and develop. This assumption is extended to the notion that attachment is the same across cultures, emerges along the same developmental trajectories, and has the same developmental consequences across cultures (van IJzendoorn & Sagi, 1999). To prove these claims, evidence from diverse cultural contexts is accumulated, yet very often on very shaky conceptual grounds when, for example, the age of the mother is taken as a measure of her sensitivity toward her infant with the argument that older mothers have more domestic helpers and therefore more time for infant care.

Although in general, biological approaches informed by ethology utilize a variability of assessment procedures (e.g., observations, contextual analyses, interviews), the universalist cross-cultural approach mainly draws on experimental methodology and self-report measures. Experiments by definition manipulate variables, so that particular functions can be observed. However, the experimental setting is always reducing the complexity of psychological processes and moreover is context-independent. Experimental paradigms as well as self-report measures have mainly been developed in Western laboratories but are nevertheless applied in diverse environments. The epistemological challenges of equivalence of meaning, structure and

function go well beyond the – nevertheless serious – problems of translation.

Although all of these so-called “cross-cultural approaches” explicitly include culture to explain human psychological functioning, little emphasis is actually assigned to the definition of culture. Culture is basically set equivalent with country. According to this understanding, individual persons belong to a culture assuming the relative similarity of all the persons who belong to the given culture as well as stability of culture over time (Valsiner, 2007). If culture is further specified, mainly overarching cultural dimensions, especially individualism/collectivism (Hofstede, 1980/2001; more sophisticated systems of value are also widely discussed, *see* Schwartz, 2006). Individualism/collectivism had an overarching success story in dominating cross-cultural research for several decades while being heavily criticized at the same time from empirical as well as conceptual grounds (e.g., Poortinga, 2011; Sinha & Tripathi, 1994). We will come back to these dimensions later. Culture as a system of meanings that can be defined and described has been left to cultural anthropology to a large extent.

Because individuals belonging to one national group have been assumed to share culture, the selection of participants for empirical studies was rather convenience-guided. Therefore, the prioritized participants of cross-cultural studies have been college students for a long period of time. College students are certainly not representative—if there is such a thing like representativeness—for their respective countries. They are higher educated, coming mainly from middle-class backgrounds, and often represent outliers in a more global perspective (for more discussion on this, *see* Henrich et al., 2010). Given the socio-demographic similarity of college students across countries, it can be assumed that they form a special cultural group in itself, so that similarities in psychological phenomena can be expected. We will revisit these contextual considerations later.

### **Cultural Psychologies**

Cultural psychology, in its most general sense, deals equally with the study of the relationships between culture and human behavior. However, the relationship between culture and person is differently conceived of as compared to traditional cross-cultural psychology: some approaches within this field conceive of culture as inside the individual (e.g., Boesch, 1980) and others as being in dialogical relationship to the person, so that culture and

personality/psychology make each other up (e.g., Schweder, 1990; Valsiner, 2007). In both cases, culture, behavior, and mind are not regarded as separate entities. Another distinction within the various approaches, which can be subsumed under the umbrella cultural psychology, is the focus on either symbolic meaning or shared practices. Because there are vast differences among different strands of cultural psychology (for an overview, *see* Valsiner, 2007; Boesch & Straub, 2006), however, we use the plural in the following.

Cultural psychologies aim at studying meanings and activities *in context* to assess how cultural beliefs and social practices regulate, express, and transform the human psyche. There is a wide spectrum of vigor concerning this conception ranging from culture-specific expressions of universal predispositions to the rejection of the psychic unity of humankind altogether. The focus is on everyday practices and routines that are considered to express as well as create culture. The prime subject of study is individuals’ creation of meaning systems—particularly shared or normative systems of social groups. The conception of a dialogical nature of person and culture requires a naturalistic approach and the study of everyday practices. The focus on meaning systems implies a primacy role of language and its constitutive function, as well as an interpretative methodology.

Moreover, individuals are not considered as passively “acquiring” culture; rather, culture is dynamically created and recreated in social interactions, which in turn are embedded in broader cultural meaning systems and practices. Individuals can “distance” themselves from the concrete activity setting by reflecting on the context of which he or she is a part. Thus cultural meaning is analyzed and reorganized in personally novel forms as it is being constructively internalized (Chaudhary, 2004; Valsiner, 2000, 2007).

In contrast to cross-cultural psychology, the conception of culture and the contextual situatedness of individual’s behavior are central to the research. The consequence is that studies are often non-comparative but concentrate on an in-depth understanding of one culture and is changing dynamics over historical time.

In her book, *Weaving Generations Together* (2004), Patricia Greenfield documents 20 years of research with the Zinacantec Mexican Indians, where she not only could document and analyze cultural practices and their socio-cultural change (e.g., changing strategies of girls learning to weave) but also the

implications of such changes on both the cultural products (patterns and designs of fabrics) and cognitive processes within this group. However, cultural comparisons are not excluded but may serve the purpose of elaborating meaning systems by the method of contrast (e.g., *see* Demuth, 2008).

As mentioned before, there is a relatively new branch of cultural psychology that focuses on cultural differences in attention, perception, cognition, and memory—especially between East Asian and Euro-American participants. This approach is rather experimental or quasi-experimental in nature. Although participants in studies are selected according to citizenship of countries, underlying cultural conceptions of the self are implied, especially the conception of the independent (Euro-Americans) and the interdependent (East Asian) selves (Markus & Kitayama, 1991). These self-construals are based on broader cultural meaning systems such as Western individualism and East Asian Confucianism.

Common to all branches of cultural psychology is the understanding of culture as an inherent part of human psychological functioning. Some cultural psychologists share with cross-cultural psychologists that cultural evidence is needed for basic psychological theories to refine and/or expand these theories so that they become more relevant to the predictions, descriptions, and explanations of *ALL* human behaviors—not just Western ones (Markus & Kitayama, 2003).

### ***Indigenous Psychologies/Psychology***

The emergence of indigenous psychologies is often characterized as motivated by the intention of decolonizing the mind. To achieve this mind decolonization, research and theories should be developed from a within-culture/indigenous perspective without participation from abroad. It is therefore a vital characteristic that indigenous psychologies can only be formulated by indigenous people—that is, cultural insiders by socialization. Particularly prominent are the Indian perspective (as formulated by Durghanand Sinha), the Philippino perspective (developed by Virgilio Enriquez), and the Mexican ethnopsychological perspective (as developed by Rolando Diaz Guerrero). This origin is different from cultural psychologies that mainly are the field of alien researchers who nevertheless spend a substantial amount of time in “their” culture and learn the local language. Indigenous psychologies share with cultural psychologies the prime subject of study—that is, subject’s creation of meaning

systems, particularly shared or normative systems of a cultural group. Besides the development of procedures and assessment tools from a within-cultural perspective, indigenous psychologies also aim at the development of psychological concepts and theories. Thus, folk theories, for example, are not an object of study as for cultural psychologies but are also the source for the development of formal psychological models and theories (Greenfield & Keller, 2004). Indigenous conceptions are part of a scientific tradition advocating multiple *perspectives* but not multiple *psychologies*. Therefore, modern proponents of indigenous psychologies have abandoned the plural form and instead talk about indigenous psychology.

The preferred participants and contexts for cultural psychologies are relatively stable subsistence village cultures, whereas indigenous psychologies mainly address elite populations like university students and deal with cultural change primarily. However, the founders of indigenous psychologies mentioned before did not primarily work empirically, with the exception of Diaz Guerrero, who developed the Mexican psychology also by contrasting it to Euro-American views. In any case, the cultural inside view serves the goal to develop indigenous conceptions of psychological functioning, which is also demanding the development of indigenous methodologies.

Indigenous psychology also has a political stance in voicing non-Western perspectives as equally important as Western ones to develop a truly international psychology—a seemingly trivial notion that nevertheless is grossly under-represented in scientific discourse still today (*see* the weird psychology, Henrich et al., 2010).

Also until today, there have been voices arguing that these different approaches are incommensurable, because they rest on different science theoretical paradigms and models of the person that are exclusive of each other. However, what is congruent or contradictory, commensurable or incommensurable, compatible or incompatible is itself a matter of the worldview one holds. A Confucian or Hinduistic worldview will have different conceptions of compatibilities than a Western eclectic philosophy or neo-Kantian analytical worldview. In the remainder of this chapter, we pursue the argument that these different perspectives are complementary in several respects. Basic to this point of view is the definition of some core terms/conceptions that will be presented in the following. The conception of

culture with which we will begin is certainly the most central one.

### Conceptions of Culture

The three approaches differ in their conception of culture. Whereas much of cross-cultural psychology equates culture with country or concentrates on the bipolar dimension of individualism/collectivism, cultural psychologies often focus on processes and neglect content and indigenous psychology spans from a process orientation to a comparative perspective (Mexican ethnopsychology) without further specification.

In the following we would like to propose an approach that defines culture as a contextual-adaptive process through differential emphasis of particular content domains. In line with cultural psychological conceptions, our starting point is culture as a socially interactive process with two main components: the creation of shared activity (cultural practices) and the creation of shared meaning. Shared activities concern the material side of culture. They are adapted to survival, which brings in the inseparable relationship between culture and biology that will be dealt with later, and it involves goal-directed action. Shared meaning (cultural interpretation) concerns values, beliefs, folk models, and ethnopsychologies. This conception situates culture in everyday contexts and behaviors (Greenfield & Keller, 2004; Keller, 2007).

### Adaptive Nature of Culture

We consider cultural practices and meaning systems to be *adaptive*. The aspect of adaptation defines culture as a functional system in an eco-social environment. Thus, cultural practices, routines, and artifacts help to master environmental challenges and define competence. Children co-construct cultural knowledge during ontogenetic development with their social partners. They profit from the accumulated cultural knowledge of the ancestral generations and the cultural niches that prior generations have constructed (Tomasello, 1999; Laland, Odling-Smee, & Feldman, 2000). During developmental processes, knowledge is acquired that is helpful for current problems and at the same time a preparation for future challenges. However, knowledge that is functional at one ontogenetic level must not need to be helpful at later levels and vice versa (Bjorklund & Pellegrini, 2002).

Culture, as such, is part of our biological nature. Humans are equipped with the means to acquire

and to transmit culture. Therefore, development can be understood as cultural learning. Culture has evolved to facilitate individuals' social encounters with each other as a faster track than genetic adaptation. Therefore, culture is situated in social processes. For too long, an unsubstantiated rejection of the role of biology for human psychology has dominated all three perspectives represented earlier. It is therefore necessary to develop a differentiated view on the interplay of culture and biology.

### The Role of Biology for Cross-Cultural Psychology

A consideration of the impact of biology and the evolutionary history of humans beyond the physical body structure has been regarded as an attack against the free will, self-determination, and reflexivity. Although this debate can by and large be regarded as historical, there are occasionally voices coming up that try to question the role of biology for human psychology. The sometimes hostile attitude toward biology has been expressed from cross-cultural psychologists who, interestingly enough, share with ethologists the search for universals and by cultural psychologists who emphasize the uniqueness of humans, however, without consideration of the content, hence also focusing on a universal nature. It is amazing that the self-evident question, "How can the universal human nature appear irrespective of extremely different environments?" has so far not been raised. This question on these premises would lead logically only to one answer: Culture does not matter—a truly biologicistic attitude. On the other hand, nobody questions that, for example, plants develop very different phenotypes depending on the ecology in which they grow.

In fact, evolutionary theories assign culture a systematic place for understanding human psychology, and there is a conceptual closeness between genuine cultural and evolutionary approaches. This closeness will be demonstrated with a comparison of one of the most important conceptions of psychocultural research, the Whiting model (1975), which has set the stage for the famous six cultures study, the first cultural comparative study of child-rearing and development with basic assumptions of evolutionary theory (Keller, 2010).

Whiting summarized the philosophy of the psychocultural model in the introduction of the six cultures book on child-rearing (Whiting, 1963, p. 4):

Implicit in the research design is a general concept of the relation of personality to culture, which may

be presented as follows: The ecology of the area determines the maintenance systems, which include basic economy and the most elementary variables of social structure. In other words, the type of crops grown, the presence or absence of herding, fishing, and so on, depend on the nature of the terrain, the amount of rainfall, the location of the area vis-à-vis centers of invention and diffusion. These basic economic conditions determine in part the arrangement of people in space, the type of houses, and household composition. These in turn set the parameters for child-rearing practices.

(p. 4)

And continues:

It is assumed that different patterns of child rearing will lead to differences in the personality of children and thus to differences in adult personality.

(p. 5)

Child-rearing practices eventually lead to the shaping of the adult personality. Thus, the original model assumes a causal chain from ecological context to the adult psychology.

#### THE INPUT FROM EVOLUTIONARY THEORIZING

Evolutionary theorizing also considers the environment as the starting point of the causal chain leading to human psychology and behavior but adds to the proximate level of functional relationships between context and psychology the ultimate goal of reproductive success, or optimal genetic fitness. Thus, the core assumption is that humans, like any other species, strive for optimal representation of their genes in the next generation. This is, of course, an assumption of unintentional, maybe unconscious, “as-if” decisions. Environmental conditions comprise material and ecological resources as well as social complexity including material and social niches that prior generations have created. The crucial components in the environment are the resources that an individual is able to exploit and possibly to accumulate. Whereas the model for psychocultural research deals with the environment on a descriptive basis, evolutionary theory differentiates types of environments with respect to strategic reproductive decisions.

Both conceptions are turning the prevailing theories of socialization upside down:

Rather than analyzing the age, sex, and cultural differences in children’s activities and companions as simply the result of developmental changes of

socialization pressure by parents, other caregivers, and teachers, we are analyzing these differences as a cause in the process of socialization.

(*Whiting & Pope Edwards*, 1988, pp. 5–6)

Age, gender, and context are the major determinants of behavioral and psychological differentiations from evolutionary theories as well.

Moreover both approaches share the common interest in universal as well as differential patterns. “... [I]n spite of individual differences, there are behavior regularities for children of a given age and sex in each cultural community. That is, there are meaningful norms ...” (Whiting & Pope Edwards, 1988, p. 10)

To test the universal patterns, a cross-cultural approach is crucial, because looking for universal principles can best be achieved “... by replicating studies in a variety of cultural contexts” (Whiting & Pope Edwards, 1988, p. 10). This approach is clearly different from cultural (as well as anthropological) perspectives that assume that behavior is infinitely malleable and that cultures produce uniqueness. The focus of the research following the Whiting psychocultural model is on normative aspects, on the “natural man” approach, indicating great psychobiological similarity among the peoples of the world (Whiting, 1977).

We are impressed that there is a finite number of general programs governing the lives of children growing up throughout the world, as well as a finite and transculturally universal grammar of behaviour that children can use in interpersonal interactions.

(*Whiting & Pope Edwards*, 1988, p. 17)

This matches exactly the biological notion of an inborn reaction norm. A reaction norm describes the pattern of phenotypic expressions of a single genotype across a range of environments. The pattern, however, does not contain numerous options but a limited number of possibilities (Keller & Chasiotis, 2006).

Both approaches stress the contextual adaptation, on the one hand, and consequent necessary variability, on the other. This does not mean universality with regard to human psychological functioning but phrasing the assumption that universal principles underlay the human nature that allows for diversity.

As a species, humans are biologically primed to acquire, create, and transmit culture. Cultural differences are variations on themes of universal importance and differential emphases put on particular practices (Rogoff, 2003). Culture represents

the legacy of preceding generations as expressed in the dispositions, the consciousness, and the psychology of each living individual whose plasticity allows change to adapt to changing surroundings. At the same time, humans inherit niches that are composed of material and social resources. As such, culture is the primary mode of human adaptation (Keller, 2007).

Culture and biology are not opposites, and they are not independent forces. They are both part of the human nature and have to be conceived of as systematically inter-related. Culture selects, reinforces, and optimizes biological predispositions. The challenge for cross-cultural psychology in the future will be to assign a systematic place to biology, especially evolutionary theorizing for its further development. Moreover, process and content need to be addressed. The question that therefore has to be addressed is: How can groups of people be defined who share culture?

### ***Who Shares Culture?***

Because culture is the nature of humans, it is evident that humans generally share culture. However, this statement is not as trivial as it sounds at a first glance. This statement has wider epistemological implications. Human culture is defined by some cultural psychologists as self-reflexive, intentional, and self-conscious agency that is shared by all humans and that distinguishes humans from other species, including their closest primate relatives. There is, however, more and more evidence that chimpanzees, bonobos, orangutans, and other primates teach their offspring, have developed rituals and traditions, not only use tools but go with tools to particular places (e.g., for nut-cracking or fishing and keep the tools afterward), cooperate, and murder their own offspring as well as other conspecifics. Although quantitative and qualitative differences are substantial, culture in this sense cannot be claimed as being uniquely human (for a detailed discussion of this field, *see* Boesch, this volume).

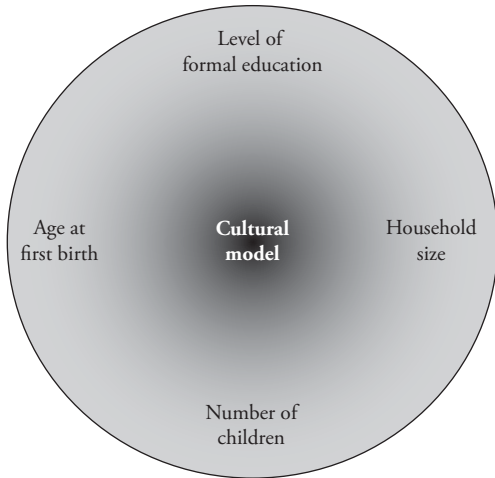

Therefore, the question is: Is it possible to systematically identify characteristics of groups that share particular cultural practices and meaning systems that differ from other groups? Here, we have to come back to the role of adaptation. With the model of psychocultural research, Beatrice and John Whiting (1975) proposed a conception linking human psychology, human culture, symbols, and artifacts directly to the eco-social environment, composed of physical parameters (like climate and geography),

history (including migrations), maintenance systems (including economic parameters), and settlement/family structure (like household composition and family type). This model, developed from a cultural psychological and anthropological perspective, has much in common with an evolutionary view on the human psychology that also relates human behavior and psychology to contextual demands of the environment. This closeness/coherence in perspective, however, is considered as incompatible by some cultural psychologists, because culture and biology are thought of contradictions—a view that rests on multiple theoretical and empirical misconceptions (*see* Boesch, this volume).

Based on the literature and our own research program, we propose to capture the environmental parameters as socio-demographic characteristics, as they can be understood as contingent on the physical characteristics of the environment as outlined in the Whiting model. We especially understand the level of formal education, age at first birth, number of children, and household size as forming particular cultural milieus. People sharing these characteristics are likely to share similar worldviews, norms, and values that are represented in particular cultural models. Cultural models are understood as overarching meaning systems that organize and coordinate different domains of life. We will discuss cultural models in more detail later (Keller, 2003, 2007).

From a traditional cross-cultural psychology understanding of culture (as characterized earlier) and from experimental thinking in general, this view is often criticized as confounding variables such as SES or education and culture. The argument, however, only holds true if we conceive of them as independent variables that can and should be manipulated with the assumption that their explanation of variance can be independently calculated. We argue, however, that they cannot be conceived of independent, because they inter-relate structurally and psychologically. The structural inter-relationship is expressed in statistics documenting that higher levels of formal education are correlated with later parenthood and less offspring, irrespective of the country or society. Psychologically, they together form a social milieu, a developmental niche, a particular learning environment. The conception is presented in Figure 6.1.

Gender is certainly another candidate that should be included in this conception. Gender studies have recently employed a similar strategy with the intersection analysis. Intersection analysis

**Figure 6.1** Cultural models as representation of socio-demographic variables.

is understood as the necessity to conjointly address gender, ethnicity, social class, health, age, language with respect to worldviews, daily practices as well as sexual orientations. It is considered as important to assess the simultaneity of effects and not separate or statistically control them (Krüger-Potratz, 2005).

This definition of the cultural environment makes countries or societies obsolete as units of analysis. Every country hosts multiple socio-demographic environments and, according to these criteria, multiple cultures. The consequences for research strategies in this understanding would imply selective sampling of individuals who share socio-demographic characteristics.

A related question here is whether the same differential variables have the same effect in different countries. That is, are individuals with higher levels of formal education more similar in psychological variables across different countries than individuals with higher and lower levels of formal education within the same country? These kinds of analyses would help to further specify the culture concept.

The challenge for the future of cross-cultural psychology is to adopt a differentiated view of culture along these lines and to define cultural groups more carefully—with the required conceptual background. The relationship between cultural and individual levels in cross-cultural research should be addressed from this conceptual perspective.

### **The Contents of Culture**

Another aspect that we consider to be crucial is to look at what are the particular *contents* of shared

behaviors and shared meanings that differentiate cultural groups. Historically there have been two extreme positions within cultural psychology: a complete neglect of content, referred to in the last paragraph, and the concentration on single case studies with all individual idiosyncrasies that some cultural psychologists share with cultural anthropologists. However, cross-cultural psychologists are interested in comparisons with regard to content of shared meanings and practices. Yet, comparisons are often made prematurely. As argued in the previous section, samples are seldom theoretically selected, but more or less a matter of convenience. Mainly social psychological studies have utilized questionnaires, assessed data sets from foreign locations wherever possible (a practice that especially criticized by indigenous approaches) without denying the role that local scholars have played. Many studies have compared only two samples, so that the *Journal of Cross-Cultural Psychology* has pursued for some time the policy—namely, that studies comparing two samples from two different backgrounds/cultures are not acceptable for publication, as the results could just reflect sample differences/similarities that do not pertain to cultural differences/similarities.

It is obvious that adequate translation and other questions of equivalence were crucial to these strategies. However, this resulted in a focus on cross-cultural methodology at the expense of theoretical/conceptual development. This may be one reason why the dimensions specifying cultural contents (power distance, individualism/collectivism, masculinity vs. femininity, uncertainty avoidance), when first introduced by Geert Hofstede in his 1980 book *Culture's Consequences—International Differences in Work Related Values* (second, extended edition 2001), received such an extraordinary attention. The dimension of individualism/collectivism especially dominated cross-cultural research for some decades. This dimension measures how individuals define themselves in relation to group memberships. In *individualist* cultures, individuals develop and display their unique personalities and select their social relationships and affiliations. In *collectivist* cultures, individuals are primarily defined and act as group members, like the family, a religious group, a workplace, and others. This dimension has been found to be related to countries' economies.

A similar, equally named dimension was proposed by Harry Triandis (e.g., Triandis, Leung, Villareal, & Clark, 1985) as one of several cultural syndromes. *Cultural syndromes* consist of attitudes,

beliefs, norms, and values that are shared, for example, by people in a particular historical epoch or geographical area. The shared ideas are organized around themes—syndromes—and form subjective culture as a society’s “characteristic way of perceiving its social environment” (Triandis, 1972, p. viii).

Individualism and collectivism form one such syndrome. Triandis (1994) has suggested that individualism evolves in societies that are complex, like information societies and loose societies, (i.e., norm and values for correct behavior are not completely mandatory); collectivism accordingly emerges in societies that are both simple, like hunter and gatherers, and tight (i.e., normatively regulated). Triandis’ conception is psychologically much more complex than Hofstede’s concept; nevertheless it also represents a one-dimensional bipolar dimension.

Although individualism/collectivism has become an all-time citation star and has influenced decades of research, methodological and conceptual criticism has been raised right from the beginning as well. One of the major points of criticism was and still is the bipolar one-dimensional nature that is regarded as too simplistic, dividing the world into two cultural groups with nothing else (grand divide theory). Of course, it is not implied in the conception that there is nothing else beyond individualism/collectivism (not to forget that Hofstede had proposed 4 and later 5 [adding time perspective later] dimensions, and Triandis named at least 10 cultural syndromes).

Yet, the major assumption of one-dimensional bipolarity has been seriously challenged, because autonomy and relatedness, as the core concepts of these dimensions, can in fact co-exist in individuals as well as in cultures. Çiğdem Kağıtçıbaşı (1997, 2005) has made a strong case for this co-existence of autonomy and relatedness that she applied to families and selves. Also the conception of the independent and interdependent selves, which Markus and Kitayama proposed in a very influential paper in 1991, conceives of two constructs that are defined as independent from each other. One difference that is notable among individualism/collectivism, Kağıtçıbaşı’s model, and the Markus and Kitayama’s approach is the scope of reach. The cross-cultural conceptions of individualism/collectivism have been applied on a worldwide scale, where countries are ranked with respect to the distance to the individualism pole. Also, Kağıtçıbaşı’s four-field schema is basically a general worldwide model, although it was mainly developed with studies concerning

social change in Turkey. Markus and Kitayama (1991, 1998), on the other hand, restrict their model to the comparisons of U.S. Americans and East Asians—mainly Japanese—which is one reason why this approach is qualified as cultural instead of cross-cultural. Kağıtçıbaşı (2005) as well as Triandis related their models to socio-cultural context (societal and socio-demographic characteristics)—that is, they differentiated between social milieus and accordingly based their studies on participants from different socio-cultural background (SES, level of formal education, urban-rural distinction, etc.), whereas the individualism/collectivism and the conceptions of Markus and Kitayama refer to nationalities. Moreover, they base their studies on a specific socio-demographic group (IBM employees in Hofstede’s case, mainly university students in the case of Markus and Kitayama) and generalize these findings on a national level. It is interesting that the psychological core conception of individualism/collectivism and independence and interdependence have been proposed from these very differing approaches, as well as from cultural anthropology (Shweder & Bourne, 1984).

In this sense, it is commonly stated that individualism/independence is based on autonomous and separate agency that is self-contained, self-assured, and self-determined; others are perceived and defined in terms of individual wishes, desires, and intentions. Interdependence/collectivism is defined as prioritizing the needs and intentions of the (reference) group as prior to individual concerns. Relationships are modeled by roles and social expectations. Harmonious social relationships are defined as a mature way of being. The theoretical and methodological frameworks, in which these conceptions are embedded, nevertheless are very different.

### *Autonomy and Relatedness Reconsidered*

Based on the essence of these conceptions, we have proposed concentrating on the dimensions of autonomy and relatedness as the basic and organizing principles of broader cultural worldviews. Beyond stating that they are independent of each other, we define the relationships between them and differentiate different modes of autonomy and relatedness that are qualitatively distinct from each other as adaptations to different environmental demands.

We differentiate the following two modes of autonomy as universal capacities, albeit with different adaptational value in different environments. *Psychological autonomy* refers to mental processes,

based on reflective and self-reflective ways of being. It centers on the realization of personal desires, wishes, and intentions. Individual psychological autonomy can be defined as the self-centered feeling of having control and being in control of all available choices. This conception represents what is usually defined as autonomy or agency in the literature. It describes and is adapted to the Western middle-class lifestyle with high levels of formal education. From the first day of life, children are mirrored their feelings, wishes, and intentions and are supported to realize them. We have suggested a complementary facet of autonomy that focuses on actions and their responsible performance and control. *Action autonomy* represents the individual's capacity to perform actions and comprises the intention, the plan, and the performance of an action under the control of the acting individual. Action autonomy is a universal human capacity. However, the nature and timing of actions that are individually controlled varies across cultural contexts. Action autonomy is the preferred mode of autonomy for a cooperative lifestyle as, for example, in subsistence-based farming economy with low levels of formal education. Children are trained from early on to take responsible actions to support the family.

Relatedness can also have different faces. *Psychological relatedness* may mean self-selected relations between separate, self-contained individuals that can be defined and negotiated from the point of view of the individual agency. This conception of relatedness can be understood as in the service of psychological autonomy. Thus, psychological autonomy would be the leading principle for the lived conception of relatedness. *Hierarchical relatedness* is defined as a network of relationships, based on hierarchically structured roles that are mandatory life long. There is no room and also no wish for individually negotiating expectations and obligations related to (family) relationships (Keller, 2007; Keller & Otto, 2011). Hierarchical relatedness can be associated with action autonomy. In this case, hierarchical relatedness is the leading principle also for (action) autonomy.

These two models are conceived of as prototypes. Prototypes imply that the patterns can be found empirically in relatively pure modes. This does not exclude, however, variability across and between the prototypes. The prototypes as described here imply partly mutually exclusive views on processes and behavioral regulations. For example, mother-child symbiosis is regarded as a pathological condition

from the point of view of psychological autonomy but as the healthy way of development from a hierarchical relational perspective. This exclusivity, however, does not mean that the conceptions are one-dimensional, bipolar, and monolithic. It also does not imply, neither logically nor empirically, that autonomy and relatedness are the only relevant dimensions of human functioning.

Cultural stereotyping can be avoided when culture is defined in terms of socio-demographic profiles as we suggested earlier. The milieu of socio-demographic characteristics has to be complemented with the nature of economic activities. There is psychological and anthropological evidence supporting different worldviews of farmers and herders, fishers, or nomads living in the same ecological environment. The history of settlement patterns also has been demonstrated as influencing cultural conceptions of the self (Kitayama & Imada, 2010). Differentiated conceptions of contextual models will need to be defined. With Pervin and Cervone's (2010) definition of personality, we suggest that cross-cultural psychology deals with what all humans have in common, with what some humans have in common, and with what is particular to the individual.

Another challenge for cross-cultural psychology for the future will certainly be to deal with the content of culture in terms of autonomy and relatedness and to identify possible other dimensions, from a contextual perspective.

## Plurality of Methods

Cultural, cross-cultural, and indigenous psychologies together host an armamentarium of research strategies and methodologies. Traditionally cross-cultural psychology has been associated with quantitative methodology from experiment to survey, whereas many cultural as well as indigenous psychologies employ more qualitative approaches. Recently there has been a trend advocating mixed-methods approaches (e.g., special issue of the *Journal of Cross-Cultural Psychology*, 2009), thus linking back to the heritage of the psychocultural approaches of the Whittings and others. Whiting and Child started with statistical analyses of relationships in the dataset of the Human Research Area Files (Whiting & Child, 1953). Whiting and Pope Edwards (1988) analyzed "the mundane or typical patterns of interaction between frequent social partners" (p. 10) from quantitative data recorded with the use of systematic standardized observations, and

“these quantitative data enable the researcher to validate subjective impressions” (p. 10). However, this understanding of the relationship between quantitative and qualitative methodology is not shared by many cultural psychologists.

The six-culture study itself represents a mixed-method research design (Whiting, 1963), where ethnographic information is compiled and portraits of individual life stages are drawn based on behavioral observations and interviews with qualitative data used to illustrate general patterns. As such, the different approaches thus use an impressive array of methodologies and research strategies, although individual scholars may have strong preferences as well as strong dislikes for particular methods.

The future challenge for cross-cultural psychology will be to develop more tolerance for diverse methodologies as well as more sophisticated designs and analysis methods from a mixed-methods perspective.

### **Introducing Development in Cross-Cultural Comparisons**

We have argued that the human psyche can be understood as result of adaptational processes to contextual demands. Therefore, cross-cultural differences in psychological functioning cannot be present from birth on—they need to develop in the particular context in which the baby is born. We have proposed to define development along these lines as the cultural solution of universal developmental tasks (Keller, 2007). There is an extensive literature in psychology on how to define developmental tasks. We propose a broad understanding in terms of topics or themes that have evolved during the history of humankind to solve adaptive problems. Therefore, their solution must be contingent upon the particular environmental conditions. This enables the development of contextual competence (Weisner, 2002). Developmental pathways are organized in coherent and meaningful sequences. The conceptions of autonomy and relatedness, as discussed earlier, provide such meaning structures in terms of developmental organizers. The socialization goal of psychological autonomy supports the early development of an independent self as expressed in contexts (e.g., babies sleep in their own beds), practices (e.g., child-centered dyadic social encounters), and interactional exchanges (e.g., contingent mirroring of infant signals). The socialization goals of hierarchical relatedness supports the early development of an interdependent self as expressed in

contexts (e.g., co-sleeping), practices (e.g., training motor development), and interactional exchanges (e.g., body contact and body carrying). Accordingly, children’s developmental achievements as well as developmental trajectories may differ in content, timing, and structure.

The particular solutions of earlier developmental tasks prepare pathways for the solution of later ones. However, these pathways are not deterministic in the sense that the early pattern allows only for one particular set of later consequences. It is obvious that along developmental pathways, a multiplicity of influences shape developmental outcomes. And the human plasticity allows for modification, compensation, and restructuring at any time of development. Nevertheless the development of continuity is easier than that of discontinuity, and most individuals experience coherence and consistency throughout their biographies.

This conception of development combines a causal sequence of influences with a co-constructive mode of development. Because experiences are individually constructed and appropriated, the active role of the developing individual and the contextual constraints and affordances form one system. The emergence of cultural phenotypes is crucial for understanding cultural/cross-cultural differences. Therefore, more emphasis on psychological development is necessary for the future of cross-cultural psychology.

### **Conclusion: Taking Culture Seriously and What It Implies**

Cross-cultural psychology, as any psychological discipline, is inevitably a cultural science, because any attempt to understand psychological phenomena needs to take into account the social cultural environment, ontogenetic history, and ancestral heritage. Cross-cultural psychology, on the other hand, is also inevitably a biological science, because any attempt to understand psychological phenomena needs to take into account the evolved predispositions and the behavioral constraints and affordances that evolved over the history of humankind. In the previous paragraphs, we have proposed reconceptualizing cross-cultural psychology on the basis of such a unified conception of culture and biology with a focus on the emergence of cross-cultural differences during developmental pathways with consideration of cultural content domains. Cross-cultural, cultural, and indigenous approaches can and should be meaningfully combined. This

will only be possible when scientists and researchers develop openness for other worldviews and particularly accept the equivalence of different worldviews for human functioning in different contexts.

This paradigm shift has tremendous implications also for the applied fields and social policy. Two examples should demonstrate the implications. Example 1 concerns policy programs that international organizations like the World Health Organization (WHO) or the United National Children's Fund (UNICEF) promote in poverty-stricken environments. The support of breastfeeding is a common focus of such programs. Breastfeeding is generally considered as a very important way to improve infants' health and development as the best source of nourishment for infants and young children. Adequate breastfeeding support for mothers and families could save many young lives.

The WHO, in line with other associations, recommends 6 months of exclusive breastfeeding. However, breastfeeding rates are not reaching the necessary timelines to be beneficial. Globally, less than 40% of infants under age 6 months are exclusively breastfed. Nevertheless women in very diverse environments (e.g., middle-class German mothers as well as Nso farmer mothers) agree that breastfeeding is the healthiest way of infant nutrition. However, the reasons that women from these two contexts consider are very different. For the Western middle-class mother who is on maternity leave, the breastfeeding situation is a time of exclusive mutual attention with abundant eye contact. For example, a mother from Los Angeles says in an interview that breastfeeding is "... a great time to do the bonding thing with your child, cause they stare in your eyes and you stare in their eyes." For the Nso farmer mother who has to continue the household chores and the farm work after delivery, it is important that she can do breastfeeding as a co-occurring activity. The following is an excerpt from an interview about breastfeeding with a Nso farmer woman: "At times she wanted to prepare something and the child was disturbing her, when she was already anxious to prepare something quickly, then she is selling potatoes and breastfeeding the child at the same time."

Programs to promote breastfeeding, however, do not account for these diverse contexts with the different needs. Breastfeeding is promoted with the Western middle-class philosophy as creating a special bond between mother and baby and fostering the exclusive dyadic interaction between the mother and child. UNICEF recommendations for

breastfeeding positions are all exclusive, face-to-face situations. Cultural environments like the Nso farmers practice multiple caregiving systems with less emphasis on special bonds between mother and child beyond the nurturing one. Therefore, programs often fail and do not succeed in raising breastfeeding rates, because they do not account for the cultural realities of the people whom they address. The important message is that there is no one best way to raise a child but contextually adaptive pathways.

Example 2 concerns the reality of migrants who shift from a rural farming background into the Western urban metropolis. Many migrants have internalized the cultural model of relatedness with its strong family connectedness based in hierarchy and obligations. The public life and the educational system, however, is organized according to the cultural model of autonomy, which is adaptive to Western middle-class families. Daycare and kindergarten treat the small child as an autonomous agent by providing multiple choices during the day and encouraging active verbal participation of children in the daily activities. Migrant parents often experience the curricula as a massive threat against their family cohesion and the core values and norms. Accordingly, they do not send their children to the educational institutions anymore, which otherwise would be very beneficial (e.g., in terms of second language acquisition as well as support of developmental domains that are considered as important in the host culture). Many misunderstandings are also pre-programmed in the Western middle-class expectation of active participation (educational partnership) of parents in the kindergarten, whereas many migrant parents expect a strict separation of responsibilities between family and institution—educational efforts and attainments are clearly not seen as the family's responsibility.

Daycare providers and other professionals profit enormously from learning to know other cultural models beyond their own. However, there is a step further to go. The often heard message, "Now, they are here, they have to do it our way," grasps it too short. Family values and norms are very deeply rooted in the personality and resistant to change, because they coincide with what is considered a good person. The confrontational method therefore is clearly prone to misachievement. Programs need to be developed from cultural knowledge to acceptance.

The wide-ranging implications also afford paradigm shifts of the culture free or better monocultural mainstream psychology. If culture is acknowledged at all in textbooks and handbooks of psychology, it is considered to provide variability. The argument that is put forward here is that the systematic influence of culture for human psychology needs to be fully introduced with a necessary paradigm shift (for a discussion of the reception of culture in psychology, see a special issue of the *Journal of Cross-Cultural Psychology*, Lonner, Smith, van de Vijver, & Murdock, 2010). Cross-cultural psychology, including cultural and indigenous approaches, therefore has to become an essential ingredient of the psychological sciences. As we have said earlier, psychology cannot be based on the investigation of WEIRD people (Henrich et al., 2010) only but also needs to include Non-Western, Indigenous, Colored, Emic people (NICE). But NICE people are not one homogenous category, a contextually based careful description of samples that deliver study results is an unquestioned necessity.

### Future Directions

In the previous paragraphs, we have identified challenges for the future of cross-cultural psychology. First, we argue, that the careful conceptualization and definition of culture for empirical studies represents an area of neglect. We have proposed to abandon the strategy to define citizens of particular countries as cultural groups and to adopt a contextually based view of culture as representation of socio-demographic variables. This conception should be further developed, including the nature of economic activities that also inform patterns and structures of lifestyles. The relationship between cultural and individual level in cross-cultural research should be addressed from this conceptual perspective.

An integrated conception of culture and biology is an inevitable necessity for the future of cross-cultural psychology. We have proposed an integrated understanding of evolutionary approaches and cultural psychologies as the basis to explore similarities and differences in human functioning at a non-random basis.

We have also stated an amazing neglect of the consideration of the content of culture for a long time and an overly inclusive application of the conception of individualism/collectivism. However, the manifold and often justified criticism of individualism/collectivism should not supersede the fact the autonomy and relatedness are core themes of

humans that need to be negotiated from any individual in any culture. We have proposed to differentiate autonomy and relatedness along contextual demands. Nevertheless, the search for other possible panhuman themes should also be pursued.

Finally, the study of the emergence of cultural phenotypes is crucial for understanding cultural/cross-cultural differences. Therefore, more emphasis on psychological development is necessary for the future of cross-cultural psychology. All these conceptual challenges afford a pluralism of methodologies and methods that have been existing in the beginnings of cross-cultural psychology. Thus, the future also has to be linked to the roots.

These challenges, however, are not particular to cross-cultural/cultural psychology only. They address important dimensions that need to be addressed for all of psychological science. Behavior and mental representations emerge during ontogeny within particular cultural contexts. As we have argued in the introduction, we only have knowledge about the psychology of a very small part of the global population that is even unique in different respects in affluence, level of formal education, and related socio-demographic characteristics (Henrich et al., 2010). It has to be understood that this context is associated with one kind of psychology only. There is a tremendous task to master in the future to construct psychological knowledge in diverse contexts. The cross-cultural perspective can take the lead in establishing a psychological science that better represents humankind.

# Archeology and the Study of Material Culture: Synergies With Cultural Psychology

Alfredo González-Ruibal

## Abstract

Human cognition does not rest upon individual minds alone but is distributed across persons, things, and time. Archeology, the discipline of things par excellence, has much to offer to researchers interested in cognitive processes. The material world is crucial in processes of enculturation and cultural transmission, in shaping daily experience and perceptions, and in orienting action. In this chapter, the concept of material culture is examined as it is commonly understood today in archeology and material culture studies. Furthermore, the diverse roles of material culture in relation to cognition are explored through specific examples from prehistoric, historic, and contemporary societies.

**Keywords:** material culture, material agency, distributed cognition, built environment, enculturation, archeological theory

## Psychology and Archeology

Archeology's links to psychology are stronger and more diverse than usually acknowledged, although the interest to establish such links has been mostly unidirectional so far: Since the mid-1980s, archeologists have been exploring the complex issue of mind and cognition from the material remains of the past—a daunting but certainly not impossible task. On the contrary, psychologists have not been interested in the lessons that might be obtained from archeology. They may think that because archeologists work with the material world, they are in a disadvantaged position to access the human mind. Also, they may perceive archeology as a field far removed from the theoretical debates that affect other sciences, such as anthropology or sociology, which intersect with psychology in several ways. As we will see, neither idea is really true.

The theoretical current known as cognitive or cognitive-processual archeology is responsible for the psychological turn in archeology, which has had

its greatest impact among those working in the earliest phases of the evolution of humankind (Renfrew & Zubrow, 1994; Renfrew & Morley, 2009). In fact, the concerns of cognitive archeologists have been basically centered on evolutionary matters—that is, the development of cognitive skills in human beings: When did abstract thought, aesthetics, or the use of material culture as external symbolic storage appear for the first time? The field more akin to cognitive archeology is not cultural but evolutionary psychology and cognitive science and, therefore, this approach will not be discussed here. However, also in this case, it has been archeologists who have approached cognitive and evolutionary psychology, rather than the other way round.

Another meeting point between archeologists and psychology (rather than psychologists) is learning and the configuration of motor skills: Which psychomotor changes have to occur so that an apprentice becomes proficient at making wheel-turned pots or a certain kind of flaked stone tool

(e.g., Roux & Corbetta, 1989; Stout, 2002)? Again, this is not a matter that has to do specifically with cultural psychology *per se* but with cognitive science (*but see* Boesch, 1993).

Beyond the evolution of cognitive skills, the truth is that at least since the early 1980s, archeologists and psychologists have been sharing more concerns than they may think: identity, personhood, and self (Hernando, 2002; Fowler, 2004), human and social agency (Robb & Dobres, 2000), emotion (Tarlow, 2000a), perception of the environment (Tilley, 1994; Ingold, 2000), memory (Jones, 2007), distributed cognition (Malafouris, 2004), and enculturation (Hodder & Cessford, 2004; Stark et al., 2008), to mention but a few.

### ***Can Archeology Be Useful for Cultural Psychologists?***

Perhaps surprisingly, there has been no attempt at dialogue between cultural psychology and archeology. This is despite the fact that archeology (the only science that has the methodological tools to study human beings from 2.5 million years ago to the present) can contribute to cultural psychology by increasing the number of cultures and cultural contexts at the disposal of the psychologist. Archeology's potential contribution to cultural psychology does not end there—rather, it starts there. [The gist of archeology lies in its being the science of material culture *par excellence*; the discipline of things (Olsen, 2003, p. 89), and material culture, as Latour (1991) said of technology, is society made durable. The main aim of cultural psychology is to understand how the mind is affected by culture. Traditionally, visions of culture as proposed by anthropologists have emphasized its immaterial side (ideology, institutions, myths, kinship) and, similarly, visions of psychological process as developing on a disembodied mind have predominated in psychology (Cole, 1998, p. 118). This disembodied image of culture and mind has come under attack during the last decade, and today many researchers agree in that human beings do not create and live culture in an ethereal, ideal void. Their lives and thoughts are inextricably entangled in a material world. As a matter of fact, almost everything in the cultural lives of human beings could be considered material culture, because there are very few—if any—activities that are not materially mediated in one way or the other—even singing or storytelling implies materiality: at the minimum, a technique of the body (Mauss, 1973).

Besides, the particular aim of cultural psychology is closer in one sense, at least, to archeology than to anthropology. According to Shweder and Sullivan (1993, p. 508) “Cultural psychology is the study of constituted or compiled experiences (what Geertz has called ‘experience-near’ concepts) in contrast to explicated experiences (‘experience distant’ concepts).” Material culture is all about constituted experiences: there is nothing closer to experience than materiality. In recent years, interest among cultural psychologists in material culture has increased (Valsiner, 2009, pp. 22–24), a fact that has to be related with an awareness of the importance of objects in culture. For Cole (1998, p. 144), artifacts, because of their simultaneous material and ideal nature, are the fundamental constituents of culture, which in turn is fundamental in shaping cognitive processes. It would be unfair to forget, however, that one of the first psychologists to point out the relevance of material culture—or tools—was Vygotsky himself. “The most significant moment in the course of intellectual development which gives birth to the purely human forms of practical and abstract intelligence, occurs when speech and practical activity, two previously completely independent lines of development, converge” (Vygotsky 1978, p. 25). Practical activity, for Vygotsky, was characterized by the use of material tools. Furthermore, he considered practical intelligence in children as prior to independent speech, given the existence of this practical intelligence in primates as well.

However, the difference between humans and apes is the capacity to make complex tools by the former, which implies a developed anticipatory cognition. I am not referring here to the use of non-modified tools (such as twigs or stones) among primates or to the debate on primate cultures (for this, *see* C. Boesch, Chapter 31) but to the making and use of secondary tools (such as retouched flakes). The first lithic industries of 2 to 2.5 million years ago, although apparently rough, imply a complex and elaborate thinking that goes well beyond the abilities of chimpanzees (*cf.* de la Torre, 2004). Interestingly, however, as Vygotsky already noted, this sophisticated practical intelligence exists before the appearance of speech. In this sense, it is worth noting that for archeologists, evolutionary biologists and philosophers alike, one of the defining characteristics of human beings is the capacity to make and use composite tools. Other elements, such as a developed speech and symbolic capacity, come later. However, Vygotsky was right at pointing at the

relevance of studying practical intelligence and the use of signs together, instead of as two separate phenomena. He did not just encourage the study of both signs and things as intertwined but considered them equally important: “[S]peech and action are part of one and the same complex psychological function, directed toward the solution of a problem at hand” (Vygotsky, 1978, p. 25). The elaborate operations involved in the production of early stone tools are not possible without some process of signification that is absent in apes. These operations comprise two elements that according to Christopher Boesch (this volume) distinguish humans from primates: the persistence of cultural traits for extended periods of time (e.g., bifaces, used for more than a million years) and the presence of nonadaptive cultural traits: there is more than one way of making a lithic point—technical diversity here indicates a cultural logic that goes beyond pure adaptation.

Archeologists, who work with the material results of past human activity, are in a privileged position to explore practical intelligence. This is by no means restricted to the period before the appearance of speech, inasmuch as in *Homo sapiens* nonverbal behavior continues to play a paramount role. A final quote from Vygotsky leaves clear the importance he conceded to tools as an inextricable part of what is to be human: “The entire existence of an Australian aborigine depends on his boomerang, just as the entire existence of modern England depends on her machines” (Vygotsky & Luria, 1993, p. 74). Things make people.

In this line, my main concern in this chapter will be to show how materiality shapes the lives of human beings, mediates their relation with the world, directs their actions, triggers or inhibits feelings, educates them in the social environment, and participates in cognitive processes, such as memory and learning.

### **Material Culture, Materiality, Distributed Cognition**

Psychologist and neuroscientist Merlin Donald wrote: “[W]e cannot have a science of mind that disregards material culture as we cannot have an adequate science of material culture that leaves out cognition” (Donald, 1998, p. 186). This is widely acknowledged in archeology and material culture studies today. The question at the moment is not as much whether mind and materiality are related but how to envisage that relationship. This relationship is better perceived as symmetrical: we should avoid understanding either

mind or materiality as having the leading role. It is more an issue of subtle and ongoing adaptations between the two (Boesch, 1993).

Cognitive-processual archeologists, those who most explicitly draw on psychology and cognitive science in their work, have tended to view material culture as a form of “symbolic storage” (Renfrew & Scarre, 1998), following Donald’s concept of “exographic storage” (see below, **Memory and Material Culture**). Written texts and signs are well-known forms of exographic storage, but things can be used for coding information as well. They help us remember past events, historical episodes, or myths, sometimes in a very explicit way, such as the decorated sticks of the Maori that allowed them to remember long geneologies or the *churingas* used by Australian aborigines, wooden plaques encoding the history of a totem (Rodríguez Mayorgas, 2010, pp. 42–45). In other cases, the relation between artifacts and information is less similar to textual transmission. Artifacts can store and convey nonverbal information about economic and political status, age, gender, ethnicity, and personal identity (Wobst, 1977; Ames, 1984; Schiffer & Miller, 1999). Cognitive-processual archeologists have not been the only ones in exploring the capacity of things to transmit meaning. Actually, it was post-processual or interpretive archeologists who first drew attention to the fact that material culture is meaningfully constituted (Hodder, 1982, 1986) and, as such, can be decoded. Although cognitive-processual archeology relies on cognitive science, and interpretive archeology is based on hermeneutics and semiotics (Hodder, 1994; Preucel, 2006), the truth is that differences are not as great as one might think. In both cases, material culture is perceived as something external that is loaded with meaning and manipulated by human actors (or minds).

### ***Toward a Symmetrical Approach to Mind and Materiality***

Since the early 1980s, many archeologists and anthropologists have called attention to the importance of things in determining culture and have criticized the oblivion to which the material has been subjected (see an overview in Olsen, 2006). In recent years, some of them have insisted that objects are not just important—they have agency as well. They are not passive containers of culture. Thus, Gosden has noted that it is not necessarily the mind that imposes its form on material objects but very often just the opposite: things shape thoughts (Gosden, 2005, p. 196). Anthropologist Alfred Gell (1998) also

remarked that material objects—particularly art—have agency. Nevertheless, saying that artifacts have the capacity to affect people does not really imply a transformation of the ontological perspective on the relationship between mind and matter. As Knappett has pointed out, “in acknowledging that objects can be agents and agents can be objects, a dualism between objects and agents remains” (2002, p. 98). A more radical stance, and a real break with previous perspectives, came during the last decade with the debates on the limitations of Cartesian or more generally—modernist dualisms. Archeologists, like practitioners from other disciplines (e.g., Butler, 1993; Latour, 1993; Descola, 2005), have critically examined the divides established between present/past, individual/collective, subject/object, culture/nature, material/immaterial, and mind/body. Following the principle of ontological symmetry defended by Latour (1993), Law (1991), and Callon (1991) as well as other proponents of Actor-Network Theory in science and technology studies, some archeologists argue for a “symmetrical archeology” that considers things and people as fundamentally inseparable (Olsen, 2003, 2007; Shanks, 2007; Webmoor, 2007; Witmore, 2007). This is a radical change with regard to previous theories that espoused the primacy of human actors over things *and* the separation between humans and objects.

However, similar views have been defended by other scholars within cognitive science and cognitive archeology (Knappett, 2002, 2005; Knappett & Malafouris, 2008). Clark (2008, p. 13), for example, has insisted that we have to abandon the image of ourselves as disembodied, reasoning engines and goes as far as to suggest that “certain aspects of the external world . . . maybe so integral to our cognitive routines as to count as *part of the cognitive machinery* itself” (Clark, 2008, p. 15, author’s emphasis). In turn, Malafouris (2004, p. 57) has argued that human cognition is embodied, situated, extended, enacted, distributed, and mediated, as opposed to the ethereal and independent mind of earlier cognitive archeologists, which projected itself onto the material world. Like symmetrical archeologists, he considers that the relationship between the world and human cognition is one of “ontological inseparability.” To illustrate his point, Malafouris (2004, p. 59) resorts to the potter’s wheel: “the cognitive map of knowledge and memory may well be extended and distributed

in the neurons of the potter’s brain, the muscles of the potter’s body, the ‘affordances’ . . . of the potter’s wheel, the material properties of the clay, the morphological and typological prototypes of existing vessels as well as the general social context in which the activity occurs.”

The material turn of the last decade has made us more aware of the inseparability of people and things and the relevance of the material world in shaping our cultural and psychological experience. If cultural psychology is the study of “the way culture and psyche make each other up” (Shweder & Sullivan, 1993, p. 498), then taking the material side of culture seriously should be a must for cultural psychologists. In the following section, we will see which are the main characteristics of material culture as it is currently understood.

### Ten Points on Material Culture

**Material culture is used to think** in both an explicit and in an implicit way (Henare et al., 2007; Knappett, 2005). Cognitive processes are distributed among people and things. As cultures vary, so do the particular relations among individuals, groups, and objects in any particular culture. Although cognitive scientists often take into consideration technology alone and more specifically explicit cognitive technologies (such as computers or navigational devices; e.g., Hutchins, 1995; Dror & Harnad, 2008), cognitive processes are distributed also among other, less technically complex, things. If we bear in mind that for human beings, social orientation is as important as spatial orientation, we can consider, for example, that mausolea—which simultaneously help us remember, mourn, and know about social classes—are important navigational devices implied in social cognition. On the other hand, even from the point of view of spatial orientation, we do not have to think of extremely sophisticated machines: a broken branch that allows a hunter to find his way in the tropical forest is also a cognitive device. In this sense, Coman et al. (2009, p. 126) rightly consider that to understand the navigation of a blind person, a researcher must account for the mechanisms of the brain and the nervous system on the fingertips, but also “the nature of the cane—its length, rigidity, graspability, and so on.” Objects, then, are also involved in our cognition in an unconscious way in daily practice. We think through things even when we do not think about them. In fact, as Heidegger (2002, pp. 13–14) noted, it is precisely when we

do not think about things that the thingness of the thing is working best:

The equipmentality of equipment consists in its utility. But what about this utility itself? In understanding it do we already understand the equipmentality of equipment? In order for this to be so, must we not look out for the useful piece of equipment in its use? The peasant woman wears her shoes in the field. Only then do they become what they are. They are all the more genuinely so the less the peasant woman thinks of her shoes while she is working, or even looks at them, or is aware of them in any way at all. This is how the shoes actually serve. It must be in this process of usage that the equipmentality of equipment actually confronts us.

The cognitive role of common artifacts is even more important in those societies that have no other means of transmitting information and preserving memory apart from oral communication (Kus & Raharijaona, 1990, p. 23).

As the example of the cane of a blind person shows, things are not something that merely interact with our minds and bodies. **Material culture is an inherent part of ourselves**, of our own physical existence. Consider bodily ornaments, clothing, body modifications, hairstyles, but also glasses, microscopes, or audiphones, who have become part of ourselves as sensory prostheses (Witmore, 2006, p. 281). It is not only our mind that is extended through things (Clark & Chalmers, 1998) but our entire body. We are material culture (Webmoor & Witmore, 2008) or, as Haraway (1991, pp. 149–181) has argued, cyborgs, “hybrids of machine and organism,” a mixture of technology and biology that blurs the distinction between nature and culture. This is not just the case of postmodern humans but of every hominid since at least 2.5 million years ago, when the first stone tools were made (Knappett, 2002, p. 98).

**We are material beings immersed in a material world.** We may say that we are in a “state of thrownness” (Heidegger’s *Geworfenheit*) in the material world, or even better, as Tim Ingold (2009, p. 5) eloquently puts it, we live “in the throwing,” as this is better described as a fluid process. The world, then, is not just a blank, neutral scenario for human dramas to unfold, a source of problem-specifying inputs (Clark, 2008, p. 16), or something to be fashioned by thoughts that emerge in a separate sphere of mental activity (Thomas, 1998, p. 155). It is something deeply enmeshed in our lives. The

active materiality of the world is fundamental for understanding the human being. As Ernst Boesch (1991, p. 334) has eloquently remarked:

“it is the permanence of things that provide individuals with a cadre permitting the building of over-situative action structures. Thereby, they provide the conditions for those constancies in I-world-relationships without which the construction of identity would be difficult to conceive.”

We cooperate actively in the making of the material world that surrounds us, but **making things makes ourselves** simultaneously. A potter is constituted through her making pots, a basket-maker through his making baskets. Making things affects sensorimotor skills (Boesch, 1993; Roux et al., 1995; Crown, 2001; Stout, 2002) and, more importantly, perceptions of oneself, society, and the world, as the teaching of technical processes incorporates social information and attitudes that are not strictly oriented to technical ends (Dobres, 2000; Wallaert-Pêtre, 2001).

Yet making artifacts is only part of the constitution of the self in relation to materiality. **Subjects are made through the use of things** as well (Miller, 1987), especially in those cultures where handicrafts have vanished and technological knowledge is socially very restricted—for example, in industrial and post-industrial societies. In the modern world, we construct our subjectivities through the consumption of fashion (Boesch, 1991, pp. 321–324; Roche, 1996), homes (Miller, 2001a), vehicles (Miller, 2001b), food, art, and many other things. Furthermore, the way we abandon and destroy material culture is also part-and-parcel of our identity (e.g., Marcoux 2001). Although destruction might be particularly characteristic of the modern world, it has always played a role in culture. The first agricultural communities of the Balkans destroyed their houses purposefully after a certain period, in what was in all probability a ritual cycle (Stevanovic, 1997, *see below*). The Malanggan of New Ireland (Küchler, 2002, *see below*) leave their elaborate funerary carvings to be slowly destroyed by the elements (as opposed to our emphasis on monumental preservation). This is related to conceptions of death, for sure, but also to a peculiar experience of what to be human is. It has recently been argued that different types of structural forgetting are specific to different social formations and that late modernity is characterized by massive oblivion based on superhuman speed, megacities, consumerism, and

perishable urban architecture (Connerton, 2009). In the same vein, it can be said that late modern subjects cannot be understood without their intimate relationship with the continual and massive destruction of things and the environment (González-Ruibal, 2008). One of the defining characteristics of the twentieth century has been the proliferation of artifacts purposefully designed to bring destruction on a large scale and aimed at civilians. The concept of the mass destruction of cities shaped a peculiar psychology in the industrialized world even before cities were actually destroyed by bombers. The abolition of time and space brought about by modernity created at the same time a hitherto unheard-of sensation of extreme vulnerability (everybody, everywhere can be annihilated), which was further spread by the nuclear menace of the Cold War (Escalona, 1982).

In sum, it is the whole life cycle of things and people (from birth to death) that is ineluctably intertwined, and this implies looking simultaneously at how people use (and discard) things, and how things use (and destroy) people. However, the relationship between consumption and destruction is more ambivalent than one may think. We have to bear in mind that the destruction of objects may turn out to be liberating: iconoclasm has often played a revolutionary role in the history of humankind. We only have to remember episodes such as Luddism (the destruction of machines by enraged workers in the early days of the Industrial Revolution) or the destruction of the Berlin Wall. Similarly, consumption can become alienating and create dependencies where there was none, a fact well known in situations of culture contact.

**Material culture has agency.** This is perhaps one of the most widely agreed tenets in current archeology and material culture studies (Gell, 1998; Olsen, 2003; Gosden, 2005; Knappet & Malafouris, 2008) but also among psychologists: This is what “active externalism” is all about—the capacity of the environment to act upon us (Clark & Chalmers, 1998, pp. 8–12). We could even argue that culture at large has agency thanks to material culture. “Culture, reminds Valsiner (2007, p. 255), regulates action ... It opens some possibilities for acting, thinking and feeling, while simultaneously closing others.” For its very physical nature, materiality is in a privileged position to regulate social and individual action. It promotes, inhibits, or sets the pace of certain actions and operational sequences. A particular kind of key, for example, can force us

to close a door in a way that no human actor ever could (Latour, 2000). A pot with a handle forces us to hold it in a particular way, and throwing a spear involves a different bodily gesture than using a bow and arrow. A mosque imposes a bodily behavior and a mental attitude. Wearing a toga and wearing trousers preclude and allow different sets of actions and prescribe a different bodily hexis. In sum, objects impose on us the necessity that is inscribed in them (Boltanski, 1990, p. 141). They order and orchestrate our behavior and, in doing so, they play the role that Durkheim recognized to supra-individual social norms inscribed in collective consciousness (*ibid.*).

Cognitive processes are not just distributed through people and things; they are also distributed through time (Cole & Engeström, 1997, p. 19). Past actions and events can condition the future actions and events. Yet time is embedded in things and **things have their own temporality**, which does not have to coincide with human time (Olivier, 2008). Actually, the temporality of things is entangled with human temporalities in manifold and complex ways. Things are made in the past and conceived for the future: in this way, they abolish the radical divide between past, present, and future (Witmore, 2006; González-Ruibal, 2006a). Therefore, the material environment has an outstanding capacity to exert an influence in people, long time after their creators have passed away (Cole & Engeström, 1997, p. 9). They continue to guide our actions and participate in our cognitive processes even when the original meanings of those artifacts have been deeply transformed—for example, the plan of a Roman city (Olivier, 2008). Something of the deep and more abstract meaning of things, however, may still work in the present in an unconscious manner. The complex ways in which temporality is weaved into the fabric of past objects has attracted the attention of scholars outside the discipline. The case of Sigmund Freud is well-known in the realm of psychology, but many others have found inspiration in ruins: Walter Benjamin, Alois Riegl, and Georg Simmel are three of the best-known examples of thinkers of ruination. It is the combination of a particular temporality with the blurring of nature and culture that has elicited more investigation (Simmel, 1959, p. 260; *see also* Hetzler, 1988). This simultaneous collapsing of nature and culture, present and past bewilders modernity but not necessarily other rationalities and time perspectives, where Cartesian boundaries are less clear or simply absent

(cf. Descola, 2005). Meaningfully, the perception of ruins is tightly linked to notions of landscape that developed in northern Europe after the sixteenth century (cf. Simmel, 2007). Our fascination with ruins speaks volumes, then, about the peculiarities of the Western mind in more than one respect. The “fascination of patina” (Simmel, 1959, p. 262), on the contrary, does not seem to be a Western prerogative, as Alain Schnapp (1996) has proved: The ancient Chinese, for example, already showed a keen interest in the ruins of their ancestors and valued ancient artifacts for their historical and aesthetic qualities. Ancient bronze vessels from the Shang Dynasty (mid-2<sup>nd</sup> millennium BC) achieved extraordinary prizes among collectors and antiquarians, centuries before Western-style archaeology arrived to China.

Sometimes **material culture carries codified symbolic information** (Wobst, 1977; Schiffer, 1999), and it is often designed to be communicative and representational (Hodder, 1994, p. 395): for example, the choice of clothes, transmits information on ethnic (Wobst, 1977) or social status (Hodder, 1994, p. 395). Thus, we not only live immersed in a material world but also in a material world that is full of, even saturated with, meaning. The advantage of material meanings is that they are always at work. They do not normally need to be activated to transmit information (like a myth that has to be told or a story that has to be read from a book). Following the Peircean terminology (see Preucel, 2006, for an archaeological take on the subject), we can say that material culture can be iconic, indexical, or symbolic. A wedding ring is an example of a material symbol (Knappet, 2002, pp. 103–104), whose explicit meaning is conventional. Icons are another category of material signs that are clearly conceived to transmit coded information. Trajan’s column in the Roman Forum (Fig. 7.1.), for example, is to be read as a commemoration of a specific military victory (the conquest of Dacia, modern Romania, by the Roman army) and therefore has a well-structured and accessible iconographic program that combines images with written text. Very often, artifacts carry at the same time iconic and symbolic information: Trajan’s column does not just transmit an iconic message of military victory, it is also a metaphor (a symbol) of imperial power. And in some cases the indexical, symbolic, and iconic are combined. Consider World War I memorials that incorporate actual elements from the war (such as a rusty bomb shell), symbolic representations of the nation, and iconic representations of soldiers.

**Fig. 7.1** Trajan’s column in Rome. It depicts the conquest of Dacia (modern Romania) by Emperor Trajan between 101 and 106. Material culture here works like a text that can be read.

However, **most objects are not symbolic in the same way as a text**: The relationship between material culture and meaning is seldom completely conventional and arbitrary. Unlike verbal symbols, material ones bear a direct material relation to their referents (Beach, 1993). This is because most artifacts are actually better understood as indexes than as symbols (Knappet, 2002, p. 104; Jones, 2007, p. 19). An example of an index is the young breasts modeled in mud that the Gumuz women of Ethiopia use to decorate their granaries (Fig. 7.2). There is a relation of contiguity, typical of indexes, between the breasts (representing human fertility) and the granary (representing the fertility of the fields). Furthermore, this indexicality brings the whole body into play, blurring the distinction between human and non-human materiality: By modeling breasts on mud, Gumuz girls are extending the surface of their bodies beyond their anatomic limits. The meaning of material culture is not just produced by social convention but also through pragmatic understandings of the material world—the relationship between the breasts and the fertility of the fields is based on a real, indexical connection between two reproductive processes.

**Figure 7.2** Decoration of a Gumuz granary in western Ethiopia. An indexical sign that works in practice.

This is related to another point: the relationship between material culture and practice (Hodder, 1994, p. 396). Most of the time, **material culture works through the evocation of sets of practices** that are not discursively perceived and that, sometimes, cannot be put into words. A roof tile is not meant to consciously represent anything, to convey any explicit meaning (as Trajan's column or even the Gumuz granary). But this does not mean that they are not meaningful. They are enmeshed in cultural practices and systems of meanings that involve other artifacts, ideas, memories, bodily gestures, speech acts and built spaces: a kitchen knife may not have any powerful symbolic meaning attached, yet the (culturally mediated) associations it can bring to mind are many and varied. They are certainly not the same if the knife is in a kitchen, at an airport control, or flashing in a dark alley. As archaeologists insist, context is vital to understand things. Context and things together allow us to behave in practice. Material culture is therefore tightly related to practical knowledge that allows us to act in specific domains of action (Hodder, 1994, p. 398).

Starting from the concept of material culture outlined above, I will address now four main concerns of archeology and psychology where it is possible to see how the discipline of things can contribute to the project of cultural psychology: personhood, emotion, space, and memory.

### **Self and Personhood**

The last decade has witnessed an important debate in archeology concerning the idea of personhood in

prehistoric and historic times. For a long time, the issue of how persons are constituted as such was undertheorized in the discipline, as opposed to history and anthropology. The panorama started to change in the 1980s, with the import of postmodern interests in individual agency and identity, and by the 1990s many archeologists were looking for individuals in the past (e.g., Meskell, 1999). The post-processual take on personhood came under severe criticism in the early 2000s because of their anachronistic nature. Critics point out that by trying to find individual agents in other cultures, the highly individualized late capitalist person is being projected onto past societies, which are thus perceived as amalgamations of self-conscious individuals endowed with fluid and changeable identities in constant negotiation (Casella & Fowler, 2005). The interest in particular individual lives came along with the introduction of the post-modern politics of identity (age, class, race, gender, sex, nationality, ethnicity) in the discipline, which further fragmented prehistoric and historic identities along post-modern lines (Díaz-Andreu et al., 2005). Although post-processual archeology has been relevant in expanding the research agenda and in pointing out the relevance of identity and personhood, the approach has resulted in a transformation of all past societies into a sort of distorted mirror image of our own late modern existences.

Archeologists like Felipe Criado (2001) and Almudena Hernando (2002) were among the first to call for a more critical exploration of selfhood in the past, drawing upon anthropological and

historical theory. They emphasized the collective and relational nature of prehistoric concepts of personhood, an idea that was later independently developed in the Anglo-Saxon archeological tradition (Fowler, 2004). British archeologists relied on Melanesist anthropology—particularly in the work of Marilyn Strathern (1988)—to support their perspectives on prehistoric personhood. Strathern contends that the Melanesian person is not individual, but “dividual,” multiply constituted through relations with other persons. Besides being dividual, members of Melanesian societies are also partible. They are composed of different substances inherited from the parents or acquired through kinship and affinal relations. In certain contexts, such as marriage, ceremonial exchanges, and death, persons can be decomposed—they give away parts of their selves in the guise of pigs and other valuables. But the bodies themselves are conceived as decomposable, too: people can detach from parts of their own bodies as well as attach to themselves parts (or substances) of other peoples’ bodies. Relational identities have also been described as fractal and permeable (Fowler, 2004), as opposed to the bounded and indivisible self of modernity. Currently, there is a widespread belief in archeology that self-identity is either relational (most prehistoric societies), and suspiciously similar to the Melanesian self depicted by Strathern, or individual and well-bound (historical and, especially, modern Western societies). This dual schema reminds the independent/interdependent distinction proposed by Markus and Kitayama (1991) and is sometimes perceived in too radical terms. LiPuma (1998) considers that we have to take into account elements of individuality in the construction of the self among non-modern societies and, similarly, elements of relationality (or dividuality) in societies with highly individualized persons. For Hernando (2008, p. 68), both relational and individual identities have at least one thing in common: they are both fantasies, creations of the human mind whose aim is to neutralize the anxiety that would cause the true understanding of the powerlessness that defines our relation to the world. And what could be better to give an appearance of solidity to a fantasy than material culture?

Materiality is deeply involved in the construction of both relational and individual selves. Societies where relational forms of identity prevail tend to produce homogeneous objects and styles that underscore the shared identity and relations between members of the society, whereas individualistic

societies normally produce a proliferation of distinct artifacts and categories of artifacts to satisfy a myriad of tastes that are enmeshed in complex social strategies (Bourdieu, 1984). Nevertheless, even in collective cultures, there are people that tend to develop more individuality than others. Ritual specialists in segmentary societies, for example, tend to use a very peculiar material culture and wear extravagant clothes and adornments (Devlet, 2001). We have to understand this not just as a mere symbol of status or a materialization of mythologies but also as an index of the more individualized self of the ritual specialists, which leads them to channel their need for differentiation through the use of artifacts. Actually, following a symmetrical approach, we could say that extraordinary objects and apparel are indistinguishable from the ritual specialist’s self: the shaman or diviner is a very particular cyborg within a society of more homogenous cyborgs. Similarly, even in highly individualized societies, there are material elements that reinforce the ties between different members of the community and therefore have a very important psychological role. In the case of late modern Western society, we can see this in the urban tribes that resort to the same clothing and items to create a sense of belonging among their members.

### *Relational Identities*

Relational identities were prevalent in the world at least until the sixteenth century AD. It was probably not before the twentieth century that the individual self came to dominate globally. Relational identities are characterized by a series of material markers, some of which explicitly encode information about the identity of a particular community, whereas others are of a rather unconscious nature. Among those objects that explicitly encode social information, we may consider bows and arrows (Wiessner, 1982; Pétrequin & Pétrequin, 1990). In many cultures, arrows have an assertive character—that is, they express personal identity, craftsmanship, and taste. However, they also convey, in a very explicit way, information about the identity of the group to which the person who made the arrows belongs. Thus, the Ye-Ineri, an ethnic group from Irian Jaya (New Guinea), make different arrows depending on age, function of the arrow (war or hunting), and personal ability. However, it is still possible to distinguish easily a bundle of arrows from the Ye-Ineri group and a bundle of arrows from the Tangma community. Whereas in a society

where independent selves prevail there are scarce limits to personal innovation, among the Ye-Ineri and Tangma, despite an apparent liberty, the limits are very well-demarcated. The boundaries for personal creativity are enforced in daily practice through moral sanctions and social disapproval that do not necessarily imply explicit verbal condemnation. A way of curtailing personal creativity in a society of interdependent self is not buying, exchanging, or accepting in ritualized occasions (or accepting grudgingly) those artifacts that clearly deviate from the norm.

Some artifacts and technical knowledge in societies of interdependent self are so crucial in promoting identity that they can be considered technologies of the self, following Foucault (1988), but rather than an individual self, they help create a collective self. Unlike items that bear explicit ethnic information (such as bows and arrows), technologies of the collective self are often unconscious or, at least, beyond verbal discourse. A good example is the technology of food consumption. This technology includes artifacts, body techniques, and operational sequences. Changes to the technology of food consumption often imply dramatic transformations in society and identity: Deetz (1996, pp. 86–87) has equated the evolution from communal vessels to individual dishes in North America

during the seventeenth and eighteenth centuries and the evolution of independent selves from collective ones—a phenomenon that has its correlates in the organization of domestic space and refuse disposal. The relevance of the technologies of food consumption for shaping a collective self is clearly visible among many Sub-Saharan communities. The case of the Komo is telling. They are a highly egalitarian small-scale society of slash-and-burn agriculturalists, who live in villages of less than 200 inhabitants in the Sudanese-Ethiopian borderland (Theis, 1995). As in other neighboring groups (James, 1988), community values are continuously enforced in daily life. One of the mechanisms for buttressing a communal identity is the working party: a family calls relatives and neighbors to lend a hand with the harvest or the building of a hut and, in compensation, provide food and beer. The artifacts and the body gestures employed in these rituals are essential for the perpetuation of relational selves (Fig. 7.3): Everybody forms a circle and drinks from the same big pot using straws, giving their backs to the outer world and their faces to neighbors and relatives (González-Ruibal et al., 2009, p. 60). A sense of solidarity is extraordinarily reinforced in this way.

Relational identities are also expressed in the way the dead are treated. It seems logical that if persons

**Figure 7.3** A group of Opuuo (a people closely related to the Komo), drink beer from a common pot in a working party (western Ethiopia).

are considered partible and decomposable, their bodies are too (Jones, 2005). Burials from Europe and the Near East during the Mesolithic (i.e., the period of the last hunter-gatherers before the emergence of agriculture in the Old World) often kept only disarticulated bones (Verjux, 2007), because the human remains were buried after a period of exposure to the elements or because the bones were dug up and reburied. These practices continued with the first agrarian communities in the period known as Neolithic (Thomas, 2000). Some egalitarian societies still practice, or practiced until recently, secondary burials. That is the case of the Uduk of Sudan (James, 1988), who used to dig out one or more of the bones of a recent tomb, anoint them with red ochre, and return them to the grave, a ceremony that was meaningfully called “Settling the Grave” (James, 1988, p. 131). The idea was to ensure that the spirit could make a complete and clean break from the body (*ibid.*, p. 127). The skull, in particular, tends to receive a differential treatment in many cultures. Modified and decorated skulls abounded during the late Mesolithic period in the Levant (Kuijt, 1996), and this practice is well-known from ethnographic contexts in areas like Melanesia (Zegwaard, 1959). Kuijt (1996) interprets skull removal and other mortuary practices (such as lack of grave goods) in the Near East as part of the strategies developed by complex hunter-gatherers and incipient agriculturalists to limit the accumulation of power and authority.

As people are perceived as inseparable from the collective in relational cultures, tombs are often collective. The skeletons of different people appear mingled together and sometimes it is difficult to refit individual bodies (Fowler, 2001). Sometimes, even animal bones appear mixed with human remains: this probably means the relational self included relations with non-humans as well (Descola, 2005). The treatment of the deceased was a very straightforward way of transmitting ideas of the self and community in the broad sense. There seems to have been a tendency among those societies where corpses and bones were manipulated not to hide away the event of death, as opposed to societies with only one death ritual. In fact, many of the rituals of excarnation, dismemberment, burial, and reburial of bones were attended by the entire group, and sometimes parts of the dead were ritually consumed (Conklin, 1995; Boulestin, 2009), which is the most powerful way of showing a sense of community.

### *Individual Identities*

The strong development of individuality in the West since the fifteenth century comes hand-in-hand with an extraordinary increase in the number and variety of artifacts through which new, diverse, and often conflictual selves were channeled and constituted: gardens (Leone, 1984), houses and headstones (Deetz, 1996), portraits (Burke, 1995), and even toothpicks (MacLean, 2009). Some of these items are used in a communicative manner to consciously display personal and social taste and status—that is, as symbols: clothes, silver, or chinaware (Goodwin, 1999; Schneider, 2006, pp. 206–207). In other cases, things become intrinsically related with the self in an unconscious manner—this is the case of toothbrushes and other items of personal hygiene and bodily care (Gaitán, 2005), as well as writing and reading materials (Hall, 2000, pp. 80–83). Both categories of artifacts are related in that they have to do with ideas of care (physical or psychical), and they are therefore crucial in fostering and cultivating the individual self. In this sense, they are technologies of the self (Foucault, 1988; Fowler, 2004, p. 13) but also “core objects,” as Boesch (1991, p. 333) has called them: “one which, by its usages and ritual connectedness, appears to be vital for the definition of a culture.” A particular technology of the self that has developed since the mid-sixteenth century in the context of the Counter-Reformation has been the material culture of bodily discipline. Whips, sticks, *cingula*, and cilices (Brandão & Nassaney, 2008) were aimed at purifying the self by mortifying the sinful body. Although cilices have been used since Antiquity, their success in early modernity has to be related to the progressive imposition of dualistic ideas that created a divide between mind and body—the first being equated with the self (and soul)—and the increasing importance of the individual person and individual salvation.

It would be wrong, however, to think that technologies of the individual self exist only in modernity or in evolved state societies, such as the Greek and Roman world examined by Foucault (1988). Technologies of bodily care that evince a strong awareness of the individual self have developed since the mid-2<sup>nd</sup> millennium BC in Bronze Age Europe, when razors and mirrors, dress pins, and individualized weaponry became widespread among elites (Treherne, 1995). Those items were indispensable to constitute individual selves in the midst of rather homogeneous communities.

The difference with modernity is that technologies of the self and individualized material culture become extremely generalized, eventually cutting across social classes, race, and gender. In our globalized, late capitalist world, almost everybody wants to be unique. In fact, artifacts in modernity can be a powerful way of holding the self together in disruptive scenarios, such as civil conflicts, wars, and dictatorships. Artifacts may help to link one with his or her self prior to the traumatic experience (e.g., the handicrafts made by prisoners) (López Mazz, 2009, pp. 39–41) or to create a new self, which incorporates (and domesticates) the traumatic experience. This is the case of trench art, the artifacts produced by soldiers in World War I (Saunders, 2009).

To summarize, material culture is fundamental in constituting the self as relational or independent and the whole spectrum between one possibility and the other. A child belonging to a small-scale, egalitarian community will arrive to a homogenous world in which all artifacts look the same and private possessions are minimal—he will associate himself with sameness rather than difference. Through those artifacts (houses, pots, or cultivated fields), the child will learn to live in a society where relations among humans and non-humans are more important than individual persons. Furthermore, as the child grows, he will progressively use technologies of the collective self—that is, techniques, technical knowledge, and artifacts that make him relate to others and that will constitute his psychical existence as part of a communal body—for example, weapons and strategies used in communal hunting or spindles and songs in communal weaving ceremonies. In some cases, such as in many societies of hunter-gatherers, private possessions are reduced to almost nil. Everything has to be given away if someone asks for it (and vice versa: one is allowed to use almost everything from everybody). The boy who is born in a community of relational self will never see or make an iconic representation of himself, only idealized representations of Men, Women, Ancestors, Gods, and everything in between. By attending funerals where bodies are manipulated, carved up, buried, dug up, and reburied, he will learn to perceive his body as plastic and decomposable, a continuum in the mass of human and animal bodies that populate the world.

If we consider now a girl born in a late modern, highly individualistic society, we will see her exposed from her birth to a highly differentiated material world. She will learn to understand social and

group differences through artifacts, but she will also become aware of her own uniqueness as an individual through the use of particular objects and through the consumption choices that she will be compelled to make (Baudrillard, 1968, pp. 196–197): toys, clothes, books, cars, DVDs, web-blogs. From her earliest childhood, she will recognize herself in photographs. She will learn that her self is modifiable but not decomposable, both in its physicality, in its social attachments, and in its psychic qualities. She will read self-help books or philosophy, sculpt her body in the gym, or operate her breasts. Yet there is a limit to what an individual can become even in modern societies: prisons, reform schools, and asylums are institutions that model the deviated self through all kinds of material and immaterial tools (Foucault, 1975; Casella, 2007), which, again, are aimed at the individual person—individual cells, solitary confinement cells, psychological assistance.

### Emotion and Material Culture

Emotional experience is universal, but emotions are culturally variable, as anthropologists have abundantly demonstrated (Lutz & White, 1986; Tarlow, 2000a): cultural meanings, experiences, and values attached to emotions vary from society to society. According to Shweder:

To understand the emotional life of a person is to understand the types of feelings (anger, envy, fear, depersonalization, shame, joy, love, homesickness, and so on) felt by that person, the distribution and frequency of those feelings across time and context, the kind of situations that elicit them, the wishes and fantasies that occur with them and the action tendencies set off by them.

(1991, p. 242)

What can be the contribution of archeology to explain the emotional life of individuals and societies? We have to take into account that emotions are not always easily verbalized, especially overwhelming emotions—what Valsiner (2007, p. 312) calls “hyper-abstracted and over-generalized higher level total feelings.” Actually, feelings themselves cannot be observed, only indexes of them (gestures, facial movements, heartbeats) (Shweder, 1991, p. 242), and indexes are the raw material with which archeologists work. Besides, emotions are often triggered, oriented, or conditioned by the material world (Valsiner, 2008).

Emotion has figured prominently in recent archeological debates (Tarlow, 2000a). The basic

problem is how can we actually know what other peoples experienced in the past? Unlike ethnographers, archeologists rarely have the opportunity of an intersubjective experience—or “subjective pilgrimage,” as Valsiner (2007, p. 311) aptly puts it—with living people. In the case of historical archeology, this can be somehow mitigated through the use of texts (including personal diaries and letters). For illiterate societies, the problem we face might be deemed insurmountable. We are forced to make inferences based on analogies with similar societies documented ethnographically as well as on our own subjective experience. The latter has been the object of much discussion. Since Christopher Tilley’s seminal book, *A Phenomenology of Landscape* (1994), the philosophical insights of phenomenology have been widely applied to prehistoric archeology, especially in the British Isles (Brück, 2005). Interest in past feelings has led, in some cases, to subjective excesses and to a trivialization of phenomenological theory (cf. critique in Olsen, 2006). However, most archeologists have avoided both the most objectivist and the most subjectivist positions, adopting nuanced perspectives. Therefore, there are those who, from a relativistic and constructivist stance, stress the enormous difficulty of approaching subjective experiences of people belonging to other cultures (Tarlow, 2000a; Brück, 2005), even if basic human similarities across cultures are acknowledged. On the other hand, there are those who emphasize our ability to connect with past senses of place through our own bodily experience (Tilley, 1994), although they accept that specific meanings and precise feelings mostly escape the archeologist.

Admittedly, access to particular emotions of other cultures from material remains alone is extremely difficult and always requires some sort of cultural translation. There is no true immediate experience of the past: in the case of prehistoric societies, we are dealing with people who had a wholly different cosmology and rationality, which deeply shaped their perceptions of the world (Thomas, 2004, pp. 216–217; Brück, 2005, pp. 54–55). Nevertheless, we can still have some access to past emotions without resorting to texts. On the one hand, the work of cultural psychologists has proved that most basic emotions (such as anger, disgust, fear, happiness, sadness, and surprise) appear in most cultures, although they are expressed in very different ways (Heine, 2010). After all, there is a shared biological basis that explains human emotion. On the other hand, the physical engagement of the human body

with the material world is central to experience, and the materiality of the body offers some possibilities of experience and precludes others (Tilley, 1994). Thus, cold, heat, hunger, or pain—although conceived in different ways and endured to different degrees by different cultures—affect all human bodies, and these have limits as to what they can see and interact with from a certain topographical position. Also, the materiality of the landscape itself has not changed much in many cases: the physical environment interacts with physical human bodies in specific ways, irrespective of culture (Tilley, 2004).

The important point to bear in mind is that the emotions archeologists are better able to retrieve are those related to hyper-abstracted and overgeneralized feelings—the kind of feelings one has when entering a gothic cathedral, a megalithic tomb, or a prison cell. Instead of trying to discern in detail particular emotions, archeologists are at their best when they explore the material mechanisms that trigger those emotions in different cultural contexts. In which places was the greater investment made in material devices oriented toward affection? Which spaces were more emotionally charged? Those related to collective identity, political power, religion, punishment, individual achievement, life, death, liminal states? Which spaces displayed more varied devices for triggering sentiment?

If a place is emotionally invested to a high degree, it can help us know the importance of such place in society, as well as the activities related to that place—for example, tombs of children in the West are often overcharged with indexes of affection. It is difficult not to feel moved by some of these tombs displaying a variety of toys, teddy bears, letters, photographs and flowers. This is because children are not supposed to die in an industrialized society but also because childhood has been marked as a well-defined and valuable period of human life mostly in modernity (Ariès, 1987). On the contrary, in many pre-industrial societies, child tombs are very inconspicuous, and in some prehistoric cultures they were not even buried at all (Scott, 1999). However, prehistoric or ancient societies should not all necessarily show the same kind of emotional behavior, although some tendencies applied. In her study of the Egyptian village of Deir el-Medina (late 2<sup>nd</sup> millennium BC), Meskell (1999) proposed that the death of children was experienced as a painful event, based on the elaborated burials of non-aristocratic children and on contemporary texts.

## EMOTIONAL FRAMING OF POLITICAL LIVES

Another case has to do with elements of affection in political life. Political celebrations tend to mobilize different kinds of emotions: power is sensuous and corporeal, and not just in premodern societies (Kus, 1989; Mbembe, 2000; Linke, 2006). As Tarlow (2000a, p. 719) reminds:

“Hegemony and authority in social contexts are constituted through such emotional experiences as awe, respect, fear, shame, and guilt, as well as familiarity and security.”

These emotional experiences are framed by material apparatuses. However, emotion in political contexts varies wildly from culture to culture. To use two opposite examples: Versailles was devised so as to arouse overwhelming feelings of superhuman grandeur, a fact that fits well with a divine conception of power. A place that is known by its address (*10 Downing Street*) on the contrary, is completely bereft of material devices to trigger emotion, although these may arise for different motivations. This speaks eloquently about the conception of power in contemporary liberal democratic societies.

### *Death and Emotion: Neolithic Europe and the Modern West*

Understanding emotion in context, then, helps us understand culture. In what follows, we will look at a place loaded with emotion—cemeteries—in two different cultural environments: Neolithic Western Europe and Euro-American modernity.

## NEOLITHIC EUROPE

Megalithic tombs were built all over Western Europe by early farmers during the period known as Neolithic (i.e., between the early fifth and early third millennia BC). They were the first monumental, collective tombs—the first monuments at all—in most places where they were built (Fig. 7.4). During the second millennium BC, monumental burials still existed in different places of Europe, such as southern Britain and southern Portugal, but they were erected for individual persons or particular powerful families. Megalithic tombs soon developed into a very complex architecture with immense possibilities to shape and direct emotion. Subtle changes in temperature, texture, darkness and light, sound, and visibility configured very particular experiences of community, death, afterlife, and the sacred. Also, the tomb itself was not the only important element for framing social experiences. Tombs were inserted in meaningful landscapes in which other monuments and natural features interacted to create a sense of place (Tilley, 1994). During the last decade, there have been many attempts to avoid intuitive approaches to Neolithic emotions. Archeologists try to provide contrasted accounts of the ways in which “hyper-abstracted and over-generalized feelings” were fostered and enhanced inside tombs and in megalithic landscapes. Regarding landscape, Geographical Information Systems (GIS) have been used to recover the way it was experienced in the past in a more objective manner (e.g., Criado & Villoch, 2000; Llobera, 2003; Wallace, 2007). GIS

**Figure 7.4** A megalithic tomb from Galicia (Spain) after excavation. Ritual activities took place around the mound, in front of the entrance and inside between 3800 BC and 2700 BC.

analyses allow making visible connections, which are unknown or known intuitively, between different monuments and natural features.

Megalithic tombs were open monuments in which rituals took place and where corpses were being buried, exhumed, and reburied in a regular basis. They are excellent examples of “scripted dramatic everyday life situations” (Valsiner, 2007, p. 250) that are crucial in the psychological development of human beings. Overwhelming feelings were achieved through different means: one is the art that covers part of the huge stones (Fig. 7.5). Unlike in the modern world, art was not a normal occurrence in the Neolithic. People did not live in an “ornamented world” (Valsiner, 2008) as we do. Thus, entering a profusely engraved tomb must have certainly been regarded as a liminal event, an entrance into another world—and it is precisely entrances and passages that are most often decorated (Bradley, 1989). Sensations were probably enhanced, at least in some cases, with the use of consciousness-altering substances, which interacted with the images to foster hallucinations and visions (Dronfield, 1995a, 1995b). The images—spirals, lozenges, arcs, meanders, and curves—are thought to be inspired in the visions themselves. Dronfield (1995b, p. 547) proved that Irish passage-tomb art is fundamentally “similar to (as opposed to merely resembling) arts derived from endogenous subjective vision.”

However, it is not strictly necessary to consider the use of drugs to explain the way the mind was altered inside the tomb. Songs, sounds, dancing,

speech, and movement could have been used to provoke an altered state of mind. The issue of sound has received significant attention. Watson and Keating (1999), for example, analyzed the particular sounds of a stone circle (a sort of sanctuary or shrine) and a passageway-type megalithic tomb. The authors of the research discovered that a single drum was capable of generating approximately 4 Hz to 5 Hz at between 120 decibels and 130 decibels inside a megalithic tomb, a level of exposure that could result in balance disturbance, pressure on the ears, speaking difficulties, vibration, drowsiness, and headaches. Also involved in enhancing experience and creating meaning was texture, which involved touching and therefore a bodily experience of the monument (Cummings, 2002). In this context, it is worth remembering, with Warnier the basic role of the skin in the ontogenesis of the human subject: “The psyche is constructed as an envelope by ‘anaclisis’ on the anatomical-physiological functions of the skin” (2006, p. 187). Here, anaclisis is understood as related to a process by which psychic experiences build on—or are propped against—bodily motions and emotions. Differences between smooth and rough surfaces in megaliths could have triggered different emotional responses and be imbued with different meanings. Finally, the textures of light must have been very important in the megalithic experience. Light is manipulated in many architectural traditions to orient emotional responses (Bille & Sorensen, 2007). Although similar effects to those of megaliths could have been previously achieved in natural spaces, such as caves, by hunter-gatherers

**Figure 7.5** A decorated slab from the megalithic tomb of Knowth in Ireland.

(Reznikoff & Dauvois, 1988; Waller, 1993), the difference is that megaliths were the first explicit attempt at creating and manipulating sensory conditions to affect the subject in an artificial way.

The relevance of megalithic tombs in the social lives of early agriculturalists should not be underestimated. As I have pointed out, these were regular arenas for social interaction (much more than modern cemeteries). The term *tomb* is misleading for us, as we divide the world of the dead and that of the living in a very clear-cut way and try to avoid any contact with the former. In addition, the megaliths were probably used if not by the whole community, at least by a large part of it, including children and adolescents. Although the most secluded parts of the tomb could have been accessed only by a few, the ceremonies in the necropolises were attended in all likelihood by the entire group. Watson and Keating (1999) proved that sounds made inside a megalithic tomb could be heard outside, emerging from the passage entrance. Megaliths, then, were an essential element in the emotional economy of the early European farmers. The rituals carried out inside and around the tombs were emotionally intense and involved the whole community: actually, they helped reinforce the sense of community—and *communitas* (Turner, 2002). The sensorial qualities of the megaliths enhanced the experience and channeled and amplified the emotions. The relation with the deceased and with the ancestors was very close: One literally entered the house of the dead and manipulated the bones of one's relatives.

#### THE MODERN WESTERN WORLD

Quite the opposite is the case of modern cemeteries. Despite cycles of ostentation and restraint in funerary ceremonies, the general trend in European and North American funerals during the nineteenth and twentieth centuries has been toward the restriction of emotions. For the last hundred years, ostentation in tombs and funerals has been regarded in most Western societies as a sign of bad taste and low or marginal status (Cannon, 1994, p. 440; Parker-Pearson, 1982, pp. 104–107). This process has been explained on economic and social grounds—investments in status markers changing from funerary display to other realms to maintain class distinctions. However, there seems to be deeper reasons for this general trend toward more sober cemeteries and rituals: It seems that an excess of materiality in funerary ceremonies and tombs was unconsciously equated with an excess of

emotion. And with good reason—as we saw in the case of megaliths, a redundant, saturated material environment was fundamental in triggering and amplifying emotions.

One of the main differences between modern and pre-modern cemeteries is the prevalence of visual experience and visual codes in the former, in line with the enormous importance conferred to the sense of vision in modernity (Levin, 1993). Although hearing still plays a role (choirs, sermons, reading of religious texts), bodily senses are less prominent than in non-modern communities. Tombs (much less corpses) are not designed to be touched or to have a particular sound—and human remains do not smell. The experience of death is sober, clean, individual, and introspective. The suburban cemeteries that spread through northern Europe from the late eighteenth century onward—particularly the Anglo-American garden cemetery (Tarlow, 2000b)—played a prominent role in shaping the emotions of death as individually experienced. Garden cemeteries were located in pastoral locations. This was justified on hygienic grounds, but in fact, it was not only physical dirt and pollution that preoccupied urban reformers but also the moral and emotional cleanliness that the new cemeteries brought with them (Tarlow, 2000b, p. 227). The isolated tombs and the manicured landscape had a double effect (Fig. 7.6): On the one hand, they calmed down and sifted emotions, fostered introspection, and enabled self-reflective attitudes (just the opposite of emotionally loaded, collective megaliths). On the other hand, they permitted the experience of emotions (even the more violent ones that one could not restrain) without being seen by many people, a situation of relative intimacy that could hardly be achieved in overcrowded city churchyards.

Although similar trends toward suburban, hygienic cemeteries have existed in southern Europe from the mid-eighteenth century (Calatrava, 1991), there are important national differences. Anglo-Saxon cemeteries are much more individual-oriented than Mediterranean ones. In the United Kingdom, the United States, and other places with a strong Protestant tradition, tombs are individual and situated wide apart in vast cemeteries. On the contrary, in Spain and other Mediterranean countries, tombs are often cramped together around churches, often in multi-niche structures (Tarlow, 2000b, p. 222)—a translation to the material world of a more relational identity within a culture of the

**Figure 7.6** Victorian cemetery in Glasgow: isolated monuments to the individual self.

**Figure 7.7** Between the individual and the relational self: a cemetery in Galicia (Spain).

individual self (Fig. 7.7). Anglo-Saxon cemeteries are spaces for melancholic, individual feelings. Mediterranean necropolises are more appropriate for open, collective emotions and expressions of family and neighborhood solidarity. According to Tarlow,

An appreciation of Protestant virtues of simplicity and nature was a central part of British identity in the nineteenth century. In their own understandings, the Protestant nations were distinguished from their overblown Catholic neighbours by an authenticity of unmediated, pure moral feeling. (2000b, p. 224)

However, the more interdependent Catholics would interpret this as aloofness and individualistic behavior.

Finally, another element that can be enlightening as to the relation among self, emotion, and death in societies of independent self is the issue of memorials. In modern cemeteries, it is the performative act of reading the name of the deceased on a tombstone—an individual act—that provokes the most powerful feelings. Significantly, one of the most successful war memorials ever built is the Vietnam Veterans Memorial in Washington D.C. (Wagner-Pacifici & Schwartz, 1991), in which reading is absolutely essential for unleashing intense

feelings. Its success lies in two facts: it commemorates individual lives (the entire monument is a list of names), and it abolishes the difference between past and present (by uttering the name of the dead, people are able to evoke a strong sense of presence). This fits better the modern self than collective, abstract memorials, as those built after World War I. Whereas in the Vietnam Veterans Memorial the focus is on the individual, in World War I memorials the focus is on collective sacrifice (Winter, 1995, pp. 78–116). Unlike other monuments, and because of the controversial and divisive character of the war, the Vietnam Veterans Memorial was actually explicitly designed so as to avoid collective messages and to evoke instead “feelings, thoughts, and emotions’ of a variant and private nature” (Wagner-Pacifiçi & Schwartz, 1991, p. 393). In short, the Washington memorial can be considered the quintessential monument to the dead in highly individualized late modern societies. However, what the memorial achieves in the short term, it loses in the *longue durée*, a fact that is also eloquent of modern identity: after a few generations, it will fail to trigger intense emotions, when the names of the individual dead fall into oblivion (Wagner-Pacifiçi & Schwartz, 1991, pp. 417–418). This is in opposition to the megalithic chambers, where the bones of the remotest ancestors and the newcomers to the tomb were mingled together. Every ceremony held in the megalith was an intense, emotional experience. Individuals did not matter—it was the always-regenerated, cyclical self of the community that mattered. The Vietnam War Memorial will fail to evoke presence in less than a century. The megaliths evoked it for millennia.

## Space and Order

The agency of material culture as a framework over our actions is nowhere more obvious than in the built environment (Parker Pearson & Richards, 1994): it orients everyday life by offering certain spaces for programmed action, while closing other possibilities (Dovey, 1999, p. 11). Walls, rooms, doors, and decorations act as “semiotic blockers” (Valsiner, 2007, p. 68) that regulate the semiotic hierarchies of the dialogical self. The agency of buildings is clearly seen, for example, when we enter a library and immediately start to speak in a low voice (Donley-Reid, 1990, p. 116). It is not only the verbal messages (signs of “Silence” or the librarian’s command) that make us lower the volume of our voice. It is the material environment as

a whole that is forcing us to adopt a certain attitude: the quality of light, the books, the curtains and shelves, the texture of the walls and floors. Houses, in particular, are a critical element in every culture and are endowed with an especially powerful agency. They intimately shape our behavior and experience of the world beginning in our childhood; they give us ontological security by creating predictability and routinization (Giddens, 1984); they replicate the cosmos (Preston Blier, 1987); help us know our place in society (Donley-Reid, 1987); and guide affection (Bachelard, 1964). They even shape our bodily memory: “The house where we are born,” writes Bachelard (1964, p. 32), “is physically inscribed in us. It is a group of organic habits.” Another important consequence, in psychological terms, of the built environment, is its capacity to affect our modes of spatial reasoning. It seems obvious that the perception of space cannot be the same among a group of slash-and-burn agriculturalists who live in single-celled huts separated wide apart and among people living in square, multiroomed houses in a cramped city. Kent (1990) has demonstrated that structures become more segmented as social organization becomes more complex and hierarchical. Segmentation of the space increases in parallel to conceptions of intimacy, individualism, political power, religion, and, more generally, with the development of modes of rationality that tend to fragment, divide, and sort out the world in specific categories. All these transformations in space and the self are particularly visible in modernity (Deetz, 1996).

I will review here two cases that exemplify well how domestic space is deeply inscribed in persons’ minds and bodies: the Swahili house of the Eastern African coast and the Bertha house of Ethiopia. They are not, properly speaking, archeological cases: the first is an ethno-historical study and the second an ethnographic one, but research was carried out in both cases by archeologists with archeological methodologies and questions in mind.

### *The Swahili House: Hierarchical Order*

The Swahili house is a perfect example of how social values are materialized in space and hence internalized through daily interaction with the built environment by those who use it. The Swahili live in the coast of Eastern Africa, from southern Somalia to northern Mozambique, and they are a mixture of native Africans and Arab merchants, who traded

in this area since the eighth century AD (Horton & Middleton, 2000). Their hybrid culture takes elements from the indigenous cultures and the foreign traders. Swahili houses of the patrician group (*waungwana*) had a rectangular layout and two floors, as opposed to the circular huts that prevailed in Eastern Africa. Also, unlike traditional houses in the region, they were substantially built in coral, lasted several generations, and were richly adorned with elaborate geometrical carvings. The possession of long residence in a single place (*ustaarabu*) was considered to be a moral quality inherent to being Swahili—and different from the local “barbarians” (Horton & Middleton, 2000, p. 179). For a start, then, living in a coral house made their *waungwana* owners feel different (and superior) from the surrounding African communities and Swahili commoners. But it also made them anxious: They were in a minority position in relation to both the African and Islamic worlds and to disenfranchised communities (slaves). The solidarity between the *waungwana* and their fear of the outside was materially expressed in the bridges and internal passageways that connected the patricians’ houses and allowed the Swahili to avoid the street and present a united front toward strangers (Donley-Reid, 1982, p. 65). It is logical that this anxiety was also expressed through rituals related to the boundaries of the house (Donley-Reid, 1987, p. 189) and an obsession with purity. The house, besieged by the polluted city, was the locus of purity par excellence, but this had to be continuously maintained through cleansing, whitewashing, prayer, and ritual observance (Horton & Middleton, 2000, p. 183). Purity was a quintessential moral quality of women, too, who were strongly linked to the house (as in other Islamic societies). Women shared other moral qualities with the house, such as shame and beauty (*ibid.*). In a sense, the materiality of the house determined the woman’s personhood and identity. Inside the Swahili house, the female mind, body, and spatial order were bound together.

The house was not the residence of the *waungwana* only. Female slaves (*madada*) and concubines shared the home with their masters. The built space was loaded with explicit and implicit meanings, and it was used in daily practice to show everybody his or her place within the house and within society at large. Thus, the lower story—where the slaves lived and slept on the floor on mats—had unplastered and undecorated walls. Slaves were considered unclean and therefore did not need any devices to

protect them (Donley-Reid, 1982, p. 66). The dirtiest and less valued part of the house, the kitchen, was also located in the lower floor. The masters lived in the richly decorated upper story and slept in beds. Within this story, polluting activities (such as sexual intercourse, childbearing, and cleaning of corpses) took place in the most secluded room of the house, the *ndani*, which was the most lavishly decorated part of the house as well (Donley-Reid, 1987, pp. 187–188). Valsiner (2008, p. 69) notes that the meaning of decoration is often linked with the notion of nonfunctional or excessive kind of decoration. This certainly applies to the baroquely ornamented *ndani*—an index of a strong fear of pollution.

The different qualities of the materials employed in the construction of the house; the difference in textures, decorations, and furniture; and the differential location of the masters’ and servants’ rooms all helped to make people internalize through daily practice the social order of the Swahili world. In addition, some ceremonies made social order even clearer and more redundant for those who inhabited the house. The ritual *kutolewande* took place 40 days after the birth of a free-born child (Donley-Reid, 1982, p. 70). The baby was then carried around the house, from the *ndani*, where he or she was born, to the rest of the rooms in what could be considered a prototypical “social guidance drama” (Valsiner, 2007, p. 233). The mother, the female relatives, and the slaves accompanied the baby in his or her first tour of the social world that he or she will inhabit. The child was shown the rooms, their function, the artifacts, and furniture associated to each room as well as the people who use them. The tour ended in the entrance door where, if the baby was a girl, she was told that the outside belonged to men only. That will be the limit of her world. Naturally, the ritual was only symbolic for the child, but it helped emphasize in a powerful way the social order that was reproduced in practice by the household members every day. It also marked the beginning of the slow and long process of enculturation for the child.

### ***The Bertha House: Order Without Hierarchy***

The Swahili are a deeply hierarchical society and with a complex state religion. The case of the Bertha (González-Ruibal, 2006b), who live in western Ethiopia and eastern Sudan, is quite different. The Bertha are Muslim, too, but their concern with

pollution and purity is very different—and less pressing. They are a rather egalitarian community, with little social differentiation. Like the Swahili, the Bertha are a hybrid people as well, heavily influenced by the Islamic Sudan. The equivalent of Swahili patricians in Bertha land was the Watawit, the traditional ruling class, a mixture of Arab merchants and local women. However, the indigenous element has always had an overwhelming weight among the Bertha and an egalitarian ethos tended to curtail the most visible manifestations of power. The order of domestic space among the Bertha has little to do with the anxieties of the Swahili. However, the Bertha house is also a structuring structure and a faithful representation of the cosmos.

The house itself is much simpler, from an architectural point of view, than the Swahili mansions. Although there are three different types of houses (González-Ruibal, 2006b, pp. 383–384), they all share some features, such as a circular layout, bamboo walls, and thatched roofs. Externally, they are very recognizable, even from afar, because of their particular rooftop (*shimbir*), crowned with four long and thin poles. The rooftop and the long stick planted near the house to protect it against the evil spirits of thunder are symbols of the Bertha identity. They have an “emblemic” use—that is “they transmit a clear message to a define target population about conscious affiliation or identity” (Wiessner, 1983, p. 257). However, the most important material elements

that sustain the Bertha’s identity are neither explicit nor representational.

Despite their regional variations, all Bertha houses follow a similar spatial logic, that is deeply imprinted into the Bertha’s mind and that regulates their cultural behavior and their practical understanding of the world (González-Ruibal, 2006b, pp. 392–397). As in other vernacular African traditions (Preston Blier, 1987), the Bertha house is anthropomorphic: the roof (*alu*) is the head of the house; the space indoors, the stomach (*iyu*); the entrance, the mouth (*ndu*); the poles flanking the entrance, the eyes (*are*, which also means “face”); the rest of the poles are the feet (*khu*); and the rear part of the house, the back (*gundi*). This perception of the house as a human body has far-reaching consequences, because it means that the regionalization of the body (Giddens, 1984, p. 124) is transferred to the domestic space, with all its implicit meanings and connotations. Like the human body, the house is divided into two main parts: the front and the back (Fig. 7.8).

The front is where all human communication and relations take place: it is the area of the sight (*are*, eyes) and the speech (*ndu* means both mouth and language in Bertha). It is also the place of knowledge (*are p’adiya*, lit. “eye strong,” means “wise”). In front of the house, men gather to drink coffee early in the morning, women chat and care for the small children, men weave baskets and bamboo mats, and women make pottery. Rituals and ceremonies also occur in the frontal space: Islamic praying,

Figure 7.8 The Bertha house: a structuring structure. (Adapted with permission from González-Ruibal, 2006b.)

rainmaking activities, traditional sacrifices, wedding rites, beer drinking in working parties, and so forth. The space is kept clean by women, who sweep the floor at least twice a day. The rear of the house, on the contrary, is a space devoid of activities, people, and artifacts. It is the place of death and dirt, where rubbish is thrown away, where small children were traditionally buried, menstruating women urinate, and rituals related to the exorcism of evil spirits take place. The back of the house is never swept. The same front-back organization is replicated indoors, with clean, social activities taking place in the frontal area (such as sleeping, entertaining guests, and making coffee) and dirty ones in the rear area (such as brewing beer and cooking fermented food).

For the Bertha, then, as for the Swahili, ordering the domestic space is not an abstract activity that can be verbalized and rationalized in an explicit way. It basically works in practice. Practical logic enables the organization of “all thoughts, perceptions and actions by means of a few generative principles, which are closely interrelated and constitute a practically integrated whole” (Bourdieu, 1990, p. 86). It has often been said that the organization of space among egalitarian, small-scale societies is much more flexible and less scripted than among hierarchical ones. Yet even egalitarian societies live in a material world that precludes certain actions in certain spaces and favors others. Under the apparent chaos and disorder of the Bertha house lays a powerful order that is no less strict—even if it has fewer rules—than the one enforced by the Swahili house. A Bertha woman would never, ever, make pots behind her house. The relation between back space, dirt and death is heavily imprinted in her mind from her earlier childhood, even if she cannot render those relations explicit in speech.

Both the Swahili and the Bertha house, then, allow knowing the order of the world for those who inhabit them. Furthermore, both houses are concerned with purity and pollution. The difference is that the logic of the Swahili house—as a hierarchical society—is basically concerned with contamination caused by the violation of the socio-political order (masters and slaves, locals and foreigners), whereas the central theme in the Bertha house—as an egalitarian community—is pollution brought about by disturbances in the cosmological order (life and dead, good and evil, society and the Other).

In sum, built space is crucial in the psychological development of human beings within any particular culture. People—and especially political

visionaries—instinctively know that. It is not by chance that social engineering has always aimed at changing architecture for changing people’s minds. This was the case with Soviet buildings: Buchli (1999) studied the evolution of the Narkomfin building in Moscow, an attempt at achieving the communalization of daily life by eliminating petit bourgeois domesticity. Nonetheless, other attempts at transforming ways of thinking and behaving through space can be counter-hegemonic. That was the case with the architecture of the Pueblo Indians after the 1680 revolt and the utopian communities of the first half of the nineteenth century in New England, studied by Preucel (2006). After the Pueblo revolt, the Cochiti leaders of the rebellion founded villages endowed with a double plaza that encoded the cosmological and social principles of the Cochiti worldview, so as to fix and make effective in practice the revitalization discourse, which was critical with the exploitative system of the Spanish empire. Similarly, the followers of Transcendentalism who founded utopian communities relied heavily on architecture to create a new social order—and a new individual—that stood against incipient industrial capitalism and its dehumanizing practices. Culture, according to Shweder and Miller (1993, p. 512) is “that subset of possible or available meanings, which by virtue of enculturation . . . has so given shape to the psychological processes of individuals in a society that those meanings have become, for those individuals, indistinguishable from experience itself.” The built space, in any society, goes a long way in achieving that seamless conflation of meaning and lived experience.

## Memory and Material Culture

With the rise of cognitive archeology in the 1980s emerged the interest for material culture as a form of memory container. Renfrew (1998), one of the main proponents of the paradigm, argued that the appearance of the first agrarian societies (ca. 9500 BC in the Near East) coincided with a new cognitive phase in the development of the human mind, characterized by external symbolic storage employing material culture. This phase (the Neolithic in archeological terms) would lie between two periods previously described by Donald (1991): the linguistic and mythic culture of the early *Homo sapiens* and the theoretic culture of literate societies. The materials put to mnemonic uses varied with the development of agrarian societies. Probably, the earliest containers of memory were houses, especially in

the Near East (Hodder & Cessford, 2004) and the Balkans (Borič, 2003). In Western Europe, tombs became the focus of collective memory (Edmonds, 1999), later to be replaced by artifacts that were ritually deposited in public ceremonies (Bradley, 1990). In places like Mesoamerica and North America, cultic spaces materialized collective remembrance among early farmers and complex hunter-gatherers (e.g., Shady Solís et al., 2000; Pauketat & Alt, 2003). More generally, the diversification of material culture with the Neolithic and the appearance of new supports to convey messages (such as pottery, textiles, and architecture) and the generalization of old ones (sculpture and painting) certainly favored the storage of memory. The semiotic world of the first agriculturalists, then, was very different from that of the hunter-gatherers, with its limited amount of human-made symbolic containers. Some of the mnemonic devices developed by early agrarian and sedentary societies developed through time to such an extent so as to evolve into writing; this is the case of the Mesopotamian tablets of the late fourth millennium BC (Rodríguez Mayorgas, 2010, pp. 97–103). Other mnemonic devices were very complex but did not become proper writing systems, such as the Inca knotted strings (Cole, 1998, p. 168; Rodríguez Mayorgas, 2010, pp. 104–107).

#### BEYOND EXTERNAL STORAGE

The idea of material culture as a form of mnemonic external storage has been under attack from different quarters, including some cognitive archeologists. Malafouris, for example, considers the computational model of cognition (based on a process of encoding–storage–retrieval) does not adequately explain the mnemonic role of objects (*also* Thomas [1998], from an interpretive perspective). Artifacts, writes Malafouris (2004, p. 57), “remind you, sometimes even force you to remember, without including the content of what precisely is to be remembered,” unlike texts or information contained in a hard disk. The most serious objection to the theory of external symbolic storage is that it does not truly consider a dialogical self. It envisions culture (and cognition) as something that takes places in the head and that is projected into a passive world (*see* above **Material Culture, Materiality, Cognition**). Recently, archeologists have been more interested in how places and things are suffused with memory and the effect that this has on people (Van Dyke & Alcock, 2003; Jones, 2007) rather than in the way particular objects or monuments are explicitly

codified in order to store specific memories. This is related to the growing interest in the social sciences on collective memory. It is now widely accepted that memory is not something exclusively individual but socially shared (Connerton, 1989), as Halbwachs (1994 [1925]) proposed more than 80 years ago. In fact, the archeological record preserves more instances of social remembrance, from monuments to fossilized daily routines, than personal (or group) mnemonic devices. This turning away from the notion of symbolic storage is also related to a wider awareness of the peculiar mnemonic nature of things, as opposed to texts. Things are ontologically closer to what Connerton (1989, pp. 72–73) calls incorporating practices than to inscribing ones. Inscribing practices are devices for storing and retrieving information (books, computers, sound tapes). Incorporating practices imply the intentional or unintentional transmission of information primordially through bodily posture, which is, in turn, tightly interwoven with technology and artifacts (Mauss, 1973).

Andrew Clark (2008, p. 14) comments that certain Alzheimer’s sufferers maintain an unexpected high level of normal, independent functioning. Their success is explained by the use they make of diverse external aids such as labels, memory books, diaries, and leaving important objects in open view. This is, for Clark, just an extreme example of the normal use of external aids (computers, compasses, maps). The author, however, like other psychologists and cognitive scientists (Beach, 1993; Klumb, 2001), focuses on explicit and conscious cognitive uses of material culture, those that are closer to the idea of things as external symbolic storage. Yet we are not capable of orienting ourselves just when we use a map, read a history book, or write a laundry list. We live in a material environment that is saturated of social meanings and memory traces. Even if we do not want to remember, artifacts force us. This is because, as Boesch has noted:

our objectual surroundings establish and environment of meanings, often delicate and intimate, expressing itself even in unreflected banalities ... the lavender sachet in the lingerie drawer, symbolising, *without us realising* it, the blending of opposing principles, such as the enclosed space and the open air, the civilised and the natural, the daily and the unusual.

(1991, p. 331, my emphasis)

This is why we throw away our ex-lover's possessions, despite not being mnemonic aids proper and never intended to be (in the way a grocery list or a knot in the handkerchief are). The lover's possessions are indexes that remind us of his or her presence, as the lavender sachet brings out memories of nature and openness. The things Clark mentions in his example are (with the exception of the objects put in a visible place) symbols; but material culture, as we have already seen, works more often as an index (Jones, 2007, pp. 22–26). There lies the power of things: They keep reminding us of other things, people, places, and events to which they are associated, whether we want to or not. If we scale up and go from personal cases to society at large, we can get an idea of the important role that materiality plays in shaping collective remembrance, which is in turn crucial for shaping our present (and future) behavior. This mnemonic and prospective power of things is well-exemplified in the following examples. As in previous sections, I will resort to both ancient and modern cultures.

### ***Keeping History Cold: Materiality and Memory in Prehistoric Societies***

Çatalhöyük, in modern Turkey, is one of the most important early agrarian villages studied by archeologists (Hodder, 2006). In its main phase of occupation, around the seventh millennium BC, it could have hosted up to 8,000 individuals. The village had many mud huts, tightly packed together, with no streets or plazas; people entered their houses from the roof. According to Hodder and Cessford, in Çatalhöyük,

instead of social rules being imposed by centralized authorities manipulating public rituals ... the reproduction of dominant groups (elders or lineage heads) was intimately tied to the construction of bodily routines that were repeated in daily house practices over days, months, years, decades, centuries, and even millennia.  
(2004, p. 22)

One of these practices was the replastering of walls, which was carried out annually and for up to a hundred years before the house was completely rebuilt (carefully following the old plan). Other repetitive activities, such as sweeping and plastering certain floors or burying people under them, were important in the processes of enculturation through practice but also in perpetuating in time meaningful, ancestral ways of doing things. Hodder and

Cessford (2004, p. 31) have argued that daily practice and memory were inseparable in Çatalhöyük, because social regulations were not simply imposed but constructed through habituation practices, which, in a nonliterate society, play the same role as writing in the construction of social memory. Connerton (1989) has explored this duality through the concepts of inscribing and incorporating practices. The second are particularly characteristic of nonliterate peoples. Although Connerton referred basically to bodily gestures and performances, we have to include here the use and manipulation of artifacts as well as the artifacts (including architecture) that shape bodily practices. The fact that houses follow exactly the same plan for hundreds of years proves their fundamental role in preserving collective memory. It also reveals the prospective qualities of material culture, as technical decisions taken at a certain point in time were still having an effect on the regulation of society and community life 2,000 years later. Sometimes even specific iconic decorations (such as depictions of bulls) were repeated through several phases spanning hundreds of years (Hodder & Cessford, 2004, p. 35), a phenomenon that guarantees the long-term transmission of mythological knowledge. Furthermore, in Çatalhöyük there are some houses whose mnemonic role seems to be more prominent than in others: They have long sequences of occupation, elaborate decorations, and many burials. They were formerly interpreted as shrines and today as houses of powerful lineages (Hodder, 2006). At any rate, they epitomize the need for preserving memory that is present in every other house and reveal the link that existed between memory and power.

The logic of Çatalhöyük is present in other Neolithic communities in Europe and the Near East. A compelling example is that of the so-called "Linear Pottery Culture" (LPC), which represents the expansion of early farmers from Hungary to eastern France between 5500 BC and 5000 BC. Despite its vast territory, the LPC is extremely homogeneous in house form, burial practices, and pottery decoration. Jones (2007, pp. 93–105) considers that this homogeneity is related to specific memory practices, which are again clear in the domestic sphere. The long rectangular houses had their doorways oriented toward the previous area of settlement (the LPC people expanded from Hungary toward France), as if remembering their origins, and they preserved the original layout for centuries—"a kind of mythological archetype"

(Jones, 2007, p. 103). These material practices, in Jones' opinion, provided a way of coping with new environments. Cultural memory enabled people to move forward while remaining attached to the past (Jones, 2007, p. 100). I would argue that the memory practices of Çatalhöyük and the LPC are best understood as mechanisms to “keep history cold.” Assmann (2001, p. 35) suggests that in all societies, there are devices whose purpose is to maintain the “cyclical time of regeneration.” In egalitarian, non-literate communities, mechanisms of regeneration prevail, in opposition to what Assman calls the “loci of history,” which account for events and change. The latter are to be found in some state societies, where transformation is perceived as positive—especially in modernity after the fifteenth century.

### ***Destruction As Memory Practice***

Material memory is not necessarily based on constructive processes. Destruction can be a positive way of maintaining memories (Rowlands, 1993), provided that it takes place in a dramatic, ritualized setting and is regularly repeated. A good example is the destruction by fire of Neolithic mud houses in the Balkans (Stevanovic 1997). Every few years, houses were destroyed and then built anew following the previous layout, in what can be considered an act of cyclical regeneration. Another case of social remembrance through destruction is the *malanggan*. The people of New Ireland make very elaborate funerary sculptures (called *malanggan*) that take months to be finished and require great skills. The ritual itself lasts a few hours, and after that, the wooden sculptures are left at the mercy of the wind and rain in ritual areas (Küchler, 2002). Memory is thus deposited in the technical cycle as a whole, which includes the creation of the statue and use but also its abandonment and eventual disappearance. Rowlands (1993, p. 149) has described other contexts in which the destruction of material culture serves to remember, such as the deposits of bronze objects that were ritually buried in Europe during the Late Bronze Age (1200–800 BC) or the famous potlatch of the Kwakiutl Indians of the British Columbia, in which large amounts of commodities were not only given away by wealthy patrons but also burnt and destroyed. The ceremonies in which artifacts are destroyed, buried, or abandoned are, in all cases mentioned, dramatic enough to be deeply impressed into collective memory.

However, destruction can also be an effective way of erasing memory. As we saw in the section of

space and order, people are often instinctively aware of the agency of material culture in shaping social life. They also know that things transmit memory and that with memory comes certain moral values and cultural predispositions—hence, the widespread phenomenon of *damnatio memoriae* since Antiquity. The idea is to cut short forever not just a particular remembrance but also the possibilities of repetition, because it is repetition (Assmann's “time of regeneration”) that makes the past always present. Thus, the destruction of *malanggan*, potlatch commodities or bronze axes was not actually aimed at putting an end to something (those particular things) but to regenerate something else (society or the cosmos). It is the cycle of production and destruction that maintains memory in those contexts. The problem is when destruction itself becomes an end—that is, when the central point is to obliterate a cultural world and start a new one *ex nihilo*. The annihilating thrust implies a radical change in the notion of temporality, from a cyclical time to a linear one, with millennial or teleological connotations. It is not by chance that revolutionary programs based on destruction often imply the emergence of linear notions of time (or even the very notion of time): that is the case with Christianity (Cullmann, 1964, pp. 51–60) and modernity. Significantly, the French Revolution and Fascist Italy simultaneously inaugurated new calendars and tried to raze previous cultural landscapes (Zerubavel, 1977; Bosworth, 2005, p. 201). The purpose of destruction is to obliterate the old material civilization and the old ways of thinking embedded in it.

This is exactly what is happening in the more traditional parts of Spain under the impact of modernity. In Galicia, in particular, the destruction of the traditional material environment has acquired enormous proportions (González-Ruibal, 2005). This results from the traumatic character of the process of modernization in the region: hundreds of thousands of peasants were forced to emigrate to other European countries and the Americas in search of jobs. During their stay abroad, Galicians were exposed to a radically different material culture in places like New York and Buenos Aires. In a strange and often hostile social environment, their remembrance of their birthplace was heavily tinged with nostalgia and affection; a highly idealized ancestral homeland emerged from their daydreaming.

This ideal image suffered a hard reality check when they returned to Galicia from the late 1970s onward. The idealization process was reversed on

arrival and the birthplace began to be characterized in negative terms, as a backward, oppressive locale—the source of all moral and material miseries that forced people to emigrate. Yet it was not enough with destroying in the mind the memory of the cozy traditional home. The entire cultural landscape had to be shattered and replaced by a new one, free of the social and mental constrictions that characterized the premodern environment. Using Sigmund Freud’s terminology, we can say that what the Galicians suffered was not a process of mourning caused by the disappearance of something that had been loved, but melancholia, marked by ambivalence toward the object (loved and hated at the same time):

Just as mourning impels the ego to renounce the object by declaring its death ... each individual battle of ambivalence loosens the fixation of the libido upon the object by devaluing, disparaging and, so to speak, even killing it.

(Freud, 2006, p. 324)

Devaluing and even killing the object that summoned traumatic memories was what the Galicians did. They engaged in a rage of destruction of the old material world: from plows to houses (Fig. 7.9).

**Figure 7.9** A traumatic breakage with a relational identity: forgetting the past in a Galician village.

The new material culture exemplifies the change from a culture where a relational self prevailed and where memory was communally built and transmitted within the community to a society of independent selves, where individual memories—successful biographies—try to impose themselves in the cultural landscape. Mechanisms to shape and regulate the relational self and preserve memory (traditional clothes, agricultural implements for collective work, vernacular houses) were replaced by monuments to the individual self, material memories of personal triumphs (expensive cars, luxurious modernist houses). Nevertheless, the relationship with the past, as in every melancholic process, is ambivalent. Traditional artifacts are often not destroyed but just left to decay. Something of the old love prevails and haunts the former peasants.

The Galician case is only an extreme example of the forms of oblivion that are embedded in late modern materiality. For Connerton (2009), late modernity is characterized by a particular regime of forgetting that is enforced in everyday life through the built environment. The scale of human settlement, the production of speed, and the destruction of the urban fabric generate a particular “cultural amnesia” (Connerton 2009, p. 99). Whereas medieval and early modern cities used to have conspicuous landmarks that created an effect of spatial cohesion and places of gathering that fostered social cohesion, new cities are formless, segregated spaces and, therefore, unmemorable and unsocial. Besides, the continuous refashioning of the built environment prevents any possible social recollection of shared places. We might say that supermodern cities fail to transmit memory, but we may as well argue that they succeed in creating forgetfulness: Connerton (2009, p. 125) makes the point that the production of oblivion is intrinsic of the political economy of late capitalism. Cultural amnesia is not produced by accident but by a necessity of the system—so that we forget where things come from (González-Ruibal & Hernando, 2010). The question that emerges from the study of material memory practices in late modernity is: How does living in a post-mnemonic culture affect human cognition?

## Conclusions and Future Directions

Archeology works with more cultural variation than any other social science, because archeological methods can be used to understand all prehistoric, historic, and contemporary societies from

the beginning of humankind to the present. The possibilities for cultural comparison are almost infinite, and differences often emerge when contrasting opposite contexts. However, archeologists agree that working with the past is just one of the defining characteristics of their discipline. The other, and perhaps more important, is its focus on materiality. In this chapter, I have tried to show the great relevance that material culture has in shaping our perceptions and experiences of the world. Material things are a crucial component of the “extended mind” (Clark & Chalmers, 1998), and this fact is enjoying increasing recognition by psychologists and cognitive scientists. As we have seen, Cole (1998, p. 144) argues that things are the quintessential constituents of culture because of their twofold character, simultaneously material and ideal. Here, I have argued that a third dimension of things has to be taken into account to understand their relevance in shaping the social mind: temporality. Things from the past have a continuing effect in the future. Our experiences are framed by an inherited material environment, sometimes hundreds or even thousands of years old. From this point of view, archeology is doubly pertinent, because—unlike other disciplines engaged in the study of things—it deals both with materiality and with time. For cultural psychologists and archeologists, it should not be difficult to find a common ground. After all, they are interested in similar phenomena as mediated by culture. The development and constitution of the self in relation to society, the social shaping of emotions, the way the built environment affects human experience, and the material frame of memory practices are the four themes that I have chosen to explore in this chapter because of their meaningful and manifold ramifications.

Cultural psychology could benefit from studying things with an archeological sensibility—that is, with an understanding of the agency of material culture, its inseparability from human beings, and its temporality. Some new lines of research for an archeologically inspired cultural psychology that takes things seriously could be the following:

**1. The interactions between human psychological processes and material culture beyond cognitive technologies and explicit symbolical objects.** Psychologists interested in material culture have often focused on explicit cognitive or mnemonic technologies and artifacts—maps, computers, GPS, compasses, and so forth. Here, I have tried to show that many

other types of cultural objects are involved in both social and spatial orientation and are, therefore, worth of study by psychologists. In fact, other categories of cultural objects, such as houses or cars, have recently been taken into account by cultural psychologists (Valsiner, 2008, p. 23). Their point in common is that they are artifacts explicitly inscribed with meaning. The focus is in people openly making statements with objects. Although those studies are certainly an important and exciting line of research, it would be interesting to look at other kinds of artifacts that are less obviously loaded with meaning. This implies a turn from explicit to implicit meanings, from the symbolic and iconic to the indexical. To make better sense of the indexical, of unconscious traces and practical behavior, psychologists have to span their range of research and include things that do not seem too relevant or meaningful at first sight, things that are overlooked or taken for granted by human actors. Archeologists know well that every single object counts, no matter how humble.

**2. Systems of artifacts involved in psychological processes.** Things cannot be understood in isolation or out of context: archeologists and anthropologists of technology know that we have to explore entire material inventories and their structural relations (Baudrillard, 1968; Lemonnier, 1992; González-Ruibal, 2006a). As signs are only meaningful in relation to other signs, artifacts are only meaningful in relation to other artifacts (including the human body). Thus, cars have to be explored in relation to urban space and houses but also in relation to late modern technologies of the self, such as web-blogs and cloth, and cloth, in turn, has to be understood as related to furniture and cell phones. Real things have also to be confronted with virtual things and with the products of the cultural and moral imagination. How do artifacts that are explicitly encoded with meaning and artifacts that work in practice relate to each other? How do they interact to frame daily experience?

**3. The temporality of things.** People are born to a material milieu that they have not created but that deeply affects their being. The psychological development of individuals takes place in a cultural landscape saturated of meaningful memory cues, some of them extremely old, some very recent. Does the human mind develop differently in heavily material and conservative

historical environments and in landscapes where memory is swept away every generation or not materialized in the first place? How do different memory practices and temporalities of things affect the way people perceive themselves, society and the world? Thus, whereas Europeans live in cultural landscapes that have grown through accretion of diverse material pasts, the materiality of which is considered important for the present (at least since early modern times), the Buddhist tradition tends to regenerate the past by destroying or altering its materiality, which is not valued, and by rebuilding it anew (Byrne, 1995). Also, how do the different layers of time have an effect on people? The issue of time is inextricable from memory: What is the role of material culture in creating and reconfiguring habit, cognitive, and personal memory (Connerton, 2009, pp. 139–141)? What is the relation between open commemorative practices and unconscious mnemonic traces?

## Positions in the Field

*This page intentionally left blank*

Cor Baerveldt and Theo Verheggen

**Abstract**

Enactivism is an emerging perspective both in cognitive science and in cultural psychology. Whereas the enactive approach in general has focused on sense-making as an embodied and situated activity, enactive cultural psychology emphasizes the expressive and dynamically enacted nature of cultural meaning. This chapter first situates enactivism within a tradition of expressivist thinking that has historical roots both in radical Enlightenment thought and Romantic reactions against the rationalization of human nature. It then offers a view of our human biology that can be reconciled with an account of meaning as irreducibly normative. By emphasizing the consensual rather than the supposedly shared nature of meaningful conduct, enactivism avoids some of the classical pitfalls in thinking about culture. In the conclusion a genetic enactive psychology will be presented, which understands sense-making not as a mediated activity but as a competence acquired through cultural training and personal stylization.

**Keywords:** enactivism, expression, consensual coordination, emotion, normativity, cultural training

*Enactivism* is an emerging perspective in cognitive science proposed most explicitly by Varela, Thompson, and Rosch (1991) as an alternative to representational theories of cognition. As a perspective in cultural psychology, it was first proposed by Baerveldt and Verheggen (1999) as a way to give an account of consensually orchestrated personal conduct, without evoking culture as an already established meaningful order. Both enactive cognitive science and enactive cultural psychology are characterized by a focus on *sense-making* as a situated, embodied activity.

Like cultural psychology itself, enactivism has roots that predate psychology in its modern academic form. Cultural psychology and its historical precursors have been associated with expressivist streams with roots grounded particularly in German idealism, through the work of Georg Wilhelm Friedrich

Hegel (1770–1831), Johann Friedrich Herbart (1776–1841), and Wilhelm von Humboldt (1767–1835) (see Jahoda, 1993; Diriwächter, 2004). But cultural psychology can also be seen as more broadly connected to secularizing tendencies in Western cultural history going back to Baruch Spinoza (1632–1677) and running through the work of Giambattista Vico (1668–1744), Johann Wolfgang von Goethe (1749–1832), and Johann Gottfried Herder (1744–1803). The Enlightenment in its different forms spurred a strong call for cultural pluralism and an emphasis on a broad ideal of education. Particularly in Germany, both ideas were strongly linked to that of the unity of a people in terms of a cultural tradition. Informed by both Enlightenment ideas and Romantic reactions against the rationalization of human nature, the psychologist Moritz Lazarus (1824–1903) and his brother-in-law, the

philologist Hajim Steinthal (1823–1899), followed in the footsteps of Herder, Herbart, and von Humboldt and proposed the new discipline of *Völkerpsychologie* (Eckhardt, 1997; Diriwächter, 2004). The new discipline concerned itself with spiritual and mental (*geistige*) processes not so much at the level of the individual but at the level of cultural communities. Central was the idea of a people (Volk) as unified not by biological heritage but by common language, taste, poetry, and customs. Of particular interest to our own argument is the way Lazarus and Steinthal already saw psychology as a third science, situated between the natural sciences and historical disciplines (Diriwächter, 2004, p. 90). As such, their *Völkerpsychologie* rejected reductively biologicistic or organismic understandings of the individual, stating instead that individuals inherently emerge within a network of communally enacted meanings and linguistic practice. In contrast with the newly emerging hermeneutic disciplines, however, *Völkerpsychologie* remained committed to giving lawful accounts of psychological processes (Eckhardt, 1997; Diriwächter, 2004). Although in hindsight fundamental questions can be asked about the success of Lazarus and Steinthal's new program, with the notable exception of Vygotsky's cultural-historical psychology, the possibility of a genetic psychology situated between the biological and the human sciences still remains scarcely explored.

### ***Enactivism and radical Enlightenment***

Enactivism aims at giving an account of situated meaningful action that remains connected both to biology and to the hermeneutic and phenomenological studies of experience. Enactivism in the form that will be presented here is most closely related to the work of the biologists Humberto Maturana and Francisco Varela, who have attempted to offer a radically new understanding of life and knowledge. However, to see the historical connections between their program and that of the expressivist tradition that informed early cultural theory and cultural psychology, we need to see it as part of a particular “radical” tradition in Western Enlightenment thinking that can be traced at least to Spinoza. Although it advances the central tenets of a secular, deterministic, and hence fully scientific worldview, this strain of thought has also provided a radical—but somewhat forgotten—alternative to reductionist forms of rationalism. It can potentially serve as a basis for a form of cultural and historical thinking that

is fundamentally different from the social-political thought that follows, for example, from the writings of Locke, Hume, Hobbes, and Montesquieu (for an extensive discussion of Spinoza's historical role in the “radical Enlightenment,” see Israel, 2001).

Particularly interesting for our discussion here is the way Spinoza already understands perception: not as the result of the impact of external stimuli but as a consequence of the way the perceiver is *disposed* to the world. “The human mind is adapted to the perception of many things, and its aptitude increases in proportion to the number of ways in which its body can be disposed” (Spinoza, 1677[2001], p. 62). The Latin *disponere* means “to arrange,” or to put in order. In the Nicomachean Ethics, Aristotle uses both the Greek *diathesis* (from *dia* + *thithenai* to set), which refers to dispositions in a more general sense, and *hexis* (translated in Latin as *habitus*), which refers specifically to deeper and more active dispositions like the ones involved in moral character. Already for Aristotle such dispositions are deeply embodied and cannot just be passed on by simple instruction. Instead, a *hexis* is acquired by the cultivation of our “natural” tendencies by repeated action.

Anything that we have to learn to do we learn by the actual doing of it: people become builders by building and instrumentalists by playing instruments. Similarly, we become just by performing just acts, temperate by performing temperate ones, brave by performing brave ones. (...) In a word, then, like activities produce like dispositions. Hence we must give our activities a certain quality, because it is their characteristics that determine the resulting dispositions.

(Aristotle, 2004, p. 92)

The notion of “disposition” that derives from Aristotle and was passed on through the Scholastic tradition to such diverse thinkers as Spinoza, Herder, Wittgenstein, and Bourdieu implies a particular understanding of determinism that is highly relevant for an enactive cultural psychology and strongly at odds with the causal assumptions of mainstream cognitive and representationalist accounts of perception. This understanding of determinism is crucially related to what could now be called “organizational autonomy,” a concept that—with all its biological connotations—is central to enactive thought. Interestingly, Spinoza already claims that “a composite individual can be affected in many ways and yet retain its nature,” as long as “the bodies composing

the individual continue and reciprocally communicate their motions in the same manner as before” (ibid., p. 61). The link, in perception and action, between determinism and autonomy characterizes enactive thought from Spinoza, through Vico and Herder, to Bateson, Maturana, and Varela. We find it as well in the work of Vygotsky (see below), for whom Spinoza was an important source of inspiration.

### *Johann Gottfried Herder and Expression in Psychology*

With regard to enactive cultural psychology’s historical precedents, next to Spinoza the work of Herder is particularly relevant. Herder was a central figure in the neo-Spinozist movement that swept through Germany in the late eighteenth century. Where it proved hard for Enlightenment thinkers to radically break with a providential understanding of history, Herder stands out as a thinker who attempted to reconcile, on the one hand, a secular and empirical understanding of history and the differences between cultures with, on the other hand, a general cognitive understanding of the “powers of the soul” as an embodied meaning giving capacity (Herder, 1778/2002b). Taylor (1995) credits Herder for standing at the beginning of an expressivist understanding of language and mind that is in contrast with the designative or representational understanding still dominating psychology and cognitive science.

It is remarkable that Herder’s understanding of language does not only resemble the account given by Maturana, which we will discuss later, but that in a way strikingly similar to Maturana, he already connects it to what can be considered an early version of the idea of the self-referentiality and operational closure of the nervous system (Herder, 1778b/2002; see also Fischer, 1997). Herder speaks of the soul as an “organic but self-referential being that acts according to its own laws of mental connections” (Herder, 1989, p. 182, op cit. Fischer, 1997, p. 307).<sup>1</sup> Rather than understanding perception as merely the result of an imprint of the external world on our senses that reaches the brain mechanically, Herder speaks of sensual activity as the way the soul “imagines” an outer object and of the image beheld by the soul as “a phenomenon that is constructed by the soul itself upon the instigation of the senses” (ibid.). Herder (1778/2002b) frequently uses the word “irritation” (*Reiz*) in a way similar to Maturana’s use of the term “perturbation” (see below). He also insists that the active power of the soul is not merely innate but

largely learned, or acquired as a consequence of our socialization. Although the nervous system is equipped with “sympathetic abilities” and a general capacity for emotionality, the structure of human reason is essentially the structure of language (Fischer, 1997).

Herder also already presented a holistic conception of culture wherein culture is neither a mere aggregate, nor a homogenous unity, but the dynamic product of reciprocal relations between its constituent parts or individual actors—each an autonomous whole in its own right—which are not mechanically activated by external forces but by their own source of energy. In culture, moreover, the parts that constitute the whole through their interconnections are characterized by *self-generated* activity, indeed not unlike the Leibnizian monads, with the important understanding that for Herder those monads are not wholly self-contained (for a more extensive discussion, see Barnard, 2003).<sup>2</sup>

Like Maturana, Herder recognizes that the notion of *operational closure* or *self-generated activity* does not preclude, but rather qualifies the idea of social interaction. Thus, despite what could be considered an organismic view of culture, human reason and meaning are for Herder always historically and culturally bound. Herder was one of the first to see the need to link advances in historical methods to advances in psychology, particularly by connecting what he called the *Zeitgeist* (the particular “spirit” or style of thinking and feeling of an age) to insight into human motivation (Barnard, 2003, p. 108). Herder may also be the first to have made room for a psychology situated between the explanatory methods of the natural sciences and the “*Verstehende*” methods of the human sciences.

Through nineteenth century German *Völkerpsychologie*, this idea would come to have a profound influence on Wundt (1900–1920), who particularly in his later work expressed his belief in “a distinct methodological approach to analyze and explain the ‘psychic processes that are bound, in virtue of their genetic and developmental conditions, to spiritual communities [*geistige Gemeinschaften*]’” (Kim, 2006). As Danziger (2001) notes, for Wundt, “mental or cultural communities were not formed through deliberate decision making but through spontaneous forms of interaction at a pre-rational level” (p. 87). Wundt was interested in cultural domains of behavior insofar as these domains are governed by psychological laws of development, rather than by contingent historical conditions. Where the second

half of the nineteenth century would see a battle between biologically or racially oriented understandings of the unity of a people on the one hand and cultural-historical orientations (represented by Herder and *Völkerpsychologie*) on the other, leading to the gradual demise of the latter, Wundt still saw the possibility of formulating genetic psychological laws—not at the level of micro-functional or physiological processes, but at the level of cultural expression (e.g., Wundt, 1897/1902, p. 23). According to Wundt, the expressive features of consciousness lie beyond the scope of experimental research but require genetic-historical research of the mind and its creations.

### ***Cultural Psychology and the Wrong Enlightenment***

In the historical link between cultural psychology and the idea of expression lies the main inspiration of enactive cultural psychology but also the point of contention between enactive and representational understandings of culture. We claim that early historical attempts to link culture and psyche were largely based on the idea of *expression* and not on that of representation. The word *representation* (French: *représentation*, German: *Vorstellung*) functions prominently in the work of early cultural theorists like Durkheim, Wundt, and the *Völkerpsychologen*. However, whereas in the French and German language, the concept clearly has an expressive or presentational connotation, this sense gets largely lost if it is mistakenly translated as *representation* in the English language and appropriated by a psychology dominated by cognitivism and mentalism. For Durkheim, for example, the word representation referred not only to the conceptual depiction of reality but more even to a *dramatic enactment* of the meaning and unity of societal life (Verheggen, 1996).

Even social psychologists who claim to offer a more psychological understanding of Durkheim's *représentations collective* (e.g., Moscovici, 1988) have typically only taken up the more conceptual, representational understanding and ignored the expressive one. Consequently, they miss a crucial opportunity to propose a psychology of cultural life and remain, instead, caught up in the study of “lay representations” of life or of the dissemination of scientific representations into everyday discourse. Spinoza, Vico, Herder, German *Völkerpsychologie*, and Wundt all offer a primarily expressivist understanding of mind, culture and life, which is fundamentally at

odds with the representationalism of the Cartesian tradition. We maintain that recovering an inherently social and cultural psychology remains impossible as long as the links with representationalism and Cartesian mentalism are not radically severed. Enactive cultural psychology, as we will argue, is an attempt to draw out the psychological implications of an ontological understanding of life and meaning that remains radically nonrepresentational.

### **The Enactive Program**

Although the word enactivism was introduced by Varela, Thompson, and Rosch (1991) to denote a particular paradigm in cognitive science, it has its roots in the program of a biology of cognition initially proposed by Maturana (1970, 1975, 1988a, 1988b) and further developed by Maturana and Varela (Maturana & Varela, 1980, 1987; *see also* Varela, 1979, 1981). The enactive approach as presented by Varela, Thompson, and Rosch can be seen both as an attempt to reconcile the study of cognition with the systematic examination of human experience and as an effort to offer a radical alternative to representational accounts of cognition that divorce cognition from embodied action. Although we sympathize with the general tenets of the enactive program thus conceived, our own interest has been in the possibility of an enactive *cultural* psychology (Baerveldt & Verheggen, 1999; Baerveldt, Verheggen, & Voestermans, 2001; Baerveldt & Voestermans, 2005, Verheggen & Baerveldt, 2001, 2007). As we hope to demonstrate in this chapter, a radically cultural enactivism requires more than an account of human experience that builds up from biological autonomy to society and culture. It requires us to acknowledge the irreducible normativity of everyday life and of even our most personal actions and expressions. For humans, to perceive and to act is to perceive and act in a way that always remains sensitive to normative (hence social) correction: we can be “right” or “wrong” about what we see or do in ways that cannot be accounted for merely in terms of the constraints imposed on us by our physiology.

To develop an account of this irreducible normativity, which still remains biologically possible and does not lose itself in subjective idealism, we draw from Maturana's work on language and sociality (particularly Maturana, 1978a, 1978b; Maturana & Verden-Zöllner, 1996). Maturana has occasionally talked about the idea of cognition as the *bringing forth* rather than the representation of a

world, a notion that has made some of his interpreters call him a “bring forthist” and not, for example, a constructivist (Proulx, 2008). Both the notion of “enactment” and that of “bringing forth” are meant to orient the audience to “knowing” as an ontological category, and it is this ontological understanding of knowing that we take up in our program for an enactive cultural psychology. Hence, when we use the term *enactivism* to refer to our own work, we use it in a sense that takes it out of the confines of a more narrowly conceived cognitive science program and into the realm of cultural expressions of reality.

### ***Enactivism and a Humanized Biology***

Maturana and Varela’s thinking is complex and wide-ranging but has been discussed in great detail elsewhere (for a concise summary of their own thinking, *see* particularly Maturana & Varela, 1980). In this section, we will expound some of the formal underpinnings of their work and draw out implications for psychological understanding. While briefly touching on Maturana and Varela’s biological understanding of “life” in general, we will discuss in more detail their biological understanding of cognition and social interaction and its possible implications for the psychological understanding of behavior, action, and expression. We are interested in cultural psychology at the cross-section with biology, but contrary to the mainstream in Western rational thought, we believe that the irreducibly normative nature of culturally shaped conduct cannot be understood in reductionist biological terms. Yet, rather than pursuing a human psychology cut off entirely from its biological roots, we maintain that the psychology of human behavior can in principle be reconciled with a properly “humanized” biology (Voestermans & Baerveldt, 2001).

Far from proposing some kind of anthropomorphic projection onto our pre-given biological nature, what we have in mind here is the recognition that any attempt to describe and explain human behavior necessarily sets out from the pre-reflective, practical understanding of that behavior within the cultural normative realm. For example, to call a certain action “walking,” or “writing,” or “conversing” is to already identify it in light of a practical cultural understanding, without which the very notion of behavior or action is meaningless. Therefore, what is to be explained, biologically or psychologically, is in some sense always already understood and distinguished within the coherences of our normative practices. If a hermeneutic explication of

those normative practices is to be reconciled with our biological nature, we first need to ask the question what, biologically speaking, makes us human. And this, in turn, brings us back to the question what constitutes a biological account. Indeed, any account of ourselves and of what makes us human stands within a fundamental circularity. This circularity cannot simply be dismissed in the name of a science that privileges linear logic but needs to be acknowledged as indispensable to the aim of understanding itself. For Maturana, the question of our humanity is crucially related to us being able to ask such questions and to account for ourselves and our actions by constituting a metadomain of distinctions that allows us to operate as “observers.” Human beings are biological entities, but they are simultaneously the kinds of creatures that are partly constituted by their own self-understanding (Taylor, 1985; Hacking, 1995; Martin & Sugarman, 2001). The question, therefore, becomes: How is self-understanding biologically possible? Only after the biology of understanding and self-understanding has been formally laid out will we be able to address the outlines of an enactive cultural psychology.

### **The Formal Roots of Enactivism**

Although their collaborative work is most often associated with the theory of autopoiesis and is even called “autopoietic theory,” Maturana and Varela’s thinking can in large part be seen as a series of implications following from two related concepts. The first is the idea of *structural determination* and concerns the issue of what it means to give a rational or scientific account of the behavior of any kind of natural system. The second is the concept of *self-reference* and *closure*, as expressed in the *organizational closure* of living systems and more particularly in the *operational closure* of the nervous system. Together, the concepts of structural determination and self-reference/closure lead to radical implications for our understanding of living systems, intelligent behavior (cognition), and social action.

Maturana and Varela are biologists and their work is often linked to advances in biological systems theory and cybernetics, as represented by the work of Warren McCulloch, Norbert Wiener, John von Neumann, Gregory Bateson, and Heinz von Foerster. However, enactive cultural psychology is not just an elaboration of biological systems theory but a radical attempt to rethink psychological and social thought in light of a non-reductionist ontology that potentially allows us to think of the

irreducibly normative and historical character of human conduct, yet without cutting off humanity from the rest of the natural world. Laying out the basis of such an attempt requires us to rethink some of our basic understandings concerning cause, determinism, and human agency.

### **Structural Determinism**

Any system that is observed as a composite unity—that is, an entity composed of parts—is distinguished as such in terms of its structure. *Structural determinism* refers to the principle that for any natural system, it is the structure of the system itself that determines its behavior and the changes it can undergo. Although natural systems obviously undergo structural changes as a consequence of interaction with an environment, those interactions with an environment can only trigger the system's behaviors and changes, but they cannot bring them about. To use a simple example from the biological world, a honeybee may be able to navigate using the ultraviolet light of the sun, whereas a human being lacks this particular spectral sensitivity. This is so because the structure and organization of the bee's compound eyes is different from the retinal structure of human eyes. Although the "trigger" (e.g., the multispectral light of the sun) can be seen by an observer as in both cases the same, this trigger does not determine the structural changes in the respective systems.

Maturana and Varela distinguish the *structure* of a system from its *organization*. Where organization is understood as the *relations* between components of the system that constitute the system's class identity (eggs, rocks), its structure is defined as the actual material embodiment of that organization (Maturana & Varela, 1980; Maturana, 1988a, 1988b). Consequently, a system's structure can change while its class identity remains the same, as long as the system maintains the network of relations between components that specify its defining organization. In Maturana's words, "a particular composite unity conserves its class identity only as long as its structure realizes in it the organization that defines its class identity" (Maturana, 1988b, pp. 6, iv). For example, putting an object on a table will create a series of specific structural changes in the table, but the table will remain a table as long as it maintains the network of relations that specify it—in the eye of an observer—as a table. As long as the table maintains its integrity or class identity, the perturbations it undergoes can be seen as

*compensable*, thus specifying the system's range of possible interactions without disintegration. In other words, the structure of a system at any given moment in time determines what entities and events in its medium it can interact with, as well as the way it will behave in each of those interactions.

It is important to realize that on Maturana's account, structure is not a static entity. On the contrary, the structure of a system necessarily alters with every interaction it undergoes. Its organization, however, remains constant as long as the system maintains the integrity of its own constitutive internal relations. As a general term for the range of possible interactions in which a system can engage, Maturana uses the word *domain*. Hence, a system's domain of possible interactions is determined by its own structure, whereas the domain of interactions in which it can enter without disintegration is constrained by its defining organization (see Maturana, 1988a, 1988b).

The principle of structural determinism leads to one of the central explanatory constructs in enactive theory with regard to the interaction between different systems: that of *structural coupling*. Because natural systems are determined by their own structure and not by anything outside of them, interaction between different systems cannot be mutually instructive. Instead, two (or more) systems can engage in a history of recurrent interactions by mutually triggering (not determining) structural changes in each other. Such a history of interlocked conduct means that the systems mutually select congruent paths of structural change in each other, leading to structural congruence: as long as the systems in interaction maintain their own defining organization, they change together, in practical agreement. On an enactive account, structural determinism and structural coupling are precisely what constitutes a system as a historical system. The system's *ontogeny* is its history of structural transformations—that is, the course of its structural coupling with its environment and with other structurally determined systems. The result of the structural coupling of a system with its environment is called *ontogenic adaptation* (Maturana & Guilloff, 1980, p. 140) and the result of the structural coupling between two or more organisms is called a *consensual domain* (ibid., p. 141). An example of ontogenic adaptation in the everyday cultural realm is wearing a pair of shoes: in a history of recurring and recursive interactions, our feet and our shoes change together, such that the degree of congruence between them increases and

we experience our shoes as becoming more comfortable (Maturana & Poerksen, 2004, pp. 83–84). Other examples are playing a musical instrument or using a fountain pen.

Similarly, we also become mutually adapted to others in a history of consensually coordinated action. A consensual domain is a historical domain that requires continuous structural changes in all systems involved. Again it is crucial to realize that although we may speak of mutual “influences” those influences are not instructive. For example, I can say that I am influenced by my mother or by a certain historical author, but as becomes particularly clear in the case of the latter, this influence is not one that runs in a causal line from the author to me but precisely the other way around, from my affective and intellectual dispositions to the author. I read the author because I am interested, and my reading is not a receiving of information but a dwelling in the style of the author, as Merleau-Ponty (e.g., Merleau-Ponty, 1964) has frequently stated. This is what makes my relation to the author a historical one.

Because the behavior of the systems establishing a consensual domain is *structurally* coupled, once a consensual domain is established, each member of the coupling can (in principle) be replaced by a system that is equivalent with respect to the structural features involved in the coupling (Maturana, 1978a). This is crucial for an understanding of culture and language, which rely on the structural or dispositional equivalence of their participants for their maintenance and historical continuation. Speakers of a particular language can (in principle) understand each other, and members of a culture are (in principle) able to make sense of each other’s expressions. Consensual domains are both determined by the respective structures of the coupled organisms and by the history of their recurrent interactions. Yet, they are neither shared representations nor are they mediated by anything external to the history of interlocked conduct between the organisms involved. We will return to this after we have dealt more explicitly with the problem of cognition and language.

Before we move on to the particular characteristics of living systems (organisms) and sense-making systems, let us make a few intermediate comments. The above remarks about structural determinism apply to *all* systems that can be rationally understood and not just to living systems, although only living systems can *actively* adapt to

an environment and establish consensual domains. Maturana presents a general outlook on science, which, although explicitly mechanistic, is also holistic and non-reductionist. Maturana’s use of the word *mechanistic* differs principally from that of reductionist Newtonian science and makes use of the etymological roots of the words “mechanism” and “machine” as referring to a *structured whole* (Greek: *mēkhanē*) rather than *partes extra partes* only connected by external forces. Science, according to Maturana, can only deal with structure-determined systems, and any explanation of the changes a system undergoes should be one in terms of the system’s own structure and not in terms of the external forces that impinge on it (Maturana, 1988a, pp. 36–37). Whether a table collapses under the weight put on it is determined by the structural properties of the table and not by the objective weight as measured by an external observer. Hence, to understand Maturana’s strong insistence that science can only give *mechanistic* explanations, it is extremely important to see that his understanding of this term is fundamentally at odds with the conventional use.

Consequently, Maturana has been explicit in his rejection of the standard notion of causality and causal relations in scientific explanations:

(...) the notion of causality is a notion that pertains only to the domain of descriptions, and as such it is relevant only in the metadomain in which the observer makes his commentaries and cannot be deemed to be operative in the phenomenal domain, the object of the description.

(Maturana & Varela, 1980, p. xviii)

The notion of structural determinism allows Maturana and Varela to maintain that their account is fully deterministic or mechanistic, yet to escape at the same time the reductionist implications of a Newtonian worldview in which the behavior of bodies is seen as entirely determined by *external* causes and impacts, or the dualism of Descartes in which the movement of bodies can be caused by a mind that remains ontologically entirely external to it.<sup>3</sup> In this sense, their work also shows a close resemblance to that of Gregory Bateson, who, while remaining within a thoroughly naturalistic framework as well, spoke of the biosphere as a complex dynamical system, characterized by circular chains of determination and possessing all the defining properties of “mind”<sup>4</sup> (Bateson, 1979).

## ***The Organizational Closure of Living Systems***

Maturana's general orientation with regard to science made him realize that an adequate characterization of living systems could not be one in terms of referential (e.g., functional or semantic) relations specified by an observer within a metadomain of description. Maturana's early work with others on the visual system of the frog (e.g., Maturana, Lettvin, McCulloch, & Pitts, 1960) already convinced him of the need for a novel understanding of perception that was not based on the idea of information abstraction from sensory data and that did not rely on some notion of representation.<sup>5</sup> He became aware that to that end he would have to characterize perception and cognition as biological phenomena, which in turn required him to reflect on the fundamental nature of any biological phenomenon. Maturana wrote later that the key insight came to him when he realized that the questions "What is cognition?" and "What is a living system?" were essentially the same (in Maturana & Varela, 1980). Given the principle of structural determinism, he realized that an adequate answer to this question could only be one in terms of the particular *structure* and *organization* that distinguished living systems from non-living systems. With Francisco Varela, he proposed a formal definition of "autopoietic systems," introducing a term that has since come to be a cornerstone of his work and that of Varela on biological autonomy (e.g., Varela, 1979), the biology of language and social systems (Maturana, 1978a, 1980), the biology of cognition (e.g., Maturana & Varela, 1980), enactive cognitive science (Varela, Thomson, & Rosch, 1991,<sup>6</sup> Thompson, 2007), and the biology of love (Maturana & Verden-Zöllner, 1996, 2008).

Maturana and Varela (1980; *see also* Maturana, 1978b; Varela, 1979) have defined an autopoietic system as a system that is organized as a network of relations between components that (1) through their interactions, recursively regenerate and realize the network—components and relations between components—that produces them, and (2) constitute the system as a unity distinguished from its background. Autopoietic systems can therefore be considered as *homeostatic* systems that keep their own organization invariant while going through continuous structural change (Maturana, 1975, p. 318). Autopoietic systems are *autonomous* in the sense that they are distinguished from a background by their own operations and they are *organizationally*

*closed* in the sense that "(...) their organization is a circular network of interactions rather than a tree of hierarchical processes" (Varela & Goguen, 1978, p. 292). In addition, an autopoietic system *produces* its own components (e.g., molecules, cells) and its own boundary with its medium. In the operations of an autopoietic system, everything has to be subordinated to its autopoiesis, or it disintegrates (Maturana, 1978, p. 33).

Maturana and Varela are careful in the use of formal terms like *autonomy* and *organizational closure* to avoid the confusion that often results from a less rigorous use. For example, their point is emphatically *not* that autopoietic systems exist independently from interaction with a medium, as self-enclosed entities that can only confront other such self-enclosed beings without hope of any meaningful contact. Rather, it is that living systems can only be defined *as* living systems in terms of their closed organization—the relations between components that remain invariant through structural changes—and not in terms of their interactions with anything outside of them. Organizational closure and self-production determine the relations and interactions in which a living system as a unit can engage without disintegrating, and hence those relations and interactions with a medium<sup>7</sup> cannot specify the system as a living system. Indeed, for Maturana and Varela, the notion of autopoiesis serves as a formal minimal definition of a living system, with the understanding that living systems are autopoietic systems realized within a physical space. But autopoiesis also serves as a formal minimal definition of a cognitive system, because an autopoietic system is essentially a system that "acts" effectively with regard to its own self-maintenance, regardless of whether it is endowed with any particular cognitive architecture, like a nervous system, and regardless of whether its behavior appears as meaningful to an external observer. Defining cognition as *effective action* dispels the need to introduce representation or some other class of mediational entities between the cognizer's world and the cognizer's actions. Thus, the concept of autopoiesis entails at the same time an ontological and an epistemological claim: to live is to know and to know is to live.

## ***The Operational Closure of the Nervous System***

A structurally determined system can be seen to operate in two non-intersecting phenomenal domains: the domain of its internally realized states

and the domain of its interactions as a unity with its environment. The human body, for example, can both be seen as a micro-operational system in terms of its physiology and as an expressive behavioral system in terms of its interactions with a natural or cultural medium. However, although these domains are operationally non-intersecting, they are nonetheless orthogonally interdependent or coupled, through the system's particular history as both a *composite unity* with a differentiated internal structure and a *simple unity* (the organism as a whole) interacting with its environment (Maturana, 1988b, **Section 6.3**). In humans, this history or ontogeny involves a process of cultural training, and below we will return in detail to the implications of Maturana and Varela's understanding for an understanding of cultural training.

The domain of structural states and the domain of interactions cannot be reduced to one another. For example, we cannot explain actual behavior in the relational domain in terms of the internal operations of the nervous system nor can we explain what happens in the nervous system in terms of the objective stimuli or sense data to which an organism is presumably exposed. That we can nonetheless make general statements about the relation between brain and behavior is a consequence of the way the sensory and motor surfaces of the human organism—as a consequence of its evolution—are mapped onto the topology of the brain. Because the organism's sensors and effectors operate in a dual way, both in the domain of interactions of the organism and as part of the closed relational dynamics of the nervous system, the two domains intersect *structurally*, although they remain *operationally* separate (see particularly Maturana, 1988b; **Section 7.6**). This is the reason that the relation between those two domains cannot be understood in causal terms but only in historical terms.

Cognition as such does not inherently rely on a nervous system, then, but a nervous system dramatically expands an organism's domain of possible interactions, both by expanding the space of its possible internal states and by allowing it to interact with its own internal states. To illustrate the former, we could use the analogy of our pulmonary system. Just like the progressively subdividing system of bronchi, bronchioles, and alveoli dramatically extends the effective surface of  $\text{CO}_2/\text{O}_2$  exchange, so does the infinitely more differentiated internal structure of our nervous system extend the effective sensory and motor surfaces that allow us to interact with a

world. But, in addition to that, the nervous system is also a dynamic self-referential system that constantly interacts with its own self-generated internal states (Maturana, in Maturana & Varela, 1980, p. 13). Although Maturana and Varela explicitly reject the language of input and output with regard to the operations of the nervous system, we could stretch the language a bit and say that in a sense the brain is the main source of its own input.

As a consequence of the brain's internal coherence and self-referential activity, activities in an organism's sensory surfaces cannot be seen as straightforward signals from which the nervous system somehow extracts information about the outside world. Rather, such activity serves merely as a *modulation* of the complex internal dynamics of the nervous system itself. Maturana and Varela claim that the brain does not function like an input/output machine but as an *operationally closed* system, yet structurally participating in the organization of the organism as a whole. The brain is organized as a network of reciprocally related subnetworks, which continuously maintains certain invariant patterns of sensory-motor correlations. Consequently, it gives rise to behavior of the organism as a whole within a delimited space or relational topology. An organism without a nervous system may interact with its medium in a physical or chemical way, but it cannot make the *relations* holding *between* physical events part of its domain of interactions (Maturana, in Maturana & Varela, 1980, p. 13). Possessing a nervous system means that an organism can be *disposed* to the world in a greatly expanded variety of ways and can therefore *perceive* the world in an equally large number of ways.

Note that in the vast majority of cases, activity in the sensory surfaces of the nervous system is brought about by the organism's own motions in the broad sense of that word. For a living system, moving around in the world and perceiving the world are inseparably entwined. In light of that, it is impossible to speak of perception as simply the result of neutral sensory stimuli emitted by a perceiver-independent world.

“(...) the overall concern of an enactive approach to perception is not to determine how some perceiver-independent world is to be recovered; it is rather, to determine the common principles of lawful linkages between sensory and motor systems that explain how action can be perceptually guided in a perceiver-dependent world.”

(Varela, Thompson, & Rosch, 1999, p. 173)

Similarly, O'Regan and Noë (2001) present their *sensory motor contingency theory* of perception as an enactive theory and claim that perception needs to be understood not in terms of sensory input but in terms of the dynamic interdependence of sensory stimulation and embodied activity.

On all those accounts the particular nature of a perceptual experience cannot just be derived from an objective account of the reality perceived. What appears from the perspective of an external observer as the world outside of the organism is, seen from an operational perspective, only an a modulation of experiences that arise as a consequence of the self-organizing properties of the nervous system. According to Varela (1984) the mechanisms that are involved in self-organizing behavior of this kind are inherently hermeneutic. Operationally closed systems do not adapt to the properties of a prefixed world but *bring forth* or *enact* a world as a domain of significance with respect to the maintenance of the organism's systemic integrity. Operationally closed systems live in a phenomenal domain that remains closed to the external epistemic eye.

### ***Consensual Coordination and "Common" Sense***

As we indicated above, the notion of operational closure does not prohibit social interaction but rather qualifies our understanding of it. On an enactive account, interaction cannot be instructive and social interaction can only be interaction between operationally closed systems—that is, structurally determined systems capable of actively engaging the world. This does not imply that the social can be reduced to properties of individual cognitive systems. As argued, the domain of internal relations of the nervous system and the relational domain of social interaction are non-intersecting and non-reducible. Rather, it does imply that systems in social interaction are always mutual *interpreters* of each other's actions. Precisely because they can neither have access to each other's experience nor determine the content of each other's experience, they have to express themselves and make sense of each other's expressions *consensually*, yet each within their own cognitive or experiential domain. Indeed, expression in social interaction is *con*-sensual, but without experience, strictly speaking, being shared. The necessity to maintain cognitive integrity requires mutual attunement rather than mutual instruction or mutually imposed regulation. Hence, social interaction involves "agreement in action"—to borrow

a Wittgensteinian notion—but not propositional agreement or equal mental content. We will come back to this point later in this chapter.

In everyday life, we respond to each other's actions and expressions in terms of what we take them to mean. Meaning in this sense is not prefixed in the expressions themselves—as messages to be decoded—but grasped in a practical, situated way. One of the main points of contention in the discussion between enactivist and representational understandings of culture concerns the issue of what allows such embedded interpretations to be mutually meaningful. Precisely in answering this question, proponents of a representational or mediational cultural psychology see the need to evoke culture as a system of already meaningful representations or semiotic devices. Obviously *culture* can be studied as a symbolic system or as the history of objectified expressions. However, problems emerge when culture as an objectified semiotic system is first epistemically *cut off* from the dynamic consensual coordinations of action by which meaning is continuously produced in the first place and then only subsequently used to *explain* sense-making practices in everyday life.

Although there is clearly a place for the hermeneutic study of historical objectifications (e.g., in art, in technology, in established cultural rituals), it makes epistemologically and psychologically no sense to explain everyday sense-making as mediated by culturally available semiotic tools or to understand socialization as a process of internalizing objectified cultural meaning. Notions like "internalization" and "externalization," which since Berger and Luckmann's seminal text have come to be commonplace in the social sciences (Berger & Luckmann, 1967), often present a superficial dialectics and mistakenly put mind and culture in external causal relation to each other.<sup>8</sup> The notion of operational closure is meant to prevent us from this epistemic smuggling that occurs when sense-making is explained on the basis of sense already made. It allows us to focus more clearly on the activity of sense-making itself, as a consensual coordination of actions between human agents, who remain as such experientially autonomous. From an enactive perspective, the practical intelligence involved in grasping embedded meaning, or "sense," requires no mediation but only our ability to act within a consensual domain.

It is particularly the notion of operational closure that has been criticized by advocates of a cultural

psychology that emphasizes openness, social interaction, and the possibility of sharing a semiotic cultural system. Unfortunately such critiques have often been based on misreadings and conjectures triggered by the word “closure.” For example, Kreppner (1999) accuses enactivism to be a new kind of monadology, in which fully self-enclosed individuals are considered to operate blindly within a system of pre-established harmony, but he is thus confusing the notion of closure as a formal operational term with that of closedness and the impossibility of interaction.<sup>9</sup> Similarly, Chryssides et al. (2009) consistently mistake operationally closed systems in social interaction for self-contained individuals, although the literature on enactivism and autopoiesis makes abundantly clear that self-conscious individuals can only arise in the relational domain of language (Maturana, 1978a, 1988a, 1988b; Baerveldt & Verheggen, 1999). As we have adamantly pointed out elsewhere (Baerveldt & Verheggen, 1999; Verheggen & Baerveldt, 2001, 2007), the central concept in enactive cultural psychology is that of the *consensual coordination of actions*, but such a consensual coordination cannot be adequately understood without the notions of structural determinism and operational closure. Before we move on to the enactive understanding of language and normativity, let us be clear once more that Maturana and Varela deliberately and consistently speak of closure in the operational or mathematical sense of *recursivity* and not of interactional closedness (Maturana & Varela, 1980). Obviously, the formal need for any autopoietic system to maintain its own defining organization and to distinguish itself as a unity from its background requires it to maintain a dynamic relation with its medium. But as our discussion above shows, such a dynamic relation cannot be understood in terms of mutually instructive interaction or shared mental content. It can only be understood as a consensual coordination of actions.

### ***Autopoiesis, Purpose, and Intentionality***

The theory of autopoiesis as discussed until now presents a minimal account of meaning or significance in the biological realm. If it is to contribute to a psychological account of culture, however, then we will need to find a connection between the minimal signification implied in the organization of the living and sense-making as a culturally embedded normative practice. Normativity in the realm of everyday conduct involves implicit standards for

the correctness and appropriateness of actions and expressions. As Wittgenstein (1956/1978, 1980), probably more than anyone else, has extensively demonstrated, such standards for correctness require *normative stage setting*, which can be provided only by regular community practices and not by isolated organisms or individuals. The normativity of practices and of personal action/expression embedded within such practices is at the heart of any genuinely cultural psychology.

Historically, the study of human behavior has been caught up in unproductive oppositions between those who understand human behavior as part of the natural world and those who see it as an expression of something that is uniquely and distinctively human. Varela (1991) has expressed the hope that the notion of autopoiesis may help to overcome the fruitless opposition, originating in nineteenth century biology, between mechanist/reductionist viewpoints on the one hand and holist/vitalist on the other. If that be the case, it may also have implications for psychology, which itself has been divided between a largely mechanist biology on the one hand and the more holistic humanities on the other. Fundamentally rethinking the relation between the component elements of a living system and its organization as a whole has historically been at the heart of several attempts to think of human physiology as involving a precarious part/whole dialectics (e.g. Plessner, 1928/1975; Goldstein, 1935/1995; Von Weizsäcker, 1940/1995; Buytendijk, 1965/1974; Polanyi, 1958; Merleau-Ponty, 1942/1963, 1945/1962; Bateson, 1972, 1979).<sup>10</sup> Important in all these accounts is the idea that somehow even in the basic physiological operations of a living system, the organization that specifies the organism as a whole is already implied. The radical implication, still to be rigorously elaborated, is that in a crucial sense our own physiology is already a characteristically human physiology.

Buytendijk (1974) expressed the need for an “anthropological physiology,” centrally concerned with the body as expression of sense and Merleau-Ponty (1942/1963) spoke of “le corps sujet,” the body subject, as an ambiguous unity of subjectivity and anonymity and always exceeding “le corps objectif,” the objective body as conceived by an observer. Attempts to humanize our physiology have (in principle) different implications for the relation between body and culture than accounts deriving from a reductionist physiology that is grounded in a causalistic ontology. They require us to admit

“meaning” and “significance” in their fully human sense as part of the natural world, yet without implying biological reductionism. The relation between the body as organism and the body as expression of sense is at the heart of enactive thinking, but, as we will see, this relation can be interpreted in different ways, depending on how “organism” and “sense” are understood

Enactivism, as conceived by Varela, Thompson, and Rosch (1991), is an attempt to connect the body as an organizational whole to the body as lived experience. Varela, in the final years of his life, came to see autopoiesis as a way to give a formal naturalistic grounding to Kant’s idea (in the *Critique of Judgment*) of the organism as a “natural purpose” (Weber & Varela, 2002; Thompson, 2004). Kant already linked this idea to that of self-organization but, according to Thompson, only lacked the formal language of self-reference we possess now. From the perspective of a radically cultural enactivism, however, what is still lacking in Kant is not so much the mathematics of self-reference and nonlinear dynamics but an adequate account of the *historical* dimension of sense and purpose. This is a critique already voiced by Wilhelm Dilthey, who argued that although life encompasses both the organic and the mental, the values and purposes that inhere in it could only be fully understood in their temporal or historical fulfillment (Dilthey, 2002, p. 249).

Whereas Varela and Thompson in their subsequent work—and despite their earlier critique—increasingly came to link the idea of biological sense-making to Husserl’s phenomenological idea of intentionality (e.g., Varela, 1999; Thompson, 2007), we remain critical of attempts to move too quickly from the operational domain to consciousness and intentionality, without fully acknowledging the inherent embeddedness of human conduct in normative cultural practice. Even in his later work, Husserl arrived at culture only secondarily, through the philosophy of transcendental consciousness, whereas on the cultural account that we are proposing here, the intentional relation of human actors to their world is inherently a normative one: meaning, sense, purpose, and intentionality are ever so many words for actions that remain sensitive to the possibility of getting it wrong. For example, the meaning of a word like “honor” is not derived from honor as an ideal object in a self-sufficient consciousness but stands in relation to the countless cultural performances that can properly be called honorable or dishonorable. Even a Husserl who is stretched and

bent to fit the study of the life-world is unsuited to address the life-world as normatively structured.

Attempts in contemporary cognitive science to naturalize a Husserlian phenomenology still rooted within the philosophy of consciousness (e.g., Petitot, Varela, Pachoud, & Roy, 1999) may in fact come dangerously close to a sophisticated form of representationalism, as Dreyfus already argued almost three decades ago (Dreyfus, 1982). Thompson (2007) admits that their initial dismissal of Husserl in the 1991 book was inspired by Dreyfus’ depiction of Husserl as a proto-cognitivist, and he expresses his current belief that enactivism can be reconciled with a sophisticated reading of Husserl’s later work. As cultural psychologists, we are interested in meaning in a normative sense; hence, we remain skeptical of attempts to derive an understanding of normative conduct from a philosophy of consciousness or biologically grounded intentionality. Following Dreyfus in this regard, we maintain that enactive psychology and cognitive science may be better served by breaking more radically with the philosophy of consciousness and by following Heidegger, Dewey, and Wittgenstein in asking about the intelligibility, unity, and order of public normative conduct rather than private experience (Dreyfus, 1982, pp. 26–27). Like Dreyfus, we are interested in connecting the idea of normative practice to that of skillful coping at a psychological level. If human conduct is irreducibly normative, then we cannot work our way up to it from a theory of intentionality grounded in the individual organism.

Although autopoiesis may (in principle) provide a basic naturalized understanding of purpose and intentionality in the biological realm, it can as such not deal with the normativity of intention and purpose in the human cultural realm. Thus, the problem of intentionality and natural teleology brings us back to the problem of culture and the meaning or sense of historically situated action. Indeed the notions of sense and purpose are, as Thompson acknowledges, emergent relational properties and do not belong to the organization of autopoietic systems proper. On our account, they are indeed irreducibly normative notions that cannot simply be derived from the natural teleology of individual organisms. Instead, they require a historical understanding that nonetheless fully recognizes the particular organization of our closed human physiology. This brings us to the crucial issue of how embodied human beings enter the domain of language and culture and how our natural teleology becomes

attuned to a historical normative world. Given the principles of structural determinism and organizational closure, we cannot suddenly bring in a meaningful cultural order from the outside, as it were, or introduce language as a semiotic system that makes shared cultural meaning possible. The question is not “How does culture enter the human mind?” or “How is culture transmitted into and transformed within the individual?”, as Kreppner (1999, p. 209) suggests, but *How does a particular coordination of our actions historically give rise to both “mind” and “culture”?* An account of human conduct as irreducibly normative need not be at odds with the recognition of the biological roots of cognition. Thus we return to the issue of the relation between human physiology and human normative conduct and ask how, to paraphrase Herder, “die Natur dem Geist halbwegs entgegenkommt” ([how] nature meets spirit halfway).

### *Living in Language*

The role of language is crucial in the way enactive cultural psychology understands the entwinement of personal conduct with the normative order of culture. However, on the formal grounds we just spelled out, language itself cannot be understood as a superpersonal structure detached from lived embodied practice. As Merleau-Ponty has shown, language never fully breaks the bond with the lived significance of bodily perception and expression, and in living speech there is no separation between what is expressed and the manner in which it is expressed. For Merleau-Ponty (1964), language’s meaning is therefore always indirect, ambiguous, and allusive, just as for Maturana, it is connotative or implicative before it can be denotative. Although it may be possible to conceive of other generative domains of expression (e.g. dance, ritual, music, visual art), we could say that language constitutes at least a paradigm case for irreducibly normative expression. As such it must be connected both to our biology and to our history of consensual coordinations with each other.

In Maturana’s earlier writings (e.g., Maturana, 1978a, 1978b, 1980), language as a biological phenomenon is considered a direct consequence of the ability of our nervous system to recursively interact with its own states.<sup>11</sup> Language as a relational phenomenon, however, arises in the domain of human’s consensually coordinated action. As discussed above, interaction between structurally determined and operationally closed systems cannot be based

on information transfer or mutually instructive behaviors. Yet, such systems can become structurally coupled, and through a history of interlocked conduct, a *consensual domain* can be established. Given the structural plasticity of the nervous system and the fact that all of its states are internally generated, the nervous system can recursively interact with the states generated in it through consensual interaction, thus allowing for a consensual coordination of a consensual coordination of actions. According to Maturana, the consequence of such a recursive consensual coordination of actions is language or “*languageing*.”

Again, it is important to maintain clean epistemological accounting and to avoid phenomenal reductionism. Although operationally speaking language becomes possible because both internally and externally generated perturbations of the nervous system<sup>12</sup> map in the same phenomenal domain of relations of relative nervous activity (Maturana, 1978a, pp. 48–49), language as such exists only in the relational domain:

... [L]anguage is a biological phenomenon because it results from the operations of human beings as living systems, but it takes place in the domain of the co-ordinations of actions of the participants, and not in their physiology or neurophysiology. Languageing and physiology take place in different and non-intersecting phenomenal domains.

(Maturana, 1988a, p. 45)

Language has become a central focus in Maturana’s work, particularly from the late 1980s—arguably even more than autopoiesis. Whitaker (2003) has pointed out that there is also a shift in Maturana’s work on language itself, from an early focus on the “mechanics” of language as rooted in operations of structurally determined systems in consensual coordination (Maturana, 1978a) to a focus, in later work, on the orienting role of language in everyday consensual practice (Maturana, 1988a).

Although Maturana’s account of language does not principally change and remains grounded in the biology of cognition, his later focus on the *social* role of language seems to make it more adaptable for attempts to develop the enactive framework in a socio-cultural direction. Indeed, whereas Varela and Thompson are interested in the implications of the biology of cognition for enactive cognitive science, we have drawn particularly from Maturana’s understanding of language in an attempt to develop the general outlines of an enactive cultural psychology

(Baerveldt & Verheggen, 1999; Baerveldt, Verheggen, & Voestermans, 2001; Baerveldt & Voestermans, 2005; Verheggen & Baerveldt, 2007).

Although a focus on language as a social or relational phenomenon may seem to fit well with discursive and semiotic approaches to culture, we have been careful to avoid the problem of phenomenal reductionism, as displayed particularly in approaches that give regulatory or semiotic status to cultural models, representations, and mediational tools (Wertsch, 1985, 2007; Valsiner, 1998; Holland & Quinn, 1987; D'Andrade & Strauss, 1992; Moscovici, 1988, 1998; Farr, 1996, 1998; Marková, 1996, 2008) as well as discursive approaches that reject naturalism yet take the constitutive and illocutionary power of language for granted (Gergen, 1999; Edwards, 1997; Edwards & Potter, 1992). The implication of Maturana's account is that language cannot primarily be a semiotic system and that words and signs cannot be properly conceived of as tools for the control of actions, or mere rhetorical resources, but need to be accounted for in terms of culturally coordinated practices and acquired bodily dispositions. Culture as a symbolic or semiotic system does not explain consensual practice but requires explanation in terms of the historically coordinated practices that give rise to it (Maturana & Verden-Zöller, 1996; Baerveldt & Verheggen, 1999).

### *Language as Orienting Behavior*

Because interaction cannot be instructive or informative, enactivism conceives of communication as *orienting behavior*. Systems in communication do not transmit information to one another through a discrete communication channel but mutually orient each other within their respective cognitive domains (Maturana & Varela, 1980, p. 57). We live in language, but when language is used to communicate, the partners in the communication recursively coordinate their actions in a manner that orients them each within their own cognitive domain (Maturana, 1978). Those cognitive domains remain operationally separate but become structurally coupled in a history of mutually triggering behavior. Again, it is important to see that the notion of mutual "triggering" does not imply that no genuine communication occurs. On the contrary, it is a formal way of indicating that genuine communication within a linguistic domain requires some kind of embodied "attunement" and that the partners in communication can neither read each

other's mind nor simply put the right ideas in each other's mind.

Conceiving of language as orienting behavior fits well with social pragmatic approaches to language as a way to establish joint attention and *grammar* as a way to perspectively orient one another with regard to the objects of joint attention (e.g. Tomasello, 1999). The idea of grammar as an orienting device has been well-demonstrated by Bamberg (2001), who showed that in producing either an "anger narrative" or a "sadness narrative," 9-year-old children have typically learned to use grammatical features like transitivity and active/passive constructions to orient an audience with regard to discourse purposes like blame or empathy. Orienting behavior does not produce specific effects in the other—we can't *make* others empathize with us—but relies for its success on the capacity and willingness of the other to respond in a way that remains sensitive to the cooperative domain of interaction. Viewed from an enactive perspective, such orienting behavior is part of a consensual dance in which neither partner controls the behavior of the other, but both continuously adjust to one another to establish and maintain common ground for the duration of the interaction. Linguistic behavior is orienting behavior and although the notion of orientation may seem to have some similarity to that of regulation and co-regulation in semiotic and mediational approaches to culture and language (e.g., Fogel, 1993; Valsiner, 1998), it avoids the implication of those concepts that instructive interaction is possible. Of course the notion of language as orientation is not incompatible with genetic approaches to *semiosis* or sense-making as such, as we will discuss later on. But reconciling a genetic cultural psychology on more Vygotskian grounds with the enactive framework will require a reorientation from the language of mediation and control to that of coordination, orientation, and style.

### *Language and Emotion*

Whereas in his earlier work on language Maturana is particularly interested in the way language gives rise to observers as well as to objects as the products of recursive consensual coordinations of actions that conceal their own origin, he became in his later work predominantly interested in the role of *emotions*. As dynamical dispositions for action, emotions specify the relational domain in which human beings operate. Maturana maintains

that phylogenetically, our humanity did not arise directly as a consequence of our possession of language or rational thought but as a consequence of a particular configuration of emotion—particularly emotions related to intimacy—that made consensual behavior possible (Maturana & Verden-Zöllner, 1996). Rational thought as such is a consequence of us living in language, but the particular domain of rational behavior in which we operate at any given moment in time (e.g., making love, or engaging in an academic argument) is specified by our emotions (Maturana, 1997). In the flow of our emotions, we continuously move from one kind or class of relational behaviors to another (*ibid.*). As we go through an ongoing flow of emotions in our everyday lives, emotion and language braid together in what Maturana calls *conversations*, and the transgenerational conservation of living in conversations is what he calls *culture*:

In these circumstances, a culture is a closed network of conversations which is learned as well as conserved by the children that live in it. Accordingly, the worlds that we live as human beings arise through our living in conversations as particular domains of consensual coordinations of coordinations of consensual behaviors and emotions  
(Maturana, 1997)

Hence, where we saw earlier that the enactive cognitive science proposed by Varela, Thompson, and Rosch moves in the direction of a transcendental grounding of consciousness and intentionality in the natural purpose of the organism, Maturana's ideas about the entwinement of body, emotion, and language seem to point in the direction of a more immanent grounding of our ways of being disposed to the world. Elsewhere (Baerveldt & Voestermans, 2005), we discussed the entwinement of embodied normativity and affectivity in terms of the *normative structure* of our human reality. We argued that normativity is indeed inherently embodied and affective in nature, just like our emotions and bodily dispositions are inherently normative. Understanding that language occurs in two structurally coupled but non-reducible phenomenal domains and that linguistic behavior is always embodied and entwined with emotion opens the way to a genetic understanding of cultural normativity through the acquisition of durable bodily dispositions and normative skills. We will return to this below.

## Normativity, Training, and Style

Our insertion into a cultural-historical order takes place not through the internalization of cultural models or social representations nor by taking up already meaningful semiotic devices. Rather, our socialization into the ways of a culture involves a *historical process of continuous attunement to consensually orchestrated community practices*. Or, to use a different metaphor here, we are not like containers, each possessing, among other things, the shared ideational resources of our culture; we are like threads, intricately interwoven with the fabric of communal life, yet each maintaining our own unique individuality.<sup>13</sup> Enactive cultural psychology aims at a genetic psychological understanding of the “warp and weft” of personal lives in community.

### *The Pivotal Role of Cultural Training*

As argued above, we are agents capable of being *affected* by the world, and the way we can be affected is determined not by anything outside of us but by the way we are *disposed* to the world. Those dispositions involve themselves an intricate entwinement or braiding of language and emotion in the body, and this entwinement makes both our life-world and our psychological competences irreducibly normative. A central question for an enactive cultural psychology, therefore, concerns the particular history of *training* by which normative dispositions are acquired. We use the word training here very much in the Wittgensteinian sense of the word (*see* Wittgenstein, 1956/1978, 1958/1974). In contrast with representations, normative dispositions can be understood neither as states of mind, nor as states of the body. As Wittgenstein's analyses have convincingly demonstrated, skills and dispositions are dynamic and can only be demonstrated in practice—that is, in the public realm where they are susceptible to normative correction. As such, they are not merely externalizations of knowledge that we must first possess internally.

Charles Taylor (1995) has argued that the expressions of linguistic agents take place within a realm of irreducible rightness, where the appropriateness of expressions is not merely a matter of their pragmatic effect in a social situation. For example, the words “I am sorry” may be the right words to use regardless of whether they are successful in restoring the contact between us (pp. 104–106). The cultural realm of jokes, requests, apologies, offenses, and so forth is irreducibly normative, but also inescapably ambiguous, as, for example,

the question “Is this a joke or an offense?” can be resolved neither by appealing to a prefixed reality nor on the basis of representational knowledge. As Aristotle already saw, normative action requires *practical* understanding, and this practical understanding is dispositional rather than propositional. It is acquired as personal knowledge or understanding and cannot simply be passed on or internalized. It requires repetitive practice and personal training. To master a skill, one has to practice that which is to be mastered.

Training on Wittgenstein’s account is a history of trials or attempts in a context of normative correction. Indeed, like in Vygotsky’s genetic account, for Wittgenstein, cultural training initially relies on the guidance of those already more competent than the novice learner. For Wittgenstein, the crucial moment in entering the normative realm lies not primarily in the use of signs but in the nature of the training process itself, which fixes and constrains our ways of acting in such a way that we become bound to the *normativity* of cultural practices (for a comparison of Wittgenstein and Vygotsky in this regard, see Williams, 1999, pp 188 ff.). We could say that through training we develop a practical feel for the situated and dynamically enfolding normativity of particular cultural practices. To return to our metaphor above, training is precisely the way in which we are woven into the normative fabric of society.

Wittgenstein recognized that the irreducible normativity of cultural practice is nonetheless a genetic accomplishment on the level of individual actors. In Wittgenstein’s terms, the behavior of the novice may conform to a rule (in the sense that in the eye of an observer it fits certain patterns), but it is not yet genuine rule following (in the sense that the actor recognizes the normativity of these patterns). Indeed, not unlike the way Vygotsky sees a crucial qualitative change in a child’s development from pseudo-concepts to genuine concepts (see van der Veer & Valsiner 1991, pp. 264–265), so does concept formation on Wittgenstein’s account require a qualitative change from mere conformity to the rules implied in the concept to acting with a sense of the necessity of those rules. In enactive terms, this qualitative change can be seen as a move from mere repetition or regularity, as facilitated by the training situation, to participation in a domain of recursive consensual coordinations of actions that allows one to grasp that regularity. What is acquired in this process is what in the enactive paradigm

is typically called an embodied skill and what Wittgenstein calls a technique, rather than a set of rules: “[O]nly through a technique can we *grasp* a regularity” (Wittgenstein, 1956/1978, VI.2). In the case of concept formation, the crucial implication is that concepts can principally not be detached from techniques of application and hence neither from their mode of acquisition. Our understanding of a concept is inherently a genetic one. One does not simply possess a concept, but one demonstrates (L. *de-* + *monstrare* to show) conceptual understanding by showing that one can go on in practice. For Wittgenstein, as for enactivism, *to know is to show* and it is in this sense that the performances both of the novice and of the cultural master can never be truly internal; they remain bounded to public criteria and normative correction.

### ***Training and Normative Competence***

Situated normativity involves an intricate relationship between unreflective skillful action, perception, and emotion, and according to Wittgenstein, this relationship is forged by cultural training and participation in communal customs (Rietveld, 2008). On an enactive account, the transition to normative understanding is marked not by the use of tools or signs as such. Rather, it is marked by the unreflective ability of actors to recognize their own behavioral or expressive response to the expressive conduct of others at different times as in some sense the same. Normative judgments are recursive judgments of sameness in our own expressive responses. They are neither possible by virtue of some kind of introspection, nor as a consequence of conscious reflection, but rather because of the way those responses are embedded in community practices. Crucial in such recognition is the social nature of normative understanding. There is nothing in individual instances of behavior that can serve as objective standard for recognizing similar instances. For example, there are no objective standards for what constitutes a joke or an offense. To say it slightly differently: If recognition of sameness in behaviors or expressions would merely be based on the cognitive powers of isolated individuals, any behavior could be made out to be the same or different as any other behavior, at an individual’s whim, so to say (Williams, 1999, pp. 174–175). Therefore, required for recognitions of sameness are communal standards or constraints that facilitate normative correction; one has to be able to say/recognize: this is not how you (properly) use a table/pen/hammer,

this is not a (proper) joke/request/apology, or this is not the proper word for that, and so forth.

Normative distinctions require that the agent making them is capable of recursively recognizing coherences and regularities in her/his own (re) actions.

On Wittgenstein's account, the standards for the recognition of sameness cannot be provided by mere regularities in individual behavior over time; rather, those standards can only be provided by regularities in community practices. As we argued above, even perceptual features of objects are not just stimulus features (e.g., we don't *perceive* the wavelength of light falling on the retina); they are consensual distinctions in the sense described above. On an enactive account, we cannot just impose conceptual categories onto our perceptual understanding of the world; rather, in conceptual understanding, we recursively distinguish our own generic and differential response to the entities we first distinguish within a domain of regularities or coherences in forms of life—a consensual domain. Normative (e.g., linguistic or conceptual) distinctions are necessarily second (or higher)-order distinctions—that is, consensual distinctions of consensual distinctions. Therefore, normative sameness relies on regularities in consensually coordinated actions and what is recursively recognized as the same is not the objective stimulus features of pregiven entities or events but one's own repeated behavioral response to certain events or situations as part of regular or repeated community responses. Things (tables, hammers, jokes, offenses) are the same because we are recursively (but not necessarily reflectively) aware that we *typically* respond to them in similar ways and that this is the way we ought to respond to them under normal circumstances.

Take a simple concept like “table.” The concept of table is not merely an abstraction of the stimulus features of all (or many) particular tables. We don't arrive at it through inductive extrapolation, like Bruner, Goodnow, and Austin (1965) have proposed, but through a certain repetition in our practices. Tables are tables by virtue of the practices we have organized around them. The concept “table” can therefore only be a recursive consensual coordination of those practices. In everyday life, we use tables to sit around, to put things on and to eat from. Those consensual practices are not prescribed by any particular rule, but they are the dynamical consequences of a history of consensually coordinated actions. The concept of table arises when we

are able to recognize sameness or regularities in our consensual uses of tables, such that particular uses come to have normative status. This is when we can say: “This is (not) how you use a table,” or “This is (not) really a table.” No particular table is inherently a standard or exemplar for tables in general. A table can only acquire this particular normative status by its place within a particular cultural practice.

In practice, there is always a possibility that a table is used in a nonconventional way (e.g., to slide down a hillside, to block a door) or that something else than a “standard” table (e.g., an orange crate, a glass plate hanging on four cables from the ceiling) is used as one. However, nonstandard uses and deviations can be recognized as such not because we have a fixed concept of things like tables but because we have regular, common, or normal uses for them within our everyday practices. This means that concepts and normative uses must be rooted in historical regularities—that is, in the practical harmonious agreements over time of a community of people. We can only have a concept of table if there is a regular and largely harmonious use of tables—that is, a *custom* concerning tables. Moreover, what is true for a concept like “table” is even more evident in the case of concepts for intangible entities like “honor” and “motherhood.” The concept and normativity of honor and motherhood cannot be an abstraction from anything that is given to us in terms of mere stimulus features. Instead, the concepts of honor and motherhood can only arise against the background of historical practices that are recursively recognized and idealized in a way that allows both for normative correction and creative stylization.

Hence, our response to entities like tables, or jokes, or offenses is never fixed. On the contrary, in our cultural training we gain a certain expressive freedom, not—as some have argued—by the mediational use of signs but by acting within a domain of recursive consensual coordinations of actions that allows signs to have meaning in the first place. Such recursive consensual coordinations involve both skillful conformity with normative community practice and coherent deformations or stylizations of those practices (Baerveldt, 2007, 2009). Herein lies the difference between a linguistic or normative agent and a nonlinguistic animal like a dog. Behaviorally speaking, a dog could be conditioned to respond in a predictable way to a signpost, but this would not yet imply that it has a conceptual or normative understanding of the signpost. The dog has no awareness of getting it right or wrong.

Taylor (1985, p. 228) has noted that historically the role of the awareness of the normativity of our expressions is what distinguishes Herder's expressivist account of language from Condillac's more designative understanding. Herder (1772/2002a) uses the word *Besonnenheit*, which typically gets translated in English in terms of "reflection."<sup>14</sup> But as argued above, this *Besonnenheit* is not a cognitive power of isolated individuals; it is the hallmark of operating within the irreducibly normative realm of language.

In his introduction to the 1962 English translation of Vygotsky's *Thought and Language* Jerome Bruner credits Vygotsky for being the true architect of the "Second Signal System," proposed initially by Pavlov, "that provides the means whereby man creates a mediator between himself and the world of physical stimulation so that he can react in terms of his own symbolic conception of reality" (Bruner, 1962, p. x). As Bruner explained 20 years later, the notion of the Second Signal System captures the distinction between stimuli that act directly on the nervous system (the First Signal System) and those that are *mediated* by language and concepts (the Second) (Bruner, 2004, p. 10). As we discussed above, on the enactive view, there are no stimuli that can act either directly or in a mediated way on the nervous system. Instead, in humans, a recursive consensual coordination of actions facilitates the normative stage setting that is required for the use of signs, tools, and concepts. The proper genetic question is therefore not primarily how we take up culturally available signs but how we acquire the embodied dispositions that allow us to act competently within human consensual domains and language.

## Culture and Belief

Now that we have discussed the idea of the normativity of culture as involving an intricate entwinement of linguistic behavior and emotion, established through cultural training, are we in a position to confront some of the problems that plague a cultural psychology still caught up in a mentalist framework? Cultural psychology, in many of its incarnations, is often seen as an attempt to overcome Cartesian dualism and self-contained individualism by introducing the idea of the inherently social nature of knowledge and understanding. Yet, at the heart of such attempts remains often a more insidious form of Cartesianism that remains mentalist in its orientation and that maintains a fatal gap between knowledge and being. Philosophers like

Heidegger, Wittgenstein, and Merleau-Ponty have most cogently critiqued the insidious Cartesianism at the heart of our understanding. Critical to the program of an enactive cultural psychology is whether their critique holds up against the enactive view we have presented.

## *Representation and the Problem of Normative Sameness*

Any ideational account of culture, or any account of culture as involving an orchestration of people's beliefs, has to deal with the problem of normative sameness of beliefs—that is, the issue of how the people constituting a historical community seem to have certain beliefs in common. The need to understand the sameness of beliefs in normative terms follows from some of the fundamental problems with the mentalism of a standard cognitive account. On a mentalist account, beliefs are essentially mental representations, which implies that the problem of sameness can be tackled only in terms of the referential relation involved in such representations, either to states of affairs in the real world or—as in Husserl's phenomenology—to ideal objects in the mind. It is well-known that Wittgenstein spent the best part of his later life to contest this referential view of mind, and we will only briefly deal with it here. Earlier we evoked Wittgenstein in support of the enactive paradigm and the dispositional understanding of cultural learning we are proposing here. Now we will address the implications of Wittgenstein's analysis for an understanding of normative sameness and confront the enactive/dispositional view of culture with attempts to understand culture in terms of socially shared representations. The main issue to be addressed in this section is whether introducing the idea of shared or social representations can salvage the representational view or whether social representation theory remains essentially caught up in Cartesian mentalism. We hope this discussion may cast further light on the difference between a representational and a dispositional or enactive account of normative sameness.

## *Social Representations*

Following Wittgenstein in this regard, on an enactive account, what is required to anchor referential or representational relations are not mental capacities but regular uses, or practical—as opposed to merely propositional—community agreement in the uses of words, symbols, or signs. Meaning or sense has an irreducibly normative dimension,

and standards of correctness can only exist as part of community practices. This effectively dispels the need to evoke mental representations, but of interest to the possibility of a genuinely social and cultural psychology is the issue of whether a more systemic notion of representations and common beliefs can escape the implications of Cartesian mentalism. Advocates of a *social representation* approach to psychology (e.g., Moscovici, 1988, 1998; Farr, 1996, 1998; Markova, 1996, 2008) have attempted to offer such a systemic understanding, using what they consider to be a social, rather than merely mental, understanding of representation.

From an enactive perspective, we have elsewhere critiqued some of the basic epistemological assumptions underlying social representation theory and similar theories relying on a notion of shared cultural knowledge (Verheggen & Baerveldt, 2001, 2007). Even purportedly systemic theories of the intrinsically social in psychology often remain surreptitiously committed to a form of mentalism, by conceiving of the social in psychology as shared representations, schemata, cultural models, and so forth. For example, Farr (1998) presents what he calls a “minimal definition” of a social representation: “A representation is social if it is, or has been, in two or more minds” (p. 291)—thus implying that before they are *social*, representations can be in just one mind. Nonetheless, social representation theorists have often been careful to distinguish themselves from an overly mentalist social psychology, stating, for example, that social representations involve actions as much as thought (Chryssides et al., 2009), that they involve both conscious and unconscious accounts of meaning (Daanen, 2009) and that they are dynamic rather than static (Markova, 2008). Still, Markova maintains “that representations are modalities of *knowledge* and their *functions* are to shape activities, communication and to create reality” (p. 474, our emphasis).

In all these cases, the sharedness of the representation is supposed to rescue it from mentalism, but it is precisely in the way an epistemic notion of knowledge is prioritized as “shaping” activity and “creating” reality that the Cartesian schema is essentially maintained. On the Cartesian account, meaningful order does not inhere in life but can only be imposed through knowledge. Indeed, social representation theory first limits its social account to lay *knowledge of life* and then mistakenly identifies this knowledge as that what orders life, rather than identifying the consensual practices by which

everyday life becomes orderly in the first place. When social representation theorists speak, after Moscovici, of the anchoring and objectification of knowledge, they again describe the way in which objective reality is generated by a process in which conscious *knowledge* recedes into the background of taken-for-granted, common sense knowledge. Their dialectics is similar to that of Berger and Luckmann (1967) sociology of knowledge but entirely misses the Wittgensteinian critique that points to the necessity of the *practical* normative stage setting or consensual practice that is required for anything to count as knowledge.

A more radically cultural psychology can take its cues from Wittgenstein but also, for example, Heidegger by prioritizing cultural practice over shared knowledge and conscious deliberation. For Wittgenstein, like for Heidegger, understanding is only exhibited in our doings, and as such it is misleading, even, to talk about background intelligibility as mere common sense *knowledge*. Rather, in both Wittgenstein and Heidegger, we find the idea of a total coordination of our background *practices* that generates, as it were, a total style of being, or form of life, in light of which particular things can show up for us as meaningful. Understanding the primary way in which we are bound to such a total normative world cannot rely merely on a theory of common sense knowledge. It requires an account of how practical activities become consensually coordinated and ritualized and how participants to cultural practices acquire the dispositions to act as a matter of course, with right, but without requiring justification, to paraphrase Wittgenstein.

### ***Normativity and the Holomorphic Principle***

The problems with a social representation approach become particularly clear when we confront the enactive approach with what we consider to be one of the most sophisticated attempts of social representation theorists to deal with the problem of the normativity of practices. Wagner and Hayes (2005) claim, “If meaningful practice is to be established for the social whole, (the group), one has to assume that its parts (the individual members) share a representation which contains the essential aspects of the entire situation, that is, the entire group” (p. 278). Such *holomorphic* social representations are seen by them as conditions for meaningful social practice in the sense that they allow social actors to “meaningfully correlate their actions” rather than to be at the mercy of blind “trial and error and erratic

experience.” However, how those representations acquire their semiotic and regulatory power in the first place remains unclear in their account. For example, what makes it possible for the members of a community to understand those representations in the *same* way, if indeed social representations are precisely supposed to make common understanding possible? Moreover, how does one know that one’s own representation of the total social situation is indeed the same as that of others within the community? If social representations are supposed to do explanatory work here, the argument is essentially tautological.

Advocates of sharedness and openness have rightfully argued that a psychology of ideational processes cannot be a psychology of isolated individuals. Enactive cultural psychology, too, considers fully-fledged cultural competence to exist in the relational or normative domain. As we discussed earlier, the enactive argument for operational closure has often been misunderstood as an argument for self-contained individualism or, worse, an argument for a form of reductionism that attempts to derive the properties of culture entirely from the properties of individual cognitive agents. However, as we have just argued, the problem of reductive individualism is a consequence not of recognizing the operational integrity of cognitive agents but of endowing those agents with internal mental properties like beliefs and assuming that culture as a collective system must somehow imply a mechanism for the *sharing* of beliefs.

If, in Cartesian fashion, the problem of a common world is conceived of as that of the relation of inner cognitive schemata to an independently existing world or to the cognitive schemata of others, the notion of sharedness appears to be the only way to restore common reality. Indeed, on the surface it seems that social representation theory offers a way to break out of self-contained individualism and Cartesian dualism, by opening up the mind to the possibility of shared mental content. But it is precisely the language of mental content—and not that of operational closure—that inevitably leads back to mentalism and self-contained individualism, as it is unable to adequately conceive of the normativity of ideational activity. Sharedness cannot really be a solution here. As we have argued elsewhere (Verheggen & BaerVELdt, 2007), it is the makeshift solution that remains after we have already mistakenly started our account of culture, or our common world, from the idea of mental content. Now it

turns out that not enactivist but precisely mental and social representationalist accounts of culture are essentially prefixed harmony models. They presuppose the commonalities in human understandings for which they allege to account.

Shared representation cannot underlie agreement in action, because such agreement requires both the kind of dynamical stage-setting itself facilitated by histories of consensually coordinated conduct *and* the mastery by social actors of specific semiotic competencies; competencies that, as we saw, can only be acquired by a history of training. Therefore, to remain consistent, we have to reverse the epistemic and ontological priorities by assuming that social representation is not a condition for, but a consequence of, the social-normative nature of practices. Seen in this light, the holomorphic principle is reflected in the idea of the irreducible normativity of human action and expression. Individual actions and expressions make sense only against the background of the totality of a world that in its communal and historical character is irreducibly normative. Such a totality cannot be one that is conceptually grasped or shared; it must be *implied* in the way we already live and *expressed* as a whole in an entire style of being.

Rather than representational knowledge, *cultural competence is a stylization of a total way of life, a way of simultaneously grasping the world and one’s own way of being in the world.* For example, learning to become a man in a world governed by honor requires not just the accumulation of cultural knowledge of honor but the acquisition of a general way of going about in the world—for example, by particular displays of masculinity and sexual prowess, verbal mastery in the realm of competition with other men, demonstrating proper respect with regard to superiors, showing control over the women in one’s household, and demonstrating trustworthiness and honesty with regard to equals and hospitality with regard to guests (e.g., Bourdieu, 1979; Gilmore, 1987). All of those virtues belong to an integral world, which relies for its consensual enactment on a largely implicit sense or practical understanding of the game by its participants. This practical sense, acquired through an ongoing process of cultural training, allows them to express the right things at the right time in the right proportion (Bourdieu, 1990). With Heidegger, radically cultural enactivism holds that such grasping or understanding of an entire world necessarily precedes and embraces cognition in a more narrow—merely epistemic—sense

of that world. This makes stylized cultural competence an ontological category rather than a merely epistemic one. As we argued before, this is the general ontological understanding of “knowing” within the enactive program, which makes *knowing* effectively indistinguishable from *believing* and *being* (Baerveldt & Voestermans, 2005).<sup>xv</sup>

### ***Enactivism and the Need for a Genetic Psychology***

Enactive cultural psychology is concerned with the normative dispositions—expressive skills and styles—that make us competent cultural practitioners. The crucial implication of an enactive view is that such normative dispositions cannot be understood as internalized rules, norms, or representations. There is nothing in the individuated human organism that could be recognized as normative, because normativity essentially belongs to the social domain and is inherently bound to public, or consensually enacted, standards. However, becoming a participant to a cultural community requires that our natural affective responsiveness must be brought into accordance with structured community practices. Because the demand for clean epistemological bookkeeping prohibits phenomenal reductionism, we cannot smuggle cultural normativity into an operational account of what happens in the human organism. This also precludes any straightforward account of socialization as the internalization of cultural rules. Strictly speaking, normative skills or dispositions exist neither purely in the relational or expressive domain, nor in the operational domain, but express how those domains become *structurally coupled* through a history of cultural training, so that they move in the same direction, so to speak. Hence, although we can indeed give either a relational account of social practices or an operational account of the self-referential operations of the nervous system, psychology has the possibility to insert itself, as it were, between these two accounts, not by way of phenomenal reductionism but by way of a *genetic* account of the manner in which cultural competence and normative style are acquired and enacted. Rather than being limited to either the study of cultural variation in neural processes (e.g., Chiao & Ambadi, 2007) or to the hermeneutic explication of the normativity implicit in our historical practices (as in the tradition of Dilthey’s historical hermeneutics, *see* Dilthey, 1977), cultural psychology can play a unique and critical role in understanding the genetic principles involved in

becoming a competent moral agent—that is, a person within a normative world.

### **Future Directions**

Enactive cultural psychology is centrally concerned with the dynamic consensual coordination of actions by which meaning and sense are continuously enacted or produced. One of the most important implications to follow from a radically enactive cultural psychology involves the need to resist the common tendency to attribute causal power to culture and to use it in an explanatory account of our coordinated actions. The appeal to a non-differentiated and abstract notion of culture is characteristic of so-called “cross-cultural approaches” in psychology, even where they have recently come to be called “cultural psychology” (e.g., Kitayama & Cohen, 2007). Whereas cross-cultural psychology is mainly interested in finding psychological universals through cross-cultural comparison, the label “cultural psychology” is typically used to indicate a field of psychological study that is more concerned with the ways cultural values, belief systems, and practices shape psychological processes. Unfortunately, cultural psychology thus conceived remains too often committed to an abstract notion of culture and fails to adequately describe the genetic and dynamic processes by which people become competent participants to their cultures. Therefore, enactive cultural psychology allies itself with other genetic psychological approaches to culture but is in turn careful to avoid accounts that assign causal or semiotic power to culture apart from the way cultural meaning is continuously enacted by its participants. Cultural normativity is embodied and consensually enacted. In conclusion we want to briefly point out three possible directions for the genetic psychological study of embodied normativity, involving what we call *conversation*, *ritualization*, and *stylization*. Our proposal here is not meant to be exhaustive; we merely want to point out some directions that may help us to go beyond a cultural psychology for which a mere appeal to culture holds explanatory power.

Language is at the center of most socio-cultural approaches in psychology and in this sense our enactive approach is no exception. Although we already discussed the implication of an enactive approach for an understanding of linguistic development and concept formation, a direction to be further developed concerns the microgenetic role of conversation in everyday life. As argued above, language is embodied and the normativity of conversational

interaction involves a braiding of emotion and language as we move through the consensual domains we ourselves help to constitute. This means that language cannot primarily be rhetorical or propositional. Where discursive approaches like those of Edwards and Potter (1992) mainly attend to issues of accountability and the anticipation of counter descriptions, an enactive approach would see such issues as premised against a background of consensual and largely harmonious practice. The vast majority of conversation is necessarily participatory and consensual, and although words like “I love you,” “I’m sorry,” and “Look how beautiful” may take on strategical utility, it requires a rather cynical outlook on language to claim that this strategical use is all there is to language. Still, enactive cultural psychology remains sympathetic toward the fine-grained analysis afforded by conversation analytical techniques, precisely because such techniques allow us to render visible the ways in which consensual reality is actively maintained.

Ritualization is another way in which consensual reality comes to have normative force without it having to rely in advance on a common semiotic system. Genetically speaking, ritualization is a process that can take place in different genetic domains. For example, the idea of language as a consensual coordination of a consensual coordination of actions fits quite well with both evolutionary and historical accounts of language as emerging out of gestural forms of communication through a process of ritualization (e.g., Armstrong & Wilcox, 2007). Of particular interest to an enactive cultural psychology, however, is the study of the ritualizations of everyday life. With its focus on more explicitly linguistic forms of conduct, cultural psychology so far has generally overlooked the ontogenetic role of ritual in the enactment of consensual reality. For example, how does a gift come to seal a friendship, how may going out for a coffee come to communicate sexual interest, and how does paying the bill after dinner establish social dominance; such questions require an account in terms of ritual rather than discursive “aboutisms.” Ritualization is a natural consequence of the repetitive and recursive character of human social practices. Thus, the ritualization of everyday life may give rise to countless gestures and signs whose meanings remain largely tied to the particular domains in which they arise.

The study of everyday rituals and their formation may help to re-orient a cultural psychology that now often remains biased by confusing culturally

orchestrated conduct with mere conventionality or commonalities in behavior.

A final direction for psychological research we want to point at here follows from the implication of an enactive approach that the generic normativity of culture can only be taken up by its participants by being personally expressed. Genuine expressive form, according to Merleau-Ponty (1964), never merely represents a given norm but always expresses a coherent deformation of the norm and potentially the birth of a new norm. Enactive cultural psychology invites us to move away from an account of culture as an already established normative system and toward an account of culture as an ongoing stylization of a normativity that remains, so to speak, without positive terms. On the enactive account we have presented here, the fabric of culturally orchestrated everyday life is considered to be inherently consensual and normative. Yet, each expression, or each enactment of cultural normativity, is at the same time a unique stylization of that normativity. For example, whereas all cultures may be characterized by implicit and explicit norms for the expression of masculinity and femininity, such norms are not just given and passed on; rather, each individual agent takes up and enacts those norms in a personally stylistic way. Seen in this light, culture itself is never a fixed norm. It is a style—an ongoing deformation of deformations—that allows for an almost infinite variety of recognizably meaningful expressions. A society that becomes increasingly multicultural and multiform is a particularly fertile ground for stylization. Therefore, enactive cultural psychology is not interested in culture as a fixed conventional system; rather, it asks how human agents acquire expressive or stylistic freedom by becoming masters of their own culture.

## Notes

1. The original reference is to Herder, J. G. (1989). “Ideen zur Philosophie der Geschichte der Menschheit.” In: M. Bollacher (Ed.), *Johann Gottfried Herder: Werke, Vol. 6*. Frankfurt am Main: Deutscher Klassiker Verlag; translation by Fischer, 1997.

2. Deleuze (1993) has shown that Leibniz’s monadology can be interpreted in a way that shows it as organized around the idea of *expression*. According to Deleuze, Leibniz—just like Spinoza—relies on the idea of expression to overcome the fundamental problems inherent in Cartesianism. Viewed this way, even Leibniz appears hardly as the spokesman for self-contained individualism that some such as Kreppner (1999), make him out to be (see below).

3. From their particular understanding of structural determinism it also follows that determinism does not imply predictability. Predictability is a notion that pertains only to the

cognitive domain of an observer and has no value in the domain of structural and organizational relations that determine the system under observation. Moreover, because an observer, as a system operating within the natural world, is herself a structurally determined system, it follows, first, that an observer can only attempt to predict the behavior of other structurally determined systems with whom s/he interacts and, second, that therefore the structural features that the observer can distinguish in the system whose behavior is to be predicted are limited by the structure of the observer him- or herself.

4. Bateson is generally recognized as one of the fathers of enactive thinking, and his thinking, too, has been compared to Spinoza's (e.g., see Charlton, 2008). In an attempt to radically break with Cartesian dualism, Bateson specified six criteria for mind: (1) A mind is an aggregate of interacting parts or components; (2) The interaction between parts of mind is triggered by difference; (3) Mental process requires collateral energy; (4) Mental process requires circular (or more complex) chains of determination; (5) In mental process, the effects of difference are to be regarded as transforms (i.e., coded versions) of the difference which preceded them; and (6) The description and classification of these processes of transformation discloses a hierarchy of logical types immanent in the phenomena. Although, Bateson uses the language of energy and information rather than that of structure determinism, he comes to conclusions about the systemic character of life and mind quite similar to those of Maturana.

5. In his introduction to *Autopoiesis and Cognition*, Maturana (in Maturana & Varela, 1980, pp. xiv–xv) writes that the language used in their original work on the frog's visual system was still steeped in the traditional epistemology of information pick-up and computation. In his studies on color perception in subsequent years, Maturana came to the realization that many different visual configurations can give rise to similar color experiences. Therefore, to connect invariances of nervous activity to the perception of color, rather than attempting to correlate the activity in the retina with external physical stimuli, he realized he would have to correlate the activity in the nervous system as internally determined with the color experience of the subject. Although Maturana does not use the term, his crucial realization was that the color space of an observer is *enacted* by the dynamic activity of the nervous system itself and not determined by the external world, which plays only a *triggering* role in the phenomenon of perception.

6. In fact, the word "autopoiesis" itself is not used in *The Embodied Mind*, although Varela, Thompson, and Rosch speak in more general terms about the autonomy of living and cognitive systems (see also below). Thompson (2007) discusses it in detail, however, in his more recent book.

7. Maturana and Varela use the term *medium* to refer to the space in which the organism realizes itself. The term is not similar with "environment," which refers to the surrounding context as discerned by an observer. For the existence of the organism as a structure-determined system, it is necessary to maintain its structural coupling with its medium—that is, to preserve structural complementarity between its own structure and that of its medium (Maturana, 1988b, section xiii).

8. Vygotsky and activity theorists like Leontiev have used the word *appropriation* (Russian: *privoenie*, German: *Aneignung*), which, as Valsiner (1998) notes, in the Russian language carries a two-sided connotation. Valsiner points out that appropriation is always an active, co-constructive process, yet insists—with Leontiev—that this process only exists because of an inner/

outer contrast. Valsiner's own view is that collective culture and personal culture are connected by a cyclical process of internalization and externalization or, in Vygotsky's terms, between personal sense and interpersonal meaning. This perspective allows him to understand the genetic process by which self-regulation emerges (for an extensive discussion, see Valsiner, 1998, pp 100 ff.). From our own perspective, however, both inner and outer are modalities of expression, and as such we consider the notion of cultural appropriation to be more properly interpreted in light of Spinoza's monism. Indeed, Vygotsky (1987) understands the inner and the outer on a *developmental continuum* and not as ontologically different substances or pseudo-locations (see also Berducci, 2004). We propose an enactive or expressivist alternative to the internalization/externalization thesis in the idea of "style" (see below) and leave open, here, the issue of whether this perspective can be reconciled with Vygotsky's cultural-historical psychology.

9. Kreppner also simplifies Leibniz's idea of pre-established harmony, which for good reason would later prove to be extremely fruitful for von Uexküll's idea of the *Umwelt*.

10. Most of these authors were profoundly influenced by Gestalt psychology in its various incarnations, and their thinking prefigures in many ways that of present-day enactive thinkers. For example, the German physician and physiologist Viktor von Weizsäcker (1886–1957), whose work is now all but forgotten, spoke extensively about the *Gestaltkreis* as both a dynamic unity of perception and movement and a coherency of perceiving subject and world (see von Weizsäcker, 1940/1996). Particularly in the tradition of Goethe's expressivist *Lebensphilosophie*, the German-speaking world gave rise to various forms of holistic thinking with regard to life, which predate more recent ideas of self-regulation and biological autonomy. For example, in the early 1900s, we see Hans Driesch's idea of *organischen Regulationen* and Jakob von Uexküll's idea of the *Umwelt und Innenwelt* of animals. Then, in response to the perceived atomism of his predecessor Wilhelm Wundt, Friedrich Krueger gave rise to the Leipzig school of *Ganzheitspsychologie*, later continued by Friedrich Sander in the idea of *Aktualgenese*. Around the same time we find in the Berlin tradition of *Gestaltpsychologie* Köhler's idea of *spontane Selbstgliederung* and *Selbstregulation*. Unfortunately, few of these ideas seem to have been preserved for posterity (for a more detailed discussion, see Ash, 1991; Valsiner, 1998; Valsiner & van der Veer, 2000).

11. Maturana claims that operationally speaking, language became possible when, as a consequence of having subjected acting and interacting in the domain of pure relations to the process of evolution, humans developed the ability to interact not only with physical events but also with their own internal states (Maturana, in Maturana & Varela, 1980).

12. From the perspective of the nervous system itself, there is no internal or external, and the terms refer here merely to whether—on the account of an observer—the sensory surfaces of the organism are involved in those perturbations.

13. Our use of the metaphor should not be confused with that of Cole (1992), who speaks of a mutual interweaving of person and culture. In Cole's view, culture and cognition are mutually constitutive, but we believe this way of putting it is based on a category mistake. Rather, we speak of culture as a historical process of ongoing consensual coordinations of action.

14. Forster, in his translations of Herder's *Philosophical Writings* (Herder, 2002), translates the two key terms *Besinnung* and *Besonnenheit* as *taking-awareness* and *awareness*, respectively,

and points out that Besonnenheit is for Herder a precondition of Besinnung (p. 82, note 33; on this point, *see also* Barnhard, 2003, p. 115, note 25).

15. Of course, given the inherent normativity of believing, beliefs can still be held to standards of adequacy but not by evoking a pre-given world. As Spinoza has argued, all experience is a matter of being affected in a certain way, and for him the crucial distinction is between affects that are adequately understood and affects that are not adequately understood. According to Spinoza, whether an affect is adequately understood does not depend on independent truth conditions, but on our ability to articulate the genetic links that show the cause of our affects to lie within our own nature.

# Positioning Theory: Moral Dimensions of Social-Cultural Psychology

Rom Harré

## Abstract

A fundamental way in which cultures differ is in the taken-for-granted systems of rights and duties implicit in the way lived storylines unfold in everyday social episodes. Positioning Theory developed as a method of analysis aimed at revealing the storylines and implicit (sometimes explicit) ascriptions and resistances to ascriptions of rights and duties to perform actions expressing social acts appropriate to the situations recognized by participants in a strip of life. Analysis reveals a mutual determining of the meanings of social actions as acts, lived storylines unfolding and local distributions of rights and duties so to act. The concept of “positioning” has taken on two main senses in these studies—as the attributes of a person or group relevant to positioning and, in the other sense, as an attribution of rights and duties. The extensive literature of positioning theory includes studies ranging over great differences of scale from the intrapositioning in which a person engages in private moral reflections through positioning issues between the members of a small group of people in intimate interaction, up to the positioning discourses of the protagonists of nation-states or religious communities.

**Keywords:** position, positioning, moral order, rights, duties, storylines, social representations.

To appreciate the place of Positioning Theory in cultural/discursive psychology, a glance at the recent history of psychology will be helpful. There are two paradigms for psychology that still confront one another, especially in the United States. The mainstream among psychologists in the United States still depends on a tacit presumption that psychology is a causal science and that the proper methods are modeled on the experimental procedures of a rather narrow part of physics. The rise of alternative conceptions of psychology, as a study of patterns of meaning making and incorporating attention to moral orders, in Western Europe (particularly France, the United Kingdom, and Scandinavia) with reflections of these ideas in Asia and Australasia, presents an expanding global consensus on the human sciences. Smedslund (2009) has developed a brilliant summary of the

contrast between the failed project of experimental psychology and the growing successes of the discursive/analytical approach.

## The Old and New Paradigms

According to the Old Paradigm, the task of psychology is to find the causes of behavior, although behaviorism as a primitive version of this paradigm has been abandoned in name and to a lesser extent in practice. Much research in social psychology, psychology of the emotions, cognitive psychology, and so on is still based on the manipulation of dependent and independent variables, abstracted from real-life episodes, the results analyzed using statistical measures on the relative numbers of instances of each behavioral type emitted by the subjects.

According to the New Paradigm exemplified in such developments as cultural and discursive psychology, the task of psychology is to find convenient representations of bodies of knowledge that are required for the accomplishments of the intentions, plans, and projects of human agents. According to this paradigm, psychological phenomena are sequences of meanings of thoughts, actions, feelings, perceptions, and so on, ordered according to norms, standards of correctness that may be only local. New Paradigm research projects must conform to two methodological principles:

Do not abstract phenomena of psychological interest from real-life episodes to such a degree that the original meaning is lost.

Do not eliminate persons from the analysis since the topic of investigation is the work of active embodied knowledgeable agents attempting to bring their projects to fruition.

Positioning Theory is one of the ways that New Paradigm psychology has developed both in theory and in method. The emphasis on local meanings and on local and labile moral orders of rights and duties to act and to believe links Positioning Theory very closely to cultural psychology. Indeed, it would be appropriate to see it as a part of the program of the study of psychology as a cultural phenomenon.

### ***The Second Cognitive Revolution***

The New Paradigm approach came in part from the realization that many instances of cognitive processes, such as remembering and deciding, are not located in individuals but often exist only in a network of symbolically mediated interactions between the members of a group. Perhaps cognition is primarily interpersonal and only secondarily and derivatively intrapersonal. The center of primary cognition shifts from the individual to the local group, such as family, peers, research team, and so on. This had been anticipated by L. S. Vygotsky (*see van der Veer, 2011*). It is worth reproducing the famous aphorism in which he, echoing Pierre Janet, applies this insight to an outline of the core process of human development.

Every function in the child's cultural development appears twice: first, on the social level, and later, on the individual level; first between people (interpsychological) and then inside the child (intrapychological). This applies equally to voluntary

attention, to logical memory, and to the formation of concepts. All the higher functions originate as actual relationships between individuals.

(*Vygotsky, 1978, p. 57*)

In the context of social psychology according to the Old Paradigm, social phenomena were to be analyzed as if they were the result of individuals responding to extra personal stimuli inducing dispositions to behave in certain ways and bringing about corresponding dispositions and responses in the relevant others. Then, these dispositions were activated by local stimulus conditions. Tajfel's studies of prejudice (Tajfel, 1981) treated it as a state induced in an individual, a belief or an attitude or some such, rather than a feature of a matrix of social practices. Rather than trying to identify causes and effects as the core explanatory devices in accounting for human actions, according to the principles of the second cognitive revolution, we should look for narrative conventions—storylines immanent in the discourse practices in which psychological phenomena actually exist.

It is worth noting that the priority given to public collective process over private personal cognition in the work of Vygotsky and Wittgenstein has been the topic of a long running debate among philosophers. Neo-subjectivists—particularly those who follow the lead of J. R. Fodor (1976)—have argued that the entire domain of psychology is comprehended by mental states and the causal relations between them. Language is made possible by an inherent “language of thought” reproduced in each human individual rather than as the most advanced form of the practices of social communication. In a recent article reviewing the debate Hans-Johann Glock has demonstrated the flaws in neo-subjectivism by showing that the requirement that a concept can be shared among several people cannot be met by any theory that depends on the type/token distinction, as does Fodor's. Concepts as mental particulars would be tokens of concepts as abstract types. If it is concept as type that is shared, this would require the shared concept to be abstract. However, shared concepts appear concretely in the actual discourses among human beings, focused on common topics (Glock, 2009). Cultural and discursive psychologists need not be troubled by the fear that at some deeply theoretical level, their enterprise has been undermined by an argument that purports to locate everything mental “in the mind!”

## Abilities and Skills and the Conditions Under Which We Employ Them

The rules for the use of skill and ability concepts presume that the concept of a skill includes an intentionality component, tacit or explicit. Skills and abilities are realized in activities that are directed toward some end or outcome, even if the action to accomplish the end has become habitual. Moreover, activities that realize skills and abilities are subject to assessments of success, propriety, correctness, and quality. This means that associated with any cluster of skill and ability concepts, such as those involved in musical performance or sawing wood, are one or more normative systems, involving extrapersonal, social-historical and other collective considerations.

When we come to use skill and ability concepts to explain some strip of human behavior, a three-level cognitive structure is required.

### *The Abilities Progression*

A psychologist observes a person, X, doing something, and interprets this strip of activity as the carrying out of a task—say, helping an aged person, Y, out of a chair. What should we ascribe to the actor on the basis of this observation? Presuming the task has been successfully accomplished, we can say that X has demonstrated that he or she has the ability to do it. Here is a two-level format—the behavioral sequence is the phenomenon and the ascribed skill is basis of an explanation—although more would be required, including whatever it was that set the whole process in motion. However, we then notice that Y is not a bit grateful for the assistance—he/she indeed is rather cross. To understand this, we need to insert a level between behavior and ability: the moral level. Has X been accorded the right to do this? Perhaps X is a paid caregiver and believes he or she has the duty to assist the old person to rise. Here, we have a clash of tacit beliefs—X’s beliefs about duty with Y’s beliefs about rights.

In summary, we have the following layout:

X can do Z	X has an ability
X may/may not do Z	X has or lacks some position
X does Z	X is an agent

A project may fail at any one of these stages. A person may have planned some activity but lacks the skills to carry it off. Even equipped with the necessary skills and relevant knowledge, a person may not be authorized to carry out the project in question. Introducing the moral dimension through the attention that must be paid to beliefs about rights

and duties to act opens up another dimension, that of the responsibility of the actor and of the group in which the action occurs. With responsibility goes the role of praise and blame.

### BEYOND THE NOTIONS OF CAUSALITY

When a person behaves in a certain way in a particular social and material environment, he or she and also they can be held responsible for what has been done—that is, the actors must be treated as agents. It follows that social psychology must include moral concepts in its explanatory armory. It cannot be based on hypothetical causality.

In the remainder of the chapter, I take the concepts of “ability” and “agency” for granted without further analysis. The focus will be on the implications of adopting the concept of “position” as a generic concept covering assignments of rights and duties to act and to know or believe at the core of social psychological explanations. Position displaces concepts such as “balance” (Heider, 1958), “dissonance” (Festinger, 1957) and “social comparison” (Tajfel, 1981). These outmoded concepts are embedded in a theory of social psychology that focuses on hypotheses of essentially passive and automatic personal cognitive processes that ignore the social origin and active efficacy of people as joint constructors of social and psychological reality.

### Positioning in Relation to Social Psychology *Outlines of Positioning Theory*

In all human interactions, there are asymmetries in the resources for social action that are available to each individual in concrete circumstances. Earlier theories that were sensitive to the importance of moral norms presumed that differences in moral standing as actors were to be explained by identifying the kinds of social acts that were available to individuals as members of groups or professions and so on—the domain of role theory. This was far too primitive and coarse-grained to deal with real-life social episodes. Positioning Theory is based on the principle that not everyone involved in a social episode has equal access to rights and duties to perform particular kinds of meaningful actions at *that moment* and with *those people*. In many interesting cases, the rights and duties determine who can use a certain discourse mode—for example, issuing orders, giving grades, remembering a past event. A cluster of short-term disputable rights, obligations, and duties is called a “position.”

Positions are related both to the storylines realized in the unfolding of episodes and to the acts that are the meanings of the intentional actions of the people who take part. If a man and a woman are living out a nurse–patient storyline, then the man’s expressions of concern are readable as commiseration rather than condescension.

We can explain differences in the availability of rights and duties to act in certain ways for a person in a certain situation by reference to the social and personal attributes of that person in that situation. For example, who is positioned with the right and perhaps even the duty to switch off a life support system of someone declared to be brain dead? The assignment of such a right can be a matter for debate and conflict, in short of a discursive social process, that takes account of the social and even physical attributes of the people who claim that right. There is no role of life closer (Grattan, 2008, pp. 113–145).

Positions importantly determine the way people have access to cultural resources. For an example of claims for rights of access and denial of rights of access, contemporary life offers that of women in Saudi Arabia who not only do not have a right to drive cars but do not have right of access even to knowledge of car management. This predicament can be expressed in terms of positions—in this case, rather long-term ones. In such examples, position comes close to an earlier concept: role. But in any individual Saudi family, real life will involve the negotiation of positions. Some women may learn to drive in secret.

We will be concerned with the details of the ethno-methods of distributing rights and duties among individual people, confirming existing position distributions, and/or changing an existing distribution of rights and duties, and so on. An important feature of positioning procedures is the use of estimates of personal character in making such assignments. In the early days of Positioning Theory, the two current senses of a position were in use but not clearly distinguished (e.g., Davies & Harre, 1990). The word was used to refer to personal, historical, social, and cultural attributes of a person, as these were overtly ascribed by some pattern of discursive acts. It was also used to refer to a cluster of beliefs, some implicit and some explicit, as to the rights and duties proper to a person who was taken to have the ascribed attributes, or at least claimed to have them.

The connection between positioning in the first sense and positioning in the second sense is close

because positioning someone as incompetent relative to other members is a familiar device to take away the right to carry out some task. The importance of this duality shows up in discussions of a person’s character and history as an essential part of the Congressional Hearings for appointments to the Executive or the Supreme Court in the United States. A study by Gilbert and Mulkey (1982, pp. 383–408) showed how rights to be believed can be manipulated by rival teams of researchers in debates about the acceptability of conflicting research results. The role of character assassination in such debates can be seen in terms of Positioning Theory as a way of deleting the right of the claims of a certain research team to be believed. In Classical Positioning Theory, these discursive procedures are identified as pre-positioning, on the basis of which moral assignments are made—that is, actual acts of positioning proper.

### *Alternatives to Position*

Erving Goffman (1981, p. 128) introduced the term *footing* to refer to one sort of positioning process. He noticed that it was sometimes necessary for a person to deliberately establish a place in a conversation from which to be heard as a legitimate speaker. Such a move, if tacitly accepted by the group into whose conversation the outsider wishes to intrude, allows the new member of the group the right to be heard. Establishing that right is positioning oneself with respect to the others. However, Goffman does not present the rights aspect of footing in such an overt way. It is “the alignment we take to ourselves and the others present as expressed in the way we manage the production or reception of an utterance.”

The concept of “voice” is well-established in sociolinguistics. Voice refers to a pseudo-person whose utterances are marked with the social location from which one is speaking. Torode’s study of the relation between speech patterns and social order in school classrooms (Torode, 1977, pp. 87–97) uses the idea of transcendent and mundane voices, speaking as a member of an external authority and speaking as a member of the local group. As he worked out this analysis, the voices were positioned in the sense of this chapter—that is, the relevant rights and duties of speaker and listeners relative to the social location of voice were tacitly understood and conceded by speakers and listeners alike. Only Brian Torode himself could make the implicit explicit. He showed that rights to reply to and challenge commands

were tightly restricted in conversations in which the teacher adopted the transcendental voice, the “we” of authority, not the “we” of the persons present on the occasion. Those who adopted the mundane voice of a member of the group of persons in the classroom, choosing the pronouns “I” and “you,” had greater difficulty in establishing and maintaining authority. The pupils took for granted their right to challenge the orders of the teacher because in an egalitarian group rights are equally distributed.

### ***Positioning as Pre-Positioning and Positioning as the Assignment of Rights and Duties***

Classical Positioning Theory appeared in feminist writings in the 1980s. The first explicit formulation of the concept of position to refer to both implicit and explicit beliefs that people display in their intimate social practices was a Davies and Harré (1990) study of a two-member exchange, rich in social nuances. Positioning beliefs were immanent in the speech acts people were required, forbidden, or entitled to perform, according to local tacit conventions. Positioning Theory referred to the study of the discursive processes by which people were ascribed, took up, refused, contested, and so on—the rights and duties they found themselves with in the local social world. The point was always a moral one. The aim was to highlight practices that inhibited certain groups of people from performing certain sorts of acts. Given that selves were produced in local discursive practices, these tacit restrictions were of considerable moment. Of course, there were no restrictions literally. However, in the light of the spread of a different array of practices, one can express the sense of possibilities unfulfilled in such expressions as “restrictions.” At that time and in those publications, there was a persistent ambiguity in the use of the concept of positioning, discussed above. On the one hand, it meant ascribing a characterological attribute or revealing biographical incident to someone that was germane to the assignment of positions in the other sense, rights and duties.

Something like the former sense of position and positioning appears in Bamberg’s use of the concept of position (Bamberg, 2008). Positioning from this point of view is a discursive procedure for the ascription of an *attribute* to someone. To avoid any ambiguity between the two related senses, in most Positioning Theory studies, such as Moghaddam, Harré, and Lee (2009), Bamberg’s

sense of positioning is referred to as pre-positioning, a distinction needed to keep the difference between the discursive processes by which rights and duties are assigned or resisted and the grounds that are available to justify these assignments or resistances should they be challenged.

### **THE PROBLEM OF RULE**

In a recent paper critical of Classical Positioning Theory, Bamberg (2008) makes use of an understanding of the role of the concept of “rule” in social psychology that is explicitly rejected by positioning theorists. Positioning Theory depends on taking Wittgenstein’s (1953) account of orderly human activity in terms of rule following (in PI, pp. 138–242) as emphasizing its normative character which could be signaled by the metaphor of ‘rule following’. Potter and Wetherell (1987) took the same line in a challenge to a literalist use of ‘rule’, by some social psychologists. Positioning Theory is *not* a procedure “to extract from discourse the sets of rules that people use” (Bamberg, 2008). To say so confuses rules as instructions, which indeed people do use to get things done—usually technical tasks, with rules as a term of art for psychologists and others in their writings to express in legible and shareable form their intuitions as to the implicit norms immanent in the orderly practices of a form of life. This distinction was firmly insisted on by Garfinkel and was the basis of his technique for eliciting overt formulations of tacit rules. He contrived to have people deliberately act in a manner that would have broken the hypothetical rule and recorded the ways that people marked the infraction. Only if they did was one entitled to claim that there had been a normative practice. Grammarians publish sets of rules to present the norms implicit in the orderly practices of one’s mother tongue. They are not “extracting from discourse the rules that people use.” Native speakers do not *use* these rules!

The general tenor of a very interesting recent paper by Korobov and Bamberg (in press) is to resist another fundamental idea that position theorists share with the social representation school of social psychology (see Markova, 2011). It is the idea that to account for the stability of patterns of action, one must postulate repertoires of positions and storylines immanent in a culture that are represented in the bodies of shared social knowledge distributed as social representations among the members of a group. This idea does not undermine the uniqueness of every human act. In the absence of

a body of shared linguistic knowledge, there could be no speaking or writing—but this does not show that speaking and writing cannot be both original and intelligible. The same holds for social action as the living out of storylines indigenous to a culture and the processes of distributing positions and understanding utterances as speech acts. Although we mobilize such items as beliefs and rules to get things done, we do not *construct* them *ab initio* on this or that occasion. Yet the way they are realized may be quite distinctive and unique to a particular occasion. The issue is not whether certain storylines exist as discursive resources, but how they do. They are very rarely the result of following sets of instructions!

### Positions and Positioning

Taken abstractly, a position is a cluster of beliefs with respect to the rights and duties of the members of a group of people to act in certain ways. These belief clusters may be tacit, existing only as immanent features of unchallenged patterns of action. They may be explicitly formulated as rules and conventions. Because positions are ephemeral compared with roles the focus of research interest must include the social/cognitive processes by which positions are established. This dynamics is positioning—that is, processes by which rights and duties are assigned, ascribed, or appropriated and resisted, rejected, or repudiated. The upshot of acts of positioning is a pattern of explicit and implicit beliefs, held by individuals and among the relevant group in which the action is going on.

As a process, positioning may proceed through a sequence of phases. For example, the ascription of rights and duties may be consequential on a preliminary phase in which the moral character, intellectual or practical competence, biography, and so on, of a person, a group or even a category of persons are ascribed, sometimes on the basis of explicit evidence. As suggested above it will be convenient to call this discursive process “pre-positioning.” In the second phase, explicitly or implicitly, these ascriptions are used as grounds for the distribution or deletion and withdrawal of rights and duties. These moves are accomplished by second order social acts, sometimes overt but sometimes immanent in the form of unfolding social episodes. At the meta-level, those who claim the right or duty to distribute and redistribute positions must be positioned so to do. This opens up another research dimension. By

what discursive processes is this accomplished on a particular occasion?

Positioning Theory is as much a matter of the social processes for the assignments of duties as it is of assignment of rights. Nevertheless, in the feminist input into Positioning Theory from Hollway (1981), Davies and Harré (1990), and others, rights had pre-eminence. Women had a plethora of duties and a minimum of rights in those bad old days. To keep track of all this, we need to have a conceptual analysis of the concepts of “right” and “duty,” with some sense of the historical transformations of these concepts in actual applications in the management of social order.

### THE POSITIONING TRIANGLE

The position a person occupies at any moment in an evolving strip of life is determined in part by the storyline that is realized in the unfolding episode. If the storyline is “nurse and patient,” then within this action schema there are positions such as a “right to be given care” and a “duty to provide care.” People taking part in an episode that they are interpreting in terms of this storyline can be expected to act in accordance with their then-and-there beliefs as to their positions as implicit in the local moral order. Moreover, the actions of the people who are living out such an episode are made sense as the result of the intersection of two clusters of beliefs: what storyline is unfolding and what positions are thereby available to the actors. A third component of a positioning analysis can be picked out as the social meanings to which the actors are orienting in what they do then and there. In short, we have a triangle, with the three vertices occupied by positions, storylines, and act interpretations. The constituents of the three vertices mutually determine one another. If any one changes—for example, by a successful challenge to the distribution of rights and duties—then all three change. Change the distribution of rights and duties and the storyline that has been realized thus far may be transformed. At the same time, the meanings of what has been said and done by the actors are also transformed. The future relations between the actors and the subsequent form taken by the unfolding strip of life will be different after changes in any three components of the positioning triangle.

I turn now to a more detailed exposition of the constituents of the three vertices: acts, positions, and storylines.

## THE FIRST CORNER OF THE POSITIONING TRIANGLE: RIGHTS AND DUTIES

The basic structure of the interconnected conceptual pattern of the concepts of rights and duties goes something like this:

Rights: My rights are what you (or they) must do for me.

Duties: My duties are what I must do for you (or them).

These definitions are couched in terms of social necessities. But from whence comes the “must?” The basic structure of personal attributes that underlies the way rights and duties emerge and are related depends on a simple distinction between a person’s (or a group’s powers) and the vulnerabilities of another person or group of persons. In all human relations, there is a possibility of an imbalance between the powers of some people and vulnerabilities of others. The genesis of rights and duties on particular occasions and among specific people or groups of people goes according to the following patterns:

If I (we) have a vulnerability that you (they) have the power to remedy, then you have a duty to remedy my vulnerability and I have a right to be the recipient of the exercise of that power.

A right–duty pair emerges from this reasoning and frames possible actions. These future actions are only possibilities, because whether or not the actions that would fulfill the rights–duties pattern actually occur depends on other features of a concrete situation such as the risks to the actors, the conscientiousness of the powerful, and the skill of the recipients in presenting their needs and so on.

### *The Symmetry Presumption*

In our time and place, our moral universe is built around a general presumption that for every duty there is a right and for every right a duty. The seemingly *a priori* claims to rights, enshrined in various charters and constitutions, are a modern and (for the most part) English and French innovation from the seventeenth century. The Founding Fathers of the United States quickly added a Bill of Rights to the Constitution, but they overlooked a Bill of Duties. Jefferson’s “life, liberty, and the pursuit of property” (revised by Hamilton to the pursuit of happiness) was a detailing of rights. The U.N. Human Rights charter is not matched by a charter

of Human Duties. Why? Because they can be taken for granted? Surely not.

Even in the twentieth century, the symmetry principles are not universally acknowledged, even in those countries where talk of rights is ubiquitous. On the other hand, my upbringing was old fashioned Protestant, in which only duties figured. I still find it almost impossible to claim or activate my rights, if any.

In fact, rights are generally taken to be prior to duties. People tend to think about their rights and then look for a source of dutiful response from someone else. By the 1960s, John F. Kennedy could find it necessary to remind Americans that they should take heed of what they could do for their country—a duty concept.

Everyone can find some way in which he, she, or they are vulnerable, hence engendering a right in search of a duty. “They should do something about it.” The “should” is normative and hence marks the formulation of a duty, however vaguely. It has often been remarked (apropos for example of health needs) that rights can expand seemingly without end—this is one way we can understand the origins of the client society. In the absence of a duty code, the courts have taken on a new role, in which claims to rights are adjudicated and duties prescribed by identifying who are to be the relevant dutiful.

The fact that there are societies that recognize only duties and have very weak notions of rights shows that the symmetry presumption is not a conceptual truth. There are historical examples of social systems that seem to involve complex hierarchical patterns of reciprocal duties with no explicit formulations of rights. For example, the feudal systems in fourteenth-century England and France seem to have been based on formal recognition of a vassal’s duties to the lord and the lord’s duties to the vassal. We misread Magna Carta if we take it to be a medieval Bill of Rights. King John failed in his duties to his vassals, who forced him to acknowledge that he had certain duties to them. These duties were formally set out in oaths of fealty (Critchley, 1978). The reciprocal *duty* pattern of these oaths of allegiance as fealty is very clear. Similarly, the Shogunate in Japan and the cult of bushido among the Samurai who maintained an orderly society seems to have been a predominately duty-based system. Everyone in a hierarchy of dutiful relationships was a vassal ultimately of the Shogun himself (Nitobe, 1969, Ch. IX).

In contemporary life, there is much talk of duties to the environment, in which people are positioned in sometimes quite specific ways. Duties to the environment are necessarily asymmetrical. Trees have vulnerabilities, so we who have power over nature have duties with respect to them, but trees have no rights. They are not agents, so we cannot call on them to do anything to remedy our vulnerabilities, such as climate change. Trees are instruments, not agents.

Philosophers have introduced the concept of supererogatory duty (Raz, 1975). This is a felt demand on the basis of a personal conviction that something *should* be done. In taking on a supererogatory duty, the moral force is felt only by the individual who feels committed to that duty. Such a duty has no legal or even customary force. Again philosophers have noticed that informal or supererogatory duties, when felt by a number of individuals (particularly if one or more these people are socially influential), evolve into formal obligations. Not so long ago individuals positioned themselves as having a duty not to smoke in the vicinity of other people. In the intervening era, some people felt that they had a duty to protest against smoking by others. Now this duty is enshrined in law. We have a reciprocal right to clean air.

Nevertheless there is a strong contemporary emphasis on the distribution of and claims to rights. Given the various and variable relations between duties and rights depending on culture, history, topic, and so on, positions may turn out to be very complex. If someone demands a right based on a supererogatory duty, how is such a claim to be enforced? How does positioning work in a social order that is exclusively or almost exclusively duty-based? There has not yet been any substantial research into this question. Duty-based moral orders are rare in our time. Their connection with honor moralities has been sketched but not taken up as a major research project.

### *The Second Corner of the Positioning Triangle: Actions and Acts*

Cultural and discursive psychology both depend on a distinction between taking a behavioral performance as an intended action by a human agent and the meaning that the agent and others involved give to that behavior. We can usefully adapt two vernacular terms to mark this distinction. An action is a meaningful, intended performance (speech or gesture), whereas an act is the social meaning of

an action. Both levels can be revised and contested subsequently. An actor may claim that what he or she did was not an action, that it was not intended. Even if the intention to do something is not contested, an actor may claim that the meaning or social force of the action was not as it had been supposed. A cough might be an automatic reaction to blockage of the airway, but it can be deliberately used as a warning.

Positioning Theory has been applied, for the most part, to verbal interactions, to episodes unfolding as conversations. Positioning theorists can help themselves to J. L. Austin's well-known distinction between the forces of speech actions. A speech act, such as congratulating someone, appears as the illocutionary force of the speech action, saying "Well done!"; however, the material and social consequences of the speech action being understood in that way, given that meaning, is the perlocutionary force of the speech action. Compare "*In* saying 'Stand back, I warn you!' with "*By* saying 'Stand back, I'll save you!'"

In this presentation, we will rely on common sense (folk) categories for acts. Gestures will be treated within the same analytical framework. For purpose of positioning analysis, a strip of life will be taken to be sequences of overlaying and imbricated acts borne by actions that were intended by the actors.

### *The Third Corner of the Positioning Triangle: Storylines*

The basic principle of Positioning Theory as an application of discursive psychology is simply that strips of life unfold according to local narrative conventions, some explicit, some implicit. Explicit storylines are exemplified in the unfolding of ceremonies, in the formats of rule-bound games, in the procedures in courts of law. The positions are predetermined, and there are procedures by which they come to be occupied by specific actors. Something more is needed for implicit storylines. Narratological analysis can reveal them. The study of storylines is a branch of narratology. It depends on the principle that strips of life are usually lived stories for which told stories already exist. The same story can be expressed in different media, words, film, plays, and life; in the contexts of everyday life, there is rarely any explicit recourse to plot or scenario. This is the domain of narratology proper, the study of the storylines realized in improvised episodes.

Some distinctions are in order. Explicit storylines must be distinguished from chronicles (proaeretic principles), which simply describe a time sequence of events. In Russian narratology, this appears, roughly, as the distinction between “fabula” and “sjuzhet.” For narrative, we need a plot and cast of characters. Both are limited in scope and variety.

There are two analytical schemes that prove useful. The analytical categories of Griemas (1990) are presented as six actants. These are Seeker, Object sought, Sender (of the Seeker), Receiver (of the object sought), Helper, Opponent. The scheme proposed by Kenneth Burke (1945) and picked up by Erving Goffman (1959) involves a Pentad. The five elements are Act, Scene, Agent, Agency, and Purpose. According to Burke we should attend to the Ratios, the way these elements need to be used in analytically in pairs.

Just as was the case with position and positioning so, too, the important concept of storyline appeared in early positioning theory studies with two meanings. On the one hand, it was used to describe the unfolding of the structure of an episode in terms of a familiar story—for example, “Beauty and the Beast” or one of Vladimir Propp’s folktale action sequences in accordance with his 36 action categories. (Propp, 1968). This was the sense of narrative in the writings of Jerome Bruner (1990). A *story* is told by a social psychologist as a representation of the act sequences. On the other hand it was used to refer to stories told by social actors, perhaps as accounting moves to make a lived storyline intelligible and warrantable. Although positioning theorists have drawn concepts from Agirdas Greimas for the analysis of lived storylines, the examples he presents in his (1990) book are analyses of told stories.

### ***Positioning Theory: Worked Examples***

Here are two worked examples to show how putting together the three vertices of the positioning triangle reveals the dynamics of the play of rights and duties in the unfurling of a complex episode.

#### **EXAMPLE I: INTRAPERSONAL POSITIONING**

In the case discussed in this section, the person displaying Multiple Personality Syndrome (MPS) offers two storylines to the therapist (Beran & Unoka, 2004, pp. 151–161). There is the story of herself as Elsa and the story of herself as Marian. These storylines are tied in with primary acts of character pre-positioning that supports claims of positioning each persona as having rights to be

heard as authentic independent voices. The psychiatrist attempts to meld the two story lines into one as a single autobiography. In so doing, a single personality is restored or recreated. In the classical study of MPS, Morton Prince’s record of the discourses in which Christine and Sally Beauchamp appeared as presentations of the same human being, the therapy was grammatical. Prince insisted that Miss Beauchamp refrain from talking of her life events in terms of three pronouns—“I,” “you,” and “she”—Everything she reported must be tied to “I”. In this way he hoped to recreate a single autobiographical storyline.

Autobiography can be viewed as a device for positioning oneself in the act of presenting a self-narrative. An autobiography is not a chronicle because it is not only a history but also a manifestation of personhood. Every normal human being has a repertoire of autobiographies, each freely accessible from every other. This is not the case with the storytelling of someone presenting Multiple Personality Syndrome.

A narratological analysis of MPS can be set out in formal schema as an analytical tool for the study of the problems of a patient, P.

1. P tells two distinct autobiographies, A1 and A2, which are not freely accessible one from the other.
2. Each autobiography displays a distinctive set of personal qualities, including knowledge of past events.
3. When living out A1, events relevant to A2 are not accessible, and when living out A2, events relevant to A1 are not accessible.
4. Each A1, A2, and so forth, establishes a position.

Beran and Unoka (2004), like Prince, use pronouns as persona and position indicators. Their analysis displays two persona positions presented sequentially.

Elsa positions herself as an authoritative witness of the past having the right to be heard and believed. Her narrative’s original past tense changes to present tense as she retells the story of the trial of the man who raped her.

Marian is evoked by Elsa when Elsa is asked to tell the story again, as one who is trying to stop Elsa telling the tale. This is a positioning move, as Marian is resisting Elsa’s self-positioning as one who has a right to tell the story and to be believed.

The therapist induces Elsa to talk as Marian, explaining why the story should not be told. In this telling Elsa is referred to in the third person, and Marian adopts the first person, positioning herself as authoritative—that is, having the right to be believed. Then the therapist induces Elsa to tell the story as Elsa in the first person. In this way, the therapist makes both stories available, the telling and the resistance to the telling. In the new situation, Elsa is able to explicate the significance of the second voice. Marian is the name of her husband's mistress with whom she had a quarrel.

#### EXAMPLE 2: INTERPERSONAL POSITIONING

The recent public political debates in the run-up to the recent American Presidential election provide a rich field of material for study. To illustrate how ascribing and persisting positioning moves works in a two-person discursive interaction, we will look at an excerpt from the Primary debates between Barack Obama and Hillary Clinton, selected from a comprehensive analysis of all four encounters (Harré & Rossetti, 2010). The issue in positioning theory terms boils down to this: “Do I (Barack or Hillary) have the right to stand as a candidate for a macro-positioning exercise, the general election, which will give me the right to rule?” (Harre & Rossetti, 2010).

This example is taken from *CNN Democratic Candidates Compassion Forum* (April 13, 2008). Both Obama and Clinton introduce autobiographical material as pre-positioning moves. The chain of inferences runs from an autobiographical snippet through a claim for competence or experience to a self-ascription of the right to be the Democratic candidate to achieve the ultimate ascription of a position in the formal ceremony on the White House Law—the right to rule. We need not follow every step of this progression—the first two moves are enough to show how the pre-positioning works and how Obama's moves undercut Clinton's self-positioning.

In response to the charge that he criticizes people for “clinging to their religion,” Obama responds with the following:

“I am a devout Christian . . . I started my work working with churches in the shadow of steel plants that had closed on the south side of Chicago, [I claim] that nobody in a presidential campaign on the Democratic side in recent memory has done more to reach out to the church and talk about what are our obligations religiously . . .”

Here, Obama is making a reactive pre-positioning, responding to an implicit positioning move that would entail his not having the right to rule in a predominantly Christian country.

More telling, because it is more intimate, is Obama's claim to a special attribute, the ability to bring people together. To claim this, he offers the following:

“but what I look at as the trajectory of my life because, you know, I was raised by a single mom. My father left when I was two and I was raised by my mother and my grandparents. . . . what was most important in my life was learning to take responsibility not only for my own actions, but how I can bring people together to actually have an impact on the world.”

(Obama, 2009; ABC News, February 26, 2009)

This snippet serves to rebut the “all words but no deeds” accusation that Clinton had made about him.

Responding to a neutral query, Clinton makes a pre-emptive pre-positioning move by introducing an autobiographical snippet:

“You know, I have, ever since I was a little girl, felt the presence of God in my life. And it has been a gift of grace that has for me, been incredibly sustaining. But, really, ever since I was a child, I have felt the enveloping support and love of God and I have had the experience on many, many occasions where I felt like the holy spirit was there with me as I made a journey.”

(*CNN Democratic Candidates Compassion Forum*, April 13, 2008)

As the debate unfolds, the negative consequences of this pre-positioning move become apparent. This introduces an unfortunate image of the privileged child “born with silver spoon in her mouth,” whose conscience calls for her to act as Lady Bountiful. Obama's call to duty does not come from a kind of contingent condescension but from being positioned, in the descriptive sense, as “one of us.”

#### EXAMPLE 3: GROUP POSITIONING VIA PROTAGONISTS

A conflict of this nature may take two main forms.

- The antagonists may share a story but by adopting contrary positions use that storyline to express and so to nourish a conflict.
- The antagonists may have adopted irreconcilable storylines that are such that two

positioning triads exist, and there is no discursive bridge from one to the other.

I shall illustrate both possibilities in some detail, with an analysis of the positions, storylines, and speech acts through which a seemingly irresolvable conflict between Georgetown University (GU) and the surrounding residential Georgetown Community (GC) was nourished and sustained (Slocum & Harre, 2003, pp. 110–118). Although there is a long history to this dispute, the most recent eruption of this “town-gown” conflict was instigated when GU put in a request to the District of Columbia to be permitted to increase its student enrollment in a proposed “campus plan.” An acrimonious conflict between the University and certain people in the neighboring GC began. This dispute appears, at first sight, to be chaotic, with the ground shifting in almost every encounter. Positioning Theory provides an analysis that shows that the strips of life interwoven in the stream of encounters are orderly.

There is a question of scale in any analysis where the discourses are public. Are we disputing about the role of universities in the management of student behavior? Are we disputing about exactly how many new student places Georgetown should create?

We need to know who/what groups are presented in the narratives as the main actors in the conflict. These are the beings who will be adopting and defending positions or are themselves being positioned by others. Are they individual people, voices, protagonists, and so on?

The next step consists of a detailed analysis of people’s perceptions of the conflict. The point is not to reveal what really happened but to analyze an episode to reveal one or more possible narrative forms to which speakers oriented in the course of these encounters. There is a further step in these discursive encounters in which, in commenting on the positionings of others in the debate, some of those involved take a step back and adopt a position with respect to the positionings already accomplished—the right to comment on first-order positioning triads. Some people even believe that they have a duty to do so. Thus, an analysis of the meta-positioning discourse is also required.

Finally, we should be able to discern who does and does not possess positioning power and the basis on which this power allocated. We can gain insight as to what role differences in positioning power play in the conflict. This may reveal why some of the storylines are more dominant (although not necessarily more pervasive) than others.

Six main storylines can be distinguished in the documents in which the discourse that revolved around the Georgetown town/gown conflict was carried on. Some of the storylines were challenged by dissenting opinions that were a direct negation of the storyline. Other readers would, no doubt, discern other storylines. A strip of human life is indefinitely complex—it would be a huge mistake to claim that one’s analysis was exclusive and complete!

#### *Storylines With Which Georgetown Community case Is Expressed*

1. *The Students as Savages Storyline:* Students are ravaging and violating the affluent and prestigious Georgetown neighborhood, spoken for by GC.

2. *The Aggressive University Storyline:* GU is encroaching upon the Georgetown neighborhood’s territory. GU is arrogant and hypocritical in that it cares only for its students and neglects the interests of the community.

3. *The Parent/Children Storyline:* GU is a negligent parent, and the students are unruly children.

The first and third storylines are sometimes woven together in some of the actual discourses of the activists on the community side. Although the second and third storylines are apparently contradictory, they are sometimes to be found intermingled in the discourse of one individual.

#### *Storylines With Which the Georgetown University Case Is Expressed*

4. *The Malicious Residents Storyline:* Neighborhood activists are hostile extremists who discriminate against students. They are jealous of the students and wish them harm. They are hindering GU development.

5. *The Benevolent University Storyline:* GU has been responsible and cooperative. Its students are responsible members of the community, and, in general, they are idealists and leaders.

6. *The Historical Rights Storyline:* GU and its students were here first—namely, since 1789!

The disputes, disagreements that fuel the conflict are, we contend, *maintained and made orderly and attractive by virtue of the storylines with which the dispute is expressed.*

In the dominant discourse of the GC activists, storylines 1 and 3, the Students as Savages and GU as Neglectful Parent are embedded within a

broader set of discursive conventions we label “The American Dream.” Coming to live in Georgetown is the ultimate realization of the American Dream. The story is not supposed to end with the hero surrounded by drunken, dirty, and noisy savages. In this storyline, rights (including the right to position others) are acquired to the extent that one pays taxes, owns property, and steps into the dramaturgy of the American Dream. Indeed, one so positioned also acquires the duty to “do something about ‘the destruction of the proper ending to this storyline.’” The activists’ speech acts are to be classified, from their positions, as protests, displays of righteous indignation, doing one’s duty by society, reprimands to the unruly, and so on.

In the discourses of GU, the GC activists are positioned as devoid of rights to interfere with the progression of the university’s development—particularly with the campus plan. An anonymous administrator positions herself as spokesperson for the institution as having the duty and the right to take on lower order positions rights and duties as partner and neighbor to the surrounding community, engendering, ideally, reciprocal position in the GC discourse. Accordingly, the failure of the community to accept this benevolent positioning is culpable. Positioned as rejected suitor, GU has the right to issue utterances that have the illocutionary force of rebuke, chastisement, and accusation. In rejecting the positionings of GU, GC activists appear in this storyline as morally defective—for example, stubborn and uncooperative.

Just as the generic storyline of the American Dream underlies the specific storylines of Students as Savages and the University as Neglectful Parent, underlying the storylines of both the activists’ and the University administration’s seemingly antithetical narratives is another generic storyline, the almost universal “Students are Children and the University is their Parent.” The dispute is maintained by GC pre-positioning the University as Neglectful Parent and the University pre-positioning itself as Responsible Parent, thus fixing the distribution of positions vis-à-vis the actions appropriate to each side. The position in which the University has been put involves both rights (*in loco parentis*) and duties to manage the students’ behavior. At the same time, that generic or pre-positioning puts the students into the specific position of ones without civil rights (e.g., to drink in bars), and as having the duty of obedience to the University.

### *The Psychological Status of the Relevant Bodies of Knowledge*

A great deal of local knowledge is required to act unhesitatingly and successfully in the various contexts that require positioning of oneself and others. However, it seems more natural to use the word “belief” for the cognitive resources drawn on in the ways I have described.

There are two ways that beliefs can be related to locally meaningful actions: A belief may be transcendent to an action that is held independently of the actual occasion of the action, perhaps even able to be expressed in propositional form, as a principle or rule. However, a belief may be immanent in the action—a feature of the social context of the flow of activities by the people involved in a life episode that exists as a customary practice. The background beliefs that shape positioning activities can be of either kind.

Positioning analysis of an episode can present both kinds of belief as explicit formulations. The fact that research results must be expressed in propositional form to be read and understood by other people should not tempt us to overlook the important distinction between beliefs that are immanent in patterns of action and those that are held by individuals as bodies of knowledge. Studies in the framework of *Réprésentations Sociales* (Farr & Moscovici, 1987) also display this duality in the way that the sources of social order are supposed to exist. A social representation can exist as a body of knowledge, but it can also exist as a social practice or custom that has no other existence than in the repeated actions of the members of the social group. The problem of how similarity of repetitions without a cognitive schema is accomplished is not easy to solve. Even successive imitation would require short-term memory. As Greimas (1990, p. 13) puts the point: “All doing presupposes a knowing-how-to-do . . . Thus, to discourse, which is a manifestation of a doing, there corresponds the subject of discourse [not what it is about but who produces it], a subject endowed with discursive competence.”

An important qualification of the ideas of social representations in Positioning Theory, and where it differs from Moscovici’s original Durkheimian concept, concerns the way that in many cases of public activities by a group of people, the totality of the knowledge required for the locally correct performance of an episode with positions properly distributed, the representation is distributed among the actors—some having this part, others having

other components of the total performance. The whole only comes into existence in the course of a symbolically mediated mass event. However, not everyone on the scene is positioned with the right or the duty to perform a certain element of the total action. Just think of the distributed social representation and the complex patterns of positioning among the singers, musicians, stage hands, and so on, in the performance of an opera.

However, in either case the repetition of discursive practices and the stability of storylines need to be accounted for. Social representations as bodies of knowledge shared among the members of a community have this stabilizing function. In Bamberg's previously quoted paper (2008), the paradox that takes the heart out of the Potter et al. attempt at a treatment of psychology without cognition is the use of the English language by these authors. They take for granted that there is a body of linguistic knowledge shared by their readers that enables their texts to be understood. Grammars and lexicons are shared and relatively permanent cognitive resources are necessary conditions for the possibility of their own discursive projects.

### **Positioning in Relation to Knowledge and Belief**

In the first section of this chapter, positioning analysis was used to amplify the depth of the analysis of the sources of particular social actions, in relation to the way rights and duties are assigned to the people engaged in a certain social episode. However, of equal importance is the way rights and duties are implicated in what we can know or believe. Rights and duties are also involved in how we deal with ignorance. In philosophical terms, we could call this phenomenon "epistemic positioning." There are important questions about how rights to know something are distributed and contested, how duties to remedy ignorance are imposed, and so on.

We start with the commonplace observation that people are praised and blamed for what they believe, know and don't know, forget, and are ignorant of. To take a prominent contemporary issue, journalists are often blamed for acquiring knowledge of the lives of prominent people in ways that we believe they should not have used. The evaluations expressed in such opinions tell us we are in moral territory. Once again, as in the management of social action, the key moral concepts are rights and duties. The research domain that opens up is the identification and study of the social and cognitive

processes by means of which rights and duties are distributed among people with respect to acquiring knowledge of certain matters, having beliefs about political and religious matters, being ignorant of the rules of proper behavior in this or that situation, and so on.

### ***Duties in Relation to Knowledge, Belief, and Ignorance***

Positioning processes with respect to ignorance and knowledge come to the fore most often in cases where people are held culpable for not remedying the one and for acquiring the other. People have a duty to acquaint themselves with the well-publicized dangers of swimming off certain beaches. The proper duties of paparazzi do not include the use of telescopic lenses to photograph famous people sunbathing. Turning to positioning with respect to belief there are two psychological phenomena in play here. There is belief as a disposition, and there is believing as an act. Are there certain beliefs that someone has a duty to hold? Is believing in something a duty that someone has to fulfill? Sometimes the positioning of a person or persons is content-targeted. For example, with respect to religious matters, people who are members of a certain faith or denomination are reminded forcefully of their duty to believe the tenets of that faith. In a more low-key way, a similar kind of duty seems to be implicit in science, where an experimental demonstration is not just supportive of a factual claim but engages the moral order of the scientific community. Whereas the experimenter has a duty to be competent and truthful, the onlooker has a duty to believe.

Sometimes the positioning is source-targeted. Van Woudenberg (2009, p. 50) cites examples of the positioning of doctors as having a duty to believe what their patients tell them. On the other hand, lay people are positioned as having a duty to believe what experts tell them. There are innumerable examples of such acts of positioning in discussions of what we should believe about global warming. The same holds in religious contexts. The congregation has a faith-relative duty to believe what the priest or mullah or shaman tells them.

Even a cursory survey of positionings with respect to belief reveals the presence of long-running and often acrimonious conflicts over how rights and duties are distributed. So far as I know, this matter has received very little attention from cultural and discursive psychologists.

Considering the demands of “duty to know” and its complementary demand, “duty to remedy ignorance,” there is rarely much conflict. Some of these duties are fixed in law, but some are supererogatory. The reprimand “You should have known (found out about) so and so” is commonplace in family circles and no doubt elsewhere. Again this looks like a likely area for systematic research.

The duty to acquire knowledge is a reflection of the duty to remedy ignorance. Thus what it is said that a person is ignorant of defines the dutiful task of remedy. Among the domains of knowledge where ignorance pre-positions someone with the duty to remedy the lack are social and legal rules. How far acquiring current etiquette is a matter for discussion, but learning the Highway Code in the United Kingdom and being able to display knowledge of it is a requirement for obtaining a driver’s license. The legal principle that ignorance is no excuse is routinely overruled in many cases—and here, again, is a field for positioning research. How is the positioning of someone as having a certain duty revised? In everyday life, there is much discussion of duties to acquire everyday arts in the context of some people calling on others as having the duty to perform minor technical jobs. For example, some people declare that everyone has a duty to learn how to restore a circuit breaker. Men are said to have a duty to be competent in baby care, and so on. The discursive practices by which these positioning acts are accomplished is another field for research. Positioning students as having a duty to learn as a fulfillment of a duty to know is the foundation of the grading system in a major discursive practice in educational institutions.

None of these positionings seem to attract serious controversy. There is a huge difference between the contestability and the accusations of irrationality between positionings in relation to these everyday practices and criticisms of fundamentalism and the making of hasty scientific claims—for example, in the case of cold fusion.

### ***Rights in Relation to Belief, Knowledge and Ignorance***

In the case of the right to believe, positioning practices serve to roughly distinguish liberal from authoritarian societies. This topic also introduces the idea of a mode of positioning that links rights to permissions. Positioned as having a right to something is more or less equivalent to being given permission to engage with it.

The promulgation of officially imposed epistemic positions opens a new dimension of positioning discourses. Everyone is positioned by the central positioning act, in contrast to most positing studies to date that are concerned with very local and ephemeral positionings. The authorities position everyone in an authoritarian religious society with the duty to believe the tenets of the established religion or political philosophy. The logic of the duty/right relation entails that there is no right to disbelieve.

In the absence of a right to disbelieve, the way is open for the punishment of those who do. In forced conversion, members of a community position themselves as having both the right and the duty to demand that others change their beliefs. There have been numerous studies of the psychological processes by which this apparently paradoxical transformation is accomplished. Spontaneous conversion is outside the domain of positioning processes. The Positioning Theory research question concerns the discursive processes by which someone becomes convinced of the moral basis of proselytizing.

Rights to know are severely restricted in most societies, sometimes more by law than by custom. In many cases, positioning claims by journalists eventually reach the courts, where the doctrine of the public good is used to override the rights of individuals to privacy. In Positioning Theory terms, this amounts to the denial of the existence of a position of the right to know everything about a person.

More complex psychologically are duties to remember in relation to rights to forget. One may be positioned as having a duty to forget a minor injury that one has suffered at the hands of someone else. However, rights to forget are more tendentious. For example, political activists dispute the implicit self-positionings that sustain the amnesias that occur in the historical recollections of whole nations on the grounds that we do not have the right to forget such evils as the Holocaust and the Killing Fields.

Finally, there are rights to ignorance. A physician may position a patient as having a right not to know his or her medical condition on the grounds that such knowledge might have a deleterious effect on the patient’s general health. Disputes do occur over this matter. A patient may demand to be told, regardless of how distressing the knowledge may prove to be. The doctor’s duty of care overrides the duty to inform the patient of his or her situation.

Many epistemic rights and duties were implicit until recent legislation in the form of information laws opened up rights that were not hitherto

recognized and codified those that were. This should prove a rich field for Positioning Theory research. What effect has the British Freedom of Information Act had on people's beliefs about their positions, and what storylines have been used to resist disclosures? These are questions of immediate public interest and are hardly touched on in formal research projects.

Research should enable social psychologists to catalogue some of the procedures by which epistemic positioning is accomplished. In particular, there is the question of the pre-positioning personal characteristics, histories of abilities that support positioning a person or persons as having duties and rights in respect of knowledge, belief, and ignorance. For example, one cannot be positioned as having a duty to disclose knowledge one does not have. One cannot have a right to knowledge that would be used to harm someone else. For example, information on how to make explosives and construct bombs ought not to be published on the Internet, on the Positioning Theory grounds that people do not have the right to know.

### Reflexivity of Positioning

Psychology is, in large part, a cluster of discursive practices. There are the activities of experimenters and their subjects as co-participants in the social events called "experiments." Results must be written up according to certain conventions, subject to meta-discursive activities of the peer review and so on. Positioning as a discursive practice is as much a part of the activities of those who practice psychology as a science as administering questionnaires and publishing articles and books. The practices of the sciences are embedded in long-standing conventions of the distribution of rights and duties among the participants. Even so apparently obvious a step as the inserting of a statistically analyzed table of results at the end of an article in a mainstream journal plays its part in pre-positioning the author as one with a right to be believed. Duties of care are presupposed everywhere.

### Future Perspectives

The place of Positioning Theory as a research program within the general field of cultural psychology is evident when we consider the importance of social representations of local moral orders in the management of specific cases as a discursive practice. The examples introduced above as illustrations of the power of positioning analyses are grounded in a background of common features to all the social

representations of moral orders implicit in the cases analyzed. These are roughly the features of a kind of generalized Judeo-Christian moral order from which local orders can be derived when we consider the overt formulation of a working body of shared knowledge as system of 'rules'. Many interesting contemporary examples of positioning discourses and their consequences in the lived storylines of participants arise within an implicit background of honor moralities. This matter deserves extended treatment, but it is worth noting briefly how different honor moralities are from the deontic and utilitarian moral systems usually studied by moral philosophers. Contemporary virtue morality comes closer in that issues of honor are often linked to local notions of virtue. This shows up very clearly in courtroom proceedings in murder trials where the victim is often a relative, regretfully often a sister or daughter of the accused. "She dishonored our family—therefore, we had a duty to kill her." The rights of the men of the family vis-à-vis honor are implicit in the law that the members of the community subscribe to (Harré, 1983, pp. 240–242).

Carl Ratner

**Abstract**

This chapter explains macro-cultural psychology as a psychological theory and discipline. It conceptualizes psychological phenomena as part of macro-cultural factors—social institutions, artifacts, and cultural concepts. Specifically, macro-cultural psychology explains how psychological phenomena originate in macro-cultural factors, embody their features, represent macro-cultural factors, solidify and sustain macro-cultural factors, and are objectified in them. The chapter presents examples of these points with regard to emotions, adolescence, mental illness, agency, sensory processes, and self-concept. Macro-cultural psychology is shown to be a coherent general psychological theory that encompasses biological processes and individual variations within macro-cultural cornerstones, in logically consistent ways. The theory draws on the pioneering work of Vygotsky, Luria, and Leontiev.

**Keywords:** macro-culture, interpersonal interactions, social structure, mental illness, agency, emotions, adolescence, Vygotsky, sensory processes

The central tenet of macro-cultural psychology is that psychological phenomena are elements, or parts, of macro-cultural factors. Macro-cultural factors are social institutions, artifacts, and cultural concepts. They are the broad, enduring cornerstones of social life. As such, macro-cultural factors are crucial to our survival and fulfillment. Human psychology is intrinsic to this scenario. Psychology evolved to plan and implement macro-cultural phenomena, thereby enhancing our survival and fulfillment. Psychology is the motivation, perception, emotions, self-concept, reasoning, and memory of cultural behavior that forms artifacts, concepts, and institutions. The discipline of macro-cultural psychology explores the cultural origins, locus, characteristics, and function of psychological phenomena. The term *macro-cultural psychology* may be traced to Bronfenbrenner's ecological model. He enumerates a set of social contexts

(levels, layers) from the micro, interpersonal level, to broader levels, some of which are indirectly experienced—such as children being affected by parents' working conditions, as these affect parents' interactions with children. The broadest level, which forms the framework of parameters for all the other narrower levels, is the macro-social structure:

[T]he complex of nested, interconnected systems is viewed as a manifestation of overarching patterns of ideology and organization of the social institutions common to a particular culture or subculture. Such generalized patterns are referred to as macrosystems, within a given society or social group, the structure and substance of micro-, meso-, and exosystems tend to be similar, as if they were constructed from the same master model.

(Bronfenbrenner, 1979, p. 8; Ratner, 1991, pp. 172–178)

The macro-level is the core of, and key to, all the layers and factors in a society. “Public policy is a part of the macro system determining the specific properties of exo-, meso-, and microsystems that occur at the level of everyday life and steer the course of behavior and development” (ibid., p. 9).

Cultural psychology was originally conceived as macro-cultural psychology. This emphasis was maintained by Moritz Lazarus and Heymann Steinthal in their journal *Zeitschrift für Völkerpsychologie und Sprachwissenschaft* [Journal of Cultural Psychology and Linguistics], which was inaugurated in 1860. It seems that the term *Völkerpsychologie* was coined by Wilhelm Humboldt at the turn of the nineteenth century (see also Diriwächter, 2011). It was continued by Wundt, who believed that macro-cultural factors are more conducive sites for psychological research and analysis than variable individual consciousness:

Speech, myths and customs constitute a series of closely related subjects which are of great importance to general psychology for the reason that the relatively permanent character of speech, myths, and customs renders it relatively easy to recognize clearly through them certain psychical processes, and to carry out through them certain psychological analyses. Such recognition of general processes and such analyses are much easier here than in the case of transient compounds of individual consciousness. (cited in Ferrari et al., 2010, p. 97)

Studying psychical processes in macro-cultural factors is also advantageous for understanding cultural components and features of psychology.

Macro-cultural psychology utilizes these understandings of psychology in culture and culture in psychology to conduct empirical research on the cultural psychology of individuals. The macro aspect of culture and cultural psychology was also emphasized by psychological anthropologists such as Shweder in the 1980s. However, it was displaced by more personal and interpersonal notions of culture. I have worked to expand the original macro emphasis of cultural psychologists. Vygotsky, Luria, and Leontiev developed the most interesting, original, thorough, and central principles of macro-cultural psychology. Vygotsky said, “Higher mental functions [are] the product of the historical development of humanity” (Vygotsky, 1998, p. 34, my emphasis).

Once we acknowledge the historical character of verbal thought, we must consider it subject to all

the premises of historical materialism, which are valid for any historical phenomenon in human society. It is only to be expected that on this level the development of behavior will be governed essentially by the general laws of the historical development of human society.

(Vygotsky 1986, pp. 94–95)

Likewise,

Already in primitive societies . . . the entire psychological makeup of individuals can be seen to depend directly on the development, the degree of development of the production forces, and on the structure of that social group to which the individual belongs . . . Both of these factors, whose intrinsic interdependence has been established by the theory of historical materialism, are the decisive factors of the whole psychology of primitive man.

(Vygotsky, 1994b, p. 176)

A.N. Leontiev (1977) further explains this perspective in his article “Activity and Consciousness” (available online: <http://www.marxists.org/archive/leontev/works/1977/leon1977.htm>) in his book *Problems of Dialectical Materialism*: “Despite all its diversity, all its special features, the activity [Tätigkeit] of the human individual is a system that obeys the system of relations of society. Outside these relations human activity does not exist. How it exists is determined by the forms and means of material and spiritual communication that are generated by the development of production and that cannot be realised except in the activity of specific individuals. It stands to reason that the activity of every individual depends on his place in society, on his conditions of life.” For instance, Leontiev speaks of “the objective contradictions of commodity production, which generates a contradiction between concrete and abstract labour and leads to the alienation of human activity” (ibid.).

Leontiev goes on to say that activity is fostered by social labor: “Historically, the appearance in activity of goal-oriented action processes was the result of the emergence of a society based on labour.” Activity is not a natural impulse of human beings that originates within the individual. Leontiev adds a historical note that “The method of scientific analysis of the generation and functioning of human consciousness – social and individual – was discovered by Marx.”

Of course, internal conscious activity is reciprocally the subjectivity that animates external activity. “the phenomena of consciousness constitute a *real*

element in the motion of activity” (ibid.) Therefore, both arise and function interdependently. The point is that internal subjectivity activity does not arise on its own (“first”) but only under the stimulus of external social activity. “Once we acknowledge the common structure of external, practical activity and internal, mental activity we can understand the exchange of elements that constantly takes place between them, we can understand that certain mental actions may become part of the structure of direct practical, material activity and, conversely, external-motor operations may serve the performance of mental action in the structure of purely cognitive activity” (ibid.).

Leontiev provides an important discussion of personal meanings in relation to social activity and collective representations. He acknowledges personal meanings as an idiosyncratic sense of the complex of experiences that comprise one’s personal life. “Whereas external sensuousness associates objective meanings with the reality of the objective world in the subject’s consciousness, the personal meaning associates them with the reality of his own life in this world, with its motivations. It is the personal meaning that gives human consciousness its partiality.” However, personal meanings about one’s own life are not free inventions. They interpret personal life in social terms, through social values and concepts. Individuals draw upon society in order to interpret the specificity of their personal lives: “In contrast to society the individual has no special language of his own with meanings that he has evolved himself. His comprehension of reality can take place only by means of the “ready-made” meanings he assimilates from without – the knowledge, concepts, and views he receives through intercourse, in the various forms of individual and mass communication. This is what makes it possible to introduce into his consciousness or even impose upon that consciousness distorted or fantastic notions and ideas, including those that have no basis in his real, practical life experience.” Social meanings are so powerful that they distort people’s lived experiences. This is obvious today as oppressed people routinely define their problems in terms of conservative social ideology that mystifies the sources and solutions of their lived problems. I have termed this the psychology of oppression (Ratner, 2011d).

Indeed, societies struggle to structure personal meanings so as to steer people toward a political position. Various political interests struggle mightily to capture people’s personal meanings to their side so

that people will interpret their personal experiences in ways that support the political position: “this transformation of personal meanings into adequate (or more adequate) objective meanings shows that this occurs in the context of the struggle for people’s consciousness that is waged in society.” This struggle is evident in American media stations.

Social structuring of personal meanings is not always successful and complete. Discrepancies erupt. “There is no disappearance (nor could there be) of the constantly proliferating discrepancy between personal meanings which carry the intentionality, the partiality of the subject’s consciousness, and the *objective meanings*, which though ‘indifferent’ to them *are the sole means by which personal meanings can be expressed*. This is why the internal movement of the developed system of the individual’s consciousness is full of dramatic moments. These moments are created by personal meanings that cannot “express themselves” in adequate objective meanings, meanings that have been deprived of their basis in life and therefore, sometimes agonisingly, discredit themselves in the consciousness of the subject” (ibid., my emphasis).

For instance, despite the active efforts of banks and right wing media to blame American individuals for the Great Recession that began in 2008 (by accusing them of borrowing credit that they could not afford), many people realize that they were often the victim of financial fraud on the part of financial institutions. However, these breakthroughs are few and far between.

Leontiev concludes this important article with a key statement that distinguishes macro cultural psychology from mainstream psychology: “although a scientific psychology must never lose sight of man’s inner world, the study of this inner world cannot be divorced from a study of his activity and does not constitute any special trend of scientific psychological investigation.”

This sentiment gives an entirely new meaning to psychological phenomena. They are rooted in historical forces such as government policy, wars, immigration, mode of production, technology, art, industrialization, nuclear family, religious beliefs. Psychological phenomena are subjective aspects of these cultural-historical phenomena; psychology is not a realm of its own, independent of these.

In an unpublished paper written in 1929, entitled “Concrete Psychology”—a term he took from the French Marxist philosopher-psychologist Georges Politzer—Vygotsky said, “We derive individual

functions from forms of collective life. Development proceeds not toward socialization, but toward *individualization* of social functions (transformation of social functions into psychological functions)” (Vygotsky, 1989, p. 61). I shall demonstrate that the original social forms that generate psychological functions are macro cultural factors.

Of course, history is made by people; however, when we speak of historical activity we refer to individuals acting, often social leaders and spokespeople (government officials, business leaders, leaders of community organizations), operating at the macro-cultural level to shape social policy and community opinion through cultural media such as legislation, news reports, magazine articles, and art forms. History does not refer to personal history or individuals expressing some personal inclination of their own.

A central tenet of macro-cultural psychology is that macro-cultural factors generate abstract and concrete features of psychology. Macro-cultural factors have abstract features that generate abstract features of psychology; and macro-cultural factors have concrete features that generate concrete features of psychology. Examples of abstract psychological features are: “people think, remember, have self-concepts, use language” and “people remember and think in symbols.” These are what mainstream psychologists generally study. They study memory, perception, emotions, language acquisition, and mental illness. They are rarely interested in concrete forms of these, such as an individualistic self, romantic love, contextual memory, ancient Greek sexuality, and Victorian maternal love. Even when mainstream psychologists do address culturally concrete forms of psychology, they typically misconstrue them as abstract, universal, natural forms.

Examples of abstract features of macro-cultural factors are: macro-cultural factors are socially organized and involve symbolic communication; macro-cultural factors involve positions of leadership; and schools are organized into different grades, and they measure students’ learning. These features are abstract because they are indefinite and lack any specific substance. The mere fact that cultural factors are socially organized leaves open what kind of organization it is. Similarly, grades could be determined and measured by various criteria. Similarly, the fact that society has positions of leadership is abstract because leadership could take many forms. We would expect that these abstract features of

macro-cultural factors generate the abstract features of psychology we just mentioned.

Examples of concrete features of macro-cultural factors are: leadership in society X is dominated by the feudal aristocracy, or learning is measured by paper-and-pencil tests of rote memory. We would expect these concrete features of macro-cultural factors to generate correspondingly concrete features of psychology.

Macro-cultural psychologists would trace “symbolic thinking” (in general) to abstract social interaction and communication. We would trace specific forms of symbolic thinking (e.g., deductive logic) to particular features of macro-cultural factors. For example, Goldman (1992, pp. 15, 17, 18, 83) examines the potential impact of the commodity form on consciousness by looking at advertising that transforms our meaning systems as well as our desires into commodities. Goldman examines the effects on consciousness of “the commodity-sign,” which is a commoditized kind of symbol, a sign that misrepresents products by associating them with false and irrelevant situations (e.g., cigarettes with nature, deodorant with popularity, cereal with a star athlete). The commodity-sign is a new kind of symbol that is specifically organized by Capital to serve its interest of stimulating sales and profit. Capitalism is built into the commodity-sign and into our meaning systems. This takes the form of building misrepresentation into the commodity-sign. Because humans think in symbols (an abstract characteristic of thinking), if symbols are commodified, then our concrete thinking is that we think in commodity-signs. Commodity-signs structure consciousness in concrete ways, such as accepting false associations and appearances as true, generating strong emotional desires for mundane products, stimulating impulsive action (consumerism), and defining human events (social popularity, good motherhood, happy children, love) in terms of consumer products. Improving (demystifying) consciousness therefore requires critiquing and altering the commodity-sign that mystifies consciousness.

If consciousness/agency is mystified by commodity-signs, then it can only be demystified by critiquing and altering commodity-signs. This requires a specific social analysis of the cultural mediational means that people use to understand things. Consciousness cannot demystify itself by an abstract cognitive act (e.g., “try to be more open to information”), which ignores the concrete capitalist

form that symbols have. Concrete cultural problems cannot be solved by abstract acts.

In this example, we see that abstract and concrete aspects of psychology stem from abstract and concrete aspects of macro-cultural factors. The abstract and concrete are interdependent and call for each other. When we examine abstract aspects of cultural factors and psychology, we are led to examine their concrete features that fill them out. Conversely, when we examine concrete aspects, we are led to identify abstractions. For example, when we examine why concrete commodity-signs affect consciousness, the answer lies in the abstraction that “thinking occurs in symbols.”

Macro-cultural psychology is a comprehensive theory that explains both abstract and concrete aspects of human psychology as resulting from and residing in macro-cultural factors. We dispute the contention that natural processes generate abstract features of psychology whereas only concrete features are generated by cultural factors; this would dichotomize psychology into two distinct and antithetical orders of reality with different mechanisms and processes.

Let us examine how abstract and concrete features of macro-cultural factors generate correspondingly abstract and concrete features of psychology.

### ***Macro-cultural Factors Generate Abstract Features of Psychology***

Burke and Ornstein (1995) explain that tools, cooperation, and communication in general—not any particular form of these—spurred general human advances in thinking rather than any particular kind of thinking. Hunting in groups requires “the ability to plan, communicate, and cooperate. These communicative abilities ... laid down the mental matrix necessary for thought and reason, language and culture” (p. 11).

To cut a tool demands a set of operations carried out in a specific order. The instructions for tool making might have been serial sounds specifying the sequence of physical manipulation necessary to make the tool. So it might be that the first noises accompanying the ‘grammar’ of sequential tool making might have also laid down the basics of the grammar of language, because grammar is based on sounds that only make sense (as do successful tool-making actions) if they are done in the correct sequence. The tool and the sentence would be one and the same thing. As the tools refined and

proliferated, so did the signs and sounds that described them and their manufacture.”

(p. 22)

Burke and Ornstein are speaking about “thought” and “grammar” in general, not the grammar of a particular language. The authors observe how food production changed human social organization and psychology. Food cultivation allowed a relatively great deal of food to be produced in a small area, compared with hunting and gathering, which required large areas. This allowed for larger populations to live in concentrated areas, allowing for communities. “Where it had once taken 15 square miles to support a hunter-gatherer, a settler now needed only three” (p. 38).

### **PRODUCING NATURE STIMULATES CONSCIOUSNESS, WILL, AGENCY, SELF**

In addition, cultivating food entailed artificially duplicating nature. Seeds or roots were collected and artificially planted, instead of growing naturally from plants. Nature was divided into elements (seeds, roots) and then duplicated by human action. This led to a stupendous breakthrough in consciousness. Consciousness came to represent nature and redesign it according to human purpose. According to this analysis, thinking was generated by rudimentary agricultural production. The artificial duplication of nature in production generated a corresponding artificial duplication of nature in thought. Economic production generated thought (pp. 39–40). This is why symbolic consciousness, expressed in artistic representations of things, developed during the rise of agriculture in the Neolithic Revolution 10,000 years ago (Ratner, 2006).

Of course, this development was dialectical, not linear. Rudimentary, accidental/spontaneous collecting and planting of a few seeds generated rudimentary representational thinking of seeds as representing plants. This advance of thinking led to more deliberate understanding of seeds and to more careful gathering and planting them. This stimulated more advanced thinking, and so on.

Humans’ reproducing nature led to another breakthrough in consciousness—namely, will or agency. In reproducing nature, humans made nature happen (made plants grow), and this expanded their agency and sense of self.

Social interaction that mediates responses to objects also provides the differentiation of individual from nature that is vital to forming a distinguishable self. Social mediation also generates the

cognitive mediation of behavior through planning, deliberating, and imagining. All of these activity-generated psychological functions and self then furthered the activity of reproducing nature.

Nature was no longer received as it stood. It was reorganized by humans. This marked the break of humans from natural existence. Tools greatly expanded humans' ability to rearrange nature. "Tools released the tool-users forever from the slow development of natural processes. Now tools could supplant biological evolution as the main source of change" (Burke & Ornstein, 1995, p. 10).<sup>1</sup> Paradoxically, the more humans could artificially reproduce the world according to their own needs, the more deeply they understood the world as it exists. The development of human subjectivity entailed a development of objectivity. Conversely, animals' natural existence, submerged in nature and following its cycles and dictates, results in limited, superficial consciousness of the world.

#### **SOCIAL COOPERATION/COORDINATION STIMULATES THOUGHT, WILL, AGENCY, PURPOSE**

Thinking was another psychological capacity that was fostered by social cooperation and communication. Social cooperation spurred communication that spurred symbolic meaning that spurred symbolic thinking. Let us examine each of these three steps.

1. Social cooperation requires precise communication about the social activity. This makes social interchange the object of communication; communication is a social act that involves sharing of information to further social coordination. This social act and social objective is what makes human language distinctive from animal utterances. Animal utterances are essentially automatic individual expressions of feeling. A fearful animal involuntarily shrieks. This individual expression may coincidentally alert other conspecific individuals to the danger, however, the shriek is not essentially a social act directed at other individuals for the purpose of engaging in a social activity that unities them. The absence of these social features distinguishes animal calls from human language.

2. Language needs to be precise, complex, organized, and symbolic about particular objects and social interchanges to pass specific information to other members. Linguistic symbols must contain information in symbolic form that can be

transported back and forth among interlocutors. The social interchange of information requires that it be encoded in a vessel of transportation. This is language. Animals that lack this social interchange of information never develop a linguistic system for encoding and transmitting it. Animal communication is primarily animated by one individual's reaction to an object—for example, a predator. In contrast, human language is primarily animated by social interchange—that is, the desire to share information with other humans to decide how to collectively deal with objects.

Human language is part of humans' social mediation of their reaction to objects. We do not react immediately and individually to things. We react to things by engaging in a social process. We utilize the collective strength of a social group as the basis of reacting. This involves sharing information about objects with which we are dealing before we act. Language serves this purpose of facilitating social mediation of our responses to objects. This is why language is primarily directed toward social interchange, it is not primarily a direct expression of an individual encounter with an object, as animal sounds are.

The social purpose of language is what stimulates it to be a symbolic vessel (representative) of information. The need for such a vessel is to convey information to others to mediate their reactions to nature, it is not to encode information for one's individual, immediate use. Mere encoding of objects is not the basis of symbols and language. It is the social transmission of information that is the basis of language that takes the form of encoding objects in symbols. Symbolization is a cognitive means to achieve a social end. Symbolization is a socially inspired, socially required, and socially informed cognitive process.

3. As many scholars have observed, social symbols that constitute language become the means of thought. Thought rests upon language, which rests upon social cooperation and coordination. Thought is thus a product of social activity. The social communicative basis of thought is reflected in the etymology of "conscious." It is derived from Latin *conscious*, meaning having joint or common knowledge with another person.

Because culture offers such enormous advantages over individual behavior governed by natural mechanisms, all psychological functions such as intentionality, will, self, agency, purpose, understanding, and interpretation developed primarily to effect social

activity. Psychological functions did not develop as individual functions to facilitate individual reactions to objects.

Will, purpose, and agency only exist where the actor can construct or produce behavior. This situation is characteristic of society. Society is humanly constructed; it is not natural. People have wide latitude in the kind of society they can construct. It can be cooperative or competitive, frugal or profligate (speculative), monogamous or polygamous, gender equal or unequal, autocratic or democratic, structured into classes or relatively egalitarian, militaristic or pacifistic, sexually permissive or sexually punitive, permissive child-rearing or strict child-rearing, education through apprenticeship or formal teaching in schools, religious or atheistic, state religion or secular state. This latitude of choice (which is not equivalent to free, capricious, or random choice) is fertile ground for developing will and purpose.

Animals that graze on naturally occurring grass do not, and cannot, construct/produce their conditions; they find them ready-made and are beholden to them. When grass is plentiful, the animal is well-fed; when grass is scarce the animal is hungry. The animal cannot do anything about its life conditions. It lacks will and purpose because it is a natural creature that passively endures its natural environment and is governed by automatic, involuntary, natural processes suitable to natural existence. Natural determinants of behavior are inversely related to agency, will, self, and purpose.

Burke and Ornstein are correct to identify rudimentary acts on nature (such as gathering and planting seeds) as contributing to the sense of producing and the capacity to produce. However, the opportunities for this kind of production were undoubtedly few and far between, given the independence of natural processes from man. Far more conducive to regular, sustained construction was social organization. That is why I theorize that social construction was the primary impetus to the human capacity to produce and to develop will and purpose.

#### **THE CULTURAL BASIS AND CHARACTER OF EMOTIONS**

Vygotsky emphasized that cultural factors and cultural operating mechanisms elevate and expand consciousness beyond animal consciousness. Human consciousness is more active and agentic because it has a cultural operating mechanism that deals with

complex, vast, dynamic cultural stimuli. Culture is the most complex, changeable, abstract, symbolized environment, and it requires complex, modulated, flexible, willful subjectivity to envision, maintain, and process these features of culture.

For example, when students are anxious about an impending test, the students' anxiety is based on an understanding of the educational system's rule that test scores are indicators of intelligence and that future opportunities in education and work depend on high test scores. Test anxiety is thus based on understanding of social systems and future possibilities: "There's a good chance that the admissions committee of Harvard would like my GPA four years from now."

Emotions cannot be based on a simple, immediate, animalistic sensitivity to physical colors and odors. Such simple, natural, animalistic processes are designed to deal with relatively simple, circumscribed, stable, overt, physical stimuli. As such, they cannot rise to the level of macro-cultural emotions we have been describing. A fundamentally new and different kind of emotionology and operating mechanism must exist for emotions to be appropriate to complex, variable, symbolic cultural environments and factors.

To love a country is not simply a matter of associating an animalistic emotion of pleasure to "country." Loving a country requires a different kind of love than an animal is capable of experiencing. Loving a country is loving a general abstraction that has no physical sensory attributes. With human emotion, it is not simply the object that is different from animal stimuli; the quality of love that relates to this different kind of object is also different from what animals experience. The form or quality of love adjusts to the form and quality of the object being loved. If the object of love is a massive abstraction like Russia, the love for that object is abstract. Macro-cultural factors generate distinctive psychological attributes that are geared to the macro-cultural level.

These macro attributes of psychology extend to micro level stimuli and to natural stimuli such as physical sounds, smells, and colors. For example, we become afraid of an animal in the woods because we utilize the macro-properties of emotions that originated on the macro-level to deal with macro-cultural factors. We become afraid of the bear because we recognize it to be "a bear," not simply a form of a certain size, color, and odor. The physical features trigger conceptual knowledge and

this is the basis of our emotion. Physical features do not directly generate our emotions. They are mediated by cultural knowledge of the physical features.

We utilize our conceptual knowledge of bears to construe it as dangerous. We do not simply become afraid because of its size or gestures. If we didn't believe it to be dangerous, or if we had a gun with which we could kill it if necessary, then we would not fear the bear. Our emotion depends on abstract, conceptual cultural knowledge about things ("bears are dangerous," "this gun will kill the bear"), which is required by cultural life. Animal fear is not generated by this process or operating mechanism. It is a different kind of fear from what humans experience.

The emotions we employ in face-to-face interactions similarly originate at the macro-level. Anger and guilt are based on ethical and legal values of macro-culture. If Jill injures John by mistake, then John would typically understand this and not become angry. But if Jill deliberately injures him, then he legitimately becomes incensed. The reason is that anger is triggered by the ethical and legal principle that deliberate, willful injury is wrong. Western legal principle distinguishes between willful and accidental injury, condones different responses to them, and dispenses different punishments for them. Anger is a legally sanctioned reaction to deliberate harm but not to accidental or incidental injury. (If John did become angry at an unintentional injury, this would be a sign that he lacked the social competence to assess whether a particular injury to him was intentionally or unintentionally caused by Jill—which is the cultural-legal criterion for experiencing anger). Research shows that cultures devoid of the concept of personal responsibility experience little anger. Injury is attributed to fate or accident, and it generates frustration and annoyance but not anger at a person (Ratner, 1991, pp. 77–78; 2006, pp. 106–107).

Interpersonal guilt similarly rests upon a cultural-legal criterion that one is directly responsible for an injury. If someone feels guilty after unintentionally inflicting harm, then other people will console her by saying, "Don't feel guilty, it wasn't your fault, you couldn't have helped it." They help alter her emotion of guilt by explaining that the social basis for it—namely, personal responsibility—did not exist. This revised social understanding of her action lessens her emotional feeling of guilt.

## **THE DARWINIAN BASIS OF MACRO-CULTURAL PSYCHOLOGY**

My argument for macro-cultural psychology is Darwinian—new environments require new behavioral mechanisms and anatomical features. When psychologists attempt to reduce human psychology to animal mechanisms, they are violating this Darwinian principle. They postulate similar behavioral mechanisms in radically distinct environments. They are ignoring the fact that the human cultural environment is qualitatively different from animal physical environments and therefore requires distinctive behavioral mechanisms and anatomical features.

Gordon explained the distinctive, emergent macro-cultural character of psychology with respect to emotions:

Social life produces emergent dimensions of emotion that resist reduction to properties inherent in the human organism . . . Socially emergent dimensions of emotion transcend psychological and physiological levels of analysis in terms of (1) origin, (2) temporal framework, (3) structure, and (4) change.

(Gordon, 1981, p. 562)

## **PSYCHOLOGICAL PHENOMENA MAINTAIN/SOLIDIFY CULTURE**

Returning to our macro-cultural psychological analysis of test anxiety in school, we observe that it not only reflects an understanding of the educational system—it reciprocally reinforces the system. It motivates students to adhere to the system's requirements to study material that social authorities mandate. This is an important way in which psychology is cultural. It can only direct individuals to culturally appropriate behavior if it is infused with cultural content. Anxiety must be generated by a culturally formed concern for test scores if it is to direct students to learn material that is on tests.

Intelligence is similarly socially defined by test scores so that it motivates students to study test material to demonstrate their intelligence.

## **PSYCHOLOGICAL PHENOMENA ARE SOCIALLY SHARED AND DISTRIBUTED**

Because culturally formed emotions (and other psychological processes) sustain social systems, they must be socially shared among masses of people to generate mass participation in the culture. If culturally formed psychological processes were limited to a few individuals, or if they were shot through with

idiosyncratic meanings, then they would lose their ability to promote culturally appropriate action necessary to sustain the social system.

Although each person's experience of emotion has idiosyncratic features, culture shapes the occasion, meaning, and expression of affective experience. Love, pity, indignation, and other sentiments are socially shared patterns of feeling, gesture, and meaning.

(Gordon, 1981, p. 563)

Oyserman and Markus (1998, pp. 123, 109, 107) explain why this must be true.

Although individuals are highly active in the process of self-making, the materials available for writing one's own story are a function of our public and shared notions of personhood. American accounts of the self, for example, involve a set of culture-confirming ideas and images of success, competence, ability, and the need to "feel good." The public representations of selfhood that characterize a given sociocultural niche function as common denominators—they provide the primary structure of the selves of those who live within these contexts. These shared ideas produce necessary, although often unseen, commonalities in the selves of people within a given context. Although making a self appears to be an individual and individualizing pursuit, it is also a collective and collectivizing one. From a societal perspective, self-construction is too important to be left as a personal project. Social integration and the social order require that individuals of a given group have reasonably similar answers to the "who am I" and "where do I belong" questions.

These remarks apply equally to all psychological phenomena. From a societal perspective, motivation, emotions, perception, reasoning, and memory are too important to be left as personal projects. They must all be congruent with macro-factors to ensure the endurance of these factors.

The social sharing of psychology is qualified by the heterogeneity of cultural factors. Cultural factors are neither homogeneous singly or collectively. Any one factor is heterogeneous, and there are differences among them as well. This heterogeneity of macro-cultural factors introduces heterogeneity into psychology as well.

Education, for example, is only functional for a select strata of the population for whom intellectual competencies are required. For the masses of people for whom intellectual competencies are not

demand, educational success is not useful. Society does not encourage them to acquire the educational psychology of worrying about tests and studying hard to pass them. Of course, official propaganda proclaims that all students should try as hard as they can to score well. But this is pure rhetoric that pretends that the social system is open to all applicants. In fact, it is not, and it has no room to accommodate the masses of people who would ideally like to go on for higher education and high-skilled jobs. Consequently, the social system implicitly discourages masses of students from acquiring the cultural psychology that would animate their demands for higher education and high-skilled jobs.<sup>2</sup>

Of course, educators do not acknowledge their role in discouraging (cooling-out) students from studying hard and experiencing test anxiety. They pretend that this failure is the students' own disinterest, rather than the system's. This is a classic case of blaming the victim. Macro-cultural psychology corrects this distortion by exposing the cultural basis of the psychology of people who are frozen out of the upper levels of the social hierarchy.

### ***Macro-cultural Factors Generate Concrete Features of Psychology***

Macro-cultural factors generate concrete features of psychology just as they generate abstract psychological features. This is a Darwinian argument. Darwin's environmentalism was specific regarding physical features such as particular kinds of food and predators with specific characteristics that selected for specific anatomical traits of species. Social environments of humans are equally specific, and their characteristics must be enumerated to understand particular psychological characteristics. To remain tied to cultural abstractions would be as inadequate as if Darwin had referred to environments as "composed of living matter" without enumerating specific forms and features.

Situating psychological phenomena in macro-cultural factors enables us to transition easily from abstract features to concrete ones, for both are present in the same locus of macro-cultural factors. This avoids the common problem of remaining stuck in abstractions and ignoring concrete culture and concrete psychology.

In our case of emotions, our analysis of abstract features of macro-cultural factors leads to asking additional questions about their concrete features that foster concrete aspects of emotions. We can move from abstractions about success in school

affecting future social positions and therefore generating text anxiety to inquiring into the competitive structure of grades and future educational and occupational opportunities and the differential rewards that accrue to them, which place great pressure on test scores and augment test anxiety for those students striving for the opportunities. We can inquire into a school's specific policies, requirements, pedagogy, differential treatment of students of different classes and gender, budget, quality of physical infrastructure, bureaucracy, and decision-making process.

### EMOTIONAL REGULATION

Historian Peter Stearns (1989) describes concrete historical aspects of emotions. He talks about three styles of emotional control—during the American colonial era, Victorian era, and late twentieth century. These are broadly shared cultural patterns of emotional regulation that were instigated by social leaders to facilitate new macro-cultural factors. For example, as the modern capitalistic system uprooted community structures and their corresponding religious values, the family unity and individual privacy were emphasized, and they combined to push for the creation of internalized emotional standards that would not depend on outsiders' judgment or enforcement (pp. 236, 248). The twentieth century push for new emotionology was spearheaded by leaders of the Protestant middle class in the United States who were social pioneers of new macro-cultural factors. The new, internally regulated emotionology was also spearheaded by American industrial psychologists and other personnel authorities in the 1920s, who launched a new effort to limit anger expressed in the workplace and to develop appropriate mechanisms to accomplish this end ... Secretarial training also shifted toward insistence on firm emotional control. Foremen were taught that anger control was a key part of their jobs, and by the 1940s, an array of retraining programs attempted to inculcate the lesson that smooth human relations constituted an end in itself, not a random, personal uprising. To achieve the new goals of anger control, a series of strategies were devised ... They involved a ventilationist tactic when anger boiled up: Have an aggrieved worker repeat his angry complaint several times, so that the emotion would wear off and be replaced, hopefully, by an embarrassed willingness to drop the whole affair (p. 243).

Workplace anger drew attention after a period of rising labor unrest; suppression had obvious

social control functions [to subordinate workers to capitalists] ... Middle class personnel specialists like Frederick Taylor and Elton Mayo were truly appalled by the amount of open anger they found among workers. They therefore amended their own original agendas to build in explicit attempts to banish anger from the workplace (pp. 248–249).

These macro-cultural requirements, features, and functions of emotional regulation were then incorporated into family emotionology by the 1940s. Parents were urged by specialists and authors to employ ventilationist techniques with their children. "Let children talk it out, label it, but in the process defuse the whole emotion. Gone was the idea that anger could be disciplined but channeled" (p. 243).

Stearns' description reveals that emotional regulation was a social issue; it was publicly discussed and organized by social leaders of macro-cultural factors to facilitate those factors. It was not a spontaneous, personal expression; it did not originate in the interpersonal domain of the family. It occurred at a particular historical time for historical reasons. It was a necessary subjectivity for particular cultural-historical activities.

By the 1930s and 1940s, alterations in business climate that stressed bureaucratic or sales skills over entrepreneurship placed a growing premium on the kind of emotional control that could assure smooth personal relationships outside (as well, at least ideally, within) the home (p. 251).

This research on the style of emotional regulation demonstrates that, as Vygotsky and Luria said, the form and mechanisms of psychological phenomena are historically shaped as much as the content is.

### CONCRETE CULTURAL FEATURES OF EMOTIONS: MOTHER LOVE

The cultural-historical organization of the content of maternal love is a fascinating example of macro-cultural psychology. Lewis (1989, p. 210) explains that the idealization of mother's love (in the United States) was brewed in the same cauldron as Revolutionary political thought ... The Revolutionary brew was seasoned by a variety of ingredients—republicanism, liberalism, evangelical Protestantism, and sensationalist psychology, and just as each of these strands of thought would contribute to political thought, so too would they affect the conceptualization of family roles. The late-eighteenth century revolt against patriarchy

dethroned both fathers and kings; and it said that citizens in a society, like members of a family, should be bound together by affection rather than duty. The Revolution . . . made of affection a political virtue. This is a pregnant statement because it shows how psychology is brewed in cultural-historical-political factors and also supports them, thus being a political phenomenon. Affection was additionally political in that it tended to appreciate women's gender role, which emphasized affection. Valuing a psychological element that is organized by a social role validates the social role.

The cultural-historical organization of mother's love was a cultural prop for the entire social structure that included separate gender spheres. "The 19<sup>th</sup> century's description of woman's nature and role derived from seemingly incontrovertible assumptions about the nature of a mother's love" (Lewis, 1989, p. 209). Psychology is thus a cultural linchpin. Psychology is a subjective cultural factor or the subjective side of cultural factors.

Plant (2010) deepens this description of the cultural-historical nature of maternal love. She explains how it dramatically changed—not simply that it changed—over the first half of the twentieth century in the United States. She demonstrates that this psychological change was necessary to the development of capitalism and how capitalism worked to adapt maternal love to its changing practices. Her book traces the repudiation of (nineteenth century, Victorian) moral motherhood and the rise of a new maternal ideal that both reflected and facilitated White, middle-class women's gradual incorporation into the political and economic order as individuals rather than as wives and mothers. It argues that the interwar period witnessed the emergence of an antimaternalist critique that ultimately helped to discredit four long-standing precepts that had defined late Victorian motherhood: the belief that the mother/homemaker role was a full-time, life-long role, incompatible with the demands of wage earning; the notion that motherhood was not simply a private, familial role, but also the foundation of female citizenship; the conviction that mothers should bind their children (especially their boys) to the home with "silver cords" of love to ensure their proper moral development; and the assumption that motherhood involved immense physical suffering and self-sacrifice. Of course, such ideas have not entirely lost currency in American culture today. In the early twentieth century, however, most middle-class Americans shared a conception of motherhood

based on these principles; by the 1960s, most did not. Instead, motherhood came to be conceived as a deeply fulfilling but fundamentally private experience and a single (thought central) component of a more multifaceted self (pp. 2–3).

Plant's statement reveals how the psychology of motherhood is vital to a social order of family relations, work, and politics. Traditional motherhood, and maternal love, anchored an entire social order in Victorian times. Traditional psychology of motherhood and maternal love ensconced women in the home, away from work and politics, and it tied their children to them and to restrictive moral codes. This is a crucial point about the cultural function of psychology. The sentiment that maternal love is the purest and deepest sacrifice known to mankind is not a simple, natural, circumscribed emotion; it is fraught with political origins and repercussions. It implies that women have no other social function beyond raising children. Women are to sacrifice themselves for the good of the country to rear model citizens. The notion that maternal love was sentimental also objectified psychologically women's exclusion from the masculine realm of calculated rationality. The notion that mothers were pure and were the watchdogs of moral purity similarly reflected and reinforced their exclusion from the materialistic, political, commercial "impure," "immoral" world. Every psychological element of Victorian maternal love compounded middle class women's domestic role and their exclusion from public positions of political and economic power.

Culture is objectified in psychological attributes just as psychology is objectified in cultural artifacts, concepts, and institutions. Culture is objectified in psychological attributes because these attributes are designed to accomplish cultural purposes.

Because psychology is a cultural linchpin, a new modern form of motherhood and maternal love was necessary for anchoring and facilitating a new social order in which women worked and purchased products outside the home, and in which children had to be free to cope with demands of free market jobs, consumerism, and politics. Traditional psychology of motherhood had to be undone if mothers and children were to participate in the burgeoning consumer capitalism. Attacking or defending it is a political act that has political repercussions (*see* Susman, 1979, for similar cultural changes in personality).

Traditional motherhood-maternal love was undone by the social demands of consumer

capitalism and also by its spokespeople, who explicitly attacked it and urged more consumer capitalist-friendly forms. “The demystification of mother love should be seen as part of a much broader transformation of gender ideology and sexual relations” (p. 8). “The sheer pervasiveness of consumer culture, its increasingly blatant commercialization . . . led many to view . . . sentimentalism in increasingly alarmist terms” (p. 43). Sentimentalism was an obstacle to the expansion of the materialistic, commercialized free market.

The most severe critics of American motherhood were not conservatives but liberals (p. 5). “Initially, the attacks on American motherhood emanated primarily from psychological professionals and the cultural avant-garde. By the 1940s, however, anti-maternalism had gone mainstream” (p. 8). In addition, the Office of War Information began urging cultural producers (of media) to support its Woman power campaign which sought to draw women into the workforce (p. 41). As a result of all this, “The New Woman who demanded a career, the vote, and even sexual satisfaction directly challenged accepted notions of female nature” (p. 9).

Between World War I and World War II, momism was attacked as emasculating the nation, rather than upholding its moral fiber. Sentimental maternal love was denounced as unnatural and unhealthy for mother and child. Motherhood was shifted to a private relationship between individuals rather than a cultural duty. This accorded with the expansion of the individualistic free market and consumerism. The doting mother was chastised as interfering with the individual development of children. Maternal attachment was rejected as narcissistic; it should be controlled and displaced by a love that encouraged children’s independence and emotional separation (p. 88). New emotional norms (feeling rules) were promulgated. “Wherever young couples looked—in popular magazines, Hollywood films, or professional literature—they found their desires for autonomy validated and their ambivalence and antagonism toward their parents, especially their mothers, legitimized” (p. 109). Maternal morality was condemned as restrictive of individual’s freedom—as it was on the economic marketplace. “Experts in the 1940s and 1950s repeatedly condemned ‘self-sacrificing’ mothers who concentrated all of their energies on their children” (p. 115). Mothers were urged to diversify their energies and activities as they participated in the economy and politics. Abandoning maternal self-sacrifice was

tantamount to abandoning the Victorian middle class gender role! “The decline of the iconic mother [and sentimental maternal love] reflected a fundamental transformation of the gendered structure of American political culture” (p. 56). The mother was redefined as just another individual rather than possessing distinctive capabilities outside the hustle and bustle of commercial society. “No longer a sacred calling and duty, motherhood and homemaking came to be construed as an emotionally fulfilling ‘job’—one that would ultimately end” (p. 116).

A fascinating corollary to the change in women’s maternal role and psychology of love was the change in the conception and experience of childbirth. The traditional Victorian conception and experience was one of intense, irremediable pain and suffering. This incarnated and expressed (and reinforced) the feminine social psychology of frailty, sacrifice, pitiable, and in need of condolence and protection. Women were supposed to be sickly in daily life and in childbirth. A pale complexion was regarded as beautiful because it objectified this social psychology.

“By the late 1930s, a growing number of obstetricians, writers, and mothers themselves had begun to challenge this view of childbirth by depicting it as a wholly normal and natural event” (p. 119). The new dictum was that pregnancy should be as normal for a woman as wage-earning is. “The normalization of childbirth in the 1940s and 1950s helped to fuel, but was also fueled by, the broad cultural shifts this book has traced” (p. 119). This is a keen statement of the dialectical role that psychology plays in culture. “For motherhood to be truly modernized, with the emphasis shifted from self-sacrifice toward self-realization, childbirth itself had to be transformed from a dangerous and dreaded ordeal into an exhilarating experience” (p. 120). Even the term for childbirth—labor—lost its earlier meaning of travail (pain, strenuous, self-sacrificing effort) and became a nondescript term. The association of frailty with middle class status changed to sensuous experience representing middle class status for women (pp. 121–122). Culture was objectified in new psychological attributes that functioned to maintain that culture.

As childbirth was reconceptualized away from suffering and sacrifice, and in need of chivalrous male protection, it came to be regarded as enjoyable and normal for the individual mother. And most interesting is that this reconceptualization of childbirth (in line with new social roles) led to a real change in the experience of childbirth. Childbirth

was experienced as less painful than before. Of course, it was physically uncomfortable; however, as cognitive theories of emotion explain, the discomfort was modulated by the sense of individual prowess and agency and physical satisfaction of the mother—just as athletes minimize discomfort of injury as they concentrate on the importance of the game. Childbirth was no longer regarded as a complicated, sacrificial, mystical experience. This altered the sensation of childbirth. Middle-class mothers endorsed the normal easy childbirth associated with peasant women who were known to resume work immediately after birth. The French obstetrician Fernand Lamaze popularized the sense of natural childbirth.

Now the woman who suffered least—who thrived during pregnancy and experienced little if any pain during childbirth and its aftermath—came to be deemed most worthy of that increasingly coveted adjective, “feminine.”

(p. 145)

Plant’s analysis reveals that maternal love was a product of historical forces, as Vygotsky stated. Modern maternal love was fostered by modern capitalist social institutions in combination with cultural concepts that were articulated by social leaders (experts, professionals, government policies, business and community leaders). Changing opportunities and requirements of social institutions generated a sense of new maternal love among the middle class that was articulated by social leaders.

This pincer movement was exemplified in the writing of Betty Friedan in *The Feminine Mystique* (1963). “By giving voice to the inchoate frustrations of countless middle-class women, Friedan helped to spark the feminist movement of the 1960s and 1970s” (p. 147). In other words, the institutional pressures such as economic needs for women to work and consume products generated popular inchoate frustrations and desires for a new social psychology including maternal love. Friedan articulated these and congealed them into an outlook and a cultural psychology. Women embraced this perspective and utilized it as their “mediational means” for dealing with contemporary events and relationships and their own self-concept.<sup>3</sup>

This kind of macro-cultural psychological analysis illuminates the cultural origins of psychology, and it importantly illuminates the cultural limits to psychology—for example, in consumer capitalism or Victorian domesticity. It enables us to evaluate

the liberatory potential of psychology/behavior so that we do not idealize psychology/behavior as more transcendent of society than it actually is. We apply a macro-cultural psychological critique to the psychology of people as well as to psychological doctrines that articulate this psychology.

The macro-cultural psychology of maternal love can be summarized in the following principles of macro-cultural psychology (a full list of the principles will be compiled after additional examples):

1. Abstract aspects of maternal love are rooted in macro-cultural factors such as social institutions and cultural concepts. Maternal love for children is a cultural phenomenon just as love for a country is, or just as fear of failing a school test is. Mother love involves concern for the child as a social being, with moral character, appropriate social skills for succeeding in society, even an attractive physique and health. Mother love includes a view of the child’s future and preparing her for it. All of these aspects of maternal love involve conscious thought, planning, reason. Maternal love is not natural; it is not analogous to a mother dog nuzzling her puppies, whose protective sense involves none of these concerns, mental processes, and activities.

2. The abstract aspects of maternal love are concretized by concrete aspects of macro-cultural factors. The cultural psychology of maternal love is necessary to a social system. It generates socially appropriate behavior. Psychology is an active element of society; it is not a passive byproduct. Maternal love generated social relations.

3. A social system strives to organize a culturally appropriate form of maternal love to sustain itself. Failure to organize this kind of sentiment would undermine the social system. New social opportunities and requirements for new skills generate the incentive for new psychological competencies in parents and children. In addition, spokesmen of the society explicitly attack traditional cultural forms of maternal love to discredit them and move people to adopt new cultural forms. These exhortations fall on receptive ears because people felt the need for new competencies from changing opportunities and requirements of macro-cultural factors.

4. Within the social structure that organizes the concrete psychology of maternal love, the dominant cultural factor is the political economy. The capitalist political economy is commodity production. Commoditization and commercialization were dominant influences on Western maternal love.

5. Maternal love is a complex of cultural-psychological elements that share common features while being distinct. The complex is a unity of differences, as Hegel said. Each feature contributes its distinctive character to the complex. Each feature also expresses/represents/refracts the entire complex of motherhood through its own distinctive position. For example, Victorian, middle-class childbirth possessed the distinctive psychology of suffering that crystallized other aspects—sentimental, dutiful, frail, accepting, needy—and added to them.

6. Psychology (e.g., maternal love) is formed on the macro-cultural level for macro-cultural purposes, it is objectified in macro-cultural factors, it objectifies culture, it supports culture, it is socialized by macro-cultural factors, it represents a social position within society, it represents membership within society, and it gains access to social positions.

The manner in which maternal love incarnates, and expresses macro-cultural factors may be depicted as in Figure 10.1.

7. Maternal love was not formed as a personal invention to express personal desires. On the contrary, the personal desire and quality of maternal love was fostered by macro-cultural factors.

8. Personal variations in the quality of maternal love are internal to the culturally circumscribed parameters. They must not violate these

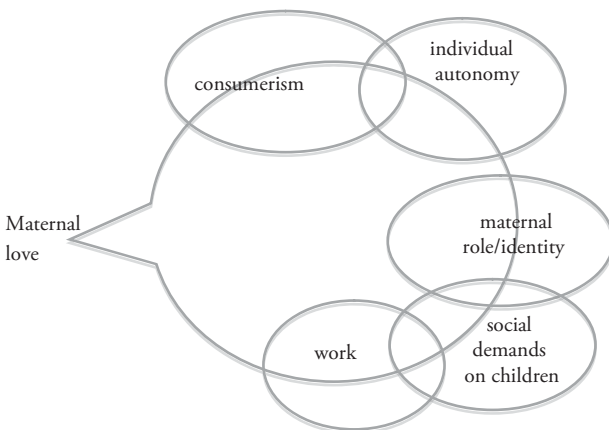

parameters or the cultural quality of maternal love will be subverted, and this would undermine the social structure that requires an appropriate maternal love to generate appropriate social behavior.

9. Psychological phenomena such as sensations of childbirth depend on cultural concepts. They are higher social mental functions, as Vygotsky said. The pain of childbirth incarnated, crystallized, and objectified the social psychology (role) of motherhood in sensory experience. The feeling state is only apprehended through a cultural-hermeneutical analysis that elucidates the social psychology (role) that it expresses.

We are concerned to demonstrate that macro-cultural psychology is a general psychological theory that explains all psychological phenomena. The example of maternal love represents how all psychological phenomena originate in macro-cultural factors, embody these factors, are objectified in them, objectify/represent them, and also sustain macro-cultural factors. To demonstrate the general applicability of macro-cultural psychology, it will be helpful to present a few additional examples of psychological phenomena.

#### ADOLESCENCE

Condon (1987, pp. 7–8) explains how changes in technology and social institutions among the Inuit Eskimos fostered adolescence and adolescent psychology. In traditional times, before Euro-Canadian

**Figure 10.1** Cultural Constitution (Determinations) of Maternal Love

contact, the transition from childhood to adulthood was rapid and unaccompanied by a prolonged period of adolescence. The harsh arctic climate and scarcity of resources forced children to quickly acquire adult skills for survival. They did so in the isolated nuclear family, which was dispersed over a wide area with little interfamilial contact. Interactions with parents far outweighed in importance interactions with peers. This complex of factors precluded an adolescent social and psychological stage in between childhood and adulthood.

In the modern period, interlocking technological and institutional changes have dramatically changed the progression of Inuit life stages. Increased economic prosperity and security allow parents to earn a living without the contribution of their children. This allows children to attend school rather than work. In addition, the population is concentrated into settlements, which enables children to form a peer culture. This peer culture adopted many of the styles portrayed on television, which became affordable with the new standard of living. These interlocking factors place children in a separate social position from their parents, which was impossible earlier. They contribute to the elaboration of a stage of life now referred to as the “teenage” years.

This description reveals how adolescence was formed by interrelated changes in institutions, artifacts, and physical demography of the population. Adolescence is a social role, a social stage of life, a social space, and a social psychology. It does not originate inside individuals from intra-organismic processes—whether natural or personal. Adolescence is a complex cultural phenomenon that includes social positions, social organization, technology, and psychology. The psychological element is part of the macro-cultural complex. It is qualitatively distinguishable from concentrated population settlements, economic prosperity, and attending school, and it can be studied as a distinctive element and promoted as such. We can reasonably talk about the psychology of adolescence and understand the subjective experience as such; it is not eliminable or reducible to the other cultural elements. In fact, we must talk about it to have a complete picture of adolescence. However, it is always an element of the macro-cultural complex on which it depends (originates), which it expresses, represents, embodies, and supports. The subjectivity of adolescence cannot exist without the objective conditions. Psychological dispositions would be impossible without the social

position, as Bourdieu emphasizes. It is the macro-cultural complex that drives adolescence, creates the space for it, fosters it, demands it, is its telos, and forms its attributes.

#### SELF

The modern Western self is a historical product that was spawned by economic changes in England during the sixteenth and seventeenth centuries. These changes entailed activities that increased the reliance on personal judgment, initiative, and responsibility. Businessmen made business decisions on their own to maximize their own profit. They did not follow traditional community business practices, consult with community members, or act for the benefit of the community. An individualistic self was therefore built into the economic changes.

The culture of modern individualism emerged most prominently and pervasively in England in the century leading to the English Revolution. It began with the rise of a Puritan opposition in the 1560s . . . Its constituents were the product of profound changes in the English economy. During that century, the privatization of agricultural holdings and the emergence of a national market had stimulated widespread commercialization with incentives for specialized production, technological improvements, and a consolidation of holdings. The increasing role of individual initiative, business acumen, and responsibility for success in this new market economy generated a rising group of enterprising rural gentry, yeomen, and artisans . . . The dependence of fortune on an individual’s own actions increased the reliance on personal judgment and initiative (Block, cited in Ratner, 2006a, pp. 82–83; cf. Ratner, 2002, pp. 41–42).

This description highlights the continuity between macro-culture and psychology. The economic revolution consisted of economic privatization that entailed and necessitated individual initiative and responsibility. The individual self was an integral part of the capitalist economic revolution. Capitalist business required an individualistic self that took individual initiative and responsibility for actions. Capitalism and individualism went hand-in-hand: macro-culture and psychology. They were two sides of the same coin; they were continuous with each other, on the same plane, indispensable for each other.

Within this spiral, capitalist development was the leading element. This is what businessmen

sought to achieve. Individualistic self was the subjectivity necessary to implement capitalism. The self was functional for capitalism; it did not arise on its own, in a vacuum. Businessmen did not one day just decide to develop a new form of self. They did so to realize a socio-economic objective. Incipient capitalist development was the stimulus and *telos* of the individualistic self. It also provided the constituents of the self, its concrete qualities. (The individualistic self is not an abstraction, as cross-cultural psychologists construe it Ratner, 2012c.) Reciprocally, the individualistic self provided the subjectivity to develop capitalist businesses. For subjectivity (e.g., the self) to implement capitalist business practices, it had to adjust itself to them and take their form. The dialectical opposite of consciousness's forming capitalism is that it conformed to the needs of capitalism.

These points are true for all psychological phenomena. Psychology evolved as the behavioral mechanism for constructing and maintaining macro-cultural factors. Culture was the stimulus and *telos* of psychology, and both the general and specific properties of culture provided the constituents of psychological phenomena.

#### AGENCY

Because cultural issues underlie psychology and behavior, agency is actually social agency. One's ability to affect one's own behavior and that of others is socially determined by the institutional structure of society. This structure mediates agency and augments or restricts it. Agency is formed by and in macro-cultural factors; it is not an attribute of an individual who freely exercises it. This must be true for agency to engage in culturally appropriate behavior, which is necessary for cultural maintenance. This point is demonstrated by considering the agency of a corporate manager and an employee in a capitalist firm.

The manager has enormous power to realize her goals and to affect her employees and the community at large. This power stems from the institutional structure of the corporation and its relation to other institutions. The manager has the power to summarily terminate the employment of her employees. They, in turn, must obediently leave the premises when she orders them to. If they do not, the police will forcibly remove them. Both behaviors are mediated by the legal structure of the institution. The manager's power to terminate employees is not a personal power based on personal qualities. If she walked up to employees as an individual, not as a

manager, and told them to leave the premises at once, they would laugh at her. Her power to dismiss them is a legal, institutional power. Anyone who occupied the manager's position, or role, would have the same power by virtue of the position, not their individuality.<sup>4</sup>

The workers' response is also determined by the legal structure of the institution. Their agency is reduced by the institutional structure (in proportion to the degree to which the manager's agency is augmented by it). This is a function of the organization of the institution. It is not a function of leadership in general.

A different institutional structure would elicit different kinds of agency from both manager and workers. The manager and workers would jointly discuss management-proposed layoff plans and investment plans in a worker-owned cooperative.

The corporate manager's agency extends far beyond her employees in her firm. It affects the education of children she has never met. This effect results from the institutional structure of society: Education is funded by tax revenue, which is taken from wages, which depend on corporate hiring policies, which depend on investment strategies.

The corporate manager does not directly affect your education by interacting with you (or with tax collectors, or policy makers) personally, as one individual to another individual. Rather, she affects your education through the network of social institutions that are linked to her corporation. It is the institutional connection between wages, taxes, educational budgets, training and hiring of teachers, and building of schools that gives her business action the ability to affect your education, and the education of millions of students (*see* Ratner, 2006, p. 60).

She could never have such vast effect over so many students individually. She could never meet and influence so many students on an interpersonal basis. As an individual, she would have no power to make you attend a school with many resources and small classes, or a poor school with few resources and large classes. But she can make your school, and many schools, rich or poor, good or bad, through her wage and investment policy as corporate manager. Her agency is far greater through impersonal institutional connections than it is through personal, individual connections.

Similarly, middle class people have more powerful agency than poor people because of the intellectual and social capital they have acquired through their class position. It is naive to believe that every

individual has agency in an equivalent form without specifying its cultural organization.

Nor does agency have any intrinsic capacity to understand, resist, and transform unfulfilling conditions and behaviors. Agency can take any number of forms. Nazis and slave owners had agency. Prisoners do also. Agency does not necessarily lead any of these individuals to transcend their conditions and behavior (Ratner, 2009). Agency has cultural origins, characteristics, mechanisms, and function just as all psychology does. Agency only becomes truly fulfilled when it pointedly adopts a critical cultural perspective and works to transform the macro-cultural factors that oppress people. Agency only becomes fulfilled and critical through the social standpoint it adopts. It is not critical and fulfilling in and of itself. Agency does have the ability to reflect on behavior and conditions; however, this is an abstract ability that must be concretized by specific social analysis and action.<sup>4</sup>

#### **SENSORY PROCESSES: OLFACTION**

Chiang explains how our sense of smell is organized by cultural and political factors. Her account dovetails our earlier discussion of pain associated with childbirth. “Odors are invested with cultural values and employed by societies as a means of and model for defining and interacting with the world” (Chiang, 2008, p. 407). The perception and evaluation of odors is part of culture, expresses culture, and is a window into culture. The smells to which we are sensitive, and the sensory quality of smells, depend on the social practices they are associated with. “In deciding what smelled good and what smelled bad, people were making decisions about what activities and people they valued” (ibid.). The natural smell did not determine the value assigned to it. For example, smells associated with racial and ethnic minorities and the working class—the smells of their bodies, homes, and labor—were evaluated negatively because these activities and their actors were socially disparaged. Wealthy people surrounded themselves with different odors (e.g., perfumes) to distinguish themselves socially. Perfumed scents were perceived as pleasant because of their social association—just as bodily appearances were infused with cultural significances that determined their attractiveness. “The social and material dimensions of odors became inseparable” (ibid.). Odor became a proxy of social standing. “Zoning laws in contemporary Western cities have created ‘domains of smell’ that separate industrial

and residential areas and their respective scents” (ibid.).

Indeed, because most smells were subject to interpretation, they were incredibly malleable and could be used to advance several agendas, whether concerning the social makeup of a community or the development of its natural environment. Using their noses, Americans thus developed an alternative way of understanding the world and of wielding power, one that responded quickly to variable circumstances and emotions.  
(ibid.)

Olfaction, perception in general, and psychology in general, is a proxy for culture, represents culture, and promulgates/reinforces culture.

Interestingly, third world cities such as Bangkok have developed different categories of odors to signify different social values/distinctions. Thais developed an “olfactory dualism” in which the public stench of refuse was not bothersome, but body odors were. This reflected the personalistic nature of Thai society that required the utmost cleanliness of individuals.

A complete cultural psychology of olfaction must emphasize that individuals invest odors with cultural meanings that define odors as pleasant or unpleasant, refined or gross. This cultural content (significance) of olfaction is one source of evaluating a group of people who are associated with a particular odor. However, people are unaware of this acculturating of odor. People erroneously assume that their perception of smell is natural and that the reason they dislike an odor and the people and activities associated with it is natural, not cultural. People thus reify their psychology—their perception—as natural and use it to explain their social behavior—for example, individuals justify their abhorrence of manual labor and laborers as having a natural basis in olfaction (“Of course I loathe them, they smell so foul”).<sup>5</sup>

Macro-cultural psychology negates the reification of psychology and social categories by explaining that cultural practices, status, and values define the physical odor and the social activities and actors who partake of an odor. It is not the case that odors have naturally unpleasant qualities that define people who emit them. Naturalistic conceptions of psychology generate naturalistic, reified conceptions of social distinctions, whereas cultural conceptions of psychology generate cultural, changeable conceptions of society.

## MENTAL ILLNESS

Forms (symptoms) of mental illness are cultural phenomena (Ratner & El-Badwi, 2011). Consider the remarkable parallel between Kraepelin's description of schizophrenia (dementia praecox) and T.S. Eliot's description of modern society. Kraepelin defined schizophrenia as "a loss of inner unity of intellect, emotion, and volition"; T.S. Eliot diagnosed the modern condition as a widening rift between thought and emotion, intellect and sensation, and a general failure to achieve unity of sensibility" (Sass, 1992, p. 357). It could not be coincidental that the inner, psychological loss of unity and the outer, social rift arouse simultaneously. The "modern condition" clearly fosters psychological disintegration. The psychological and the social are continuous with one another on the same plane. Psychologists and psychiatrists try to break the unitary plane and place psychology and society in separate realms. The unity (homology) of psychological disturbance and social relations is seen in historical accounts of mental illness. (Sass, 1992, p. 362).

The feeling of personal worthlessness (i.e., the "inferiority complex") is a historical construct of recent origin. Previously, individuals felt a sense of sinfulness but not personal inadequacy. The notion of personal worthlessness only arose during the past century, evidently reflecting a rising individualistic concern over personal inadequacy that is bred by intense competition (Ratner, 1991, p. 270). This is a momentous fact for macro-cultural psychology. For it says that even a sense of personal worthlessness is a historical construct, not a personal one. If anything seems to qualify as a personal construct it is the haunting sense that one is worthless. Yet the possibility of this feeling is itself historical. Although people have always suffered misfortune and defeat, the psychological response to this, and interpretation of it, as blaming oneself and feeling worthless is historically cultivated.

Another pathological symptom, the schizophrenic divided self, only emerged in the late nineteenth century in conjunction with multiple, disjunctive social roles. Although earlier views recognized distinct functions or components of self such as soul and body, these all revolved around one self. The nineteenth century marked a new conception of different selves or personalities within one individual. This was reflected in Robert Louis Stevenson's *Dr. Jekyll and Mr. Hyde* (1886). This cultural-historical fragmentation is recapitulated in the symptomatology of mental disorder. As one patient said,

It is as if something is thrown in me, bursts me asunder. Why do I divide myself in different pieces? I feel that I am without poise, that my personality is melting and that my ego disappears and that I do not exist anymore. Everything pulls me apart. The skin is the only possible means of keeping the different pieces together. There is no connection between the different parts of my body.

(Sass, 1992, p. 15)

The symptoms of schizophrenia—withdrawal, highly idiosyncratic and abstract patterns of thinking, and a preoccupation with hidden meanings—bear unmistakable congruence with the broad social relations and concepts of capitalism (such as individualism, privacy, privatized meaning). Sass (pp. 369–371) explains it well:

Consider the emphasis on disengagement and self-consciousness that was fostered by the ideas of philosophers like Descartes, Locke, and Kant (as well as by patterns of socialization in daily life) . . . This turned modern human beings away from the search for an objective external order, enjoining us instead to turn inward and become aware of our own activity . . . to take charge of constructing our own representation of the world . . . Central to these tendencies is a pervasive detachment, a disengagement that demands that we stop simply living in the body or within our traditions and habits, and by making them objects for us, subject them to radical scrutiny and remaking.

Related currents, more closely associated with romanticism and its aftermath, have tended to glorify the inner self, by implying that human fulfillment lies in discovering one's own uniqueness and recognizing the central role of one's own subjectivity. (It is only with romanticism that autobiographies come to be filled with forms of self-reflection focused on the drama and idiosyncrasies of one's own inner life . . .)

If schizoids and schizophrenics, like other human beings, are subject to the influences of their social milieu, it is not hard to see how a number of their core traits (the asocial turning inward, the lack of spontaneity, the detachment from emotions, the hyperabstractness, the anxious deliberation and cognitive slippage, and the exquisitely vulnerable sense of self-esteem, for example) might be exaggerations of tendencies fostered by this civilization . . .

[This is why] what evidence there is suggests that schizophrenic illness did not even appear, at least in any significant quantity, before the end of the eighteenth or beginning of the nineteenth . . .

Caratonia was not described until after 1850. Even more telling is the absence or extreme rarity of descriptions of clear instances of individual cases of schizophrenia, at least of the chronic, autistic form, in either medical books or general literature prior to the nineteenth century. The first clinical descriptions are those of Haslam and Pinel in 1809; the first literary descriptions that definitely qualify are those of the main characters in George Buccaneer's story "Lenz" and Honore de Balzac's "Louis Lambert," both written in the 1830s—and this despite the fact that easily recognizable descriptions of all other major mental diseases, including affective psychoses, can be found in ancient as well as Renaissance and eighteenth century texts. Many writers in the eighteenth century made systematic attempts to describe the known forms of mental illness, which resulted in works like Pinel's diagnostic system (1901). But despite the striking clinical picture that schizophrenia presents (at least in its acute and florid forms), one can find no account of it in these or any earlier works. (ibid., pp. 364–365). Even Eugen Bleuler, who coined the term schizophrenia in 1908, described a "specific type of alteration of thinking, feeling, and relation to the external world which appears nowhere else in this particular fashion." (ibid., p. 14)

Sass (1992, p. 10) explores "one of the great ironies of modern thought: the madness of schizophrenia—so often imagined as being antithetical to the modern malaise, even as offering a potential escape from its dilemmas of hyperconsciousness and self-control—may, in fact be an extreme manifestation of what is in essence a very similar condition."

Sass explains the methodology necessary to elucidate the congruence between macro-culture and psychological symptoms:

A comprehensive model of the social origin both of schizophrenia and of the modernist sensibility would need to go beyond this discussion of abstract ideas and mentality and to acknowledge as well how each of these conditions is intricately with the modern social order—with patterns of political and bureaucratic organization, family structures, economic practices, and technological developments of modernity. The most influential descriptions of these aspects of modernity come from the founding fathers of sociology: Karl Marx—on the alienating consequences of certain economic structures and relationships; Max Weber—on the growing rationalization, technologization, secularization,

and bureaucratization of modern life; and Emile Durkheim—on the juggernaut of industrialization and the growing reflectiveness that cause traditional values to lose their quasi-natural status. (ibid., p. 371)

### *Mental Illness and Capitalism*

Foucault describes the structural congruence between symptoms of mental illness and the alienated, exploitive character of capitalism. He debunks the idea that mental illness is a separate realm from society. In fact, the phenomenological sense of separateness and delusion that many patients experience is caused by and recapitulates the alienation, self-obfuscation, and contradictions of capitalism. It is not caused by a deficit in consciousness itself. "It is not because one is ill that one is alienated, but insofar as one is alienated that one is ill" (Foucault, 1987, p. xxvi).

It would be absurd to say that the sick man machinizes his world because he projects a schizophrenic world in which he is lost . . . In fact, when man remains alienated from what takes place in his language, when he cannot recognize any human, living signification in the productions of his activity, when economic and social determinations place constraints upon him and he is unable to feel at home in this world, he lives in a culture that makes a pathological form like schizophrenia possible . . . *Only the real conflict of the conditions of existence may serve as a structural model for the paradoxes of the schizophrenic world.*

To sum up, it might be said that the psychological dimensions of mental illness cannot, without recourse to sophistry, be regarded as autonomous . . . In fact, *it is only in history that one can discover the sole concrete apriori from which mental illness draws . . . its necessary figures.* (Foucault, 1987, pp. 83–85, my emphasis)

In sum, although individuals construct morbid symptoms, their construction is shaped by macro-cultural factors and it is made from cultural factors. Detachment, skepticism, subjectivism, and other psychological mechanisms of mental illness were objective constructs objectified on the macro-cultural level by novelists and philosophers. They were not spontaneously constructed by mental patients. This is an important tenet of macro-cultural psychology, that psychological constructs are macro-level constructs that are widely known in a population. These are the mediational means that

individuals draw on as their psychological mechanisms for dealing with stress and other social factors. Of course, not all individuals draw on the same cultural tools; however, they draw on some cultural tool for their psychological operations. This makes these operations cultural.

Macro-factors generate mental illness by exerting specific stressors and stresses on people—for example, alienation, detachment, insecurity of unemployment, and competition (which were not prevalent in other societies)—and unique models for coping with these stresses—for example, fragmentation, skepticism, detachment, subjectivism. This two-pronged cultural influence can be diagrammed as in Figure 10.2.

### Biological Explanations of Mental Illness

The fact that mental illness is generated by cultural pressures such as alienation, oppression, and social contradictions and utilizes cultural concepts such as detachment, skepticism, and subjectivism as its operating mechanism makes mental illness a cultural phenomenon that is not reducible to biochemical processes. The latter cannot determine/generate the symptoms of mental illness because they are not sensitive to the cultural stressors Sass and Foucault enumerated, nor are they capable of generating culturally specific symptoms such as detachment, depression, schizophrenia.

An operating mechanism is required in humans that is sensitive to social stress and generates cultural-psychological symptoms to it. Biological processes must be invested with cultural sensitivity before they can detect and respond to complex, symbolic cultural events. Biology must be raised to the cultural level, it must be acculturated, to process cultural events and behavior. Biology, *per se*

(e.g., the biochemistry of testosterone or a neurotransmitter), does not naturally have the ability to detect, understand, and respond to cultural events in a predefined manner (see Joseph & Ratner, 2012). The operating mechanism of mental illness is no more a simple, automatic, biological response to stress than maternal love is a simple, automatic, biological response to color, odor, and size of physical stimuli.

### Demographic Variations in Mental Illness

The fact that not everyone in a culture becomes mentally ill does not negate the fact that mental illness is cultural. Society—especially modern society—is complex and diverse, and not everyone in it is exposed to the same stressors in the same degree. The fact that some people escape it simply means that they occupy more sheltered social positions. People who are exposed to stressors intensely and extensively will suffer more illness than those exposed in lesser degrees. Detailed research has proven that mental illness is monotonically related to the number of social stressors encountered (Ratner, 1991, Chapter 6). This is why mental illness is over-represented in the lower classes where stressors are greater.

What is remarkable about the cultural content and historical specificity of forms of mental illness is that they exist among people in the depths of despair and disorientation. One might expect estranged, confused, anxious, isolated individuals to strike out with random, idiosyncratic responses that lack social significance and commonality. However, the fact is that the victims draw on cultural models (values, concepts, practices) as their mediational means for coping with adversity. Even in their misery and confusion, they display social sensitivity to, and social dependence on, macro-cultural factors to guide their psychological reactions. This is why there is social coherence to mental illness in particular historical epochs. Our epoch has schizophrenia, eating disorders, and hyperactivity that other eras lacked. Conversely, the Victorian era had thousands of cases of hysteria that disappeared today because the cultural-historical stressors, stresses, and coping mechanisms have changed.

North American and European symptoms of disturbance rest on Protestant values of individualism, self-control, rationalism, activism, and introspection. Catholic societies that value communalism, fateful acceptance of destiny, and higher authority

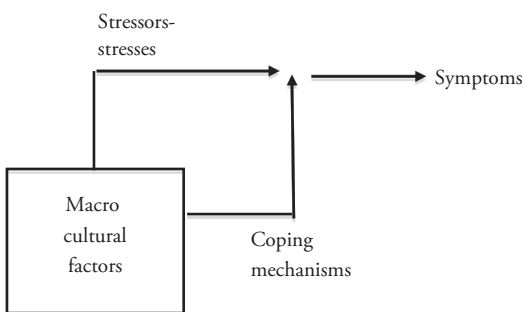

Figure 10.2 Two-Pronged Cultural Shaping of Mental Illness

manifest quite different symptomology. Whereas American patients tend toward active symptomatology with ideational distortion and elaboration, Catholic Latin patients tend toward passive symptomatology with a suspension of cognitive effort. Americans tend toward obsessional thoughts, intellectualization, guilt, and self-blame, whereas Latinos suffer more somatic complaints, sleeplessness, and obesity. Americans are more lonely and suspicious than Latinos, whereas Latinos are more dependent (Ratner, 1991, pp. 268–278; see Marsella & Yamada, 2007 for cultural variations in mental illness).

Anorexia and bulimia manifest demographic variations. These implicate cultural stressors, stresses, and coping skills in the disorders. A demographic analysis reveals that 90% of anorexics are women. In addition, these eating disorders become prevalent among non-Western women to the extent that non-Western countries adopt capitalistic social relations. Eating disorders have increased sixfold in the past 25 years in Japan with increasing industrialization, urbanization, and the fraying of traditional family forms following World War II. Additional macro-cultural factors that spurred eating disorders include middle-class gender roles for Japanese women and slim body ideals of beauty.<sup>6</sup>

Anorexia is rare on the Caribbean island of Curacao. The few cases that exist are confined to well-educated, high-income women of light skin, who have lived abroad. No cases of anorexia are found among the majority Black population. Macro-cultural psychology accounts for this demographic fact. Curacao women who become anorexic are middle class, light-skinned individuals. As such they adopt light-skinned, Western, middle class ideals of thinness. This class significance of slimness is what accounts for the “tyranny of slenderness” in modern society. Achieving the thin body that represents middle-class status (as a collective representation) is a means to gaining middle class identity. Black, lower class women have no hope of entering the middle class so they do not strive to adopt its proxies such as slim body form. Body image and eating disorders to achieve it are objective, objectified, objectifying cultural means (coping strategies) to achieve cultural objectives under particular cultural stressors and stresses (cf. Ratner, 2002, pp. 39–40, 49–50; Ratner, 2006, pp. 100–101).

### *The Normativity of Non-Normal Psychology*

Non-normative psychology is actually normative because its causes, constituents, meanings, social

consequences, and demographics are cultural. Individuals utilize cultural means to cope with cultural stressors even in non-normative manners. Individual activity does not make mental illness an individual creation. Its causes and constituents are cultural. Unhappy individuals did not spontaneously invent the thin body image as an ideal for feeling successful; they appropriated it from the macro-cultural level where it (recognizably, commonly) represented middle-class identity and success.

Jackson (1993, p. 212) explained this well:

Our subjectivities, including that aspect of them we understand as our emotions, are shaped by social and cultural processes and structures, but are not simply passively accepted by us. We actively participate in working ourselves into structures, and this, in part, explains the strength of our subjection to them. We create for ourselves a sense of what emotions are, of what being in love is. We do this by participating in sets of meanings constructed, interpreted, propagated, and deployed throughout our culture, through learning scripts, positioning ourselves within discourses, constructing narratives of self. We make sense of feelings and relationships in terms of love because a set of discourses around love pre-exists us as individuals and through these we have learnt what love means.

### *Mainstream Psychology versus Macro-Cultural Psychology Regarding Mental Illness*

Psychologists and psychiatrists are insensitive to these social origins, mechanisms, characteristics, and functions of mental illness.

In North America, especially in the United States, the discussion of social factors in the development of psychotic disorders has changed profoundly over the last 40 years. Whereas macro-social factors (such as migration and poverty) were once the subject of study and discussion, they have fallen from prominence and have given way to a preoccupation with micro-social issues; the social environment has been reduced to the clinic, and research efforts have focused on how clinicians diagnose psychosis in minority populations (Jarvis, 2007, p. 291).

### *Macro-Culture and Micro-Family in Mental Illness*

A great deal of mental illness occurs in destructive family interactions (Ratner & Badwi, 2011). However, these are precipitated by broader macro-stresses that Sass and Foucault enumerated. Indeed, this point is the crux of Bronfenbrenner’s ecological

model, which situates micro-level interactions within the sphere of macro-processes. Bronfenbrenner terms microlevel interactions as *proximal processes*, which are reflections of distal macro-cultural processes, as moonlight reflects sunlight. Shared, unifying macro-cultural factors explain why so many families in a country are so dysfunctional as to produce mental illness in their children. A purely family analysis cannot explain varying prevalence and forms of dysfunction in different societies.

Micro, proximal processes cannot be the primary source of mental illness that is historically specific and variable. Individual, separate interactions cannot explain the cultural coherence and similarity that it manifests. The millions of families in one country that generate particular forms of mental illness in their children do not coordinate with each other to produce similar stresses and coping mechanisms. The similarity in symptoms across millions of separate patients must be explained by broader cultural similarities at the macro-level. These radiate down to micro-level family interactions and unify them with shared characteristics.

Mental illness testifies to an important principle of macro-cultural psychology: seemingly personal, marginal psychological reactions are actually macro-level phenomena.

### ***Interpersonal Behavior and Macro-Cultural Psychology***

The case of mental illness demonstrates that individual, interpersonal psychological phenomena are uncannily shaped by macro-cultural factors and reflect their politics, despite the fact that the phenomena are not directly controlled by social leaders. Other personal acts are equally socially distributed *psychographics*. A striking example is the fact that Australia's homicide rate is around 1 per 100,000 population, whereas the U.S. homicide rate is around 6 per 100,000, or six times higher. Clearly, central macro-cultural factors are at work in shaping individual decisions to kill each other (and themselves in suicides).

Similarly, the quality of children's interpersonal relationships (with peers and family members) varies enormously among countries with different macro-cultural factors. A compilation of measures by the United Nations, which includes single-parent households, number of times the family eats together per week, talks together, and how kind and helpful peers are to children among OECD countries, found Italy to have the best interpersonal

relations (score of 115), whereas the United States and United Kingdom had the lowest score of 80. Only 40% of German 15-year-olds spend time chatting with their parents several times a week, whereas 90% of Hungarian children do so. Only 60% of Finnish 15-year-olds eat the main meal with their parents several times a week, in contrast to 93% of Italians. Other personal eating habits are equally structured by society. Whereas 80% of Portuguese 11- to 15-year-olds eat breakfast every school day, only 46% of American children do. Where 25% of American 13- to 15-year-olds report being overweight, only 6% of Polish peers do. (UNICEF, *Child poverty in perspective: An overview of child well-being in rich countries*, Innocenti Report Card 7, UNICEF Innocenti Research Centre, Florence, 2007). Demographic distribution of personal behaviors demonstrates that they are shaped by cultural factors; they are not purely personal choices. Purely personal choices and idiosyncratic behavior would not manifest systematic group differences.

Obviously, the majority of German children did not spontaneously (i.e., personally) decide to forego chatting with their parents. Nor did this new norm arise through sequences of interpersonal dialogues among children across Germany. Broad macro-factors, which German children do not control or even understand, structured their lives, aspirations, values, expectations, and practices impersonally, in ways that interfered with family chatting. (This kind of impersonal structuring-socializing of individual psychology by macro-cultural factors is an important topic in macro-cultural psychology.)

An important macro-cultural factor in this regard is consumerism. Consumer capitalism presses children—through numerous macro-cultural pressures, stimuli, inducements, affordances, and models—to separate from restrictive parental authority to be “free” to accept consumer pressures for impulsive shopping. (We saw that this pressure was important in loosening the bonds of maternal love for one's children.) Tight-knit families, including those that eat and chat together, keep the child within the sphere of parental authority and resist the pull of consumerism. Such behaviors on a wide social scale are only possible where consumer capitalism is weak.

Cook documents the commodification of childhood by consumer capitalism and how it pressures and requires freedom from family restraints. It is not useful to think of children—or persons generally—along the lines posed by neoclassical economic

thought, as initially independent, encapsulated beings who confront an equally identifiable “market sphere” and who thereby make discrete choices within it or become merely socialized into it. Consumption has become a necessary and indispensable context—although not sufficient in itself—in which the person’s self develops because commerce produces most of the material world with which a child comes into contact . . . It is around consumption and display—in the interaction with the material world—that personhood and agency tend to crystallize (Cook, 2004, p. 145). Cook explains that psychology is built into macro-cultural factors—for example, individualism is built into the free market—and that psychology crystallizes around the characteristics of macro-cultural factors—for example, personhood embodies the material of consumer capitalism.

### ***Macro-Cultural Psychology Is a Unitary, Consistent, Parsimonious, Comprehensive Psychological Theory***

The foregoing discussion of macro-cultural psychology can be summarized in the following theoretical principles (which are more complete than the selected principles I listed in summarizing Plant’s historical analysis of maternal love).

#### **PRINCIPLES OF MACRO-CULTURAL PSYCHOLOGY**

1. Macro-culture and psychology are mutually constitutive and interdependent—two forms of the same distinctive human order. Psychology energizes cultural factors and it dialectically acquires their cultural features.

2. Within this spiral of culture and psychology, macro-cultural factors are dominant. They are the impetus of psychological formation, and they organize the form and content of psychological phenomena.

3. Psychological phenomena are formed in macro-cultural practices on the macro-cultural level to serve macro-cultural purposes.

4. Psychological phenomena are public, objective, objectified cultural phenomena; collective representations.

5. Public, objective, objectified psychological phenomena serve as templates/scripts for

- a. acquiring psychology
- b. expressing psychology.

Psychological phenomena are thus objectified, objective, objectifying cultural phenomena.

6. Psychological phenomena embody features of macro-cultural factors as their constituent operating mechanisms and content. This is true for abstract and concrete features of psychological phenomena. Abstract features of psychology embody abstract features of macro-cultural factors; concrete features of psychology embody concrete features of culture. Macro-cultural psychology parsimoniously explains abstract and concrete aspects of psychology.

7. Macro-cultural factors are political, formed through political struggle, and impart their politics to psychological phenomena.

8. Psychological phenomena recapitulate the politics of macro-cultural factors in the subjectivity of individuals. Psychological phenomena animate politically appropriate behavior. Psychological phenomena are objectives of political struggle. Groups struggle over concepts of self, masculinity, childhood, motherhood, sexual freedom, rote memory in school, and conceptions of mental illness.

9. Psychological phenomena are cultural means (cultural capital) for achieving cultural objectives/success by individuals.

10. Psychology is a cultural state of being, a cultural state of mind, a cultural identity, and membership. Psychology objectifies culture—for example, sentimental maternal love objectifies Victorian culture and women’s domestic position, whereas modern maternal love objectifies women’s roles as workers and consumers in the free market; just as the recent sexual revolution among Chinese urban young women objectifies their changing work and family roles.

11. The fact that psychology is cultural and political—that is, reflects the cultural-political features of macro-cultural factors—does not mean that people’s psychology understands the cultural politics of macro-cultural factors. Typically, the cultural politics of macro-cultural factors mystifies these factors—to prevent people from critically evaluating and transforming them—and this mystification is recapitulated in psychological phenomena. The individualistic self is a primary example of a fictitious ideology that is recapitulated in fictitious self-understanding of people as independent of society, masters of their own action, and governed by individual mechanisms such as genes. Reincarnation is another fictitious cultural concept that mystifies people about the real origins of their personality and social position.

People's cultural psychology may be a stunted, mystified psychology that I call the psychology of oppression. It can only be comprehended as such by adopting an external, critical perspective on the social origins, characteristics, and function of psychological phenomena (Ratner, 2011b).

12. Psychological phenomena are macro-cultural factors. They represent and solidify cultural factors through animating culturally appropriate behavior. Historian Warren Susman (1979, pp. 212–213) shows how personality is a macro-cultural factor in the sense that it characterizes and represents a society: "One of the things that makes the modern world 'modern' is the development of consciousness of self . . . Consciousness itself became a key word in the 17<sup>th</sup> century . . . It is striking to see the interest as early as the 17<sup>th</sup> century in what was called 'character.'" These psychological phenomena were clearly cultural features.

Psychological phenomena solidify cultural coherence through culturally structured, shared subjectivity. Psychology binds individuals to culture through imparting cultural features of consciousness/subjectivity.

13. Psychology is embodied in macro-cultural factors, is transmitted, and is socialized by them. As Oyserman and Lee (2008, p. 331) put it, "one of the ways in which meaning is organized in context is through the meaning provided by salient and accessible culture and that once a particular cultural focus is cued, it is likely to carry with it relevant goals, motives, actions, ways of interpreting information, and processing strategies."

Clothing, for example, socializes sexuality. The American Psychological Association's Task Force on the Sexualization of Girls, 2007, studied the ways that artifacts such as clothing *sexualize* girls—i.e., make them sexual and structure their sexuality in particular forms (sexualization is a form of making subjectivity, or subjectification in Foucault's term). Goodin, et al. (2011) looked at sexualizing clothing available to preteen girls as a possible socializing influence that may contribute to the development of self-objectification in preteen girls. Sexualizing clothing was defined as clothing that revealed or emphasized a sexualized body part, had characteristics associated with sexiness, and/or had sexually suggestive writing. E.g. Abercrombie thong underwear in children's sizes with "wink wink" and "eye candy" printed

across the front. Or Abercrombie's "cute butt sweatpants" and "skinny" jeans that are "fitted with a little stretch for a sexy look to give you the perfect butt"

"We propose that sexualizing girls' clothing is an important socializing agent in which the social role of the objectified female is perhaps innocuously presented, 'put onto' girls, associated with popularity and 'coolness,' and then eventually endorsed by the girls themselves. Clothing can function as both a contributor to and a sign of the process by which some girls begin to think and evaluate themselves according to a narrow, sexualized model of feminine attractiveness" (ibid, p. 10). Evidence for this is the fact that Girls as young as age six are critical of their bodies, expressing body dissatisfaction and interest in dieting.

Girls define themselves in terms of the macro cultural factor, they do not define the macro cultural factor in terms of their "own" idiosyncratic desires. This conforms to Vygotsky's and Leontiev's conception that individual psychology depends upon social psychology.

An additional example of macro cultural factors containing, expressing, and socializing cultural psychological meanings is reported by (Shepherd, 2011, p. 129).

participants who had been shown a video of black Americans in a park had less negative associations with blacks than did participants who had been shown a video of black Americans in a gang-related context. They had similar results when blacks were shown in a sequence with a church as opposed to in a sequence with a city street. The traditional interpretation of these results is that contextual cues activate automatic stereotypes, which are assumed to be stable and unrelated to context. In this version, local context perturbs stable associations; the representation of the target is the same but the context within which the target is located varies, thus shaping activation. We could also read these results as evidence of how the types of associations (both the content and the emotional valence, positive or negative) individuals have with a member of a particular social group depend on the particular context or set of cues and there is no baseline representation of a social group apart from the context. [Thus, no fixed meaning that people have to minorities, e.g.] The meaning of a social group member is given through interaction with the context. Concepts of place (park, church, and street) carry sets of relevant

associations that alter the cognitive associations of the perceiver.

14. These aspects of cultural psychology comprise a general psychological theory—macro-cultural psychology—that explains all psychological phenomena.

15. Macro-cultural psychology is an ideal type of the main parameters of human psychology. Individual and group variations/transformations issue from this framework.

16. The discipline of psychology is a macro-cultural factor that represents and solidifies cultural factors. Vygotsky (1933/1994) spoke of bourgeois psychology, the psychology of fascism, and Soviet psychology to express this.

17. Although approaches to psychology reflect and reinforce macro-cultural factors, they do not necessarily understand these factors or psychological phenomena (just as psychological phenomena do not necessarily understand their own cultural characteristics, origins, and function—as stated in 11 above). Approaches to psychology are often unscientific and ideological and overlook and obscure important aspects of human psychology. Not all approaches are equally scientific and penetrating. Epistemological relativism and pluralism are false concepts.

For example, Vygotsky regarded bourgeois academic psychology as bogged down in a profound crisis: “the profound crisis which has afflicted bourgeois psychology during the past few decades . . . a process of degeneration and decay which had previously been woven into [its] general fabric” (Vygotsky, 1994a, p. 327). In other words, bourgeois academic psychology reflects and reinforces bourgeois society (as the name implies), yet it fails to scientifically understand bourgeois society and the psychology of its people. Psychology is in crisis precisely because it reflects and reinforces the mystifications of capitalism! One of the primary mystifications of capitalism is to deny its coercive affect on human behavior and to pretend that individuals are free to construct their own behavior. This prevents recognizing the social elements of capitalism that organize behavior/psychology. Recapitulating this mystification prevents bourgeois psychology from comprehending the psychology of people, which is, in fact, organized by capitalist social relations. (Bourgeois psychology reinforces capitalism by insulating it from criticism as a social system and attributing problems to individual deficiencies.)

Academic psychology can only become scientific if it ceases to reflect and reinforce capitalism and instead adopts an external critical perspective on capitalism—an anti-capitalist perspective. Then it can free itself of the mystifications inherent in bourgeois society and it can recognize the cultural character of psychological phenomena.

Vygotsky goes so far as to identify the errors of bourgeois (academic) psychology as the basis of fascist (academic) psychology that took root in Nazi Germany:

It would be naïve to think that these absurd structures [of fascist Psychology] are in no way connected with the general crisis occurring in bourgeois psychology and that bourgeois psychology is in no way responsible for these constructions . . . Essentially, Jaensch’s system [of Nazi psychology] is built on the same methodological foundations as all the rest of bourgeois psychology. It represents an integration of idealism and mechanism . . . In the majority of psychological schools these elements, unknown to the authors themselves, are intertwined with one another . . .

Sociology is completely left out of Jaensch’s system. It is only race and blood which immediately determine the structure of personality and through it politics as well. Here too, all that Jaensch has done is to push to the extreme and treat with cynical bluntness that which is already part of the very foundation of bourgeois scientific research.

(*ibid.*, p. 334)

Vygotsky counterpoised Soviet psychology to bourgeois psychology and fascist psychology in terms of their scientific merit and the political interests they represent. The latter two approaches are scientifically dubious and politically conservative. In contrast, Vygotsky argues that Soviet Marxist psychology is scientifically superior to the other two approaches, and it also represents the political struggle for humanity against the forces of reaction that are bolstered by bourgeois and fascist psychology (*ibid.*, p. 335). Social scientific adequacy depends on adopting a progressive political standpoint. Similarly, social scientific inadequacy and political conservatism go hand-in-hand. In this way, social science is thoroughly political.<sup>7</sup>

#### THE THEORETICAL CHARACTER OF MACRO-CULTURAL PSYCHOLOGY

Macro-cultural psychology is not simply an acknowledgement of cultural influences on

psychology. It explains the nature of psychological phenomena, their origins, constituents, mechanisms, characteristics, loci, and function. Macro-cultural psychology explains psychology as a cultural phenomenon. Macro-cultural psychology explains why and how psychology is cultural. Macro-cultural psychology develops methodology for evaluating and refining this perspective—that is, for identifying the extent to which macro-cultural factors are the origins, constituents, mechanisms, characteristics, loci, and function of psychology.

Macro-cultural psychology takes macro-level forms and processes of psychological phenomena as the basis (i.e., prototype) of human psychology. Rather than these cultural forms and processes being extensions of simpler, natural, universal, or personal ones, the cultural forms are the basic, primary, original prototypes that are the basis of intrapersonal and interpersonal psychological expressions.

For example, the prototype of human emotions is macro-level emotions such as love for one's country, anger at injustice, love of art, national shame, dejection about political trends, resentment of a rival country's technical superiority, fear of economic depression, and admiration for a form of government. These emotions, informed by consciousness of abstract phenomena, are the basis of our personal love for our spouses, children, and pets. They are also the basis of our fear of bears in the woods.

Macro-cultural psychology is a Copernican shift in our understanding of psychology. Whereas mainstream psychology explains culture in terms of the individual adults in terms of childhood experiences, the human in terms of animal processes, the large in terms of the small, the complex in terms of the simple, and the extrinsic (culture) in terms of the internal (mind, biology), macro-cultural psychology explains the small, the simple, the individual, the child, and the internal in terms of stimulation and organization by the large, the complex, the adult, and the extrinsic (culture).

Macro-cultural psychology utilizes its tenets as the foundation of a comprehensive, coherent, general psychological theory that explains, describes, and predicts all psychological phenomena. In addition, macro-cultural psychology incorporates biological and personal processes into its rubric in a principled, logically consistent fashion. It does not simply add macro-cultural principles to independent biological and personal processes. This kind of algorithmic addition of factors or variables is characteristic of interactionist models. Macro-cultural

psychology is not an interactionist model. It is a unified, integrated model in which all elements are modified so as to be congruent with macro-cultural factors. Macro-cultural factors are the dominant element because they are the cornerstones of society, which is the basis of our civilization, humanity, and consciousness.

Because mainstream psychology and psychiatry oppose this view and regard psychology as heavily determined by biological processes, we must explain how the latter are, in fact, subsumed within macro-cultural psychology.

#### **NATURAL, BIOLOGICAL PROCESSES AND CULTURAL PSYCHOLOGICAL PHENOMENA**

Being a public, socially constructed phenomenon at the macro-cultural level for cultural purposes, and possessing cultural features and mechanisms, psychology cannot logically be simultaneously governed by natural, biological processes.

Of course, psychology involves and includes natural, biological processes, such as neuronal and hormonal activity, just as it involves breathing air. However, just as breathing air is merely a precondition of psychology that plays no specific determining role in the form, content, origins, locus, mechanisms, and function of psychology, so other natural biological processes play no specific determining role either. Their role is analogous to that of breathing. Without breathing, hormones, and the brain, psychological activity would cease; however, with them it is only potentiated, not determined.

Vygotsky and Luria have cleverly argued that biology changes its role in behavior from animals to humans. It does determine animal behavior in natural environments; however, biology changes to a potentiating, energizing function with regard to human social behavior. This is only logical, and it is Darwinian, for we have seen that the fundamental principle of Darwinism is that organismic behavior is a function of environment. Culture is a radically different environment from nature; therefore, cultural behavior and its mechanisms must be radically different from natural behavioral mechanisms of animals. Vygotsky and Luria (1993, p. 170) have explained this important point as follows: “[B]ehavior becomes social and cultural not only in its contents [i.e., what we think about] but also in its mechanisms, in its means . . . A huge inventory of psychological mechanisms—skills, forms of behavior, cultural signs and devices—has evolved in the process of cultural development.”

“Higher mental functions are not simply a continuation of elementary functions and are not their mechanical combination, but a qualitatively new formation that develops according to completely special laws and is subject to completely different patterns.” “Thus, it is difficult to expect that evolution of higher mental functions would proceed parallel to the development of the brain.” (Vygotsky, 1998, pp. 34, 36)

Vygotsky and Luria make the important point that elementary natural processes operate in different ways from cultural conscious processes. This is why the former cannot govern the latter. They cannot even serve as the basis of the latter.

Elementary natural processes are actually inimical to cultural conscious processes. Elementary natural processes are automatic, mechanical, involuntary, physical processes; they possess natural properties that directly impel behavior. Natural processes, for example, operate in hummingbirds to automatically impel them to fly toward red-colored flowers; or they impel male dogs to involuntarily and mechanically mount and mate with a female dog who emits a particular scent during her fertile period. Hummingbirds and dogs do not think about what they are doing, they cannot control it, they cannot plan it or imagine it, or remember (re-live) it in specific detail; they do not appreciate the object of their behavior, as a human male appreciates his sexual partner or appreciates a beautiful sunset or painting. This is why elementary natural processes cannot determine psychology in the way that they determine behavior of birds and dogs.

It is oxymoronic to claim that intelligence is biologically determined because biologically determined behavior has the form of mechanical, automatic, simple acts such as a hummingbird flying toward a red flower. This sort of behavior is not intelligent. It is the antithesis of thoughtful, insightful intelligence. To claim that intelligence is biologically determined, even in part, is to ignore the nature of intelligence and the nature of biologically determined behavior.

Psychobiologists claim that biology determines “part of” intelligence through increasing the speed of neuronal conductivity, or the complexity of dendritic branching. However, this is unintelligible. Intelligence is a matter of profoundly understanding relationships and underlying causes and implications of things. It is a matter of insight and knowledge. It has nothing to do with the speed of conducting

neural impulses. Einstein was not a great physicist because his neurons worked quickly. That did not contribute to his knowledge and insight. And dendritic complexity is well-known to be the result of experience, not its cause. No biological reductionism of intelligence to physical processes as determinants adequately explains intelligence.

Altering and subsuming biological processes to fit within the unitary framework of macro-cultural psychological theory preserves the essentially cultural character of psychology by subordinating all other elements to it. Natural, biological processes are rendered congruent with culture and supportive of culture. They are eliminated as countervailing forces with their own determining mechanisms that could challenge and weaken (through interacting with) culture and mitigate its influence. Interactionism is pluralistic in that it postulates diverse factors/variables that each contribute a certain independent percentage of “variance” to the resultant psychology. Interactionism thus weakens the influence of each factor by countering different factors. For example, intelligence or personality are said to be X% culturally based and Y% biologically based. Whatever percentage is attributed to biology is subtracted from cultural influence. This denies the essential cultural nature of psychology. It reduces culture to just another aspect of psychology. Biological determinism or reductionism is *not* compatible with cultural organization of psychology.

Interactionism is factually wrong (cf. Ratner, 1998, 2004, 2006, 2011a), and it is also illogical because it juxtaposes incompatible mechanisms. Contemporary maternal love, for example, cannot be socially constructed amid fierce political struggle to serve cultural purposes and social positions and simultaneously be mechanically, involuntarily impelled by biochemical properties of hormones. This is obvious from the fact that Victorian women possessed the same biochemical hormones as modern women, yet their quality and experience of maternal love were qualitatively different. Hormones are certainly involved in both kinds of maternal love but only as energizing mechanisms of behavior, thoughts, feelings, and experiences whose content is culturally determined and variable. It is illogical to claim that 40% of the quality of contemporary maternal love is biological—that is, biologically determined. None of it is biologically *determined*. Biology has lost its determining function in human behavior, which is only “natural” given the unique cultural environment in which people live that calls for socially constructed, designed, voluntary,

changeable behavior. Culture determines the form, content, and conditions of behavior. In contrast, the form, content, and conditions of animal behavior are determined by natural, biochemical elements. There is no way that these two discrepant mechanisms could jointly determine the features of psychological phenomena. Elementary, natural mechanisms would *impede* the development of psychological features because natural mechanisms are antithetical to cultural-psychological mechanisms and features. The only way that biological processes can participate with cultural processes is for them to bequeath their determining properties over behavior to culture and for biological processes to recede into the background as a general potentiating substratum of behavior.

Vygotsky put it thus:

The struggle for existence and natural selection, the two driving forces of biological evolution within the animal world, lose their decisive importance as soon as we pass on to the historical development of man. New laws, which regulate the course of human history and which cover the entire process of the material and mental development of human society, now take their place.

(1994b, p. 175)

Personal expression and communication are similarly derivative functions of macro-cultural emotions. The latter are capable of explaining the former because broader, more complex phenomena can explain smaller, simpler ones. The converse is not possible. Simple, natural, physical, or personal processes do not have the scope (e.g., the great abstraction and depth of knowledge) to generate emotions that are necessary to initiate, sustain, and reform broad macro-cultural factors such as country.

### **Conclusion: Restoring the Macro-Cultural Basis and Character of Psychology**

Because psychology is part of macro-cultural factors—and is a macro-cultural factor in that it objectifies, represents, and consolidates culture—it must be comprehended by “zooming out” from the individual and family to the social system.

Unfortunately, most of psychological science has been devoted to “zooming in” on the individual and marginalizing the cultural complex of which he is a part (see Michaels, 2008, for political examples of this problem). Vygotsky (1994/1933, p. 334) decried this in the strongest terms: “Another mistake . . . which is, essentially, inherent in a greater or

lesser degree in all flaws of bourgeois psychology is the rejection of the social nature of man.”

Zinchenko (1984, p. 73) also acknowledges the overlooking of cultural psychology as a profound error: “The exclusion of the real process of the subject’s life, of the activity that relates him to objective reality, is the underlying cause of all misinterpretations of the nature of consciousness. This is the basis of both mechanistic and idealistic misunderstandings of consciousness.”

Moscovici (2001, pp. 109–110) explained this error as follows:

Society has its own structure, which is not definable in terms of the characteristics of individuals; this structure is determined by the processes of production and consumption, by rituals, symbols, institutions, and dynamics that cannot be derived from the laws of other systems. When the “social” is studied in terms of the presence of other individuals it is not really the fundamental characteristics of the system that are explored but rather one of its subsystems—the subsystem of interindividual relationships. The kind of social psychology that emerges from this approach is a “private” social psychology which does not include within its scope the distinctiveness of most of the genuine collective phenomena. It can therefore be argued that . . . social psychology has not been truly concerned either with social behavior as a product of society or with behavior in society . . . For these reasons it is ambiguous to maintain that social behavior is currently the real object of our science.

This avoidance of concrete social behavior—whether intentional or not—impedes the scientific development of psychology as a science. It also renders psychological science politically impotent as a force for social critique and change and for psychological enrichment. For the academic discipline of psychology to become scientific and to improve the social environment in ways that will enrich psychological functions and social relations, it must elucidate the macro-cultural origins, characteristics, mechanisms, and function of psychological phenomena. This is what macro-cultural psychology aims to do (Ratner, 2006, 2008, 2011a,b, 2012a,b).

### **Future Directions**

Elucidating the general features of macro-culture. Elucidating the dominant factors, marginal factors, the structural organization of macro-cultural factors in general.

Elucidating specific features of culture, such as the particular principles that govern macro-cultural factors in a particular society (e.g., how capitalist economic relations permeate educational institutions, the media, social science, religion, entertainment, and news reporting). Elucidating the politics of who controls macro-cultural factors and for what interests (e.g., is the society dominated by an aristocracy, capitalist leaders, a political party—the Communist Party?) Is the social structure egalitarian and cooperative or pyramidal; autocratic or autocratic?

Researching ways that psychological phenomena embody abstract and concrete features of macro-cultural factors.

Researching whether psychological phenomena transcend macro-cultural factors. What other kinds of factors do they reflect?

Identifying positive and negative psychological effects of the specific features of macro-cultural factors.

Identifying how positive effects be enhanced and negative effects diminished. What changes in macro-cultural factors are necessary to accomplish these changes?

What is the actual (concrete) power/agency that individuals have to control their social institutions in particular social systems?

Researching the extent to which people comprehend the macro-cultural factors that form their social relations and psychology?

Researching ways that macro-cultural factors organize psychological phenomena—which is different from interpersonal influence/socialization.

Developing methodology to answer these questions. How can we study the concrete features of macro-cultural factors and their psychological correlates? The same for abstract features.

Identifying ways that people with a given cultural psychology can critically evaluate it and the macro-cultural factors that shape it.

## Notes

1. Human artifacts eliminate any short-term natural balance humans have with nature. (Our population is not immediately dependent on what nature naturally provides us.) We must learn the limits of how much we can distress nature and still survive. We must plan and regulate our use of nature because we are not immediately consumed by our excesses as animals are. (For example, animal overpopulation quickly results in starvation to restore natural population levels.)

2. Community colleges in the United States were structured to perform this cultural function, as Brint and Karabel (1987, p. 11) document in a brilliant historical study.

The United States was, after all, a class-stratified society, and there was something potentially threatening to the established order about organizing the educational system so as to arouse high hopes, only to shatter them later. At the same time, however, the political costs of turning back the popular demand for expanded schooling were prohibitive in a nation placing so much stress on equality of opportunity. What vocationalism promised to do was to resolve this dilemma by, on the one hand, accepting the democratic pressure from below to provide access to new levels of education while, on the other hand, differentiating the curriculum to accommodate the realities of the economic division of labor. The aspirations of the masses for upward mobility through education would not, advocates of vocationalization claimed, thereby be dashed; instead, they would be rechanneled in more “realistic” directions.

3. Because Friedan articulated frustrations and desires that had been stimulated by consumer capitalism, her feminist agenda was not radical. It opposed traditional social roles for women, however, only to support consumer capitalist roles. For example, Friedan emphasized that women’s work should be paid in accordance with market commodification of labor, and she condemned volunteer work for the community. And Friedan did so implicitly without acknowledging that her feminist agenda of women’s social psychology, social relations, and social activity derived from and reinforced consumer capitalism. Consequently, “Friedan’s fans conceptualized motherhood in highly individualistic terms [of personal happiness, self-fulfillment, and involvement in work], drawing few if any connections between their maternal responsibilities and the broader social and political world” (Plant, 2009, p. 161). Friedan’s critique focused on attacking traditional psychology/behavior of women—for example, sexual passivity, limited career ambitions, and identity crises (which she called the feminine mystique)—and urging new forms of behavior/psychology without an analysis of the political economic basis of either. “Friedan portrayed [traditional] American mothers as parasitical and pathological . . . She blamed them for the mental problems of WW II servicemen, the difficulties of children suffering from severe mental illnesses like autism and schizophrenia, and ‘the homosexuality that is spreading like a murky fog over the American scene’ (p. 147). This is hardly a radical social critique.

Friedan insisted that “the feminine mystique was a mental construct and as such something women could change with equally powerful ideas. Friedan argued that women could discover the answers in themselves and not through religious, economic, political, or social change. If they had the wrong ideas, all they needed was the right ones, which her book provided” (Horowitz, 1998, p. 221).

Friedan did not articulate a critique of consumer capitalism that was necessary for women to achieve a truly more democratic, cooperative, humane social structure, social relations, and social psychology. Friedan’s work “promotes solutions (advanced education and self-realization) that tended to be feasible only for middle-class and upper-middle-class women” (Plant, 2010, p. 150). Years later, Friedan did help to found the National Organization for Women, which worked to pass the Equal Rights Amendment; however, this was primarily a middle class movement to enable middle class women to join mainstream society (a la Condoleezza Rice and Margaret Thatcher), not to transform its structure (cf Michaels, 2008).

Horowitz keenly observes how far Friedan's middle class feminism departed from her earlier political work and class analysis. From her studies in psychology at Smith College and Berkeley under left-wingers such as Tolman, James Gibson, Koffka, Erikson, and also Lewin in Iowa, she was inspired to join labor struggles, anti-fascist, and anti-capitalist struggles during the 1930s and 1940s. Yet her feminism incorporated none of this political class analysis. "In opposition to all that she knew as a labor journalist, she apparently believed that America had become a middle-class society ... The way Friedan minimized race [and class] as a factor in women's history and in contemporary society is striking" (Horowitz, 1998, p. 211).

"In addition, she ignored the efforts of working-class and Popular Front (left-wing) feminists in labor unions and in the Congress of American Women [to advance the political movement for the feminist agenda]" (Horowitz, 1998, p. 213). She made it seem that feminism was made by and for middle class women, and could be independent of broader political struggles for change in the class structure.

Friedan even denied the political origins of her own social consciousness. She claimed that she came to political consciousness out of a disillusionment with her life as a suburban housewife (Horowitz, 1998, pp. 2, 237 ff.). Horowitz's external analysis of her life and work confirms an important point that self-presentation in narratives cannot be accepted at face value in social scientific research (Ratner, 2002, Chapter 4).

4. With agency being socially constituted, it cannot necessarily be held responsible for its actions. Under conditions of oppression, alienation, and mystification, where people's agency is organized by social forces beyond their control and awareness, people cannot be held responsible for their behavior. (This is recognized in American law.) Responsibility presupposes awareness of, and control over, the factors that organize behavior. To hold people responsible for their behavior under conditions of oppression, alienation, and mystification is to insidiously divorce behavior from social conditions. It implies that people can control their behavior regardless of conditions. Holding people responsible for behavior, they do not comprehend or control is also to blame the victim of external forces. To blame people for being poor when they are deprived of work by corporate investment decisions is clearly to blame the victim. To blame consumers for borrowing credit and consuming many products is also to blame the victim. And to blame students for maintaining segregated social groups when they are recapitulating broad cultural segregation in housing, schooling, and employment is to blame the victim.

Responsibility for behavior is cultural just as agency and all psychology are. Responsibility must be achieved just as genuine agency and fulfilling psychology must be achieved through creating cultural conditions that enable them. They are not abstract, natural universals independent of concrete culture. People will only be responsible for their behavior when they live in genuinely democratic institutions which they can control. This is the same condition that enables genuine agency and fulfilling psychology.

5. This kind of reification is the essence of religion as well. People invent a concept of god(s) but they pretend that it was god who invented them and guides their behavior.

6. Most women do not achieve the slender ideal. This generates enormous anxiety and self-deprecation. By 8 years of age, 40% of American girls wish to be thinner than they are, and this percentage doubles in only 3 years, as 79% of 11-year-old girls wish to be thinner than they are. This testifies to the power that social ideals have over individual psychology, and the difficulty of renouncing them. Most women who are dissatisfied with their weight are

objectively of normal weight (75% of the women) or even underweight (30% of the women) according to health charts.

The reason for the failure to achieve slimness is that the ideal is contradicted by another aspect of consumer capitalism, the constant stimulating of consumption to increase sales and profit. One form this takes is the stimulating of constant food consumption, especially profitable, processed, addictive food such as junk food. This culminates in obesity among one-third of the American population. The clash of competing cultural pressures and collective representations generates intra-psychic struggle over which one to pursue.

Achieving the cultural ideal of slimness requires controlling oneself to abstain from the opposite culture pressure to constantly consume. This is why anorexics report intense struggles to control and renounce their urge to eat. Contradictory cultural pressures generate the need to control and renounce one in favor of the other. External pressures make control and renunciation central issues in anorexia. This is often portrayed as a struggle between good and evil, mind and body, purity and contamination. However, these meta-physical notions mask the cultural clash of slenderness versus consumption that is rooted in consumer capitalism.

7. Vygotsky says that capitalism not only impedes the development of scientific psychology, it also impedes the development of fulfilling psychological phenomena of people: "the source of the degradation of the personality [lies] in the capitalist form of manufacturing" (Vygotsky, 1994b, p. 180). Vygotsky links psychological fulfillment to social change in his 1930 essay, "The Socialist Alteration [Transformation] of Man." He says the contradictions of capitalist political economy are "being resolved by the socialist revolution ... Alongside this process, a change in the human personality and an alteration of man himself must inevitably take place" (Vygotsky, 1994b, p. 181).

Here, we see that Vygotsky explains personal degradation and degeneration of academic psychology in the same terms. Capitalism is the root of both, and socialism is necessary for scientific psychology and for fulfilling psychological phenomena. Psychological fulfillment and psychological science both depend upon critique and transformation of society. The converse is also true as scientific psychology and psychological change contribute to social critique and transformation. Psychological fulfillment, psychological science, and progressive political change are interdependent and inseparable.

# Social Life of the Sign: Sense-Making in Society

Sergio Salvatore

## Abstract

This work intends to provide a conceptualization of the power of signs to produce the sense of reality of the world to which they refer. To this end, a dynamic field model of sense-making is proposed that is based on the central idea of the *bivalence of meaning*—the meaning of X entails what is being interpreted by the meaning-maker (the *in presentia meaning*) but also the whole gestalt working as conditional context that sets the stage for the interpretability of the sign (the *in absentia meaning*). In metaphorical terms, the latter can be considered the “semiotic silicone”—as it allows the closure of the Gestalt grounding any interpretation. This model is meant to deepen the understanding of how sense-making works as well as establish the link between semiosis and social life.

**Keywords:** sense-making, sign, semiotic field theory, presentification

“I am a European!” This statement—often made—seems clear, but it is not. Identifying with a country—or even a conglomerate of countries—patriotic identity is a member of an infinite set of signs that are assumed to refer to objects, characteristics, or facts of the world (the race, the community, love, the group, childhood, human nature, the Holy Ghost, Homer, the unconscious, the market, the culture, etc.). As one can see, they refer to objects that are very different from each other. Some of these objects concern interpersonal relationships. A couple decides to separate because their love is over. Other signs (e.g., the market, the community) play a role in socio-political and economic transactions. Others are active within scientific discourse (the unconscious is a classical example of this; see Moscovici, 1961/2008). Some of these signs are confined to specific discourses and social domains (only Christians consider the Holy Ghost an existing entity). In other cases, they have a more generalized diffusion. For example, the idea of childhood as a fact of nature

is a rather recent invention (Ariès, 1960/1962); nevertheless, it is a taken-for-granted assumption orienting scientific and political discourse as well as daily life.

In this work I will refer to these kinds of signs to address a general issue, which goes beyond them and is a very basic aspect of sense-making: the *psychological valence of signs*—that is, the fact that we experience them as referring to entities that have a life of their own in the world.

I have chosen to focus the analysis on signs like “Europe”, market, couple, and the like, because of their semiotic status. As will be made clear below, every person, whether it be a student of sense-making or a soldier, a broker, or a wife, is aware that signs of this kind do not refer to *things*—namely, entities endowed with their own substance corresponding to a specific aggregate of energy-matter extended over a specific space-temporal domain (like “stone”, “mountain”, “water”, as well as “electromagnetism”, etc.). At the same time, every person conceives of and uses them as if they were *existing entities/facts*

and as such able to have an effect on experience and therefore to affect one's own and others' way of thinking and acting. Needless to say, people vary in where they put the distinction between signs referring to things and signs concerning not-things-but-however-existing-entities/facts (see below for a definition). Yet everyone in one way or another makes this distinction.

I am interested in this distinction for two reasons. First, because the latter kind of signs are the ones mostly involved in the regulation of social life and that mostly reveal the role that social life plays in sense-making. Second, because it makes it clear how the sense of referring to the world (what we indicate below with expressions like "value of existence") may not be conceived of as a taken-for-granted quality of the sign, as such grounding the sense-making. On the contrary, the fact that some signs are conceived of as referring to existing entities/facts, yet not endowed with substantial content, highlights how the valence of existing entities/facts is not the mere mirror of the fact that these entities are pieces of the world. And once it is clear that the "value of existence" is not an inherent quality of (at least some) signs, one is led to assume it is a psychological phenomenon—actually, the very basic psychological phenomenon—that needs to be modeled.

This means bringing the problem of the *presentation*, as highlighted by Continental Psychology between the nineteenth and twentieth centuries (Albertazzi, Jacquette, & Poli, 2001a), back into the scientific agenda. Already at the level of perception, psychological processes are not confined to repetitively mirroring the world (as the term "represent" implies), assembling the sensorial tracks the latter leaves on the subject. Rather, every psychic act is oriented toward an object—it is a perception, a judgment, a feeling of *something* (Brentano, 1874/1995)—that is actively construed in its psychological reality. Persons do not perceive pieces of experience that are then collected and hence signified; they perceive totalities. And, given that, as Kanizsa's (1955) experiments showed, these totalities are not held in the field of experience, they have to be conceived of as the product of the constructive activity inherent to the mind—indeed, of its capability of presentification. According to Meinong (Albertazzi, Jacquette, & Poli, 2001b; Valsiner, 2009), the psychological object has a content of being that is independent of its ontological status; some

objects (mathematical entities, objects like golden mountain, square circle, or the current king of France), even if they do not exist in the world, even if they are lacking any extentional property, *subsist*. As Eco (2009) highlights, this idea comes from Avicenna, who claimed that existence is an accidental property of the object (i.e., it does not precede and ground the object; rather, it may or may not be a value of it). It is logically required by the recognition of the fact that to state that something has no being, this something must be present. Now, if one accepts that the subsistence of the object is independent from and fundamental to its very existence, one has to conclude that the psychological presentation of the object is not based on, and does not mirror, its value of empirical existence; rather, it grounds it.

Contemporary psychology has pushed aside the notion of presentation, moving the focus onto representation. In this terminological shift, there is a major conceptual change. Cognitive psychology is not interested in how the psychological value of the representation comes about—namely, the fact that it is a re-presentation. Its functionalist standpoint led to scotomization of the issue of the generative process of psychological life, fully substituted by the task of describing its way of working. My work, in this sense, is a way of coming back to the future: to the theoretical problem of how the process of presentation is performed and how it produces the value of existence of signs.

One last preliminary observation is required. Needless to say, the issue I intend to address is laden with ontological implications—I cannot but use terms such as *existence*, *life*, *world*, and the like. Nevertheless, I consider the model I propose agnostic and neutral from the point of view of ontological assumptions.

It is agnostic in the sense that it does not provide any statement concerning the ontological status of signs. I will deliberately reduce to the minimum any statement concerning the ontological status of the semiotic process on which I focus. *The reference to the existence and reality of the signs will have to be systematically understood as concerning how the sign are considered and used by the semiotic interpreters*—not in an absolute sense. This is so because my aim is to provide a model of the *process that produces the value of existence of the signs* as the basic semiotic "fuel" for sense-making. Therefore, I am not interested in whether such value of existence mirrors the world. Once one recognizes how the value of existence

varies among people, circumstances, and kind of sign, one is justified in seeing the issue of the value of existence of the signs not as an inherent datum of the world—akin the equidistance of the points of a circumference from the center—but as a phenomenon to be addressed.

It is neutral, because it is not contingent to a specific ontological frame. It is evident that if one assumes an idealist-constructivist ontology, the problem of the value of existence of signs is easy to highlight in its relevance. This is so because assuming intensional semantics and more generally the separation between language and world (as this ontological approach does) obviously raises the issue of how signs are able not only to semantically map the world but more deeply how they are able to *present* it—namely, to make it a psychological experience for the semiotic interpreter. Yet, even from the point of view of an extensional semantics and more in general from within the frame of a radical realistic ontology, which states that only what is real is signified, one would anyway have the theoretical problem of clarifying the process of how what is real in the world becomes real for the subject representing it.

In sum, I am proposing a shifting of perspective—consider the value of existence of the signs as an *explicandum* rather than an *explicans*. I am oriented to consider this shift the main meaning of my contribution. In a recent work, Eco (2009) addresses the problem of how fictional characters (e.g., Anna Karenina), even if they are recognized as such, are able to move people's emotions and actions; the paradigmatic example to which Eco refers is the Werther effect, leading many young people, on the publication of the book by Goethe, to kill themselves, so as to share the destiny of their hero (and if one considers this just an excess of romantic souls, think that a similar phenomenon happened in 1950, this time as reaction of the defeat of Brazil with Uruguay in the final of World Cup soccer championship). On the one hand, Eco raises an issue similar to the one with which I deal. On the other, however, the very fact of addressing the issue of the capacity of fictional sign to mobilize emotions shows that the theoretical problem is much broader—it does not concern only fictional signs but every kind of sign and is not only related to the emotional reaction but more basically to the value of existence that feeds the emotional reaction.

## Signs that Create Existence

### *Acts and Consequences: Based on the Signs*

Maybe most of the people of the world have somehow had a direct or indirect impact on their life as a result of acts performed by other people in accordance to what the United States means for them. And those other people, in turn, have experienced the United States in terms of the acts that other people performed in accordance with it—and so forth, in an infinite intertwining of infinite dimensionality.

Yet, people are able to recognize that “the United States” is not a *thing* (as I have defined above—namely, an entity endowed with substantial consistency). Nobody has ever been able to touch the United States or invite them to dinner. If I forget to ask for a visa, I will not be able to enter “the United States”. Yet I am aware that it is not the United States that will prevent me from entering, but someone—a frontier police officer—who will do it as if she were executing the United States' will—that is, in accordance with what “the United States” means for her/him. Moreover, the frontier police officer will be able to have a commitment to her action insofar as she regards “the United States” *as if* it was an existing entity.

Thus, signs like “the United States”, “Europe”, as well as “family”, “love”, “will”, “motivation”, “value”, “University”, “community” and so forth, are (may be) recognized as different from those signs that refer to things, but this does not mean they are considered a virtual, fantastic representation. On the contrary, they are assumed and used as referring to a real entity—namely, an entity that has existence. And as such they are able to regulate the collective action. People kill and die in the name of such signs.

In sum, signs like “the United States” play a powerful regulating role in social life, and in this sense we can say that they have value of life, not because they are believed and used as referring to substantial entities but because *they are believed and used as referring however* to existing entities by someone and for this reason are able to affect (regulate, constrain, orient or the like) that person's acts (broadly speaking).<sup>1</sup> This means that a sign like United States refers to objects that have a contingent rather than universal existence (their existence depends on the fact that someone believes in it) within a certain domain. For this reason, we define this kind of sign as a *Value-of-Existence-Producing Sign* (VEPS), to underline that

they have a meaning that is felt, thought, and used as real—namely, as endowed with the *sense of quality-of-reality* (SQR). In sum, VEPSs have SQR.

An Italian poet and singer, Fabrizio D'Andrè, wrote: "They dreamt so hard that the blood started to drip from their noses."

### ***VEPS Is Unstable***

The VEPSs play a fundamental role in social and individual life. Subjectivity as well as intersubjectivity are shaped and sustained by this kind of signs (Rommetveit, 1992). From emotions felt and communicated to working organizations, from the care of the body to sexuality, from the system of justice and security to the distribution of duties and resources, from the sense of membership of a community to deviant behavior—all these fields of experience sustaining our personal and social lives are made up of institutions, namely generalized VEPSs, taken for granted in their SQR, and as such reifying the existential concreteness of the individual, interpersonal, and social scenarios.

Interestingly enough, the VEPSs' SQR does not need to be absolute to work. In fact, in most cases it can be present in some social and subjective domains (family, school, work, groups of peers) while being silent in others, where further institutional beliefs are salient. Take, for example, a person's desire to act consistently with and serving the "collective interest" (e.g., to behave honestly, to pay taxes, to participate in local committees, to help reduce pollution, etc.). This desire depends on the fact that the person feels she is a member of the collective community and thus feels the collective good she wants to pursue as if it belonged to her (on the rule of the identification in the construction of the collective goods, *see* Olson, 1965; Putnam, 1993). And this means that the production of collective goods requires people to feel the community as an existing entity—namely, in terms of VEPS. Yet this feeling is unstable both from a spatial (intersubjective) and a temporal (intrasubjective) point of view. For example, the Italian phenomenon of organized crime (*mafia, ndrangheta, camorra*) would not be understandable if one did not take into account that in most of the territorial areas where this phenomenon is rooted (regions like Sicily, Calabria, Campania), the feeling of being part of a public collective is notably absent or may be largely marginal in contrast with the salience of the network of primary social and family linkages.

The point at stake is that the VEPSs are a product of sense-making. As such, they are not ubiquitous and invariant phenomena. As the dynamics of participating in the collective good shows, their ways of functioning, as well as the output they provide, are variable. For example, take the ways values like Nation or Obedience, which have had an existential concreteness for whole generations, can lose all their existential meaning in a relatively short time and distance.

This raises the issue of identifying the conditions in which the dynamics of sense-making are able to produce the cultural constructions generating SQR.

### **Sense-Making and Meaning**

I maintain that a processual model of sense-making is required for this issue to be addressed. Such a model is grounded on confuting two premises.

First is the idea that the meaning is the sign's correspondence with the piece of world to which it refers. An authoritative example of this extensional theory of the sign is that provided by Frege (1892/1980), who distinguished between sense and meaning. The meaning is the thing the sign denotes, whereas the sense is the way of denoting it (i.e., of referring to it). Therefore, there can be many senses for the same meaning. For example, "Moon," "the white ball in the night sky," and "the earth's only satellite" are different senses of the same meaning (in this case, the planet we call Moon).

Second is the idea that the meaning is the content that the sign expresses/conveys. This is the structuralist vision of the sign (de Saussure, 1916/1977), which holds that a sign is made up of the link between a signifier (the expression) and a signified (the content). Any perceivable element of the world (an object, an event, an image, a sound) can work as signifier; the signified is the concept, the idea that is associated to the signifier. This association is the arbitrary product of a conventional code provided by the encyclopedia shared within a given community; yet once defined, it is quite stable and powerful, so that the sign appears as the fusion of these two components. Consequently, the occurrence of the perceivable signifier instantiates the conveyed signified.

Despite various differences, these two perspectives share a basic assumption: *the extralinguistic nature of meaning*—that is, the idea that meaning is independent and precedent to the (use of the) signs. For the extensional theory the meaning is the reference, for the structuralist theory it is the idea.

In both cases, however, it is something that is separate and prior to the displaying of the signs, as such grounding and motivating this display. In the final analysis, both these general conceptions of meaning consider it as the uphill condition of sense-making: signification is possible because there is something (the meaning) that can/must be signified. One can say “Moon” (the sign) because and insofar as there is the concept (the |moon|) and/or the concrete object of the world (the moon) it stands for.

A closer look to this extralinguistic assumption leads us to realize why it is unsatisfactory. In brief, paradoxically it assumes as its premise what is actually the consequence of the phenomenon it intends to model—namely, meaning. Take the meaning of the sign “moon.” Whether it be the moon or the |moon|, however we refer to it *through and in the terms of other signs* (in this case, moon and |moon|, entailing the use of capitals and of the sign “[ ]”), we grasp neither the thing nor the idea directly. Rather, what we do is to make an association between a sign and another sign performing the function of standing for a thing and an idea. And so on *ad infinitum*. To be more precise, what I am calling “thing” and “idea” are just signs involved in a given combination with previous and following signs.

One could say that any version of the extralinguistic assumption is necessary to understand the semiopoietic capability of language. Indeed, we imply and act out this assumption every time we use signs. Even now, as I am typing on my keyboard, I have to assume that the words I am choosing are selected because they are the ones whose meaning is the closest to the one in my mind and that I want to express. Therefore, one could turn the accusation of paradoxicality back at me and state that I am grounding myself on the extralinguistic assumption to produce a text aimed at criticizing it! Nevertheless, the very central point is that the necessity of the extralinguistic assumption is not evidence coming from outside the language. Rather, it is a representation, a sign, whose value as fundamental element of the language is in turn a sign rather than an inherent characteristic of the world. In other words, the extralinguisticness concerns the content of the assumption, not its nature, which instead is still linguistic.<sup>2</sup> However, the assumption is a sign and as such plays a grounding, regulative role on sense-making. Our mental and social life is fully immersed in such a flow of signs (Mininni, Ligorio, & Traversa, 2012). We do not doubt the world outside it; yet we do not get experience of

the world in itself but of signs and combinations of signs producing such a sense of worldness—what we call SQR here. However, not doubting is a sign.

A dictionary is the emblem of this separateness and self-referentiality of language. No dictionary defines the lemmas by connecting them to the thing to which they refer. Words are defined in terms of other words—namely, in terms of a pattern of co-occurrences of signs. The dictionary shows that meaning is not connected to ostensibility; it emerges through the way signs combine with each other. Sense-making (in the sense of the process of displaying signs) is not the mobilization of meanings pre-existing somewhere and independently. Rather, *meaning is the product of sense-making* (for operative models implementing this tenet, see Andersen, 2001; Salvatore, Tebaldi, & Poti, 2009).

### ***Sense-Making As Flow of Interpretations***

Peirce’s vision of semiosis as an infinite flow of interpretation provides a useful way for understanding meaning as the product of sense-making. A sign:

“... or *representamen*, is something which stands to somebody for something in some respect or capacity. It addresses somebody, that is, creates in the mind of that person an equivalent sign, or perhaps a more developed sign. The sign stands for something, its object. It stands for that object, not in all respects, but in reference to a sort of idea which I have sometimes called the ground of the representamen.”  
(Peirce, 1897/1932, vol. 2, p. 228)

Sign (*representamen*) stands for the object through the mediation of another sign (the equivalent sign) motivated “in the mind of that person.” The equivalent sign qualifies in which “respect or capacity,” the representamen sign, represents the object (i.e., the ground of the representation). Hence, the sign performs its semiotic function (the standing for something else) through the relation with another sign (the equivalent sign, also defined *interpretant* by Peirce) that, in turn, will be interpreted by another sign. Semiosis is the infinite process of interpretation of signs by means of other signs elicited in the mind of the interpreter.

An important point at stake here is that Peirce’s view of sense-making as infinite semiosis actually leads us to realize that semiosis never goes outside itself. The object is assumed to trigger the flow of signs; nevertheless, the kind of relationship the sign has with it (what Peirce defines *ground*) is given by

the relationship the sign establishes with the following sign (i.e., the interpretant).

Namely, a sign is something, *A*, which brings something, *B*, its *interpretant* sign determined or created by it, into the same sort of correspondence with something, *C*, its *object*, as that in which itself stands to *C*.

(Peirce, 1902/1976, vol. 4, pp. 20–21)

Using Peirce's terminology, the meaning of *A* (i.e., in which respect *A* stands for the thing *C*—namely, the ground of the representamen) is not given by the relationship *A* through *C* but by the relationship between *A* and its interpretant *B*, the latter relationship being assumed equivalent to the former ( $A \leftrightarrow C = A \leftrightarrow B = B \leftrightarrow D = D \leftrightarrow E = \dots$ ). This leads to the conclusion that meaning is the way signs combine with each other—the *trajectory of the chain of signs*.<sup>3</sup> Meaning is given by the capability of semiosis to keep signs in (some kind of) correspondence with the reality they refer to by *means of their connection with other (interpretant) signs*, in turn in correspondence with reality by means of other interpretant signs, and so on, in an infinite flow. Every new interpretant somehow rewrites the relationship with the object the previous signs have shaped through their combination; at the same time, in the very fact of doing it, it keeps this relationship active, opening to further potentiality of signification.

Sense-making consists of that recursive, asymptotic stream of interpreting signs. It is permanently stretched out toward its ungraspable object (De Leo, 2008).<sup>4</sup> And this permanent tension makes it an inexhaustible generative dynamics. We can and must always interpret because no interpretation is conclusive: each triggers a further one, just as any step toward the horizon moves the horizon itself ahead. Sense-making is thus the incessant tension of filling the emptiness between language and the world. Incidentally, this idea is quite close to the psycho-analyst Wilfred Bion's statement that thought emerges through absence (Bion, 1967).

### ***The Process of Production of SQR***

I have used the term *SQR* above to denote the semiotic value of VEPS—namely, their being viewed and used as referring to existing, although not substantial, entities. This raises the question of how the *SQR* is produced.

A processual model of sense-making is required that looks at the *SQR* as the product emerging from within semiosis (Salvatore & Zittoun, 2011).

More particularly, I propose to consider *SQR as the global effect of the stability of the flow of interpretation*, where this stability consists of the only real fact that the flow reproduces itself through time. As long as signs are used—namely, as long as people communicate with each other—there will be *SQR*. In this, the *SQR* works in a way akin to light. Light is perceived and conceived of as a thing (e. g., “Give me a light, please”) or a quality (e.g., “The room is light and airy”). Yet, it is actually a process—an incessant flow of photons. This flow is not retained in the semiotic construction of any of the versions of *light*. It is the cause of the perception, not its object/content. What we perceive is the emergent, macroscopic effects produced by the invariance (stability) of the constantly changing flow of photons. In the same way, meaning is the emergent global effect of the incessant flow of signs interpreting each other.

Let us see how this happens in more detail.

### **THE SQR AS AN EMERGENT EFFECT OF THE FLOW OF SIGNS**

To understand the semiotic mechanism grounding this process of emergence, one has to take into account that any sign is interpretable only in accordance with some constraints that reduce the virtually infinite possibilities of interpretation (Salvatore & Venuleo, 2008). These constraints are further meanings that have to be taken for granted.<sup>5</sup> This means that any interpretation is possible only under a semiotic scenario working as an *unthought premise* (Christopher & Bickhard, 2007). This scenario constitutes the *condition of interpretability* of the sign. The condition of interpretability can be seen as the definition of the *version of world*—among those possible (Bruner, 1986)—within and according to which sign is interpreted.

Take the case of a man in the sea who is waving his arms and shouting “I’m drowning. Do something for me!” Moreover, suppose that there is someone on the beach seeing and hearing him. It is easy to think that this woman will interpret the man’s words as a request of help aimed at avoiding death by drowning. And so she will dive into the water to save him or will ask someone else to do it. Now, although the woman’s interpretation may be fast, it is not *immediate*. The woman has to activate some premises qualifying the semiotic scenario, making the man’s words interpretable. In this case, some of these very basic assumptions concern the fact that people don’t want to die, that it is a good thing to help people to survive, that the content of

the sentence is representative of the state of the person uttering it, and so forth. As one can see, these assumptions are very basic generalized meanings constituting the condition of interpretability of the man's words. Without them, the man's words would remain uninterpretable and he would probably end up on the seabed.

Most importantly, what enables the interpreter to perform her hermeneutic job is not the objective "truthfulness" of her unthought premises. That would entail an extralinguistic anchor point. The fact is that these assumptions ground and shape the interpretation of the signs and therefore feed into a further unfolding of the incessant semiotic flow. In other words, the premises are not an object for discussion and validation. As conditions of interpretability, they ground and regulate the interpretation, without being involved as content of it—they are *the unthought device of thinking*. Therefore, their truthfulness is not a matter of judgment and/or agreement. Rather, it is the very product of their working as the regulative ground of the interpretations. In the terms of the previous example, the woman on the beach can interpret the man's words only on the condition of assuming a version of world and on the condition of living this version as if it were the only possible world—that is, *the world*. Actually, this world is just one of the semiotic possibilities.

One could imagine other versions of worlds—for example, a world where people like to drown (version 2) or where they consider the organization of funeral rituals more important than avoiding the death of other people (version 3). Take version 2: the woman will dive, but as she reaches the man, she will probably help him to drown, having interpreted the utterance "Do something for me" in accordance with the assumption of the desirability of death. In the case of version 3, the woman will run away from the sea to start organizing the post mortem ceremony in anticipation of the man's impending drowning.

Let us come back to version 1 (the one we consider the only version, therefore not merely a version but *the real world* as it is supposed to be), and suppose the woman will try to save the man. The interpretation of the man's word associated with this reaction will keep alive the SQR of the version of the world that works as the condition of interpretability of the woman's interpretation. And because further signs will be triggered by the woman's action—for example, the man will thank her, calling her "his guardian angel"—these further

signs will go on reproducing the SQR of the version of the world grounding them. In sum, signs are interpreted through the activation of semiotic gestalts—namely, generalized premises working as the condition of interpretability.

#### THE ROLE OF SEMIOTIC GESTALT-CONSTRUCTION: REIFICATION

These semiotic gestalts are constantly kept active through the very fact that the flow of interpretations for which they are the condition of possibility unfolds through time. And therefore, as long as and insofar as the flow of interpretations goes on, the assumption of quality-of-reality is reified—namely, *SQR is experienced not as a meaning but as a fact endowed with value of life* (Salvatore & Venuleo, 2010). SQR is a very generalized and regulative meaning: it is the basic assumption that the interpreters have to make to carry out their hermeneutic work—namely, add new interpretants to the chain of interpretation. In other words, SQR is what we need to put in the foreground to be able to think. *SQR is the basic condition of interpretability of signs*.

An imaginary example inspired by Wittgenstein (1953/1958) provides an illustration of the semiotic process of reification, which is the output and at the same time the grounding of sense-making. Imagine a man with a box that cannot be opened. And imagine that this man claims that inside the box there are some little balls. This claim triggers a dialogue about the balls—their properties, the implication of their ownership, and so forth. Imagine that this dialogue goes on for a long time, from one person to another, until nobody can remember its starting point. Now, insofar as the language game goes ahead (i.e., as the flow of interpretations reproduces itself through time), the presupposition of the existence of the ball—the assumption that is the condition of interpretability of the flow—remains valid. This means that it is believed and felt as a fact by the participants in the language game. Namely, it is reified. In sum, it is not the existence of the balls that grounds the talk on the balls, but it is the talk about the balls that reify the SQR of the balls.

Consider another instance: the financial system is a paradigmatic example of a flow of signs that constantly keeps the SQR of its premises active through the very fact of reproducing itself through time. Money is a very abstract concept, as is shown by the fact that it can be associated with an infinite number of things. Its SQR is produced by the fact that the existence of its value is the condition

of interpretability of the exchanges it prompts. Thus, we could say that sense-making is like playing Monopoly. While they are part of the game, players give value of life to banknotes and contracts—namely, the signs mediating their exchange—because such conventions are assumed *as if* they create the SQR required to play and enjoy the game. What differentiates Monopoly from sense-making is that one cannot stop playing with semiosis and therefore turn off the SQR of premises. All one can do is to change the content of the premise, not stop making premises.

### ***The VEPS As Stable Condition of Interpretability***

According to the consideration provided above, the semiotic mechanism of reification can be considered in terms of the following general law: *any meaning working as the ground (i.e., as condition of interpretability) of any practice of sense-making acquires and keeps SQR in the framework of that practice.*

The statement attributed to Jesus: “For where two or three are gathered together in my name, there am I in the midst of them” (Matthew, 18:20) is the most powerful image of this tenet I am able to find; a representation (to be there) is endowed with SQR (Jesus’ presence not as mere representation or belief, but presented and viewed *as a fact*) insofar as two or more persons share the assumption that what they believe is real (i.e., being there in the name of). This is the wonderful power of language to generate the conditions of its power!

What I want to focus on now concerns the spatial-temporal stability of the salience of the condition of interpretability. The general law given above considers this point when it states that the SQR of a given premise is contingent to the framework of the practice of sense-making that such a premise regulates. As long as it works as a salient condition of interpretability, the premise is the invariant ground of the ongoing variability of the flow of interpretations. But how stable is (or must be) the salience of the premises?

To answer this question, one has to take into account that the premises are not single meanings. Rather, they are a hierarchical<sup>6</sup> network of generalized significances.

Anderson’s tale “The Emperor’s New Clothes” illustrates this point. People see and act as if the Emperor were dressed, because they use the assumption of the royalty of the Emperor as the condition

of interpretability of the signs they are dealing with. And given that one of the properties associated with the regal status of the Emperor is that this condition is inconsistent with appearing naked, then what they see is interpreted in the light of the assumption that he is dressed in a very rare and valuable weave that has the quality of being invisible to stupid people. Thus, we see a hierarchical system of premises at work. The perception of the man known as the Emperor is a sign interpreted in accordance with the premise that his clothes are made of a kind of woven fabric that may either appear or not depending on the quality of the observer. This premise is in turn grounded on a further premise that serves as a condition of interpretability of the former—the regal status of the Emperor. It is only on the condition of assuming the royalty of the Emperor that the idea of such fantastic clothes becomes meaningful. Moreover, we need to introduce another very basic premise to close the gestalt: the very basic, grounding idea that everyone has of silliness as an undesirable status. As the tale tells us, as long as this network of premises works in a regulative role, the sense-making regulated by them endows them with SQR. When they lose their regulative salience, they lose their SQR. Yet, if one sees the issue through a more detailed lens, then one can realize that actually not all the premises have lost their salience. At least some of them keep their stability, even after the rupture of the previous framework, when the Emperor starts to be thought of and described as naked. The assumption of the Emperor’s royalty continues to retain its salience in the new framework; otherwise, the embarrassment as well as the other reactions at the sight of the naked man would be meaningless. Even more in-depth, the assumption of the undesirability of the status of stupidity is not destabilized by the transition to the new framework; it also works as a condition of interpretability in the new context (i.e., people see the Emperor as naked not because they agree to be considered stupid, but because they realize other aspects that in any case they interpret in the light of the assumption that stupidity is an unfair status).

In sum, as our interpretation of the Anderson tale shows, the premises have different degrees of stability to their salience. Needless to say, these differences do not depend on the inherent property of the premises. Rather, they are consequence of the way people and groups enact the practices of sense-making. As a result of these practices, some premises can be moved more easily from the background

to the foreground of sense-making, and in this way they can be made objects of signification and therefore subject to critique and/or falsification. Others are endowed with a higher power to hold in the background, and in this way they retain their salience as a regulative unthought source of thinking and acting.<sup>7</sup>

The VEPS can thus be conceived of as quite stable premises, able to keep their salience as the condition of interpretability through time and space. Thanks to this power, they can serve to regulate meaning, without being affected by the ongoing changes occurring within the semiotic flow; as such, they work as basic, invariant sources and grounds of SQR. From the standpoint of the dynamic theory of systems (Lauro-Grotto, Salvatore, Gennaro, & Gelo, 2009; Salvatore, Laura-Grotto, Gennaro, & Gelo, 2009), such invariance is a meta-stable trend that appears only at some level of scale—that is, a regularity in the ever-changing dynamics of the system. Figure 11.1 provides an example of meta-stable trend (from Salvatore et al., 2009). At a molecular level of scale, (that defined by 1 as the unit of analysis), the trajectory appears highly variable. At a higher level (that defined by 10 as the elementary unit of analysis), the trajectory designs a stable trend, defined by an almost quadratic curve, depicting the increasing–decreasing movement of the extension of the variability (i.e., the peaks) the

system is able to reach through time. The concept of meta-stability enables us to realize how in semiosis the invariance/stability of meaning is the product of an ongoing process, rather than the reflection of a static element.<sup>8</sup>

### Bivalence of Meaning: “Semiotic Silicone”

The discussion of the quality-of-reality presented so far leads us to focus on the mechanisms of sense-making involved in the micro-dynamics of the reification of signs. According to my thesis, these mechanisms are rooted in the bivalence of meaning (Abbey & Valsiner, 2007; Carli, 2007; Ribeiro, Gonçalves, & Santos, 2012; Valsiner, 2007). Generally speaking, bivalence is depictable in the following way: Taking A as what the sign makes present, then the meaning is not A but the bond of A and not-A (henceforth the *complement A*), according to which A emerges as a presence. In other words, the meaning of a sign does not only consist of the sign that follows the previous one in the flow of interpretation (i.e., the A); but it also encompasses the whole gestalt that makes such a sign the one that occurs instead of the infinite others that do not occur (henceforth we indicate this whole as the *complementSign*).

Complement A consists of both connections—*in presentia* and *in absentia*. On the one hand, any A entails an infinite number of connections with

**Figure 11.1** An example of meta-stable pattern.  
(From Salvatore, Lauro-Grotto, Gelo, Gennaro, 2009)

other signs. We have already dealt with this point when we stated that the meaning of a sign is the set of combinations it has with other signs. Yet, these bonds *in presentia* are, at the same time, relationships *in absentia*—saying that the set of combinations associable to the sign S contains X, Y, and Z means that S is *not* associable to M, N, O . . . ; any presence of signs is at the same time the absence of other signs. One could say that meaning concerns this split—namely, the border placed between what is thus made present and what is thus made absent.

The relationship between figure and background illustrates this point. Any time a form (A) is extrapolated, it is being made pertinent compared to something else (the complementA) that plays the role of background. Because there are infinite ways of separating figure and background, there are infinite possible figures. And this means that any figure is not the autonomous, self-contained content of a representation, but the product of a specific relationship with the background: the background is part of the meaning of the figure and not something simply put aside. It is necessary if the figures are to be understood.<sup>9</sup>

Consider the occurrence of a certain sign—say, “s”. That sign is experienced by us as holding a given content—say, |s|. For example, if someone utters the word “pipe,” everyone sharing the speaker’s code will consider this sign as having the value of denoting that device used for burning tobacco with the aim of breathing in the smoke produced. When we think and communicate, we act as if this experience of the signs were truth—namely, that sign s has a specific self-contained content |s|. Actually, this association is not given prior to the production of the sign, as an inherent property of the sign (Visetti & Codiot, 2002); rather, it is the product, the first product, of sense-making, emerging through the network of connections within which the sign is part (Salvatore, Tebaldi, & Potì, 2006/2009). The context is this network of sign combinations whose contingency qualifies the significance the interpreter attributes to each of them. Thus, sense-making always and in any case performs a double operation. On the one hand, it defines a denoting entity (what we are used to experiencing as the content of the sign)—namely, the making of a pertinent presence (henceforth, the *interpretandum*). And yet on the other hand, sense-making leads to the emergence of the complement of that presence—namely, the semiotic scenario according to, through, and in the terms of which

the *interpretandum* acquires sense. In sum, the meaning is not used up in the content of the utterance, because any practice of sense-making instantiates the whole semiotic field—namely, the infinite *in presentia* and *in absentia* bonds—grounding the “sensefulness”<sup>10</sup> of this content (Salvatore, Forges-Davanzati, Potì, & Ruggieri, 2009).<sup>11</sup>

Pantomime provides a fine image of the bivalence of meaning and sense-making. The mime produces some movements that work as signs (henceforth, S). The spectator sees these movements as an action (henceforth, A). For the spectator, S stands for A: S instantiates A, and A is the interpretation of S. Yet it would be misleading to consider A the content of S. A is not contained in S; rather, it is the spectators that build A as the interpretation of S. Moreover, the spectator performs this interpretative activity, adding a set of other data of imagination (i.e., other signs) that work as a complement of S and in so doing define the contextual totality that makes S therefore interpretable and thinkable. So the mime moves his arms and hands in a certain way; yet the interpretation of these movements as pulling a rope requires the spectator to complete the gestalt with a set of data of imagination concerning a long thin object being grasped by the mime, connected at the opposite end with something that resists the mime’s efforts. This set of data of imagination is the *complementSign* (cS) completing the interpreted gestalt—that is, the context. Thus, we arrive at the following definition: CON = (S + cS): *the context is produced by the sign performed by the mime integrated by the interpreter’s complementary activity of interpretation, thanks to which the interpreter makes a figure endowed with sensefulness*. It is only on this condition that the movements of the mime become interpretable as pulling a rope.

The interpretation starts, is constrained by, and has the *interpretandum* as its target; yet, strictly speaking *it does not concern it*. Rather, the *interpretandum* is the trigger element for the constructive function of producing a new sign complementing the former. *The interpretation does not specify something that is within the interpretandum, but it adds something further to it*. When the spectator signifies the mime’s movement, her hermeneutic work is not limited to the representation of what she perceives. Rather, she provides something else, complementing the context. It is the introduction of this data of imagination that, working as a semiotic silicone, allows the closure of the gestalt that makes up the interpretation.

### *The Backward Mechanism*

Taking into account the bivalence of sense-making, we need to conclude that sense-making cannot but reify.<sup>12</sup> The notion of bivalence of meaning leads us to expect that any incoming sign does not specify something that is already within/conveyed by the previous; rather, *it adds something further to it*: the kind of closing support (“semiotic silicone”) that is needed to bring the emerging gestalt into an appropriate form. The form of the gestalt can change through time, but one gestalt is always in the process of formation, because of the very fact that constantly new signs are introduced in the flow. Therefore, the stability of the semiotic flow is somehow kept and reproduced and with it the SQR.

Bivalence of sense-making leads to an inversion of the naïve view, according to which what comes before (the *interpretandum*) causes/regulates what follows (the *interpretant*). One must avoid confusing the occurrence of the sign with the semiotic function this occurrence performs within the flow of interpretations. Actually, it is not the sign that occurs, but a fact—it would be better to say, a sensorial modification in the interpreter that is assumed as a fact. This occurrence is a function of the state of the material field at the moment of the occurrence.<sup>13</sup> In itself, the occurrence has no meaning. What I have above called “condition of interpretability” does not concern it. The construction of the condition of interpretability is not the effect of the interpretandum’s capability to trigger an interpretant. On the contrary, the condition of interpretability works retrospectively, as the backward creation of the context (the gestalt), thanks to which the occurrence can work as a sign—namely, it is treatable *up to now* as the interpretant of the previous chain of signs. The linkage between interpretandum and interpretant works like the least common multiple rather than the greatest common divisor: the meaning is not (constrained within) which elements (the divisors) the two signs have in common but what they produce (the gestalt) through their being placed in common.

Hence, semiosis is inherently unlimited, because the chain of signs lacks the power to constrain the further possibilities of sign production. The subsequent sign defines the condition of interpretability of the previous one, rather than vice versa. And given that we cannot but interpret, any interpreter will be able to find a way to do it; even if the specific gestalt may change through time, the construction of a gestalt will be performed, and with it the

reproduction of the semiotic flow and the reification of the signs.

### **Future Directions**

The starting point of this contribution was the need for a processual conception of sense-making, modeled as an uninterrupted flow of signs, working as a dynamic field. This conception puts aside the idea of meaning as prior sense-making. Meaning is the emergent field product of sense-making. This model provides a different way of understanding how people, who inevitably speak and think from within and through the flow of signs, are able to feel and act as if there were a social world-out-there.

I have focused on a central aspect of this general issue: how some signs (the *VEPS*, as I have called them) are able to be felt and used as if they refer to things, although they have no other connection than that with other signs. My proposal is that semiosis provides the sense of its being in touch with the world from within itself, as the consequence of the very fact that the flow of signs goes on through time (and it does somehow go on).

This proposal entails a vision of sense-making based on the idea of the bivalence of signs: signs are made not only of what they represent but also of the whole field of meaning (the semiotic silicone) working as condition of interpretability of the sign itself. I have devoted the second part of this work to showing how this bivalent model allows us to conceptualize the microdynamics of sense-making, in terms of a backward mechanism—signs do not motivate the following ones; rather, they are construed as signs and interpreted as such by the following ones. Moreover, we have underlined how the bivalent model leads us to distinguish two levels of interpretation. On the one hand, any sign is recognized by how it is interpreted. On the other hand, however, this recognition is based on a hermeneutic work *in absentia*—namely, on the projection of the sign on a gestalt providing the condition of interpretability thanks to which the sign is addressed as senseful, and therefore interpretable (i.e., standing for something else). Consequently, the analysis of a set of signs (a text) means retrieving the generalized meaning grounding the semiotic encounter with the text. In this sense, hermeneutic analysis is always a recursive function, aimed at grasping the semiotic construction that has to be produced to perform an act of interpretation.

Needless to say, further developments are required to study in-depth the various aspects of the

model that have not been addressed in this paper. In particular, there are three aspects that I see as the most relevant to examine. First, the modeling of the microdynamics of the backward mechanism and more generally the way the bivalence of meaning works in sense-making. In this perspective, a line of investigation I consider promising is to use the topology to depict the field dynamics of the chain of signs. Second, at the current level of formulation, the model addresses the issue of the SQR only in its general aspect—namely, as the problem of how sense-making produces it. Yet, from a descriptive point of view, it is quite evident that signs are used with different gradients of SQR. The sign “stone” and the sign “the flying horse” differ from each other as concerns their SQR. Yet between these two extremes, there are many signs that, according to the circumstances and to users, have an intermediate level of SQR. Take, for example, fictional characters (Eco, 2009; Valsiner, 2009) that may or may not be endowed with SQR in a variable fashion and that do not have the same SQR as either “stone” or “flying horse.” Consequently, it is not enough to model how SQR is produced—one also has to understand what makes such production variable across the practices of sense-making. Finally, I consider it important to validate the model to test its capability to ground analysis of specific patterns of sense-making. In this chapter, I have made several references to phenomena of sense-making. Yet, these references have had a merely exemplificative function; I have not used the model to understand them, but vice versa. In the final analysis, it is in this possibility—that the model enables us to get a deeper understanding of the phenomena of social exchange—that the conceptual value of the theoretical proposal lies.

## Notes

1. My discussion does not require that the recognition of the fact that a given sign does not refer to a substantial entity should be fixed and systematic among people. On the contrary, it is usual for many people at certain times and in certain circumstances to regard signs like “the United States” as substantial entities and at other times, and in other circumstances, as nonsubstantial entities. What is relevant and required for the sake of our discussion, therefore, is the potentiality of this sign to be used as referring to nonsubstantial entities.

2. Confusing these two levels—the nature of the object represented by the sign and the nature of the sign representing it is like concluding that if a person says, “I am not speaking,” then she/he is not speaking.

3. The idea of meaning as the trajectory of the chain of signs is close to the seminal idea of Wittgenstein (1953/1958) of meaning as the use of the words. More generally, it is consistent

with the pragmatic approach to meaning that sees it as the effect the sign provides on the addressee. In our view, however, this effect has to be conceptualized as a further sign: an equivalent sign. Be it a reaction, a refusal, or an affective appraisal of the addresser’s sign, the addressee’s response works as the interpretant of the former, and in so doing develops the chain of signs comprising the meaning and keeps itself active and transforming through time.

4. Claiming this linguistic, processual and nonexpressive nature of meaning does not mean assuming a nihilist position that rejects any kind of connection between language and world. Actually, the separateness of language, as I use it here, does not entail its isolation. Rather, it is the condition of sense-making—not its limit. It is precisely because semiosis is an autonomous, self-referential, and recursive process that it can make meanings emerge. Autonomy is required for the development of the self-regulative intrasystemic dynamics that leads to the development of these processes of emergence.

5. This point is highlighted by Peirce’s triadic theory: the interpretant is a way of depicting the linkage between the representamen and the dynamic object. Therefore, any sign, any interpretation, is possible on condition that (1) there is a dynamic object in relation with the sign standing for it; (2) this relationship concerns a specific aspect of the dynamic object (the ground); (3) the ground is signified by an equally specific aspect of the sign (e.g., the image of the pipe stands for the pipe only in some perceptual properties and not in functional ones—that is why we cannot use it for smoking; at the same time, not all the elements of the image of the pipe are relevant to its function of standing for the pipe (e.g., the chemical composition of the paper on which it is drawn is not relevant).

6. In semiosis, the hierarchical linkage among the premises is intransitive in its nature (Valsiner, 2007)—that is, a given meaning A can be superordered compared to B, B can be superordered compared to C, and at the same time C can be superordered compared to A. This is so because the hierarchical organization of meaning is not an invariant structure but is contingent to the dynamics of sense-making.

7. The idea of the European Community as an entity is an example of how a meaning can have a variable gradient of SQR through time and space. In some areas of the European population—as well as at some points in the recent history of the European people—the European Community has been experienced (is being experienced) as a concrete entity, something to belong to and by which it is acceptable to be affected in our own lives. In other historical moments and other domains of the European population (e.g., in a not insignificant part of the Italian as well as the English population), the European Community is little more than a name.

8. The example of Monopoly can help to illustrate this point. During the game the Monopoly banknotes work as if endowed with SQR for the players. Yet, as soon as the game ends, they lose their salience. Therefore, because they do not have enough cross-spatial/temporal stability, they cannot be considered as VEPS. On the other hand, the value of money is quite a ubiquitous assumption in contemporary society. It is salient before and after the game and at the same time is not suspended during the game. On the contrary, the SQR of the money grounds the very possibility of considering Monopoly meaningful. It works as a condition of interpretability of the local condition of interpretability of the game and the acts of playing it. In sum, money is a meaning that retains its stability through many space/time frameworks. In this sense, it is a meta-stable condition of sense-

making, which is made salient through the variability of the local dynamics of semiosis. That is the same as saying that it is a very powerful VEPS.

9. Interestingly enough, psychoanalytic theory has conceptualized the affects as the first form of meanings emerging from the proto-differentiation of the field of experience as an indistinguishable totality (Bucci, 1997; Matte Blanco, 1975).

10. I use this term to stress that what is at stake here is not the semantic and/or pragmatic validity of the content—namely, if the interpreter considers it agreeable or not. In a more generalized way, “sensefulness” concerns the very plausibility of the act of interpreting the sign (of considering it a sign worth being interpreted). Thus, the content can be meaningful or not, but it is viewed so as a result of the fact that the interpreter addresses it—that is, as a result of the fact that it is considered “senseful.” Therefore, a sign can have sensefulness but not meaningfulness but not vice versa.

11. Recently, Bang (2009) has underlined the role of the emptiness in sense-making. This concept is another way of highlighting the interdependence between the visible (*in presentia*) and latent (*in absentia*) sides of meanings.

12. Needless to say, the SQR can appear in the discourse as the content of a statement. For example, this is true when one says: “I do not think that this actually happened.” Nevertheless, the SQR as a specific content of a statement (say “SQR”) is not to be confused with the SQR as the global sense of connection with the world that emerges from semiosis as a whole (say [SQR]). The latter is a highly generalized feeling, an embodied meaning, inherently associated with sense-making (Salvatore & Zittoun, 2011), whereas the former is a discrete sign that may or may not be used in communication. The latter is a recursive interpretation of the former, which is possible precisely because of the former.

13. It is outside the scope of this work to address the issue of how the state of the field produces new occurrences.

# Meaningful Connections: Semiotics, Cultural Psychology, and the Forms of Sense

Robert E. Innis

## Abstract

This chapter explores what a philosophically oriented semiotics has to offer to cultural psychology. In as much as semiotics, as the general theory of signs, deals with multiple forms of meanings, its concerns are distinctively cultural. But in as much as semiotics is concerned with the experienced reality of meanings, its concerns are distinctively psychological. Nevertheless, semiotics is not itself a cultural psychology nor a psychology of culture, nor a substitute for them. This chapter presents key elements from the semiotically relevant work of C.S. Peirce, Karl Bühler, Michael Polanyi, Ernst Cassirer, and Susanne Langer to focus on the power of semiotics to model the self, situate the semiotic frames of cultural meaning, broaden the notion of signification, and to delineate the fundamental groundlines of the plenum of consciousness and establish the thresholds of sense, including the role of the tacit dimension and the semiotic relevance of embodiment.

**Keywords:** signs, modeling the self, cultural frames

Semiotics is the study of *signification* in the most general sense of that term. It is an essentially transdisciplinary study of processes of meaning-making and the meaning systems and sign systems in which they are embodied and expressed. Because of the transdisciplinary nature of semiotics, it can and does function as a kind of “big tent” within which different types of reflections and investigations take place. Philosophers, biologists, cultural theorists, psychologists, linguists, art historians, literary theorists, and many more find its conceptual tools helpful, indeed indispensable, for carrying out their studies. The central concept of semiotics is *the sign*. What Vygotsky said about words can be said, more generally, about the sign: it too not only is “a direct expression of the historical nature of human consciousness” but also is “a microcosm of human consciousness” (Vygotsky, 1934, p. 256; see also van der Veer & Valsiner, 1991). But how we are to frame this concept is not universally agreed

upon. In fact, semiotics takes its core categories from quite different intellectual traditions and is by no means a monolithic system or framework, despite the claims of many of its practitioners and proponents.

The differentiated conceptual toolbox of semiotics actually allows it to engage very diverse analytical, critical, and reconstructive tasks in different ways. In as much as semiotics deals with multiple forms of meanings, such as language, art, ritual, myth, religion, even science and technics, its concerns are distinctively cultural. But in as much as semiotics is concerned with the experienced reality of meanings, its concerns are distinctively psychological. Nevertheless, semiotics is not itself a cultural psychology nor a psychology of culture, nor a substitute for them, although its problems and themes intersect with them at many points. In the words of Umberto Eco, the subject matter of semiotics is “co-extensive with the whole range of cultural

phenomena, however pretentious that approach may at first seem” (Eco, 1976, p. 6).

## From Semiotics to Cultural Psychology

So, what does semiotics have to offer that could be of most benefit to cultural psychology, which seems to have the same scope, from the experiential side, as semiotics does from the side of the analysis of the logic of cultural forms? What challenges does semiotics pose to cultural psychology? And where do semiotics and cultural psychology overlap to their mutual benefit?

### *Thresholds of Semiosis*

In his *A Theory of Semiotics*, Umberto Eco claimed that “signification encompasses the whole of cultural life, even at the lower threshold of semiotics” (Eco, 1976, p. 46). That lower threshold is the actional-affective-perceptual field itself in which the whole of cultural life, the upper threshold, is ultimately grounded and located. Eco’s claim was another formulation and consequence of the fundamental and startling semiotically grounded thesis of C. S. Peirce, the American philosopher and founder of a major strand in semiotics:

“[T]he content of consciousness, the entire phenomenal manifestation of mind, is a sign resulting from inference . . . the mind is a sign developing according to the laws of inference.”  
(Peirce, 1868, p. 53)

Peirce divided these laws of inference into the three distinctive forms of induction, deduction, and abduction, or hypothesis formation, to which the construction and interpretation of signs is attributed. Abduction, according to Peirce, is the source of all novelty. The human mind for Peirce, however, is not enclosed within the skin of an individual organism. Rather, the organism is enclosed within, or embodied in, or self-spinning into, a semiotic web, a network of signs and sign relations that are the support of its mental existence. Its mind is no more inner than outer. It is both, as Peirce illustrated in his famous example of the inkstand. In a provocative and eminently generalizable and remarkably contemporary passage, Peirce wrote:

A psychologist cuts out a lobe of my brain (*nihil animale a me alienum puto*) and then, when I find I cannot express myself, he says, “You see, your faculty of language was localized in that lobe.” No doubt it was; and so, if he had filched my inkstand, I should not have been able to continue the discussion until

I had got another. Yea, the very thoughts would not come to me. So my faculty of discussion is equally localized in my inkstand.  
(CP 7.366)

Mental existence is embodied semiosis. The production and interpretation of signs in which our thoughts come to us, and we come to thoughts, depends on objectively available semiotic tools in just the way Peirce was dependent on his metaphorical and real inkstand. This insight was developed and generalized by the rich psychological tradition initiated by Vygotsky. The semiotic tradition deriving from the structuralist project deriving from Ferdinand de Saussure’s *Course in General Linguistics* confirms Peirce’s and Eco’s claims. Its concurrence is epitomized in Elmar Holenstein’s laconic assertion that structuralism “draws our attention to the root-like attachment of the world’s subjective constitution to sign systems” (Holenstein, 1976, p. 5). But it is not just the world’s constitution that is at issue. It is also the constitution of subjectivity itself. Peirce’s contention that the mind is a developing sign is paralleled in Roland Barthes’ claim that “man is articulated to the very depths of his being in distinct languages” because “the *psyche* itself is articulated like a language” (Barthes, 1977, p. 47). The semiotic problem, however, is how language itself is structured and how it should be modeled. Even if language is *the* semiotic system *par excellence*, as is almost universally admitted, that really means that although it exemplifies the features of semiosis, it does not entail that it establish them or function as the prime model of semiosis. Semiotics, or the general theory of signs, takes as its task the construction of a semiotic model that is comprehensive enough to delineate the ultimate conditions of semiosis no matter what sign forms they may take. Semiotics wants to schematize the most fundamental distinctions between the various systems of signs, among which language may or may not have a certain primacy or primordially.

Near the end of his book, Eco goes on to say that “semiotics can define the subject of every act of semiosis only by semiotic categories; thus the subject of signification is nothing more than the continuously unaccomplished system of systems of signification that reflects back on itself” (1976, p. 315). This self-reflecting system is, on this account, essentially open, or continuously unaccomplished, having no greatest upper bound. The unending spiral of semiosis (or semioses) is a perpetual dynamic oscillation between two intrinsically related thresholds,

an upper threshold of systems of signs and meanings of all sorts circulating in society as cultural forms and a lower threshold defined by the limits of the lived body as a matrix of lived-through, but not explicitly articulated, activities. The problem that all theories dealing with the mind and its socio-cultural matrices have to face is how to model this whole process—or the sets of processes occurring between these two limits. And the question has to be faced of what contribution semiotics—however we define its nature, range, and scope—can make to this modeling process. What types of semiotic categories and models have been put forth? Which ones do we really need? Is there one privileged way to model this semiotic subject? Perhaps, in light of the complexity of the semiotic subject, there is, in fact, no privileged way but, rather, the various approaches to defining the thresholds of sense and meaning and the logic of consciousness have differently weighted heuristic powers of foregrounding different aspects of pertinence and relevance. This fact would have important implications for the tasks and methods of a broadly based cultural psychology and for our being able to situate its intersections with semiotic concerns.

What then, more specifically, can cultural psychology find in semiotics' toolbox that it both can and should use for its tasks? In what senses can a semiotic analytical framework, broadly and flexibly understood, be helpful for cultural psychology? How far can we push meaning or semiosis down into the perceptual, actional, and affective stratum, and how much are semiotic processes at the higher levels characterized and conditioned by *structures of semiotic* (and other forms of) *embodiment* already limned on the lower levels? If the mind is, to repeat Peirce's formulation, a sign developing according to the laws of inference and is, according to Peirce's rich and illuminating metaphor, a plenum or "bottomless lake," how are we to *model* this field of consciousness? Where are we to draw the lines through this plenum so that the significant joints of consciousness would be differentiated and characterized? And what is the exact role of a semiotic approach to accomplishing this task? Does semiotics itself point to a kind of limit to what could be called the "principle of effability"—that is, that experience is best characterized as a semiotic process? Or is recognition of such a limit actually an unexpected enrichment of the semiotic framework? Indeed, more generally, which semiotic approaches are we to use, either exclusively or predominantly,

and what are their relations to one another? And what precisely are such approaches expected to offer in the context of the problems and issues of a cultural psychology?

The following discussion will illustrate, with no claim to completeness and with a quite definite leaning toward the philosophical side of semiotics, a very personal choice of possible answers to these questions by sketching central concepts and categories from five quite different approaches to the schematization of consciousness, represented by C.S. Peirce, Karl Bühler, Ernst Cassirer, Susanne Langer, and, as a kind of philosophical wildcard, Michael Polanyi, whose work on tacit knowing and meaning stands outside of semiotic currents in the strict sense but bears upon them in challenging ways. Others, coming from other home disciplines, would no doubt look to other resources, but, as I have tried to show elsewhere (Innis, 1982, 1992, 2002, 2009), the aforementioned thinkers are of extraordinary value.

### Framing the Semiotic Matrix

C. S. Peirce, as the initiator of one of the most powerful traditions in semiotics, proposes a semiotic approach to consciousness and cognitional structure that has as its focal point its essential dimensionality. Although this is certainly not on the surface a startling thesis, and in fact is a core thesis of cultural psychology, Peirce's actual derivation of and development of it is. Peirce argued that the dimensions of consciousness are correlated with his fundamental and well-known triadic differentiation of signs into icons, indexes, and symbols. Consciousness exemplifies, and exists in, three different semiotic modes, corresponding to iconicity, indexicality, and symbolicity. Iconicity is the semiotic mode that is based on resemblance and is, on Peirce's account, exemplified by sign systems composed of images, metaphors, and diagrams, to each of which Peirce devoted clear and stimulating analyses. Indexicality is the semiotic mode that is based on existential connection. It is exemplified by all species of signs that point, be it fingers, directions of the eyes, sign posts, tracks in the snow, symptoms of disease, personal and relative pronouns, definite articles, and so forth. Symbolicity is the semiotic mode that is based on convention or law. It is exemplified *par excellence* by language and mathematical and other notation systems that have a full degree of semiotic freedom and openness. Peirce engaged in multiple taxonomic and schematic characterizations of these

sign types with their attendant subdivisions. These sign types are semiotic frames within which and by means of which we give meaning to the world. They are, looked at another way, “access structures” in which we are embodied and by means of which we articulate the world and express it in signs.

On the side of their psychological instantiation, Peirce points out that the general schematization of sign types into icons, indexes, and symbols corresponds to feeling, reaction, and synthesis or, more generally, habit-taking. These are the three fundamental—indeed ultimate—ingredients of consciousness, although they are not elements in any Humean sense, as Peirce’s commitment to synechism involved holding to a principle of continuity. They are the psychological side of the semiotic frames within which consciousness functions. A feeling, on Peirce’s account, is an immediate consciousness of a quality, such as redness, bitterness, the taste of quinine, or the odor of attar. It is by means of feelings that we access the world in its suchness and do so without comparison. Peirce illuminatingly called it “*primisense*,” exploiting the ambiguity of “sense” as both a power and a type of meaning. A reaction is a felt sense of resistance, of interruption, of a breaking into consciousness of something other, such as running into a closed door or being startled by a sudden whistle. Peirce correspondingly calls this dimension of consciousness “*altersense*.” Law or convention appears psychologically as achieved synthesis or rational habit. The ability to take on differentiated sets of habits, and to control these habits, is the mark of rationality. Human life consists more and more of the rational construction and reconstruction of habits, including on the lower threshold perceptual habits where qualities and resistant particulars are synthesized or mediated into unities. Peirce calls this dimension of consciousness “*medisense*.” It is important to realize that for Peirce, these are simultaneous present dimensions of consciousness as such. But each dimension can be foregrounded in different modes of attending, which are themselves both embodied in, and enabled by, distinct sign systems.

In as much as “*primisense*” or *qualis consciousness* explores the world through objectified and expressed systems of resemblances, Peirce would instruct a semiotically aware cultural psychology to explore the cultural manifestations and variability of our sense of finding resemblances and capturing them in systems of iconic signs. Such a cultural psychology would develop with new tools the notion that it

already works with: that resemblances are not just, in certain instances, “given” but rather “taken.” To see a resemblance on the basis of shared qualities—especially of domains seemingly distant from one another—is to perform an interpretive and semiotic act. It is an activity that is both spontaneous and methodically pursued. A Peircean semiotics would point a part of cultural psychology’s research agenda to the study of the variability of image formation, of different metaphorical networks, and of the varying conditions in which diagrammatic expressions and forms of argumentation have developed. To the semiotic phenomenology of the internal content of these forms and their historical development, for which Peirce supplied the foundation, cultural psychology would add a genetic and explicitly socio-cultural dimension. Semiotics and cultural psychology work hand-in-hand here.

As to the dimension of *altersense*, this is the realm of indexes or indices. Indexicality takes two radically different forms: natural and conventional. Natural indices belong to the most basic stratum of reading nature, of following traces, of determining which traces and indications are pertinent. There is great variability in this regard, as the anthropologists have shown us. Eskimos read the traces of their (to us) minimally differentiated environments with as much confidence as rain forest dwellers read the traces of their profuse environments. A Bedouin at home in a desert landscape sees differences that are imperceptible to the city dweller. Natural intelligence on this level, or in this dimension, which includes animal and human spheres, is common to all organisms. It is connected with sensory acuity and also with being hardwired to respond to sensory cues by reason of the body that one has inherited genetically. Ecological and environmental psychology, certainly components of a comprehensive cultural psychology, must explore these domains in the company of a semiotically informed phenomenology. But trained and habitualized natural intelligence extends further out to indices that, although natural in one sense, are also culturally discerned and maybe even determined. I am thinking here specifically of such phenomena as the symptoms of disease, slips of the tongue, inadvertent gestures, and so forth, that point beyond themselves to objects and states of affairs. Conventional indices encompass all the pointing signs of every sort that we have constructed to steer us through the world, including, clearly, language in its indexical dimension. But, it could be said without exaggeration

that natural science in its technological side is also a way of capturing the signs of nature or even of provoking nature to emit signs. In this sense, natural science would be a set of practices that attend to what is taken to be pertinent and would be subject to all the subjective factors that condition patterns of attending. Once again, cultural psychology could take another look at the history of science as a variable set of patterns of attending to particulars and ascribing relevance to experienced linkages. How is this done? Why are some linkages made rather than others? To answer such questions, cultural psychology would not only join forces with semiotics but with the history of science and with psycho-analysis in the broadest sense.

Medisense captures what is involved in the symbolic dimension of consciousness. It is the mark of human mentality as such, building as it does on the iconic and indexical dimensions. Indeed, the human approach to the world is constituted by forms of mediation all the way up, as consciousness builds a more and more coherent and interlinked world and *recognizes that it is doing so*, a point argued with great force by Deacon (1997). Peirce's emphasis on medisense is intended to foreground the abductive, interpretive dimension of consciousness and cognition. It implies a kind of semiotic constructivism—that is, the thesis that the world is known through the interpretation and production of signs. And these different systems, as formulated in objective structures, lay variable networks of concepts over experience. Symbolic consciousness is, in this sense, motivated without being caused by an objective world putatively accessible outside of some symbolic scheme. For Peirce, the latter alternative is simply not possible. There is no way, Peirce argues, of accessing reality in a mind-independent or sign-independent way, even if one asserts that there is a mind-independent reality. So, in this way semiotics' central idea coincides with the research project of cultural psychology, which studies the subjective conditions and genesis of objective symbolic structures. On this conception, the focal point of cultural psychology would be the genesis and development of meanings *in* experience, whereas semiotics itself would supply the formal frame for the analysis of the meanings *of* experience.

Peirce distinguishes a grammatical, a logical, and a rhetorical dimension of the analysis of the signs, the *representamina*, that carry meaning.

The task of a semiotic *grammar or syntax* is, as Peirce puts it, to “ascertain what must be true of the

representamen used by every scientific intelligence in order that they may embody any *meaning*” (CP 2.229). Such a task is, on first glance, one of the proper tasks of a general theory of signs. Looked at this way, on the grammatical or syntactic level, semiotics is concerned with the internal constitution of signs, their defining properties and relations to one another, and their essential differences. It wants to determine the formal features of sign types and distinguish them, in terms of their intrinsic properties, from one another. Cultural psychology, taking these properties as given, would study the social and cultural conditions of how one learns these systems of differences—that is, how they are in themselves perceived and apprehended. It would also ask whether, by reason of our semiotic embodiment in different sign types with different syntactic structures, we develop very different cognitive strategies and modes of thinking that influence how we access the world. Such an issue clearly bears upon the logical dimension of signs.

The task of a *semiotic logic* is to determine the conditions that make it possible that representamina “may hold good of any *object*, that is, may be true. Or say, logic proper is the formal science of the conditions of the truth of representations” (CP 2.229). Looked at this way, on the logical level, semiotics is concerned with the bases of the relations of signs to their objects, not their syntactic or grammatical differences from one another: resemblance in the case of icons, existential connection in the case of indexes, convention in the case of symbols. These bases have psychological reality, but it is not the job of semiotics to explore them. Rather, they are interpretive frames to be used by cultural psychology in its investigations of the variability of contents in the mental appropriation of the world in different socio-cultural contexts. Cultural psychology would study, however, which iconic forms circulate in society, which indexical signs intervene in and structure both the social and individual sensoria, and which symbols structure the life-world on its many levels. In this, it would appear that once again, semiotics and cultural psychology, looked at through Peircean eyes, would work hand-in-hand (*see* Valsiner & van der Veer, 2000)

The task of a *semiotic rhetoric*, according to Peirce, is “to ascertain the laws by which in every scientific intelligence one sign gives birth to another, and especially one thought brings forth another” (CP 2.229). Looked at this way, semiotics is concerned with the relation of signs to their users, whether

producers or receivers. On the objective side, semiotics would study the forms of argumentation, the laws of birthing of ideas in the consciousness of others, whereas cultural psychology would attempt to situate these forms in distinctive matrices and situations. A clear example of this, which also encompasses the syntactic and logical sides, is Nisbett's *The Geography of Thought* (2003). It is evident that there is an important linkage between the two disciplines in this domain.

Peirce's semiotic project, consequently, presents in an integrated way a set of conceptual tools, analytical models, and heuristic pointers. But it not just the well-known triadic schemata of (1) feeling, reaction, and synthesis; (2) icon, index, and symbol; or (3) syntactic, semantic, and rhetorical that characterize Peirce's project and set the tasks for a developed semiotic theory that would supply the linkage to cultural psychology. Peirce points out that to understand what is involved in any achieved act or process of semiosis, or meaning-making, there are *five factors* that have to be considered. (1) *Signs* make their (2) *objects* known through their proper significant effects—that is, their (3) *interpretants*, to or in an (4) *interpreter*, and they do so, as Peirce puts it, (5) “not in all respects, but in reference to a sort of idea, which I have sometimes called the *ground of the representamen*” (CP 2.228). Peirce understands this notion “in a sort of Platonic sense, very familiar in everyday talk” (CP 2.228) It appears to be introduced to maintain continuity of reference of a thought at different times. But it is also clearly meant to point out the aspectual dimension of a sign's relation to its object or to a *cluster of background conditions for a successful semiosis*.

### ***The Semiosphere***

An important thing to note is that Peirce's complex model, with its differentiation of sign types, its specification of ingredients of consciousness, its delineation of the factors of semiosis, applies not just to the upper threshold of semiosis, where we are dealing with objectively circulating systems of signs that make up the cultural order or what Lotman (1990) called the semiosphere. It also applies to the lower threshold, where the feeling, acting, and perceiving organism first starts to draw the lines in the continuum of experience. This is of the utmost importance for understanding the emergence of meaning and the variable and culturally defined situations in which it occurs, which is the main concern of cultural psychology. For Peirce, cognition

is a continuum, differently weighted at different levels and stages, but with the same ingredients at every level and stage. Feeling, reaction, and habits of synthesizing are, as Peirce puts it, “constant ingredients of our knowledge” and result from “congenital tendencies of the mind” (CP 1.374). In one sense, as Peirce formulates it in a kind of Scholastic mode, they can be understood as “three parts or faculties of the soul or modes of consciousness” (CP 1.374)—no matter what the level is or the cultural matrix in which consciousness is embodied. Peirce summarizes the three categories of consciousness in the following compressed text:

... first, feeling, the consciousness that can be included with an instant of time, passive consciousness of quality, without recognition of analysis; second, consciousness of an interruption into the field of consciousness, sense of resistance, of an external fact, of another something; third, synthetic consciousness, binding time together, sense of learning, thought.  
(CP 1.377)

The three categories, according to Peirce, are comprehensive and exclusive, characterizing indubitably “three radically different elements of consciousness, these and no more” (CP 1.382): immediate feeling, the polar sense, and synthetical consciousness (“the consciousness of a third or medium” [CP 1.382]). If we agree, as I have proposed, to call the lower threshold the “affective-actional-perceptual threshold” and the upper threshold the “symbolic threshold,” I think we can see that on Peircean terms, they are both intrinsically semiotic and can be modeled in the same way. Affective-actional-perceptual consciousness instantiates the categories of semiosis just as much as explicitly cultural consciousness does. An object on this level for Peirce is composed of a first—a qualitative suchness—and a second—an undergone set of resisting particulars—joined into a whole by means of a third—a synthetic, indeed synthesizing, lawfulness or habit. Such an object is a configuration of iconic/qualitative, indexical/reactive, and symbolic/mediating moments. Perceptual objects are emergent from a field of qualitative characters and indexical particulars synthesized by the interpreter or knowing subject. For Peirce, quite generally, “every kind of consciousness enters into cognition” (CP 1.381). Although, as Peirce puts it, feelings “form the warp and woof of cognition,” and although the will, in the form of attention (to the other), constantly enters, perceptual consciousness,

when it is carried to completion, is neither feeling nor the polar sense. It is “consciousness of process, and this in the form of the sense of learning, of acquiring, of mental growth.” It cannot be immediate for it cannot be “contracted into an instant.” It is “the consciousness that binds our life together. It is the consciousness of synthesis” (CP 1.381)—or, rather, synthetic consciousness. A semiotically informed cultural psychology then would explore the whole culturally variable configurations and panoplies of feelings, of forms of attention to the other and of symbolic construals. It is not reducible to cognitive psychology in any restricted sense. It is extended to ways of world-making, where the various worlds are not defined in purely conceptual terms but in terms of different types of sign configurations and meaning structures.

So, the affective-actional-perceptual field and the cultural field, characterized by objectively circulating sign systems, are informed by the three semiotic modalities and are not to be thought of in terms of a polar opposition between reified lower and higher levels. The same elements or ingredients are present on all levels, although they may be differently weighted or foregrounded in any specific instance of accessing the world. Icons, as objective signs, are the firstnesses of thirdness, indexes the secondnesses of thirdness, and symbols the thirdnesses of thirdness. This is the foundation of Deacon’s (1997) core insight into the distinctiveness of the symbolic species.

This introduces a real complexity into the tasks of a cultural psychology that is fine-grained and phenomenologically acute: it must oscillate between the low and the high. It also implies, on the human level, that the symbolic field, or more generally thirdness or mediation, enters into and permeates the spheres of feeling and action. The semiotic subject—that is, the semiotic self that is the object of a cultural psychology—is, according to the Peircean model, *a three-dimensional or three-layered self-assembling and, on the reflexive level, self-interpreting field.*

Indeed, corresponding to the stratification of the interpreter, or semiotic self, is, looking back at the factors of semiosis, the stratification of types of interpretants that qualify this subject. Peirce’s revolutionary insight is that a sign or a sign configuration gives rise to proper significant effects in sign users. Interpretants are the meanings of signs or sign configurations. But, as Peircean semiotics claims, the meaning of a sign can be (1) an emotion, feeling, or affect; (2) a pattern of actions, an

expenditure of energy and effort, an attending to the other in some way or the other; or (3) a concept or idea, something belonging to the logical order of mediations. But rather than looking at them as distinct, Peircean semiotics would instruct us to look at them as dimensions of meaning of signs with differential weightings in different contexts and situations. The peculiarity and richness of Peirce’s model of semiotics and of semiosis is that these types of interpretants allow us to access the realm of meanings in both a structured and a phenomenologically open way. Once again, they tell us what to look for, but they do not tell us what we will find.

In this way, a Peircean approach to understanding the semiotic subject, the socio-psychological side that is the theme of cultural psychology, by using the typology of signs and their significant effects as an access structure to the perceptual field in particular—a unity of feeling, reaction, and synthesis or qualities, resistances, and unities—allows us to model the field of consciousness, also on the higher level, generally both in its individual and social dimensions. The objective field of signs, in which we are embodied and which circulate extra- and intrapsychically, becomes an access structure to both the inner and the outer world. Between these two worlds there is no divide in principle, as Peirce argued in his early 1868 papers with their powerful attack on introspection and unmediated intuition of one’s mental states. Access to *oneself* is always mediated just as access to the *world of the non-self* is always mediated. The semiotic self (*see* Wiley, 1994) quite generally is a sign developing on the three levels of feelings, reactions/resistances, and mediating syntheses. And the access to the world for this semiotic self is through the *forms of sense* charted in the great typology of signs. Peircean semiotics, in this way, intersects with and offers analytical tools to cultural psychology and indeed would offer us a way to interpret, and maybe to re-interpret, the results of cultural psychology—at least in some respects. Knowing the world involves concrete processes of sign production and sign interpretation, being caught up in a play of inference, being embodied in one’s speculative instruments, which, in the Peircean case, correspond to the great division of signs into icons, indices, and symbols. They are, as the ultimate frames of all systems of expressions, objective trajectories, vectors, or carriers of consciousness, with their own differentiated and historically emergent internal logics and grammars.

The heuristic fertility of the Peircean semiotic categorical scheme, which is indeed powerful, does not by any means, however, exhaust the possible substantial contribution of semiotics to the tasks of a cultural psychology. Other semiotic or semiotically relevant thematizations of the field of consciousness lay rather different grids over the phenomena of consciousness in general and in so doing deepen, broaden, and refocus the problem of the nature of the ultimate distinctions to be drawn in the plenum of consciousness as such and whether these are universal or culturally determined. They help us delineate in more detail the groundlines of the psychological side of the play of signs in human life. They also illustrate in their own way the big tent character of semiotics and force us to recognize that all semiotic models, or models with intrinsic semiotic importance, are *pragmatic*. Semiotics is part of a comprehensive toolbox for analyzing the construction of meanings, but it is not some super-science that tells us beforehand all that we can, or should, know.

### The Situation of Language

This is illustrated by another close link between semiotics and the tasks of a cultural psychology, to be found in the alternative schematization of a semiotic event, the focal point of semiotics, proposed by the great German psychologist of language, Karl Bühler, whose masterwork *Theory of Language* is a classic exemplification of the fusion of semiotic, philosophical, and psychological themes (Bühler, 1934/1965). Here, we find heuristic clues directed toward cultural psychology that originate not from the philosophical side of semiotics, as Peirce's does, but from the psychological side itself.

Bühler formulated his schema, which he called the "organon model" of language, with explicit semiotic (or, as he called it, *sematological*) intent but without the recourse to metaphysical categories, or philosophical taxonomy, that marked Peirce's approach. Nevertheless, although it highlights a slightly different pattern of relations than the Peircean schema, it still shows that explicitly semiotic categories are both helpful and necessary for modeling the groundlines of the field of consciousness in the broadest sense and for establishing the basic outlines of the cognitional structure that is to be filled in by a comprehensive and methodologically self-aware cultural psychology. It is especially important because Bühler's work was marked by both methodological sophistication and

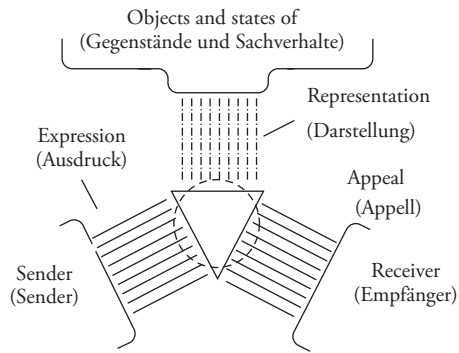

Figure 12.1 Bühler's Organon Model of Language

philosophical precision. And, indeed, Bühler himself attempted to generalize his schema.

Bühler, with no advertence to Peirce's delineation of the five factors of semiosis, has diagrammed the fundamental features of the focal semiotic event in the following way, exemplified (see figure 12.1) in the case of language:

The circle/triangle in the middle of the diagram stands for the *sign event in its material and formal reality*. It is important to recognize this duality: the sign event has a concrete side as well as an abstract side. Bühler's schema charts the realm encompassed by Peirce's five factors, but with some interesting and crucial differences, including a factor that does not appear in the schema but that is nevertheless of crucial importance for cultural psychology. Bühler, for his part, explains his diagram in the following manner, into which I have interpolated in brackets a translational gloss to generalize the schema beyond the purely linguistic level. Looked at this way, it becomes evident that other issues than those dealt with by Peirce are introduced or, at least, made more explicit and given a different weight. Bühler writes:

The circle in the middle symbolizes the concrete acoustic phenomenon [sign-configuration or sign-event]. Three variable factors in it go to give it the rank of a sign in three different manners. The sides of the inscribed triangle symbolize these three factors. In one way the triangle encloses less than the circle (thus illustrating the principle of abstractive relevance). In another way it goes beyond the circle to indicate that what is given to the senses always receives an apperceptive complement. The parallel lines symbolize the semantic functions of the (complex) language sign [sign-configuration]. It is a *symbol* by virtue of its coordination to objects and states of

affairs, a *symptom* (*Anzeichen, indicium*: index) by virtue of its dependence on the sender, whose inner states it expresses, and a *signal* by virtue of its appeal to the hearer, whose inner or outer behaviour it directs as do other communicative signs.

(Bühler, 1934, p. 35)

It is clear that the coordination of a sign configuration to objects and states of affairs, which Bühler assigns to the *symbol*, is accomplished in three ways: iconically, indexically, and symbolically. All three forms of such coordination are exemplified in language. For Bühler, they are all semiotic modes of *representation*, a term shared by Bühler and Peirce, and the proper *logical* work of a sign or sign configuration. These modes are differentiated (as has been noted) by Peirce according to their different *bases* for the coordination: resemblance for iconicity, existential connection for indexicality, and convention for symbolicity. But for Bühler, they are all modes of representation in being directed toward an objective world. Representation, which Durst-Andersen (2009) generalizes to modeling, occurs in three modes when we orient ourselves to objects and states of affairs.

The relation of the sign or sign configuration to the sender or utterer of the linguistic sign configuration, however, is not analyzed by Bühler according to a private intention. This is very important for cultural psychology. Rather, Bühler thinks of the sign configuration as having moments, *objectively discernible moments*, that reveal the subjective attitudes and orientations of the speaker—*who does not have to be an identifiable individual*. These moments belong to social forms. The moments are read off of the objective semiotic event, not the private subjectivity of the speaker, which is nevertheless *embodied* in them. In fact, the speaker utilizes them—and in creative circumstances modifies them or creates novel moments. Peirce, in another context, speaks of the “material quality” of any sign configuration, what I would call its “distinctive feel.” This quality is intrinsically joined to the sign configuration’s objectively experienced properties, which are social facts. To take an example, Bühler remarks that although the “chalk marks drawn by mathematicians and logicians on the blackboard still contain an expressive residue,” tracing the degree of effort, the carefulness of execution, the clarity of material formulation, the lyric poet’s poem or constructed utterance offers “a richer yield” of expressive features. The kinds of expressive features of an utterance, or of an objectively accessible sign event,

reveal forms of subjectivity, willingly or unwillingly—a point Langer made a centerpiece of her theory of art (see Langer, 1953). But these features can be coded and socially shared. And hence they are subject to comprehensive analysis by a fusion of semiotic and cultural psychological investigations. Forms of expressed subjectivity are social forms, as the American pragmatist philosopher and social psychologist G. H. Mead showed, not private possessions of an isolated epistemological or psychological subject. Cultures embody and are shaped by these forms. They can be studied and compared from culture to culture.

As to the sign configuration’s relation to the receiver of the sign, this is the locus of what Bühler called the appellative function or Peirce’s rhetorical dimension. The goal here is to steer the receiver, first in terms of behavior, in specific directions, giving rise to Peirce’s energetic interpretant. But in an important way, Bühler is also pointing to Peirce’s affective interpretant, to the informing of the subjectivity of the receiver in terms of affective qualities. And, further, he is pointing to the sharing of an objective orientation to objects and states of affairs. The goal of the appellative function is, therefore, also able to guide the perceptual and conceptual orientations of the receiver, provided that he or she shares the same situation with the speaker.

Bühler rightly emphasizes that these three notions—representation, expression, and appeal—are *semantic* concepts. Although he admits the relative dominance of the representational function of language for humans (confirmed and argued for, as I have already indicated, with neurological detail and in Peircean terms by Deacon), Bühler is very clear that the relation to objects and states of affairs “does not capture everything for which the sound is a mediating phenomenon, a mediator between the speaker and the hearer” (1934, p. 37). Bühler then adds a comment that I think bears upon Peirce’s murky notion of a ground, upon which cultural psychology could certainly throw some empirically derived light. Bühler, as a psychologist of language, speaks of a “speech situation,” a notion that can be generalized. He points out that

... each of the two participants has his own position in the make-up of the speech situation, namely the sender as the agent of the act of speaking, as the *subject* of the speech action on the one hand, and the receiver as the one spoken to, as the *addressee* of the speech action on the other hand. They are not simply a part of what the message is about, rather they are

the partners in an exchange, and ultimately this is the reason why it is possible that the sound as a medial product has a specific significative relationship to each, to the one and to the other severally. (1934, pp. 37–38)

Generalizing, it not just speech or language as a medial event but any sign configuration whatsoever that is at issue.

In any speech situation, or situation of the production and exchange of signs, any one of the three relationships can have dominance and be in the foreground, although Roman Jakobson (1960) later expanded the relationships to six (adding the poetic, phatic, and metalingual functions to Bühler's original three). Let us avoid these complications in the current context and consider Bühler's thesis:

... each of the three relationships, each of the three semantic functions of language signs discloses and identifies a specific realm of linguistic phenomena and facts ... 'Expression in language' and 'appeal in language' are partial objects for all of language research, and thus display their own specific structures in comparison with representation in language. To put it briefly, lyric poetry and rhetoric have something specific to themselves that distinguishes them from epic poetry and drama; and their structural laws are even more obviously different from the structural law of scientific representation. (1934, p. 39)

A complete semiotics would thematize these structural laws both generally and, in the hermeneutic mode, in particular instances. It would extend an analysis in terms of semantic functions to the whole realm of cultural phenomena, not all of which clearly have to realize all of them. It would investigate the many objective features such structural laws display or manifest. Cultural psychology's approach not just to language but to cultural phenomena quite generally would have to attend to all the ways these three (or six, if we follow Jakobson) semantic relations are encoded. They are clearly socially defined and constituted. Indeed, the focus on the situation of the speech event, or any semiotic event, injects a distinctive cultural element into it, an element that is dialogical to the core. In this respect, Bühler's investigations intersect with Bakhtin's work on the polyphonic nature of the verbal situation and of verbal interaction, as Durst-Andersen has shown (2009).

Bühler, in a way paralleling Peirce but without any reference to him, proposes in his prescient,

*Die Krise der Psychologie* (1927), to use these three semantic functions to model the whole realm of perceptions and indeed to distinguish three autonomous, but related, types of psychology: an *experiential* psychology, a *behavioral* psychology, and a *cultural* psychology. So, there is also a Bühlerian triad, with a slightly different twist than Peirce's: experience, behavior, and objective form. The focal thesis proposed by Bühler is that the three sense-functions exemplified in the sign types of symptom/indices, signals, and symbols can be used to give a theoretical account of perceptions [*Wahrnehmungen*] quite generally—admittedly a rather wide notion (1927, p. 75). The psychology of experience deals with *indices*, the psychology of behavior deals with *signals*, and cultural psychology deals with *symbols*. Accordingly, *Sinnesdaten*—what is given in the experiential field—perform three different semantic functions in structuring human intercourse with both the natural and the social world. As *indices* [*Anzeichen*], certain phenomena *indicate* both the *properties of objects* and the *interiority of associated subjects*, founding the perceptual judgment [*Wahrnehmungschluss*] whose content is a *Sachverhalt* or state of affairs in both the external common world and in the world of interiority. Bühler will locate psycho-analysis in the indexical dimension. As *signals*, the “given” sign configurations elicit and steer the behavior or action of subjects in shared actional and pragmatically oriented situations or fields, where there is a sender and a receiver, who do not have to be thematically intentional agents. As *symbols*, the sign configurations can be iconic (*abbildend*) or signifying through existential connection or conventionally—that is, through symbolizing or objectively indicating. In this way they *represent*, or point to, objects, structures, and relational complexes, eliciting (releasing) and steering recreative (*nachschaffen*) acts of reading, interpreting, and understanding.

According to Bühler, looked at from the part of the subject, the play of signs in experience—both natural and social—releases and steers (1) perception in the broadest possible sense, (2) behavior, and (3) understanding. Bühler, writing as a philosophically informed psychologist, leads us to engage in a semiotic framing of perception, behavior, and symbolic understanding, all the while showing that there is no radical gulf separating the lower and the higher thresholds on both the descriptive and operative levels. Still, Bühler's triad is not the Peircean triad of feeling, action, and mediating synthesis but

perception, behavior, and objective form. These are clearly social forms, filled with cultural content and following culturally conditioned laws. Here is another semiotic organizing device or heuristic schema for cultural psychology to work with.

A further distinguishing feature of Bühler's position that intersects with cultural psychology is its emphasis on *diacrisis* and on the *principle of abstractive relevance*, two intertwined concepts that are of great importance in determining the "forms of sense," the conditions of which, from the psychological side, cultural psychology is concerned to establish. Bühler insightfully and astutely uses the perception of a word-sign as a heuristic key to understanding not only perception and behavior but the whole field of experience. The analysis, analogous to but not identical with Peirce's proposal, reveals something essential about the lower threshold. This threshold is itself modeled according to the constitution and perception of the linguistic sign. Nevertheless, Bühler does not propose that perceived objects or structures of behavior are language-like nor that the realm of objective forms be considered in themselves as language-like.

More specifically, Bühler instructs us to take recourse here to the distinction between phones and phonemes, a distinction that is well-known in linguistic circles and was much discussed at the time he was writing. It is, in my opinion, of fundamental and permanent importance for understanding or schematizing cognitive forms with the help of semiotic categories. Phones are material entities; phonemes are formal entities, systems of significant differences immanent in the phonic reality. This commonplace distinction, Bühler insightfully claims, points to specific perceptual powers that we have. Bühler remarks:

Phonemes are sound-marks in the word's tonal reality and in every word they can be counted. But the word-image is also Gestalt-like, it has a tonal face or aspect, that also changes like a human face in the changing course of the expressive or appellative function.

(Bühler, 1934, p. 258)

Indeed, one can only agree with Bühler's further comment that there is a remarkable "constancy of the phonematic signaling of word-images in the course of their changing sound face" (p. 259). Their sound-form is a *type* that determines any particular *token* of itself, a distinction that also is found in Peirce. In fact, to go a step further, Bühler

adds a precision: "'face' and 'descriptive features' are figurative names for two, *not for one* and the same method of guaranteeing their diacritical function, for the 'face' in our sense belongs to the domain of *Gestalten* and the 'descriptive features' essentially belongs either completely or extensively to the domain of 'summative connections' [*Undverbindungen*]" (p. 2).

Phonology, for Bühler, is concerned with specific types of differential invariants, abstract types, that are present in the inexhaustible sound-fund [*Lautschatz*] of a language. It is not the task of cultural psychology, but of linguistics, to determine these. But cultural psychology must acknowledge the powers needed to grasp them and to look for differential invariants in the cultural contexts of experience. In the case of language, these invariants are ideal unities, single classes of sounds functioning as *notae* [*Kennzeichen*] in the sound-whole [*Lautgestalt*]. They are functional, not substantial, unities. This is a permanent insight of the structuralist tradition in semiotics deriving from Saussure, an insight that Bühler willingly acknowledged. Diacrisis, Bühler shows, aims at discriminating these functional unities and through them of grasping the word as a *sense-filled unity*. Now it is precisely sense-filled unities of all sorts and at all levels of complexity that a culturally informed psychology shares with semiotics as its subject matter. Cultural psychology thematizes the individual and social conditions of emergence and interiorization of these unities, whereas semiotics discovers and analyzes their "logic" and their "content." But these two tasks are not in opposition and, in fact, could be thought of as two sides of a coin, despite clear methodological contrasts and demands.

Out of this notion of "recognizing differences that make a difference" (an anticipation of the work of Gregory Bateson who made this idea a centerpiece of his own reflections), Bühler derives his *principle of abstractive relevance*, which has permanent epistemological importance despite what looks like a rather scholastic and analytic context. The notion has already appeared in Bühler's explication of his diagram of the organon-model of language. Bühler writes:

In the case of signs that bear a meaning, the situation is such that the sensible thing, this perceptible something with which we are immediately dealing, does not have to enter with the total plethora of its concrete properties into the semantic function.

Rather it can be the case that for it to fulfill its function as a sign only certain specific abstract moments are *relevant*. That, in the simplest words, is the principle of abstractive relevance.

(Bühler, 1931, p. 38)

The heuristic rule Bühler issues to cultural psychology is to study *systems of relevance* in all meaning-bearing situations. Different cultural frames perform different acts of abstraction, taking different abstract moments as relevant. The sensible thing that Bühler so laconically mentions can be a whole intricately socio-cultural situation or cultural context: meaning systems of every sort and scale. Cultural psychology, then, looked at from the point of view of a semiotics inspired by Bühlerian elements, is concerned with systems of pertinence and not with descriptions of the way the world is independently of its being taken. In this the interests of cultural psychology and semiotics coincide, and once again, cultural psychology will supply empirical content to an analytic frame that will be a part of cultural psychology but clearly not the whole of it. Cultural psychology is more fine-grained on the conditions of realization side than semiotics, which supplies a kind of upper analytical blade to the conceptual armature of cultural psychology.

It should be noted, then, that Bühler's suggestion allows us to use the *perception* of language and linguistic unities as a heuristic tool for understanding semiotic phenomena rather than using *language* itself as the primary model for understanding semiosis. Here is a ringing text in which Bühler issues a challenge, from the psychological side, to a semiotics of culture:

If linguists and language theorists today feel inspired once again to essay forth from their own domain into the age-old dispute of the masters concerning the problem of abstraction, they can give good reason for doing so. For the one who knows how to turn the old interest around, to turn the gaze of the abstraction theorist away from the things that are being named to the naming activity of the words themselves, to the tonal structure, he gains a new chance for dealing with this issue. And he does so for the simple reason that these structures are not only ready at hand but also produced by the persons who know them. Indeed, they are produced precisely for this end by every speaker of a language, so that his conversational partner can recognize correctly each sound structure for what it is and can distinguish it from others.

Therein lies the great chance for those who want to tackle anew the problem of abstraction as linguists, relying on the findings of phonology.

(1934, p. 288)

Bühler is certainly right that the phenomenon of abstraction as a cognitive achievement lies at the core of semiosis, understood as a process giving rise to abstractions—that is, products existing in objective form. It is these objective forms, and not just in the format of language, that semiotics, oriented toward the description of sign types and their contents, studies for the most part, whereas the psychological side in its empirical detail and levels is the focal point of psychology. The question semiotics would put to cultural psychology is: What are the social and cultural matrices that condition *a tergo*—that is, from behind, the processes of abstraction and what influences do the actual abstractions that one is assimilated into have on the psychological conditions of abstraction itself? Bühler himself, in this context, is pointing downward toward the lower threshold that in his opinion is already semiotically rich and to which language is not related as a veneer. The situation is quite different. Bühler writes:

The linguistic fixating and grasping of perceived states of affairs is prepared and rooted in the processes we are accustomed to calling “perceptions” and to separating off in an unjustifiably rigorous way from a “following” linguistic apprehension . . . The orientational instrument of human language which is produced in linguistic intercourse potentiates what the natural signals and symptoms accomplish, which we in the process of perception derive from things and our speech partners and to which we are indebted.

(1934, p. 252)

Nevertheless, Bühler's pushdown to the lower threshold also challenges or at least seems to modify Eco's and Peirce's thesis, but also his own, about the comprehensiveness of semiotic terminology in the description of consciousness, whether individual or social. Bühler saw the complexity of trying to balance semiotic with non-semiotic factors in the description of consciousness. More specifically, Bühler thought that the Gestalt principle was “phylogenetically originary” (Bühler 1960, p. 74). Despite his deep commitment to an explicitly semiotic model for analyzing the groundlines of consciousness, Bühler never gave up his adherence to

the validity of the concept of a whole. In his *Die Krise der Psychologie*, he wrote:

It is not correct to conflate the concepts of structure [*Struktur*], sense [*Sinn*], and value [*Wert*]. The concept of a whole [*der Begriff der Ganzheit*] with its constitutive moments is the widest concept and to it is ordered knowledge by insight. Intentionally produced wholes that are meaning structures . . . can only be a restricted domain of structures quite generally.

(Bühler, 1927, p. 137)

Clearly there is no strict opposition posited between wholes and meaning structures. Bühler is noting here a peculiar tension between diacrisis on the basis of indexical properties and the grasp of structure or form on the basis of a perceptual apprehension that does not rely on an explicit reading of determining indices. In fact, perception is marked by the *emergence* of structures as configurations from an irreducible parts/whole correlation. The whole is more than the sum of its parts, an emergence, and in the case of produced meaning structures, there is an intrinsic duality between the selectivity of pertinence, which involves elimination of irrelevancies, and the emergence of novelty, which involves a kind of addition of meaning. Bühler puts it this way, in a context where these notions apply to language primarily in its metaphorical dimension but can also be extended to cultural systems of meaning.

Overlapping, falling away, selection, the difference effect are expressions for one and the same simple phenomenon, which it is necessary to place beside the criterion of *Übersummativität*, which alone has been emphasized in Gestalt theory since the time of von Ehrenfels, in order to describe completely the role of attributive structures in language . . .

*Übersummativität* and *Untersummativität* of attributive structures increase the productivity of language to an astonishing degree and make possible a laconic form of naming. Admittedly, the system also has at its disposal a correction for the indefiniteness or ambiguities of these structures.

(Bühler, 1934, pp. 349–350)

Where is this “correction” to be found? In answering this question, Bühler introduces a most important notion, that of *Sachwissen*, or material knowledge, which certainly belongs to the subject matter of a cultural psychology, although it is introduced in a specifically linguistic context. How so?

Bühler’s language theory is based on a fundamental distinction between what he calls the *Zeigfeld* and the *Symbolfeld*—that is, the deictic field, defined by pointing, and the symbol field, defined by articulating or conceptual grasping. The general notion is that language frees itself from indexicality as it heads toward and is transformed by symbolicity. But Bühler writes:

Perhaps we overestimate the freeing from the deictic field; perhaps we underestimate the fact of the essential openness and the need, proper to every linguistic representation of a state of affairs, to be completed by our knowledge of this state of affairs. Or, what is the same thing: perhaps there is an expansion of all linguistically constituted knowledge from a source that does not run in the channels of the linguistic symbol system and nevertheless produces genuine knowledge.

(1934, p. 255)

This source is our material, or what Peirce called “collateral,” knowledge that is needed to make sense of signs. Bühler calls it *Sachwissen*, knowledge of a domain, or material knowledge, knowledge of the thing meant. Is not one of the tasks of cultural psychology to explore this dimension of our knowing, which is certainly culturally relative and differentially distributed? It is the support of our understanding of signs, which do not make a closed circle from which there is no escape.

There is, however, another form of support of our understanding that is more distinctively semiotic. Bühler asserts that the deictic field (*Zeigfeld*) and the symbol field (*Symbolfeld*) are “the two sources out of which in every case the precise interpretation of linguistic expressions is nourished” (1934, p. 149). Pointing and representing, not in themselves but as semiotic systems (rather than isolated acts), also supply collateral knowledge, but it comes from being embodied in a semiotic field. The general point Bühler wants to make is that all semiosis, and all the knowing effected by semiosis, is field-dependent. Signs must be situated or located in a surrounding field to do their work. This field is not just a linguistic field. Bühler is making a general semiotic point, which can, I think, be extended out to the whole realm of cultural analysis.

Thought that is expressed in speech, along with it every other operation with representational symbols in the service of knowing, is in need of a symbol field in exactly the same way as the painter needs

his painting surface, the cartographer his coordinate system of latitudinal and longitudinal lines, and the composer his still-otherwise-constructed surface, or put in general terms, just as every two-class system of representational signs.

(Bühler, 1934, p. 254)

The reference to a two-class system is central, exemplified in Bühler's "dogma of lexicon and syntax," or sign unit and surrounding field of relations. Is not cultural psychology dedicated to investigating the surrounding relational fields of meaning units, their genetic conditions on both the individual and social levels, and the degrees and stages in which they are learned? Does not a generalization of Bühler's insights help formulate in a laconic manner just what cultural psychology can do and is doing?

### **Between Signification and Structure: Semiotic Relevance of Tacit Knowing**

But can we take another look at the tension between structure and signification to which Bühler draws attention? Is there a way to specify their relations in more detail, this time from an epistemological position that has great semiotic relevance but was not developed within any of the major semiotic traditions? Michael Polanyi's theory of tacit knowing, which is based on a generalization of Gestalt theory, needs to be incorporated into any semiotic model that strives to contribute to framing central issues in cultural psychology and the model(s) of mind that it both presupposes and tries to develop. It also adds some new insights and concepts that bear upon other issues that lie immanent in Bühler's conceptual system.

Philosophizing, as Bühler partially did, with the tools of and against the background of Gestalt psychology, Polanyi offers us a way around the dichotomy between structure and meaning by means of his fruitful distinction between *existential and representative meanings and wholes*. He further specifies how the recognizing of these wholes arises through *tacit*, not explicit, processes and how his indispensable distinction between focal and subsidiary awareness adds a new twist to our understanding of the parallel ways we are *embodied in* or *indwell* sign systems and meaning systems at both thresholds, including our indwelling in language, which he, along with Ernst Cassirer, discuss in probal terms. The analogy of the probe is a rich image-schema of our relationship to and use of language as well as other expression systems.

The background to Polanyi's position, which stands midway between semiotics and psychology, and its relevance to cultural psychology, is foregrounded in the following texts from Wolfgang Köhler, which still maintain their challenging position in our attempts to think through the problem of the ultimacy of the semiotic project in general and its relation to supplying analytical and epistemological underpinnings to cultural psychology. They concern, first of all, the schematization of the lower threshold but bear upon the possibility and nature of a valid modeling of this threshold in upper-threshold terms.

Consider the following formulation of one of Köhler's most challenging theses:

In Gestalt psychology we distinguish three major traits which are conspicuous in all cases of specific organization or gestalt. Phenomenally the world is neither an indifferent mosaic nor an indifferent continuum. It exhibits definite segregated units or contexts in all degrees of complexity, articulation and clearness. Secondly, such units show properties belonging to them as contexts or systems. Again, the parts of such units or contexts exhibit dependent properties in the sense that, given the place of a part in the context, its dependent properties are determined by this position.

(Köhler, 1938, p. 85)

Other relevant aspects and contexts are specified by Köhler in his classic *Gestalt Psychology*:

Gestalt psychology holds [that] sensory units have acquired names, have become richly symbolic, and are now known to have certain practical uses, while nevertheless they have existed as units before any of these further facts were added. Gestalt psychology claims that it is precisely the original segregation of circumscribed wholes which makes it possible for the sensory world to appear so utterly imbued with meaning to the adult; for, in the gradual entrance into the sensory field, meaning follows the lines drawn by natural organization; it usually enters into segregated wholes.

(Köhler, 1947, p. 82)

The fundamental questions in this context are: Is the original segregation a semiotic process, and what is the relation between the notion of a *circumscribed whole* in all its varieties and a *meaning*? Are circumscribed wholes at the lower threshold sign configurations or able to be analyzed as sign configurations?

Polanyi introduces an indispensable set of concepts here that joins together in a creative unity the notion of structure with that of meaning. It is extraordinarily important for establishing a sufficiently rich and flexible model of cognitional structure that would inform, frame, and support the investigations of a cultural psychology. Polanyi argues that in any grasp of, or construction of, a “circumscribed whole,” we *attend from* certain things, *which include our bodies*, while we *attend to* the whole. In Polanyi’s terminology, we are *subsidiarily aware* of the particulars of any whole while we are *focally aware* of the whole. Now, more generally, Polanyi points out that “when something is seen as subsidiary to a whole, this implies that it participates in sustaining the whole, and we may now regard this function as its *meaning*, within the whole” (Polanyi, 1958a, p. 58). The subsidiary particular is a kind of semiotic vector that is not independent of, although clearly not identical with, what it means. Polanyi, in a deep and penetrating passage, distinguishes in *Personal Knowledge* two kinds of wholes and two kinds of meanings: an *explicit sign/object whole* and the kinds of wholes exemplified by physiognomies, tunes, and patterns. Here is an important link with Bühler and Köhler. Polanyi writes:

The distinction between two kinds of awareness allows us readily to acknowledge these two kinds of wholes and two kinds of meaning. Remembering the various uses of a stick, for pointing, for exploring or for hitting, we can easily see that anything that functions effectively within an accredited context has a meaning in that context and that any such context will itself be appreciated as meaningful. We may describe the kind of meaning which a context possesses in itself as *existential*, to distinguish it especially from *denotative* or, more generally, *representative* meaning. In this sense pure mathematics has an existential meaning, while a mathematical theory in physics has a denotative meaning. The meaning of music is mainly existential, that of a portrait more or less representative, and so on. All kinds of order, whether contrived or natural, has existential meaning; but contrived order usually also conveys a message.

(Polanyi, 1958a, p. 58)

Although this admittedly controversial passage needs some unpacking and refining, and maybe even reformulation in places, it contains fundamental insights about the nature of meaning and

about the issue of the relations between perception and semiosis and about the thresholds of sense. On Polanyi’s account, structure and meaning are not opposed in principle, once we accept his fundamental distinction between the two kinds of awareness. Most generally, his claim is that *the genesis of meaning is the genesis of ordered contexts*. It seems to me that this is a key insight to be followed up by cultural psychology as well as by a genetically oriented semiotics and philosophy of knowledge. The kind of meaning denoted by “existential” is “meaning as object,” or more generally, “meaning as ordered context,” which can be a self-enclosed world. A physical object, in as much as it is a coherence, *is* a meaning, on this account. It does not just have a meaning projected onto it. It is a resisting experienced sense-filled unity. It is *suffused* by a distinctive quality or suchness, marked by its indexically functioning particulars, and *integrated* by a mediating act. Such a characterization corresponds to Peirce’s distinctions, which we discussed earlier, and which Peirce also labeled as *primisense*, *altersense*, *medisense*, the three indispensable and ever-present factors or ingredients in cognition. Systems of contrived order such as sign systems are themselves ordered wholes, which in addition to being internally structured, with their own internal objects, inform us *about*, or *refer to*, objects and states of affairs that are in a real sense “independently objective.” On Polanyi’s account, *thing meaning* and *sign meaning* are both at one and the same time autonomous and related forms of *meaning*. The thing meant, even whole cultural orders such as mythic and aesthetic worlds, does not have to exist outside of the frame, but there is no thing meant independent of some frame. The point is to determine, both directly and reflectively, the frames. This process of determining is first and foremost active and constructive, whereas the process of analyzing the internal logic of these culturally specific frames is both empirical and interpretive.

Polanyi draws an ontological consequence from these considerations, just as Peirce did, something that perhaps a pure semiotics, focusing on the internal structures of meaning systems, and a philosophically pure cultural psychology would hesitate to do. Consider the following text of Polanyi:

Since tacit knowing establishes a meaningful relation between two terms, we may identify it with the *understanding* of the comprehensive entity which these two terms jointly constitute. Thus, the proximal term represents the *particulars* of

this entity, and we can say, accordingly, that we comprehend the entity by relying on our awareness of its particulars for attending to their joint meaning.

(Polanyi, 1966, p. 13)

The *joint meaning* is an emergence, an instance of Peircean thirdness or Bühlerian-Ehrenfeldian *Übersummativität*, which could take numerous different forms: affective in the case of feelings, actional in the case of goal-directed behavior, and conceptual in the case of language and other constructed systems. However, one of the deepest and most fateful consequences of the notion of *attending from* is its extension to how we are conscious of our bodies and the consequent notion of *indwelling*, Polanyi's term that refers to the same phenomenon that *embodiment* does in the phenomenological tradition. Polanyi writes in *The Tacit Dimension*:

All thought contains components of which we are subsidiarily aware in the focal content of our thinking, and all thought dwells in its subsidiaries, as if they were parts of our body. Hence thinking is not only necessarily intentional, as Brentano has taught: it is also necessarily fraught with the roots it embodies. It has a *from-to* structure.

(1966, p. x)

Just as we dwell in our bodies, Polanyi, observes, so we dwell in *all* the subsidiary clues that we integrate or synthesize into comprehensive wholes. The analogy of the probe is, then, extended to language—and I would add to all cultural forms. “We can, accordingly, interpret the use of tools, of probes, and of pointers as further instances of the art of knowing, and may add to our list also the denotative use of language, as a kind of verbal pointing” (1966, p. 7). The extension here is: Cultural forms are embodiments of the art of knowing. This essentially cultural process of integration or synthesis of fields of particulars into meaningful wholes, Polanyi argues—and in my opinion has shown—is essentially *tacit*. It is also not something over which we have control and so it does not involve thematic reading of signs, although we are clearly often presented with sign configurations that demand strenuous interpretive effort. Polanyi's model of tacit knowing shows, I think, that thinking of experience itself in semiotic terms does not entail postulating an explicitly cognitive relationship to the continuum or plenum of experience, into which we are drawing lines.

Consider the following passage and its range of examples:

We may instantly recognize a familiar writing or voice, or a person's gait, or a well-cooked omelette, while being unable to tell—except quite vaguely—by what particulars we recognize these things. The same is true of the recognition of pathological symptoms, of the diagnosis of diseases and the identification of specimens. In all these instances we learn to comprehend an entity without ever getting to know, or to know clearly, the particulars that are *unspecifiable because they are unknown*.

(Polanyi, 1958b, p. 45)

This is the way we are assimilated into cultural forms, through apprenticeship and practice, on both technical and popular levels. An important qualification follows:

But a particular pointing beyond itself may be fully visible or audible and yet be unspecifiable in the sense that if attention is directed on it focally—so that it is now known in itself—it ceases to function as a clue or a sign and loses its meaning as such.

(Polanyi, 1958b, p. 45)

Analysis alone does not give us access to the material knowledge of the participants in a culture. They are participants first and foremost. Analysis come afterward. *Primum vivere, deinde philosophari*. Thus, Polanyi allows us to see how signs in experience and the experience of signs are not contrasted in any principled way to one another, once we can distinguish between dwelling in and analyzing. Even tacit knowledge relies on an interpretation of signs, but an interpretation that avoids the cognitive stance ascribed to the epistemological subject. Knowing, as John Dewey put it, is not a “Kodak fixation” nor is the mind a kind of “mental carbon paper.”

Polanyi's notion of indwelling, which certainly modifies our picture of the knowing subject, allows us to understand what it means, quite generally, to be embodied in sign systems and also, from a totally different angle, shows us what unlimited semiosis entails: We are inside the play of signs and never outside. There is no explicit greatest upper bound from which we can survey the total range of experience. Read the following passage from the preface to Polanyi's *Personal Knowledge*, which talks about a post-critical philosophy and not an a-critical philosophy, in light of what I have just said and with the appropriate interpolation of semiotic terms alongside Polanyi's own terminology.

I regard knowing [semiosis] as an active comprehension [signifying] of the things known [meant], an action that requires skill. Skilful knowing and doing [skilful sign-production and interpretation] is performed by subordinating a set of particulars [signs and sign-configurations], as clues or tools, to the shaping of a skilful [semiotic] achievement, whether practical or theoretical. We may then be said to become “subsidiarily aware” of these particulars [signs and sign-configurations] within our “focal awareness” of the coherent entity [object-domains] that we achieve [signify]. Clues and tools [signs and sign-configurations] are things used as such and not observed in themselves. They are made to function as extensions of our bodily equipment [mental equipment] and this involves a certain change in our own being. Acts of comprehension [acts of semiosis] are to this extent irreversible, and also non-critical. For we cannot possess any fixed framework within which the reshaping of our hitherto fixed framework could be critically tested.

(Polanyi, 1958a, p. vii)

This rotation of our problem adds new descriptive and explanatory categories to semiotics and exemplifies, once again, the big tent, non-dogmatic, and non-overreaching nature of semiotics as an analytical framework and transdisciplinary project. As to the tasks of a cultural psychology, it points to a host of analytical and descriptive tasks: to recognize and validate the tacit dimension—that is, that we can know more than we can say, to show that knowing and skillful doing have the same logical structure, and that the body, including our exosomatic or semiotic body, is an essential component of all knowing, which is not a matter of the head alone. It also suggests that the form-structure of awareness is actually isomorphic with, while still enriching, the sign-interpretant-object triad foregrounded by Peirce and that the lines that divide up the continuum of experience can be modeled in flexible, yet complementary ways. This last claim lies at the heart of the project of a cultural psychology.

But this is by no means the end of the matter. I would like, in concluding, to point out how elements from two other interlinked semiotic theories, those of Ernst Cassirer and Susanne Langer, can contribute to the mutual enrichment between cultural psychology and semiotics.

## Forms of Sense and the Mind of Feeling: Cassirer and Langer

In his *Philosophy of Symbolic Forms*, Cassirer wrote that the “concept of consciousness seems to be the very Proteus of philosophy” (1929, p/ 48). Certainly, it is also the same for a cultural psychology that accepts the task of charting the contours of consciousness shaped in the course of cultural interactions. The task Cassirer set for himself was to uncover what he called “the original attitudes and formative modes of consciousness”—that is, a kind of *a priori* structure within which meanings are constituted and expressed. Cassirer described his goal, echoing but transforming the static schema of Kant, as an attempt to resolve “the question of the structure of the perceptive, intuitive and cognitive consciousness” (1929, p. 57), from which arise the “three form worlds” (1929, p. 448) that constitute progressively more objectifying relations to the world. These form worlds make up the ultimate frame of sense-giving and sense-reading. The distinctiveness of Cassirer’s project is that it is also based on a tripartite semiotic schema that, like Peirce’s, does not just refer to successive phases of a process of knowing and meaning-making but to “its necessarily intertwined . . . constitutive factors” (1929, p. 9), what Peirce called the “permanent ingredients” of consciousness. It also gestures toward a kind of teleology and hierarchization, as if perception, intuition, and cognition were phases in a process. The distinctiveness of Cassirer’s procedure, however, mainly results from its correlation of these factors with three different semiotic categories or sense functions. Indeed, they are, in reality, not so much phases as dimensions. The form worlds, defined by the three sense functions, are the ultimate frames or matrices of sense-giving and sense-reading, which for Cassirer are by no means restricted to the explicit and thematic use of signs.

Cassirer correlated the psychological and philosophical term *perception* [*Wahrnehmung*] with the semiotic category of *expression* [*Ausdruck*]<sup>1</sup>—that is, with the level of sense and meaning that we have been calling physiognomic or existential or qualitative. Expression is the sense function where sign, meaning, and object are so indissolubly joined that the sign is taken to participate existentially in, or have an ontological affinity with, its intended reality. For Cassirer, word magic and mythic consciousness are prime exemplifications of this stratum or form of consciousness. They are continued, although

residually, in higher forms of religion and their distinctively affective configurations. Expression, then, is the realm primarily of physiognomic and qualitatively defined meanings. Mythic consciousness is analyzed in volume one of Cassirer's *Philosophy of Symbolic Forms*.

Cassirer correlated the psychological and philosophical term *intuition* [*Anschauung*] with the semiotic category of *representation* [*Repräsentation* or *Darstellung*], with the grasp or constitution in the experiential continuum of objects with properties and their embodiment in language, the subject of the volume two of his *Philosophy of Symbolic Forms*. It is the recognition of objects by properties, functioning as marks or diacritical features, that introduces a kind of indexical feature into perception. The perceived properties support the perceptual process and do so in such a manner that the supports themselves are connected with what they point to. This second sense function, representation, is the sense function where the relations among signs, meanings, and objects have moved to a higher level of abstraction but are still bound to the sensory order. Whereas mythical consciousness, a true semiotic phenomenon, works within the dimension of affectively charged identity, or at least identification of sign with object, representation introduces difference, although in a rather different sense than one is familiar with in the structural and post-structuralist traditions. As Cassirer puts it in a way resonant with later discussions, "The aim of repetition lies in identity—the aim of linguistic designation lies in difference" (p. 189). On this level, the word is not the thing; the image is not the imaged. Words and images, doing the work of representation, articulate the world *without being a part of it*. Language and art for Cassirer exemplify in clearest fashion this sense function, albeit in rather different ways. They grasp [*begreifen*] the world, upon an intuitive [*anschaulich*] base, to be sure, but they do not take hold [*greifen*] of it in any material or magical fashion, despite their engrossing and magical effects on the psychological level.

Cassirer correlated the *scientific* [*wissenschaftlich*]—that is, theoretical—understanding [*Erkenntnis*] with pure signification [*Bedeutung*], with the grasp of abstract relations, a grasp based on free and unmotivated systems of signs. This third sense function, pure signification, is the stratum of sense functions farthest removed from normal sensory, intuitive supports. The concrete physical reality of the sensible, vectorially functioning signs and the objects

that they both point to and constitute recedes. This meaning space accesses, indeed constitutes, a world of law-governed events that are defined by their relations to one another and not to our intuitional or objectively oriented capacities. It is exemplified in modern mathematical physics and the *notation systems* that make it possible (as well as the various systems of pure mathematics and symbolic logic). A general reflection on this stratum, and a correlation of it with the two other strata, is the subject of volume three of *The Philosophy of Symbolic Forms*, devoted to the phenomenology of knowledge in the semiotic mode.

According to Cassirer, the basis for the differentiation of these three sense functions is the increasing distance between the sign and the realities accessed through it—indeed, an increasing transparency of the sign, a disappearing of its material character and physical reality and underpinnings, which, however, can never be left behind. Even abstract systems of signs have a kind of diaphanous or even disembodied feel, which makes up, paradoxically, their semiotic body. This is what Peirce called the material quality of the sign, which each sense function, semiotically considered, has. By means of this "spiritual triad" (1929, p. 101), Cassirer wanted to place precisely the forms of sense-giving in relation to one another and to analyze their inner logics and developmental stages, which he did under the rubric not just of his philosophy of symbolic forms but of a philosophy of human culture, epitomized in his *An Essay on Man* (1944). Cultural psychology engages paradigmatic exemplifications of these sense functions. Indeed, I think that cultural psychology could examine and evaluate the psychological validity of Cassirer's rather high-road schematization of these sense functions. Here, the descriptive tasks of semiotics both coincide with and inform those of a cultural psychology.

This is nowhere clearer than in the work of Langer, who consciously in many and important ways has continued and extended Cassirer's attempt to broaden the scope of semiotics to the history of culture as such and to base it on a distinctive and original model of mind. In her early work, *The Practice of Philosophy* (1930), Langer argues that philosophy's proper object is interpretation—indeed, the interpretation of interpretations that are expressed in various sign systems. In a way paralleling Peirce, but with no explicit use of his terms, Langer argues that human beings spread two very different sign systems, the discursive and the

representative, over the continuum of experience. In her classic *Philosophy in a New Key*, this distinction becomes one between discursive and presentational forms. It is the job of semiotics to study the general logic of signs and symbols and then to explore the specific logic of each general class of sign systems and their specific exemplifications in language, myth, ritual, art, science, and so on. The realm of human rationality is divided into these two semiotic modes, corresponding roughly to a distinction between saying and showing, a distinction she takes from Wittgenstein and uses in her own way—heading toward results that Wittgenstein himself would not have sanctioned. But Langer goes further in her analysis. Like Cassirer, she sees the human being as *animal symbolicum*, but she pushes the symbolic capacity all the way down to the lower threshold of meaning-making, which she subsumes under the rubric of symbolic transformation.

Langer notes that the human mind is to be understood as a transformer and not a transmitter. It not only grasps forms but transforms, rendering the data of experience meaningful. “Meaning accrues essentially to forms,” she writes in *Philosophy in a New Key* (p. 90), with a generous gesture toward Gestalt psychology’s central thesis. By connecting the grasp of form with the recognition of symbolic structure, Langer herself pushes meaning down and arrives at a position similar to Peirce’s. But, just as with Peirce, Langer does not remain on the level of individual subjective transformations of experience but extends her attention out to all those objective forms that emerge out of these transformations. Langer’s contention is that recognizing two radically different types of symbolic transformations broadens our very notion of rationality. And, moreover, in her final trilogy, *Mind: An Essay on Human Feeling*, Langer attempts to develop a comprehensive concept of *feeling* to cover the total mental field and to connect it with symbolization as the central activity of human mentation. The structures of feeling are accessed and exemplified in paradigmatic form in the rise of the art symbol, a pregnant image that displays the life of feeling in objective form.

For Langer feeling is, quite generally, “whatever is felt in any way, as sensory stimulus or inward tension, pain, emotion or intent.” It is *the* “mark of mentality” (Langer, 1967, p. 4). Feeling, on Langer’s conception, characterizes physiological systems, not as an additional reality but as a dimension or phase of the system. Psychology, on Langer’s conception, is “oriented toward the aspects

of sensibility, awareness, excitement, gratification or suffering” which belong to physiological events when they reach a certain level of complexity and are *felt* (Langer, 1967, p. 4). Mentality and feeling, Langer proposes, are synonymous. Mentality is a field of “felt impingements and activities” (Langer, 1967, p. 9) and covers not just the normal notion of feeling but also thought, sensation, dream, and actions. Feeling is “the modulus of psychological conception” (Langer, 1967, p. 21) and being felt is a phase of vital processes, “a mode of appearance, and not an added factor” (Langer, 1967, p. 21). The chief thesis explored and defended by Langer is that “the entire psychological field—including human conception, responsible action, rationality, knowledge—is a vast and branching development of feeling” (1967, p. 23) and that there is no “primitive forms of feeling which is its ‘real’ form” (1967, p. 19).

How is feeling to be known? How does it make itself known? Langer’s idea is that the heuristic key to feeling is to be found in images, *specifically art images*.

An image does not exemplify the same principles of construction as the object it symbolizes but abstracts its phenomenal character, its immediate effect on our sensibility or the way it presents itself as something of importance, magnitude, strength or fragility, permanence or transience, etc. It organizes and enhances the impression directly received. And as most of our awareness of the world is a continual play of impressions, our primitive intellectual equipment is largely a fund of images, not necessarily visual, but often gestic, kinesthetic, verbal or what I can only call “situational.”... [W]e apprehend everything which comes to us as impact from the world by imposing some image on it that stresses its salient features and shapes it for recognition and memory.  
(1967, p. 59)

This is the root of Langer’s notion of a *form of feeling*—which Langer applies to her analysis of art (Langer, 1953). But the point is actually more general. Langer thinks that the original act of the mind is, by a kind of abstraction, to impose, or recognize, a form in the flux of experience and to construct some symbolic representation of it, rooted in the symbolizing activity of the imagination. The process is most evident in the production of artistic symbols, which exist in imaginal form. But projection does not take place only in the symbolic form of art.

Symbolic projection in all modalities aims to intercept every form of meaning in experience. Once again, cultural psychology and semiotics coincide. Langer asks cultural psychology to extend its range to examining all the manifestations of mind but especially the symbolic images of art. Langer adds an aesthetic twist to cultural psychology. It asks it to contribute to a semiotic exploration of “the form of felt life” (Langer, 1967, p. 64). It introduces the notion of symbolic exemplification as a challenge to cultural psychology to make sure that it encompasses, from its own point of view, the whole phenomenal manifestation of mind. The material quality of a sign configuration can be generalized: every sign configuration has a distinctive feel, whether in the discursive or presentational mode. Each type of sign configuration embodies gradients. These gradients reflect the ways we access the world. Cultural psychology, on the experiential side, follows the lead of semiotics and at the same time enriches it with empirical detail. It shows cultural psychology to be both modeling and phenomenologically empirical at one and the same time. But it challenges cultural psychology to focus on image fields and to avoid all form of logocentrism, to insert the symbolic imagination into its object domain. Indeed, because the basic idea of semiotics is that *meaning must appear*, Langer tells us that semiotics as well as cultural psychology must collaborate not just in the analysis of the logic of the forms of feeling but in the experience of these forms as they appear to and in culturally defined and situated persons and groups.

### The Universal Relevance of von Uexküll’s Functional Circle

Finally, I would like to note that Jakob von Uexküll’s functional circle, presented in his *Theory of Meaning* (1940), displays, within what has become an explicit biosemiotic context, the circuit of meaning of any organism *qua tale*. It is extremely important, as heuristic schema, for the proper understanding not just of the task of a general semiotics but of another way of formulating the frame for a cultural psychology that understands the bodily roots of semiosis. Any organism, on von Uexküll’s account, is defined by a deep receptivity to perceptual stimuli and by varying degrees and types of reactions that change the originating stimuli in a constant dynamic spiral. The path from the meaning-bearing object to the organism von Uexküll calls the “receptor arc.” The path from the organism to the meaning-bearing and meaning-receiving

object von Uexküll calls the “effector arc.” Although we can distinguish between the “perceptual arc” and the “effector arc,” we must all the while acknowledge the intimate relations between the two. In fact, the perceptual and the effector are dimensions rather than separate spheres, because the organism is never merely passive nor purely active, never merely interpreting or materially constructing. Indeed, Cassirer saw that in the case of humans, it is precisely the ingression of articulate meaning systems, what he called the “symbolic network,” into these two other systems that transforms the whole. von Uexküll’s revolutionary insight is that we should think of all these arcs in semiotic terms—that is, in terms of meaning and of differential cue carriers. The receptor arc is marked by the grasp of differences in the perceptual field, which Gregory Bateson also foregrounded. Although other organisms are for the most part confined to predetermined fields of cues, humans are open to a vast array of articulate cues, having not an *Umwelt* but a *Welt*—that is, not an environment but a world—or in Langer’s terms, an “open ambient.” This human world is an open world, permeated by articulate, exosomatic systems that inform and embody perception, in the broad sense of that term. This world is constituted by the material and semiotic *results* of human constructive action, which introduce vast systems of differences into the natural and the social world. These effected differences are themselves perceived by the organism in a continuous and ever-expanding spiral.

Cassirer’s delineates our situation in a ringing remark:

Physical reality seems to recede in proportion as man’s symbolic activity advances. Instead of dealing with the things themselves man is in a sense constantly conversing with himself. He has so enveloped himself in linguistic forms, in artistic images, in mythical symbols or religious rites that he cannot see or know anything except by the interposition of this artificial medium.

(Cassirer, 1944, p. 25)

Is this not the goal of both semiotics and cultural psychology—to study this sign-dependent and -constituted artificial medium and process in which human beings “weave the symbolic net, the tangled web of human experience?” Can we not adapt and extend Vygotsky’s closing reflection to the widest semiotic frame, thinking of “sign” when he speaks of “word.” “Consciousness,” he writes, “is reflected in a word [sign] as the sun in a drop of water.

A word [sign] relates to consciousness as a living cell relates to a whole organism, as an atom relates to the universe. A word [sign] is a microcosm of human consciousness" (1934, p. 256). As Peirce puts it, "the word or sign that man uses *is* the man himself" (Peirce, 1868, p. 54).

### Conclusions and Future Perspectives

Cultural psychology and a broad-based semiotics, it is clear, intersect at many levels and in many ways. Cultural psychology, in as much as it deals with human meaning-making on the experiential and socio-cultural levels, is in need of explicit schemas of the various forms that meaning-making takes. Semiotics, however, does not offer one unified schema but, rather, a bundle of schemas that can guide cultural psychological investigations. The various semiotic schemas have different points of origin and consequently rather different kinds of relevance for cultural psychology. They foreground and schematize different features of meaning-making processes and give them different weight. Prior to concrete investigations, they do not tell cultural psychology what it will find, but they do point out some distinctive types of things with which cultural psychology will concern itself and supply it with analytical tools that will inform and thicken its empirical investigations.

The Peircean schema has a twofold value: (1) it offers a triadic model of sign types—icons, indexes, and symbols—that has great heuristic power, and (2) it delineates with remarkable clarity the five factors of semiosis, of the production and interpretation of signs, that make such a process the entangled phenomenon that it is. Of special importance is Peirce's notion of an interpretant, or the "proper significate effect" of a sign. Peirce's model of the self shows it to be three-leveled, with the self engaging the world on the level of feeling, effective action, and cognition. Semiotics would point cultural psychology toward empirical investigations of the social and cultural exemplifications of these interpretant realms and the varieties of contents mediated by icons, indexes, and symbols at the various stages of an individual's and a culture's development.

Karl Bühler offers a semiotic schema developed not from a logical or philosophical point of view but from a generalization of a speech event. Bühler showed that language is not just a representational tool, carrying out a representational function. A speech event also reveals or expresses the subjectivity of the speaker and it steers the behavior of the

addressee. Furthermore, Bühler's organon model foregrounds the pivotal phenomenon of abstraction and the mental processes of diacrisis. Bühler sees the human mind as focused on systems of relevance both in the apprehension of the linguistic sign and in the cultural world quite generally. Moreover, the differentiation of expression, appeal, and representation, as semantic functions is correlated by Bühler with the semiotic distinction between indexes, signals, and symbols. On this basis, Bühler saw three principal domains for psychology to study: (1) the structures of experiencing subjects, (2) the forms of behavior and behavioral steering, and (3) the systems of formed content found in objective meaning systems. Cultural psychology should avail itself of Bühler's suggestions here in terms of the tasks of psychology as well as drawing on his advanced notion of a field, which is not restricted to a purely linguistic field.

Michael Polanyi adds to the focal concerns of a cultural psychology the important notion of a tacit dimension, that we can know more than we can say, and the notion of skillful knowing and doing. Could cultural psychology, taking up Polanyi's hints, not be advanced by adverting to the revolutionary nature of Polanyi's distinction between focal and subsidiary awareness and the consequent key concept of indwelling? Moreover, Polanyi's insistence on the tacit assimilation of cues and clues shows that knowing does not involve an explicit or thematic cognitive stance. It also shows that knowing is fraught with the roots that it embodies, roots over which we have no control at the primary level of assimilation.

Ernst Cassirer and Susanne Langer point the way to a semiotically grounded philosophy of culture, Cassirer by offering his own tripartite schema of sense functions, expression, representation, and pure signification and pointing to how they inform and structure the whole realm of symbolic forms that make up the world, Langer by developing the general notion of symbolic transformation and a comprehensive concept of feeling. Both rely on a vast realm of data from the human sciences and show how semiotics does not legislate from on high but exists in symbiotic relationship with the whole cultural and biological world. Such a position joins them to von Uexküll's attempt to fuse the biological and the cultural, the lower and upper thresholds of human meaning making.

The various positions with which we have dealt in this article have one major lesson for cultural

psychology. They all teach us that semiotics without the study of cultural forms is empty, and the study of cultural forms without semiotics is blind.

# The City As a Sign: A Developmental-Experiential Approach to Spatial Life

Nikita A. Kharlamov

## Abstract

The galloping urbanization of the world simultaneously transforms human society into a thoroughly urban society and dismantles the traditional “rural–urban” dichotomy. It is increasingly recognized in urban studies that human spatiality entails a complex pattern of settlements and dwellings. I propose a developmental-experiential theoretical framework for addressing what Stanley Milgram called the experience of living in cities. This framework particularly focuses on the atmosphere of living in cities. Founded on organismic-developmental axiomatic base introduced by Jacob von Uexküll, Heinz Werner, and Bernard Kaplan, and developed as cultural-developmental approach by Jaan Valsiner, the proposed framework centers on the experience of individual organismic relating to spatial environment. I draw on the work of Manuel Castells, Edward Soja, and Yi-Fu Tuan to conceptualize the emergence of meaningful places as the outcome of experiencing space. The concept of encounter introduced by Ash Amin and Nigel Thrift is used to locate the experience of the banal, everyday city life. Following Erving Goffman, the central question for the framework becomes the question of organization of experience. This question is tackled through Jaan Valsiner’s notions of semiotic mediation and regulation. I specifically focus on spatial signs that humans use to regulate the meaning-making process that creates as meaningful what Georges Perec called species of spaces, such as towns and cities. “The city,” from this standpoint, becomes one of the most important signs that mediate and regulate our experience of environments we inhabit. I discuss a number of theoretical and methodological directions in which this framework could be further developed to revive the urban, or settlement, psychology, which failed to develop as a viable subdiscipline despite the proposals of Georg Simmel and Nikolai Antsiferov in the early twentieth century, and the latter proposals of Milgram. This discipline should join efforts with settlement sociology and settlement geography to tackle the multiple challenges of urbanization by exploring its experiential dimension in its fascinating cultural diversity and intra- and interindividual variation.

**Keywords:** city, development, encounter, experience, meaning, person-environment-behavior, place, space, sign–spatial, Umwelt, urban psychology

“The metropolis reveals itself as one of those great historical formations in which opposing streams which enclose life unfold, as well as join one another with equal right.”

—(*Simmel*, 1903/1997, p. 185)

“Every city has its own face.”

—(*Antsiferov*, 1925, p. 25)

“The Great Khan owns an atlas in which are gathered the maps of all the cities: those whose walls rest on solid foundations, those which fell in ruins and were swallowed up by the sand, those that will exist one day and in whose place now only hares’ holes gape . . . The catalogue of forms is endless: until every shape has found its city, new cities will continue to be born. When the forms exhaust their variety and come apart, the end of cities begins. In the last pages of the atlas there is an outpouring of networks without beginning or end, cities in the shape of Los Angeles, in the shape of Kyōto-Ōsaka, without shape.”  
—(Calvino, 1972/1974, pp. 137–139)

“Don’t be too hasty in trying to find a definition of the town; it’s far too big and there’s every chance of getting it wrong.”  
—(Perec, 1974/2008a, p. 60).

Georg Simmel, whose lecture, *The metropolis and the mental life* (1903/1997), attained a monumental position in urban literature and in the imagination of urban scholars, understood the city as the mediating vehicle between societal-cultural transition to modernity and the everyday life of the people (Kharlamov, 2009). For him, metropolis *existed* as a spatial and psychic,<sup>1</sup> or even *spiritual*,<sup>2</sup> environment and was visible, ostensive, and palpable. In fact, Simmel’s metropolis is well-known to have been the *fin-de-siècle* Berlin (Jazbinsek, 2003). However, only 70 years after Simmel’s piece, Italo Calvino conveyed an image of the great omniscient Kublai Khan flipping through the pages of a wondrous atlas that predicted the end of the city form as we know it. Calvino’s friend Georges Perec simply stated that there is no quick way of arriving at a structured understanding of what a “town” is, instead proceeding by way of scrupulous documentation of town-ness of that, as he called it, “species of spaces.”

*Method:* you must either give up talking of the town, about town, or else force yourself to talk about it as simply as possible, obviously, familiarly. Get rid of all preconceived ideas. Stop thinking in ready-made terms, forget what the town planners and sociologists have said.

(Perec, 1974/2008a, pp. 61–62, italics in original)

And yet, as Nikolai Antsiferov succinctly stated, places where people live have unique identities (“faces”), so that we still can recognize Los Angeles even if we agree that it has no form but the vast, endless sprawl. We even ordinarily recognize it as a

city! But what does it mean then to live in a post-city? *What is the experience of living in the city?*

Defining the meaning of the terms “urban” and “city” is a monumental task that radiates the feeling of futility. These words—along with mind, society, power, economy, and many others—belong to the class of *foundational concepts* that travel through human sciences, ever settling the research interests, guiding generation of questions and research programs, and at the same time evading attempts to create solid and agreed-upon definitions and operationalizations.

What makes the notions of *city* and *urban* special among foundational concepts is that they are to some extent *ostensive*. That is, there is some *a priori* obviousness to these notions, a possibility to detect the presence of *the urban* by merely looking at a place, pointing a finger at a location, and suggesting that it is an urban location, before invoking powers of reflection and scientific reasoning (Fig. 13.1). But how do we approach this ostensiveness?

### The “Soul of the City”: Calls for an Urban Psychology

At least some (and probably all) cities have such a powerful grasp on our sensory and cognitive apparatus that they attain a lasting and individual *identity*. Nikolai Antsiferov, an early Soviet urbanist, developed a holistic, organicist conception of the city (1925). He identified three dimensions and, correspondingly, divided the urban science into three branches. The physical form, “the physical nature of the city constituting its concrete, material base”

**Figure 13.1** An urban place—Malaya Ordynka Street, Moscow, Russia (Photograph by author, 2005)

(*ibid.*, p. 21), was to be the subject matter of *urban anatomy*. The functions of urban organism, “the city pulsing with all its organs through the activity of the society” (*ibid.*, p. 22, italics removed), were the domain of *urban physiology*. Finally, Antsiferov asserted that the city has a synthetic image, recognizable in the flow of time, and stated that “the *soul of the city* [is] a *historically* formed *unity* of all elements, constituting the urban *organism* as a concrete *individuality*” (1925, p. 26, italics in original). In this secular definition he attempted, predating many concerns in urban studies of the late twentieth and early twenty-first centuries, to capture the constellation of landscape, history, memory, and architectural and planning styles (*ibid.*, Chapter 4) that makes the city. This was what, according to Antsiferov, urban psychology should study.

Writing 45 years after Antsiferov, Milgram (1970/2010) proposed an agenda for urban psychology. In addition to the issues familiar to social psychology—such as bystander intervention and role behavior—Milgram’s seminal article contained a section entitled, nebulously, “Further aspects of urban experience” (*ibid.*, pp. 20 ff.). Echoing Antsiferov (1925), and presumably independently from him, Milgram proposed to study the “‘atmosphere’ of great cities” (*ibid.*). This phenomenon encompassed such things as the “vibrant” and “frenetic” character of New York’s city life. Milgram treated this phenomenon in terms of how people *perceive* cities and suggested that at least three factors are responsible (1970/2010, pp. 21–22):

1. “Implicit standard of comparison,” such as the person’s hometown;

2. “Whether the observer is a tourist, a newcomer, or a longer-term resident”;

3. “The popular myths and expectations each visitor brings to the city.”

Milgram suggested that a program of research on these subjective dimensions of perceiving the city should be augmented by measures of objective factors, such as population and its density, characteristics of urban society such as the geographic origin of migrants, national culture, and history of a given city (*ibid.*, p. 25). He even suggested to study, in addition to behavioral measures, and following the work of Kevin Lynch (1960), the “cognitive maps” people have of their cities.

The urban psychology according to Antsiferov and Milgram, however, apparently never blossomed, especially with respect to proposing integrative theories and conceptual frameworks. In the United States (and elsewhere) “urban psychology in the year 2009 barely exists as a discipline, with no journal, organization, or degree program” (Takooshian, 2009, p. 916). Takooshian suggests that the impact of Milgram’s proposal has dissipated, even as the original article became a citation classic. Indeed, today what amounts to urban psychology is concerned quite narrowly with a range of familiar psychological topics—such as prosocial and antisocial behaviors, attitudes, health, locating them in the cities as external settings—*essentially as independent variables*. A recent report of the American Psychological Association Task Force on Urban Psychology (American Psychological Association [APA], 2005) stated that urban psychology deals

with urban environments, ranging in scale from inner cities to metropolitan areas, and:

the central question for urban psychology concerns how the distinctive characteristics of the people and places that make up urban environments give rise to particular types of experiences and behaviors, and have particular consequences for mental health, well-being, and human development.

(APA, 2005, p. 2)

Although this definition sounds promising, in reality it furthers the dissipation of its subject matter by approaching the notion of urban in a *non-problematic way*: the urban, for APA Task Force, is what the U.S. Census Bureau defines it to be, through a threshold of population density. It also includes what is non-rural, or non-agricultural, and what is “part of the global system of economic production and distribution” (ibid., pp. 1–2). Consequently, the rest of the report documents a wide range of issues psychology has been studying for varying lengths in the past century, such as acculturation, aging, gay, lesbian, bisexual, and transgender identities, homelessness, substance abuse, physical and mental health, urban decay, urban schools, and even vulnerability to terrorism.<sup>3</sup> In studying all these, psychology largely takes urban for granted and dissolves in absence of an integrating, central psychological concept that would define the subject matter of this subdiscipline.

### **Developmental-Experiential Approach to Life in Spaces: Structure of the Argument**

The present chapter is an attempt to approach spaces *Homo sapiens* live in, or dwell in, or inhabit, beginning with the guiding intuition of *ostensiveness*. It is an attempt to provide novel theoretical and methodological tools for addressing the very basic question about urban life: *What constitutes the city?* It is also an attempt to find the subject matter for an urban psychology—or psychology of human settlement spaces—in *developmental axiomatic base applied to the phenomenon of spatial experience*. An answer to this question is the ontological foundation for any further inquiry into human settlement form. I explicitly adopt a perspective focused on persons—the sentient inhabitants of environments—and their *intentionality*, which is the source of meanings and activities that define cities as spatial forms, and focus thus on psychic experience of urban living. Hence the title of the chapter: furthering the move taken by Gottdiener and Lagopoulos (1986), whose seminal collection on urban semiotics was entitled *The City*

*and the Sign*, I suggest that the city is a meaning, or, more specifically and importantly, it is *the sign* that organizes meaning-making around human settlements and ultimately defines what we mean by the city and what it means to live in a *good place*.

The chapter begins with an examination of the notion of “the city” in context of recent discussions on the end of modern city forms and the emergence of radically new settlements such as decentered urbanized regions. This establishes the *core problem*: If today there is indeed a new essence to the urban form and urban life, what is the experience of living in these new settlements? And how do people make sense of these new surroundings? The remainder of the chapter is devoted to outlining a developmental-experiential approach to encountering space and making sense of it. I consecutively discuss the developmental axiomatic base, the notions of space and place, and introduce the concepts of experience and encounter. I then examine the semiotically mediated nature of experience and the regulative function of culture. The final part of the chapter is devoted to discussing how humans recognize different species of spaces on the basis of spatial signs, and the implications of this approach to understanding the nature of cities and urban life. The chapter concludes with a number of future directions of inquiry.

### **Are We Really All Heading Urban? Or, What Are the Spaces We Inhabit Today?**

“Sometime early next [twenty-first] century, if present trends continue, more than half of the world’s population will be classified as urban rather than rural,” predicted David Harvey (1996, p. 403). He went on the Marxist track to elaborate on the notion of urbanization as a process fueled by technological innovation and founded on the social-economic-political process of “relentless capital accumulation”: “We are all embroiled in a *global process of capitalist urbanization or uneven spatio-temporal development*” (p. 414). Indeed, in 2007 a United Nations (U.N. Population Fund [UNFPA], 2007) report stated, “[T]he world is about to leave its rural past behind: By 2008, for the first time, more than half of the globe’s population, 3.3 billion people, will be living in towns and cities” (ibid., p. 6). This statement was immediately picked up by urban practitioners, pundits, and academics from across the spectrum of disciplines dealing with cities and urban life.

Remarkable as this statistical statement is, however, it raises more questions than it provides

answers. It is a *statistical assertion* of the highest, most general scale.<sup>4</sup> Unpacking its meaning requires asking: What constitutes a city? Given the galloping pace of urbanization all over the world, is there still salience to the dichotomy “urban–rural”? Or maybe the distinction becomes an example of unity of opposites—as with sustainable local agriculture initiatives in the heart of American inner cities and with high-speed Internet connections in Northern Russian villages? What kind of life then is urban life? How is the city shaped by its inhabitants, and how is it, in turn, shaping them? What is cultural about this process? What is the future of human settlement forms and human mobility patterns in face of fossil resource exhaustion and global warming? And not least—as thinkers such as Iris Marion Young (1990) and David Harvey (1996) remind—what is the justice dimension of human settlement process? These questions form the crux of urban studies and demand cooperation and integration across disciplines. The underlying complexity of “50% urban population” statement underscores the topicality and urgency of these questions about urban life not only for abstract scientific thinking but for broad domains of public concern and applied policy.

### ***The New Urban Form: Urban, Suburban, Post-Suburban, Apocalyptic . . .***

One possible track of unpacking the issue of what constitutes a city is to start with the assertion that today cities go beyond the traditional, modern urban form into something radically new—such as the *sprawling urbanized region with multiple centers*. In 1987, Robert Fishman, in his seminal history of the American suburban model, suggested that the traditional model of city with an identifiable core (which in modern times has been “augmented” with a rim of bedroom suburbs) is being replaced by “technoburb”: “With its highways and advanced communication technology, the new perimeter city can generate urban diversity without urban concentration” (p. 17). Fishman’s vision of “technoburbs” and “techno-cities” (1987, Chapter 7) was inspired first and foremost by Los Angeles—the iconic urban sprawl developed literally from a scratch of a few thousand homesteaders over (at best) some 150 years into a megalopolis of well over 16 million people. The entire region manifests the dissolution of rural–urban dichotomy.

In effect, Southern California constitutes a single metropolitan district which should be characterized

as *urban*: neither city nor country but everywhere a mixture of both. Just as Southern California is the least rural of all the regions in America, so, paradoxically, Los Angeles is the least *cityfied* of all the cities of America.

(McWilliams, 1973, pp. 12–13)

For today’s urban studies, Los Angeles has become a *paradigmatic city*: “the city that displays more clearly than other cities the fundamental features and trends of the wider urban system” (Nijman, 2000, p. 135).<sup>5</sup> Jan Nijman—who claims that Miami, rather than Los Angeles, could serve as a paradigmatic American city for the twenty-first century—inserts a caveat that the paradigmatic city is not a city that all other cities will become but, rather, a future-projected extreme most clearly manifesting the general trends. The imagination of Los Angeles found its way into concepts underscoring the regionalized nature of settlement patterns, such as the “multicentered metropolitan region,” which Gottdiener and Hutchison have called “the first really new way people have organized their living and working arrangements in 10,000 years” (2006, p. 5). In contrast to the bounded traditional city with a recognizable central core, such as the city reflected in the classical concentric ring growth model of the Chicago School (Burgess, 1925), the “new form of settlement space . . . can be typified by two features: It extends over a large region, and it contains many separate centers, each with its own abilities to draw workers, shoppers, and residents” (Gottdiener & Hutchison, 2006, p. 5). Fishman succinctly expressed the gist of this new city: “the creation of a decentralized environment that nevertheless possesses all the economic and technological dynamism we associate with the city” (1987, p. 184).

Fishman’s vision could create an impression of optimism toward this new form of city living. Not all observers are that optimistic. Davis (1990/2006) painted a bleak picture of Los Angeles as a city of inequality, oppression, disenchantment, and unfreedom, an apocalyptic landscape before apocalypse itself. Among other things, Davis’s pessimistic vision epitomizes a wider trend of post-1990 urban studies, with a prominence of calls for social and, importantly, spatial and urban justice (following, among others, the theoretical proposals of David Harvey, 1996, and Iris Marion Young, 1990) juxtaposed with an overarching pessimism toward the present and future of the city as a *livable* space. The looming question is whether cities today indeed are the seats of the “good” dynamism and diversity or the spatial train of modernity is headed uncontrollably toward the catastrophe

of *dystopia*, as visualized in movies such as *Blade Runner* (1982).<sup>6</sup> The *utopian dimension* of this question is of primary importance: utopian thinking, as John Friedmann defined it, is “the capacity to imagine a future that departs significantly from what we know to be a general condition in the present” (2000, p. 462), and this capacity requires combining a critique of the present condition with a constructive vision for the future (ibid.). The answer to the question “What does it mean to live in the city?” is foundational, for without a clear understanding of this, it is impossible to constructively proceed along constructing normative visions of cities without falling into the traps of ideal cities (Kharlamov, 2010).

### ***Life in Places and Thirdspaces: Locating the Urban Experience***

Even if Los Angeles may be just one of the urban places of today, and other cities may assume different spatial forms—especially outside the United States with its car-centered highway mobility regime—there appears to be a broad consensus in urban studies that cities today are on the forefront of the broader social, cultural, political, and economic<sup>7</sup> change. One of the possible approaches to this new configuration of human life is offered by Manuel Castells. Castells’ trilogy, *The Information Age: Economy, Society, and Culture* (1996/2010), offers a grand survey of human condition in the late twentieth and early twenty-first centuries informed by the overarching concept of network society, Castells suggested that cities—especially megacities such as Tokyo, New York, Mexico City, and, of course, Los Angeles—manifest the *spatial logic of this new society*. In a statement echoing Fishman’s, Castells captures the nature of mega-cities: “It is [the] distinctive feature of being globally connected and locally disconnected, physically and socially, that makes megacities a new urban form” (1996/2010, p. 436, italics removed). He called the new spatial logic “the space of flows.”

The space of flows is the material organization of time-sharing social practices that work through flows. By flows I understand purposeful, repetitive, programmable sequences of exchange and interaction between physically disjointed positions held by social actors in the economic, political, and symbolic structures of society.

(Castells, 1996/2010, p. 442, italics removed)

In a nutshell, space of flows is about the disconnection of simultaneous interaction, communication,

and shared (or collective) activity (or “time-sharing social practices”) across the domains of human life from the constraints of material, physical space.<sup>8</sup> Castells, however, did not embark on the track of unbounded techno-optimism. His cautious note is founded on the distinction between “space” and “place.” Defining *space* as “the material support of time-sharing social practices” (ibid., p. 441), and thus grounding it in material, objective realm of practice, he introduced the subjective, meaningful dimension of space by defining *place* as “a locale whose form, function, and meaning are self-contained within the boundaries of physical contiguity” (ibid., p. 453, italics removed). The overwhelming majority of people, according to him, “still live in places” (ibid., p. 458)—and thus there is a mismatch, a “structural schizophrenia” (ibid., p. 459) between the logic of places and the logic of flows.

In this statement, Castells captured *the essence of the urban problem today*. If the social, economic, political, cultural life is becoming increasingly detached from the identifiable and personally recognizable locale in space, then how should we account for the personal experience of spaces and places? And what is the relation of this personal experience to the objective configurations of space such as those captured by concepts like “multicentered metropolitan region?”

Another way to locate this problem can be drawn from the work of Soja (2000), whose discussion of “postmetropolis” rests on the conceptual foundation he called “trialectics of cityspace.” It is worth examining this conception at some length. Addressing the “spatiality of human life” and highlighting the intrinsic spatiality of the city as a “material and symbolic habitat for human life” (ibid., pp. 6–8), Soja drew on the work of Henri Lefebvre to conceptualize *Firstspace* as a perspective that views cityspace as “physically and empirically perceived as form and process, as measurable and mappable configurations and practices of urban life” (Soja, 2000, p. 10). Conceptualizing the city in terms of, for example, spatial distribution of population and arriving at a concept of “multicentered metropolitan region” is an application of Firstspace perspective. In terms of *Secondspace*, “cityspace becomes more of a mental or ideational field, conceptualized in imagery, reflexive thought, and symbolic representation, a *conceived* space of the imagination” (ibid., p. 11, italics in original). Thus, Secondspace could be interpreted as a meta-perspective on phenomena such as urban theories and personal representations

of cities in memories or “mental maps.” In addition to these two perspectives, Soja suggested employing a *Thirdspace* (a term derived from the work of Bhabha, 1990) perspective and recognizing and understanding cityspace as “fully *lived space*, a simultaneously real-and-imagined, actual-and-virtual, locus of structured individual and collective experience and agency” (ibid., italics in original). In three main parts of his book, Soja outlines, respectively, the three perspectives, focusing first on the “geohistory of cityspace,” outlining the evolution of human cities that culminates, not surprisingly, in Los Angeles. The second part of his book is a sweeping overview of urban theory, particularly that which takes Los Angeles as its paradigm and source of imagination. The third part—concerned with Thirdspace—withdraws from the scholarly writing of the first two parts. In it, Soja presents a collage of fragments—poetry interspersed with newspaper excerpts and quotations from philosophers and urbanists—all focused in different ways on the 1992 riots in Los Angeles that followed the acquittal of four White police officers who beat up a Black driver (Rodney King). This collage is an attempt to approach the lived space of Los Angeles and the complexity of experiences and perspectives involved in one particular iconic event.

Castells’ suggestion of a “structural schizophrenia” between the logic of space of the network society and the experiential world of living humans and Soja’s attempt to grasp the lived space of post-metropolis point toward a lacuna in urban theory and methodology of urban studies. Every objective measure in the urbanists’ toolboxes points toward changes in urban form, urban process, and urban life. Population growth; migration patterns; changes in economic structure, production, and consumption; emergence of creative/knowledge economies; religious and ethnic tensions; the demise of traditional structures of urban governance; explosion of the city territory and the dissolution of urban/rural dichotomy; and the development of mostly urban “evil paradises” (Davis & Monk, 2007)—pockets of neoliberal exploitation and totalizing negation of human rights across the world, from Los Angeles to Dubai and Kabul—suggest that urbanization became the global *conditio humana*. And yet it appears that *the urban experience*—especially those transient qualities of urban life that Antsiferov (1925) called “the soul of the city” and Milgram (1970/2010) referred to as the atmosphere of great cities—escapes from the urbanists’ nets.

John Urry, following the work of Heidegger, suggests that *atmospheres* “stem from how people are ‘attuned’ to particular places” (2007, p. 73). How do we approach these atmospheres in Thirdspace? One interesting path is to concentrate on the multiple “texts” that the city produces as a result of expressive activity of the urbanites. This was the path Soja (2000) took in his excavation of Thirdspace of 1992 L.A. “Justice Riots,” as he called them.<sup>9</sup> I suggest that another fruitful path is to *develop theoretical and methodological tools to grasp the psychic experience of the city*. I will now turn to assembling a theoretical framework geared to this task.

### **From Space to Place: Development of Meaningful Environment**

I am learning to drive a car. My friend, who is teaching me, sits in the passenger seat and guides me while I am concentrated on safely keeping the vehicle on the road, maintaining speed, and making turns at my teacher’s command. One day I make a left turn into a long stretch of road outside the dense residential neighborhood, and for the next 10 minutes or so I drive at the speed of about 40 miles per hour on a well-paved freeway with few cars. We like this road so much (it has little traffic, the turns are wide and easy, there are no confusing intersections or blind driveways, and the other drivers appear to be polite) that for the next couple weeks we use this road for our lessons while I am getting more comfortable with operating the car on an open road. One evening as I drive into one of the most beautiful sunsets I have ever seen, I suddenly realize that this road, which I by now know down to each turn, lane, and road sign, actually goes past Worcester Regional Airport. Not only has my newly developed level of comfort with the car allowed me to pay attention to the sunset and notice that it is very beautiful—it has also allowed me to pay enough attention to the surroundings to realize that what used to be just a road in the middle of nowhere (I could not remember after the first couple drives how we got there and where we drove) in fact is *somewhere*—and this somewhere is near the regional airport. What could be *anyplace* become a specific, defined, relatively meaningful place marked by a landmark. What has happened to this stretch of urban space? Apparently, the physical, built environment on the fringes of the city of Worcester has not changed because of my newly developed recognition. But for me *as a person*, it is no longer an undefined space—instead, it is a place

imbued with meaning and (admittedly romantic) memory of the first prolonged experience of driving a motor vehicle. How did this happen?

### ***Assuming a Developmental Perspective on Human Spatiality***

*How do spaces become places?* The answer to this question requires exploring the notions of space and place from a developmental standpoint. This exploration will open the pathway for tackling the issue of what the city is and how it acquires the urban quality for humans.

#### **AXIOMS OF DEVELOPMENTAL APPROACH**

The “*developmental perspective in any science entails investigation of general laws of emergence of novelty in irreversible time*” (Valsiner, 2000, p. 17, italics in original). Valsiner further suggests that *novelty*—the new phenomena that are different from those that have happened in the past—emerges on at least two distinguishable levels: on an *individual* level and on the *comparative-collective* level. What was novel for me as a person in recognizing the airport was not novel on a collective level of the population of drivers driving past it—and yet it was novel at the time when the road was first opened. Similarly, the notion of airport for me was no longer novel, although at one point in my past I discovered what an actual airport is when I first went to an airport to fly for the first time, armed with the culturally shared—but, until that point, abstract and not validated by personal experience—knowledge of what is an airport. And yet in the past there was an emergence of the airport as a cultural-technological phenomenon as humans extended the existing technologies such as the harbor and the train station to accommodate the newly invented flying machines.

The developmental axiom of “becoming and dynamic self-maintenance” (Valsiner, 2000, p. 20) implies that the study of emergence of meaningful places necessarily deals with the question of how these places become meaningful and how the meaning is maintained in irreversible time as a stable phenomenon. This dynamic, processual axiom is a pathway to access the lived reality of Soja’s (2000) Thirdspace and to understand how people create meaningful locales that Castells (1996/2010) called places—and to unpack their atmospheric qualities. Developmental treatment of this question requires applying the “orthogenetic principle”: “organisms are naturally directed towards a series of transformations—reflecting a tendency to move from a state of

relative globality and undifferentiatedness towards states of increasing differentiation and hierarchic integration” (Werner & Kaplan, 1963/1984, p. 7; *see also* Valsiner, 2000, Chapter 2). It follows from this principle—which is a fundamental axiomatic principle of developmental science according to Werner and Kaplan—that differentiation, articulation, and integration of space (Valsiner, 2000, p. 20) by the organism is inherent in its very basic functioning in relating to environment.

#### **RELATING TO ENVIRONMENT: HUMAN SPATIALITY AND HUMAN UMWELT**

The notion of *relating to environment* derives from von Uexküll’s theoretical biology. Central for von Uexküll (1940/1982) has been the concept of *Umwelt*—the subjective phenomenal world that each organism inhabits and that is the only reality accessible to this organism.<sup>10</sup> “Everything that falls under the spell of an Umwelt (subjective universe) is altered and reshaped until it has become a useful meaning-carrier; otherwise it is totally neglected” (ibid., p. 31). von Uexküll develops the model of *functional circle* to account for the organism’s relation to environment. This model accounts for perception of objects as meaning-carriers and activity of the subject (organism) as meaning-receivers in that subjects perceive objects as perceptual cue-carriers and act on the objects as effector cue-carriers. At the center of the functional circle is the notion of sign, which is the general mediator of meanings of any events, internal and external. Thus the model of functional circle accounts for perception of the world, making sense of it (making it meaningful for the organism) and acting on it as a meaningful reality (*see* Magnus & Kull, 2012, for a more detailed explanation of Uexküll’s theory; *see* Chang, 2009, for a range of its applications in cultural psychology).

Werner and Kaplan’s (1963/1984) developmental theory explicitly relies on von Uexküll’s conception and allows one to *treat it dynamically and to ask how meanings emerge*, or develop, in the process of the organism’s living in environment, and what *function* these meanings play in maintaining the relation to this environment. This is what they call “organismic-developmental framework” (ibid., Chapter 1). Given the concern of this chapter with the “city” as meaning, this question becomes: What is the nature and role of the meaning of the city in human relating to built environment? To proceed with this discussion, it is necessary to apply the

organismic-developmental framework to emergence of places from undifferentiated space and to introduce the notion of “experience of space.” A conceptual framework pertinent to this task was developed in human geography by Yi-Fu Tuan.

### *Experiential Geography and the Emergence of Meaningful Places*

There isn't one space, a beautiful space, a beautiful space round about, a beautiful space all around us, there's a whole lot of small bits of space, and one of these bits is a Métro corridor, and another of them is a public park . . . In short, spaces have multiplied, been broken up and have diversified. There are spaces today of every kind and every size, for every use and every function. To live is to pass from one space to another, while doing your very best not to bump yourself.

(Perec, 1974/2008a, pp. 5–6)

Georges Perec, the French writer and the keenest observer of the “infra-ordinary” in the fabric of our everyday life, understood the problem of this chapter only too well. His book, *Species of Spaces* (1974/2008a), which he himself aptly called a “sociological” undertaking on “how to look at the everyday” (Perec, 1978/2008c, p. 141), covers exactly the different *species* of spaces—arranged on the scale of rising abstraction from the book page to apartment and street to the world and space in general. In terms of the organismic-developmental framework, emergence of species of space is the result of *differentiation of space*—the “nothingness, the impalpable, the virtually immaterial; extension, the external, what is external to us, what we move about in the midst of, our ambient milieu, the space around us” (Perec, 1974/2008a, p. 5)—and its *articulation* into meaningful places (which could be followed by hierarchical integration according to, for example, the relation to home).

#### THE NATURE OF SPATIAL EXPERIENCE AND ITS ORGANIZATION

What fuels this developmental process of differentiation and articulation, for Yi-Fu Tuan (1977), is experience of space. It is the key to conceptualizing space and place and a means of distinguishing the two without giving any of the concepts primacy. *Experience* is another foundational concept in sciences that resists stable definition. Tuan defined experience as “a cover-all term for the various modes through which a person knows and

constructs a reality” (1977, p. 8; *see also* the notion of experience in Boesch, 2012). Experience encompasses the entire spectrum of possibilities of relating to a reality<sup>11</sup>: sensation, perception, and conception on a continuum from more emotional to thoughtful modes. It is externally related and ranges from passive contemplation to active exploration of the world and acting in it.<sup>12</sup>

It should be noted that Tuan's treatment of experience is in broad accord with phenomenology, and a relevant parallel can be made to Erving Goffman's *Frame Analysis* (1974/1986). Goffman, who was drawing on William James's question, “Under what circumstances do we think things are real?” (James, *Principles of Psychology*, quoted in Goffman 1974/1986, p. 2, italics removed) as well as on Alfred Schuetz's (1945) phenomenology of multiple realities defined as “provinces of meaning” (rather than provinces of being or physical existence), interpreted experience as *anything that occurs to a person in a situation*. Goffman assumed “that when individuals attend to any current situation, they face the question: ‘What is it that is going on here?’” (Goffman, 1974/1986, p. 8). *Definitions of situations* (a familiar term from phenomenology and symbolic interactionism) stem from answering this question.

The crucial research problem becomes: how can people make sense of situations, come up with their definitions, and proceed with their activities? That is, how is experience *organized*? Goffman's aim became “to try to isolate some of the basic frameworks of understanding available in our society for making sense out of events” (*ibid.*, p. 10)<sup>13</sup>—and his conceptual device was “frame”<sup>14</sup>: “definitions of a situation are built up in accordance with principles of organization which govern events—at least social ones—and our subjective involvement in them . . . [frame analysis is] the examination in these terms of the organization of experience” (*ibid.*, pp. 10–11). The relevance of Goffman's conceptualization for the present theoretical framework is that it explicitly postulates the fundamental necessity of meaning-making in situations—that is, of making sense of experience—and raises the question of organization of experience. Although his arguments are made for social situations, and the present chapter is concerned with spatial experience, the general question is the same, and the core issue is to approach it developmentally: How do meanings emerge in situations, and what is the effect of signs on experience?

What is spatial experience? Amedeo, Golledge, and Stimson underscore the relation of space to situations: “[S]pace’s most dominant expression in the human context [is] its role as a dimension in *situational surroundings* in which human activities are commonly enacted and experiences are felt” (2009, p. 5). For Tuan (1977), similarly to Pereg (1974/2008a), space is general, unspecified, vague, and expansive; there is little human attachment to space. In von Uexküll’s terminology, it is nothing more than a sign-based orientational framework for the organism’s Umwelt. Space is the physical environment *before* human experience. The developmental process of experience of environment transforms it into place, which begins with a “pause in movement”, allowing for the minimal moment of attention to environment. “An object or place achieves concrete reality when our experience of it is total, that is through all the senses as well as with the active and reflective mind” (Tuan, 1977, p. 18).

#### FROM SPACE TO MEANINGFUL PLACES

Tuan postulates that the process of experiencing the world and thus creating places is a *universal human process* that also closely follows development of human organisms through life-course, from birth to death. “All people undertake to change amorphous space into articulated geography” (ibid., p. 83). This is the essence of environmental meaning-making and environmental knowing—and this conceptualization corresponds to developmental axioms expressed in Werner and Kaplan’s orthogenetic principle (1963/1984). It occurs on an individual level—as when I slowly learned the details of a stretch of the road to realize at one point that it passes by an airport. I acquired novel spatial knowledge (see Golledge & Stimson, 1997, Chapter 5). For each organism, development of complex spatial knowledge presupposes mobility—movement, with occasional pauses, through spaces and making sense of them (Jensen, 2009; Urry, 2007). It also occurs on collective level—“Polynesian and Micronesian navigators have conquered space by transforming it into a familiar world of routes and places” (Tuan, 1977, p. 83)—and today, when satellites have ended geographical discoveries on Earth, we continuously re-enact this articulation through the practices of tourist gaze (Urry, 2002), which has not subsided with the proliferation of electronic media and instantly accessible images of faraway places but, on the contrary, is further reinforced by them.

Thus, Tuan reinforces what is implicit in von Uexküll’s Umwelt conception: Space is not in and by itself a causal factor. Space alone is static and inert. *It is spatial experience, the developmental process of meaning-making, that produces an articulated and organized world of sensible places.*<sup>15</sup> This is consistent with the notion of space as a *form* of social life introduced by Simmel in his attempt to develop the sociology of space in the seminal chapter (*Space and the Spatial Ordering of Society*) of his opus magnum, *Sociology* (Simmel, 1908/2009, Chapter 9): “[S]pace remains always the form, in itself ineffectual, in whose modifications the real energies are indeed revealed . . . Not space, but the psychologically consequential organization and concentration of its parts have social significance” (pp. 543–544). Filippov (2008) clarifies that this is, in its foundation, a Kantian position, and that what Simmel had in mind when he developed his sociology of space was a “concrete phenomenology of sociality” (ibid., p. 106)—that is, an inquiry into how, in the course of social life, specific, concrete, particular forms such as the “territory” or the “boundary” become socially meaningful and hence attain an important role in social life (ibid., p. 116). Importantly for the present discussion, the city could be interpreted as one of such *meaningful forms*.<sup>16</sup> Thus, Simmel’s sociology also leads to the issue of the organizing principle that transforms abstract form of space into socially meaningful forms such as the city.

As Agnew (2005) has suggested, Tuan’s conceptualization was one of the first attempts in contemporary human geography to seriously define space and place in a way that would not make one *prioritized* at the expense of the other. Agnew has indicated that there are at least three meanings of place that have to be accounted for: “as location or a site in space where an activity or object is located and which relates to other sites or locations because of the interaction and movement between them”; “as locale or setting where everyday-life activities take place”; and “as sense of place or identification with a place as a unique community, landscape and moral order” (ibid., p. 89). Implicitly, Agnew has already situated these meanings on a continuum from more detached and abstract to more personal and embodied. In a humanistic perspective, which both Tuan and Agnew follow, “the focus lies in relating location and locale to sense of place through the experiences of human beings as agents” (ibid.).

**SPATIAL COGNITION AND SPATIAL BEHAVIOR:  
LESSONS FROM ENVIRONMENTAL PSYCHOLOGY  
AND BEHAVIORAL GEOGRAPHY**

Thus far, the outline of a developmental perspective on meaning-making in the spatial *Umwelten* of human beings bypassed the notions of *spatial cognition* and *spatial behavior*. These notions, however, demarcate well-developed research programs in the closely related fields of environmental psychology and behavioral geography, and therefore it is imperative to clearly identify their relevance in context of the present discussion, keeping in mind the overarching interest in the meanings of spaces we inhabit.

Research on *spatial cognition and learning* focuses on how people acquire, store, and operate with the information about space they inhabit (Golledge & Stimson, 1997, Chapter 7). It is concerned with orientation in space, and it assumes that humans routinely form *representations* of their environments, that environmental experience leaves a discernible trace in human memory, and that this trace is accessible at some later point in time. This research program fits into the broader paradigm of cognitive science, whose “founding axioms are that people come to know what is ‘out there’ in the world by representing it in the mind, in the form of ‘mental models’, and that such representations are the result of a computational process working upon information received by the senses” (Ingold, 2000, p. 163).

One particularly salient concept integrating research interest in spatial cognition is that of *cognitive map*—“an individual’s knowledge of spatial and environmental relations, and the cognitive processes associated with the encoding and retrieval of information from which it is composed” (Kitchin & Blades, 2002, p. 1). This definition explicitly employs the metaphor of “map,” essentially positing that each of us has in our head a representation, a version of space we know, and that we use it in a way similar to the way we use a paper map—to find our way around. Kitchin and Blades (2002) have provided one of the most integrative syntheses of research using this concept.

Historically, cognitive mapping approach received a powerful thrust with the publication of the seminal work of Kevin Lynch (1960). His book, *The Image of the City*, explicitly adopted a *textual metaphor* of urban environment as he was concerned with legibility of the city—that is, the capability of the environment to be read and understood by the urbanites.<sup>17</sup> He used the notion of mental map—a

synonym to cognitive map—and clearly translated theoretical concern with representations of the city into practical terms of urban planning and architectural design (his latter book, *Good City Form* [1981], further developed normative standards for the highly legible city). The prominently applied character of Lynch’s research and the clear path to practical recommendations led to lasting popularity of mental mapping as well as the widespread focus on cognition of built environment.

This applied focus on orienting in space has its twin in research on *navigating in space*. Behavioral approach to the city favored by behavioral geography is focused on the role of perception, cognition, memory, and ability play in *performance of space-related tasks*. A particularly important task is orientation, or wayfinding (Golledge, 1999)—how humans get around the urban environment and what factors facilitate success in these tasks.

Both spatial cognition and spatial behavior perspectives have particular practical relevance to design of environments—architectural design on scale of small buildings, and urban and transportation planning on the scale of cities and urban districts as wholes.<sup>18</sup> They also often share the *cognitive-representational axiomatic base*. Some integrative attempts have focused on linking cognitive representations and computations with behavioral performance, as in the proposal by Carlson, Hölscher, Shipley, and Dalton (2010) to consider the *intersection* of built environment, person’s cognitive map, and individual strategies and abilities, as constituting the complex outcome of navigation in space. Presumably, good fit between the three would lead to successful performance, whereas (as in their example of the recently constructed Seattle Public Library) lack of fit leads to confusion and frustration on part of the users.

It follows from the cognitivist, representational, and behavioral axiomatic bases of these approaches that the inquiry is geared toward examining those ways of relating to space that are relevant to task performance, *at the expense of other kinds of engagement with environment*, including aesthetic engagement. The latter is often subsumed under pragmatically defined qualities of aesthetic response to environment, and linked back to cognition. Generally, this makes the inquiry functional—that is, it conceives of humans as users of environment who respond to it with more or less success and satisfaction. Indeed, since the early years of environment-behavior research, satisfaction is often posited as the ultimate

goal of experience: “environmental experience is an active process in which the individual utilizes his resources in order to create a situation in which he can carry out his activities with a maximum of satisfaction” (Ittelson, Franck, & O’Hanlon, 1976, p. 199). In less teleological versions it is still posited as the most important evaluative domain of experience. Thus, Jack Nasar (1989) proposed to examine experience of urban public spaces (perception, cognition, and evaluation) through related concepts of urban cognition (“knowledge of where we are—orientation—and how to get to desired destinations—wayfinding” [p. 33]) and urban esthetics (“urban affect or perceived quality of the urban surroundings” [ibid.]). Nasar’s suggestion to assume that relations between “urban physical features, perceptual/cognitive measures of those features, affective appraisals of the scene, psychological well-being, and spatial behavior” (p. 37) explicitly frames urban esthetics as following the same cognitivist input–output axiom. It thus reinforces the prominent “person–environment” dualism as well as the older Cartesian ontology that “divorces the activity of the mind from that of the body in the world [so that the] body continues to be regarded as nothing more than an input device whose role is to receive information to be ‘processed’ by the mind, rather than playing any part in cognition itself” (Ingold, 2000, p. 165).

Transactional approach in environmental psychology (Werner & Altman, 2000) offers a less explicitly teleological and cognitivist perspective that attempts to bridge the gap between environment and the human as it defines people and situation holistically “by their unifying processes, and the changing relations among them” and “emphasizes the dynamic unity between people and setting” (ibid., p. 23). Werner and Altman have further stipulated that time and change are intrinsic to the person–environment phenomena and that there are multiple perspectives on the same situation, which should be interpreted in terms of its patterns and forms rather than determinist cause-and-effect chains. This approach, however, does not specify what role *meanings play in relation of people to environments* nor does it contain conceptual tools to approach cultural diversity of possible person–environment relations.

To sum up, cognitive-representational and behavioral approaches broadly focus on representations of space that people have and the behavior people manifest in space. This essentially replaces

von Uexküll’s phenomenological meanings with cognitive schemata, which potentially follow universalist principles. There is also a question regarding whether it is possible to apply a developmental axiomatic base to these approaches. Cultural variability is another domain where these approaches fall short as they implicitly follow cognitivist axioms of universal perceptive-cognitive apparatus. The less clearly definable atmospheric (Antsiferov, 1925; Milgram, 1970/2010; Urry, 2007) qualities of environments, such as memory, desire, and spirit recognized by Leonie Sandercock (1998/2003), also easily evade such frameworks.

Finally, and most importantly for the purposes of this chapter, neither approach is concerned with the *specificity and distinctiveness of “species of space”*—assuming uncritically that space, such as “city” or “town” or “Lake District” beloved by Romantic poets Samuel Taylor Coleridge and William Wordsworth, is a given environment that people relate to using their particular mental schemata or practical schemes. In that sense, space remains an external “independent variable” that is not explicitly addressed from a psychological standpoint. Indeed, it could be said that the urban focus of wayfinding studies stems much more from the demands of urban policy and concerns of traffic planning than from internal theoretical concerns. In this it much more follows what Ingold (2000) called the *building perspective* than the experiential, existential, phenomenological *dwelling perspective* he has advocated.

### ***Encountering the Environment***

If persons and environments are in a mutually constitutive relationship, then the issue becomes how to *conceptualize the connection between them*. In Goffman’s (1974/1986) framework, experience of social situations presumably requires *being in* a social situation or being exposed to one. What does it mean to be an environmental situation? What does it mean to be exposed to the world? More apposite to the task at hand: If space as such is undefined and abstract, and place is a result of its becoming meaningful through human experience, then what are conditions under which experience happens? And what is the nature of the emerging meaning?

What is missing in the scheme so far is a conceptual tool that would bring together persons and environments and clarify *where* and *under what circumstances*, spaces become places and pauses occur in movements. The nature of the intersection of

time and space, that moment of being open to the world (cf. Agamben, 2002/2004) at which experience creates places and emerges as *urban* experience, should be identified.

One of the ways of conceptualizing this intersection is to use the term *encounter*. Amin and Thrift (2002) have developed this notion to establish a basic ontology for an everyday urbanism that would attempt to “grasp the significant banality of everyday life in the city” (pp. 8–9). Encounter, the minimal building block of urban life, is the coming together of different entities. In our case, these entities are human and the urban environment (although Amin and Thrift forcefully reject limiting the enquiry to just humans but include all the different kinds of life in the city, such as animal life). “The city is made up of potential and actual entities/associations/togethernesses which there is no going beyond to find anything ‘more real’” (p. 27). *Process* and *potentialities* are the watchwords of encounter ontology that focuses on processual, dynamic character of reality. Encounter is the formative “being there,” which all experience of spaces begins with, the moment of exposure to the environment, the moment when human (without differentiating mind and body) is phenomenally exposed to the world.<sup>19</sup>

The most important contribution of this notion to the present framework is that it explicitly renders the city in a processual, developmental way, emphasizing the moment of becoming: “encounter, and reaction to it, is a formative element in the urban world” (Amin & Thrift, 2002, p. 30). Neither the city nor the human experience of it is thus *pre-given*, as built environment or as cognitive representations. On the contrary, they only come together, and inseparably, in the actual encounter. Encounter of human and space is exactly what gives rise to experience that transforms mere point in space into what Agnew (2005) interpreted as a defined location, a locale of activities, and a sense of place. The dynamic character of encounter emphasized by Amin and Thrift allows us to clarify two of Tuan’s (1977, p. 198) relevant arguments on place and time. Tuan has stated that it takes a *pause* in time and movement for a place to emerge and that it takes time for *attachment* to place to develop. Conceptualizing experience as an emergent outcome of encountering space allows making these arguments dynamic. First, no place is just one pause in movement. Indeed, even for the “stable” aboriginal communities referenced by Tuan, keeping place stable is an achievement, a result of routine day-to-day work akin to maintaining urban

infrastructure in the largest metropoli of the world. Second, attachment to place and meaning of place as a dwelling or home is itself never fixed, a reached goal, but always a meaning-in-the-making.

In developmental terms, then, *encounter is what brings the city into being as a novel experience in the irreversible time*. It is only in encounters that places become “urban”: “places ... are best thought of not so much as enduring sites but as *moments of encounter*, not so much as ‘presents’, fixed in space and time, but as variable events; twists and fluxes of interrelation” (Amin & Thrift, 2002, p. 30). In a similar way, Jensen defines place as “mobility-defined spatio-temporal event that relates to the way we configure narratives of self and other” (2009, p. 147), thus connecting place to subjectivity and identity. In summary, places are not stable and given in advance, not external independents—as they are for cognitive-representational environmental psychology and behavioral geography—they only become places when humans encounter space, and only in this encounter places develop as such.<sup>20</sup>

### ***Organizing Experience: Signs and the Regulatory Function of Culture***

Experience emerges in the encounter of human and environment. It is what transforms spaces into meaningful places. It is also what constitutes urban life on the most basic level. Experience, however, is not predetermined by the setting so that each person entering the setting would experience the same thing (this is what the adepts of spatial determinism would have us believe, and this is what cognitivist-representational frameworks tend to draw in through the back door). Neither is it entirely free-flowing. The crucial issue is to consider what *regulates* the emerging experience.

### **CULTURALLY SPECIFIC WAYS OF RELATING TO THE WORLD: ERVING GOFFMAN’S INSIGHTS**

This question logically follows from the developmental approach as it is the question about how novelty—in each moment of experience—emerges and develops. Ingold identified the anthropological dimension of this question (the anthropological problem of perception and cognition) as the problem of *cultural variation*: “Take people from different backgrounds and place them in the same situation: they are likely to differ in what they make of it” (2000, p. 157). This is what Goffman (1974/1986) was concerned with when he constructed his frame analysis. For Goffman, it is the

“primary frameworks,” “schemata of interpretation,” that are responsible for “rendering what would otherwise be a meaningless aspect of the scene into something that is meaningful” (1974/1986, p. 21). These frameworks are shared among members of a group and are the foundation of its culture<sup>21</sup>:

Taken all together, the primary frameworks of a particular social group constitute a central element of its culture, especially insofar as understandings emerge concerning principal classes of schemata, the relations of these classes to one another, and the sum total of forces and agents that these interpretive designs acknowledge to be loose in the world.

(Goffman, 1974/1986, p. 27)

Human culture is thus first and foremost the specific *way of relating to the world*. Unfortunately, the notion of frame, apparently contrary to intentions of Goffman as well as Bateson (1972), from whose work on play and fantasy the notion originated, has come to bear a lot of resemblance to cognitivist computational schemata. Also, in Goffman’s treatment this notion and the entire analytical apparatus of frame analysis is limited to social situations and their definitions—leaving out nonsocial experience as well as affective, emotional dimension of experience.<sup>22</sup> How then could we approach the issue of organization and regulation of experience—in our case, spatial experience—while keeping in mind Goffman’s insight about its cultural specificity?

#### SEMIOTIC MEDIATION AND REGULATION IN UMWELTEN

One conceptual advantage of von Uexküll’s conception of Umwelt is that it is explicitly concerned with theorizing the relation between the organism and the environment. Instead of following a behaviorist mechanistic tradition<sup>23</sup> of theorizing this relation away, he established a functional circle between the inner and the outer world of the organism.

Umwelt as the world of meaningful objects, is always paired by its intra-organismic counterpart—*Innenwelt* (inner world). If *umwelt* denotes the outside world as it appears to the animal via its perceptual and motor apparatus, then *Innenwelt* refers to the experience side of the phenomena as experienced by the organism.

(Magnus & Kull, 2012, p. 651, italics in original)

The vehicle of this relation is *meaning*—which plays a connecting role (von Uexküll drew a musical analogy to counterpoint in composition, 1940/1982,

p. 52 ff.) between the organism’s inner world and its environment (as well as between Umwelten of different organisms and species). Thus, the relation is *mediated* by meaning.

Valsiner (2007, p. 32 ff.) interpreted this mediating function of meaning as *semiotic mediation* within the larger understanding of culture as reflexive distancing of human and the world, which at the same time plays a regulative role vis-à-vis psychic processes.

The person creates a distance—by way of semiotic mediation—in relation to the here-and-now context . . . This reflection—which is cognitive and affective at the same time—allows the psychological system to consider contexts of the past, imagine the contexts of the future, and take perspectives of other persons (in the form of empathy).

(Valsiner, 2007, p. 33)

Culture “takes the form of constructing and using signs to transform the here-and-now setting of the human being . . . *human cultural relating to the world entails simultaneous closeness to, and distancing from, the actual situation* the person is in” (Valsiner, 2007, p. 72, italics in original). In place of Goffman’s frames and cognitivist computational schemata, this conceptualization identifies *signs* as specific mediators and regulators. Through specific identifiable signs, culture regulates the affective engagement with environment. Emergent meanings (or, in semiotic terms, signs) serve a function of connecting the inner world of the organism with the world around the organism. Some of these signs attain the property of being “promoter signs”—signs that guide “the possible range of variability of meaning-construction in the future” (Valsiner, 2007, p. 58).

This raises the question of *levels of development*, and given the present concern with the most basic encounter with space in Thirdspace (Soja, 2000), the proper level to start the inquiry would be *microgenesis*—“a form of emergence (and disappearance) of biological, psychological form within an immediate, short time frame” (Valsiner, 2007, p. 356, n. 1). As “the human immediate living experience is primarily *microgenetic*, occurring as the person faces the ever-new next time moment in the infinite sequence of irreversible time” (ibid., p. 301), humans organize this experience developmentally through signs. This microgenetic process is part of a larger hierarchical developmental structure involving also mesogenesis (process in structured, repetitive situated activity contexts) and ontogenesis (development over the

life-course). Encounters develop microgenetically (see Valsiner, 2007, Chapter 8, for methodological approaches to microgenesis; Wagoner, 2009, develops constructive microgenesis as an experimental methodology).

Thus, microgenesis is regulated by culture. Culture, however, is not a whole outside the individual (and thus having an objective reality *qua* Durkheim's social fact), akin to society or economy. Culture in this sense is *personal* (Valsiner, 2000, p. 55 ff.; Valsiner, 2007, p. 60) and is constituted by development of the person and their prior experience in the realm of "interpersonal signs-mediated communicative processes" (ibid.; the latter forming collective culture having no reality and causality outside these interpersonal communicative semiotic processes).<sup>24</sup> Accordingly, the process of experience is developmentally regulated by culture through specific signs.

### Spatial Signs as Species of Spaces

How does the organization of spatial experience look in light of this framework? It is time to bring all elements of the *framework* together. A developmental perspective entails assuming a processual vision of experience as emerging in irreversible time. Experiential humanistic geography interprets places as created and maintained by human spatial experience—as entities imbued with a certain meaning. Encounter ontology presupposes that the only reality spaces have is the reality they assume when humans exist and live in space, and places are thus moments of encounter of organism with environment. Finally, it follows from the notion of Umwelt and semiotic mediation perspective on microgenetic organization of experience that through specific signs, personal culture regulates the functional relation of organism and environment—environmental experience—and mediates it.

#### THE NATURE OF SPATIAL SIGNS

Spatial experience is organized by specific *cultural signs*. What are these signs? They are precisely what Perce's (1974/2008a) *species of spaces* are for each of us. From the standpoint of individual experience, signs that we draw from our personal culture and create on the basis of it function in the domain of spatial experience as those meanings that space attains for us, thus becoming *identified as meaningful place*. It is on the basis of this identification that our past experience of space is re-interpreted and future experience of space is projected. On the same basis, our cognitive and affective relation to environment

is regulated once a meaning of space is established. When we encounter space, we interpret it as *something* (e.g., as an "urban street"). Our future relation to it as well as our memory of all past experience of it is developmentally mediated and regulated by this newly emerged *spatial sign*—a mediating-regulating sign that constitutes the meaning of place (or one of several such signs). *Space is identified as species*.

"The Rue Vilin starts level with No 29 in the Rue des Couronnes, opposite some new blocks of council flats, recently built with something old about them already"—thus George Perec (1977/2008b, p. 212) identified his object of interest, recognizing it as a "member" of the species of "the street" (cf. his analysis of this species, 1974/2008a, p. 46 ff.). Choosing his scale and applying boundaries to his object of interest (operations he did as a person—and which regulated his further inquiry into this street; what for us as geographers and sociologists is a matter of heated debates is resolved practically *out there* on a daily basis for us as persons), he proceeded to meticulously record and describe six encounters with "Rue Vilin," each connected to the previous and each organized by this *sign*.

#### DEVELOPMENTAL MODEL OF EXPERIENCE OF SPATIAL ENCOUNTER

This conceptual framework could be integrated into a *microgenetic developmental model* represented in Figure 13.2. At the center of the model is encounter—the lived presence of the person in the spatial world. Experience of this encounter is mediated and microgenetically organized and regulated by spatial signs and proceeds by way of von Uexküll's functional circle of perception and action. Spatial signs emerge out of personal culture and achieve a unique encounter-specific configuration that defines that particular experience (although it may bear resemblance, or similarity, to other encounters). Through their promoter function, spatial signs create grounds for future meaning construction within the same encounters (at the very next moment) and beyond it. By the same token, space is articulated into places, which enter memory as encounter fades into the past to form the foundations for future potential encounters in irreversible time. Thus the process of living in space is formed by a multitude of encounters that flow into one another as we move through space in time (or stand in one place while time goes by).

Thus my own experience of the road near Worcester Regional Airport is partly mediated and regulated now

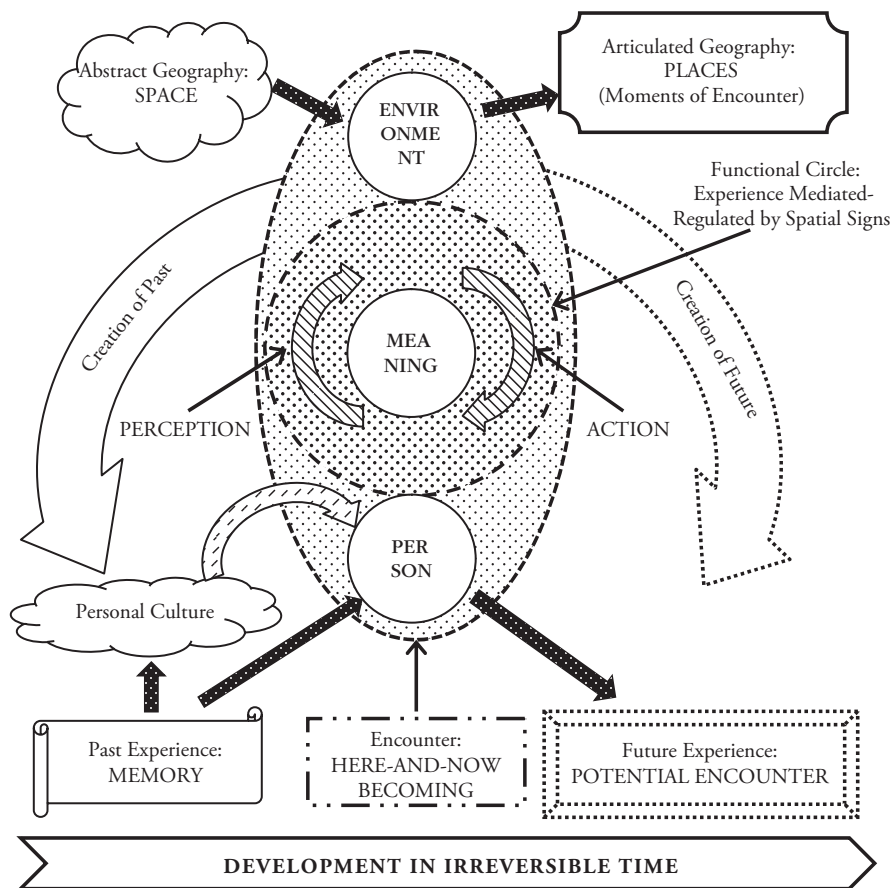

Figure 13.2 Microgenetic Developmental Model of Experience of Spatial Encounter

by the sign “Worcester Regional Airport”—and given that whenever I was driving there I did not know or remember the name of the road (as an anxious learner, I was more concerned with making a smooth turn into the road without making my encounter with the nearest telegraph pole a bodily encounter than with reading the sign with the road’s name), this road is still identified for me by that sign in terms of its location. Even as I write these words I have no map and no Internet access to discover its true name. (Does it have any relevance for me though?)

But there are many other signs that regulate the experience of that road for me—some of those being hypergeneralized affective semiotic fields (Valsiner, 2007, pp. 51, 312 ff.) belonging to the upper levels of affective regulation and only partially accessible to my verbalizations of them. Those semiotic fields encompass my subjective, personal, private experience of driving the motor vehicle for the first time myself and the associated combination of excitement, anxiety, and other feelings that will possibly reverberate in my memory for years to come. Other semiotic

fields feed on specific affective states (such as fear and panic) and elevate these states into high-level regulatory signs such as “night,” associated with fear of strangers and feeding into our perceiving the same places differently at night and during daytime. In this way we can read, through developmental-experiential lens, Williams (2008) excavation of night spaces as fundamental spaces in social life in terms of dynamics of territorialization (control by forces of governmentality), deterritorialization (transgression and disruption of social order), and reterritorialization (re-establishment of control).<sup>25</sup> For example, the same street in Moscow (Figs. 13.3 and 13.4, taken at the same date) during daytime and nighttime exhibits vastly different visual cues related to light, darkness, presence of people, speeds of cars, and others; but importantly, we microgenetically make sense of all these visual cues here-and-now, in an encounter, under the regulatory influence of night as an overarching cultural meaning.

Thus, “species of spaces” signs are only part of the story of semiotic mediation of environmental

**Figure 13.3** Myasnitskaya Street, Moscow, Russia, in daytime  
(Photograph by author, 2006)

(Photograph by author, 2006)

experience. They are not the least important part, however, and this part is especially pertinent when it comes to *recognizing the city as a sign*.

### The City As a Sign, or Recognizing Species of Settlements

Water of Leith is a small river that runs through the city of Edinburgh. It ends in Leith, where it flows into the Firth of Forth. A pedestrian walkway (Fig. 13.5) was constructed some years ago on the bank of the river. On this walkway, a person can walk through Edinburgh starting in the suburbs and finishing the walk on the shore of the sea. Depending on the exact starting location, an average person could walk this route in about a day, passing different parts of Edinburgh, for a while being very

close to the city center and the Edinburgh Castle, yet hardly noticing it.

An array of spatial signs such as “Edinburgh” and “pedestrian walkway” regulates experience of this walkway. One such sign is “city.” Indeed, although several parts of the walkway could appear suburban (assuming that “suburbia” could be recognized visually through features such as single-family homes with lawns), knowing that the walk goes through Edinburgh leaves its impression on experiencing this walk, depending on, for example, whether the person associates “danger of crime” (another regulating sign) with “the city.”

Similarly, recognizing that some place is an “inner city” in the United States is enough to trigger a panic affective response in many people, although

**Figure 13.5** Water of Leith Walkway, Edinburgh, Scotland  
(Photograph by author, 2007)

it may have nothing to do with whether this place is “objectively” an inner city (as defined by urban sociologists and demographers) or whether at the given time of the day in the given place there is any “objective” (as defined by crime statistics) or “real” (as defined by the actual presence of criminals looking for someone to mug or rape) danger of crime.

### ***“The City”*: Spatial Sign Designating a Specific Species of Space**

The story of Water of Leith indicates that for a particular person, the experience of encountering space proceeds by way of semiotic regulation before and partially independently from *objective* (physical, material) properties of that space. For the meaning of the city—or for *construing the city as a sign*—this entails that “*the city*” is *precisely a regulative sign that operates as a guide for the emerging experience*. When this sign is activated in an encounter with environment, it serves as a field-like promoter sign that allows the entire setting and the experience of this setting to be recognized as—and thus made sense of as—urban setting and urban experience. It follows that if the person is not equipped with a sign that bears that meaning, meaning-making can proceed in a way that will not designate experience of place as urban experience. Similarly, if these signs are not activated, meaning-making may organize

experience as something other than urban—as with someone from Western Europe “failing to recognize” a middle-sized American city as a “city” in the sense that urban life has for them (Fig. 13.6).

Developmental-experiential approach to meaning of the city thus starts with the encounter and emergence of experience. It is concerned with the ongoing, here-and-now process of meaning-making, as opposed to relatively static representations of space that are supposed to have stability and duration in human memory—such as cognitive maps and attitudes. The focus on meaning-making process means that task-performance fades into background, and non-pragmatic ways of meaning-making, such as aesthetic judgment (beyond simple “good–bad” dimensions), emerge as visible to this approach. In short, “the city” is one of the spatial signs that we routinely employ as an organizing principle for our experience of environments where we live and travel.

### ***Reversal of Objectivist Urbanism: Exploring the Meaning of the City***

The concern with meaning of the city thus takes the following form: *What are the conditions for emergence of such a meaning attached to space, that places emerge as urban places?* In other words, in which kinds of situations humans in their everyday

**Figure 13.6** Dewey Street, Worcester, MA  
(Photograph by author, 2010)

life understand their surroundings as being urban surroundings?

Behind this simple wording, in fact, is a *reversal of the usual way of defining the city* “from upside-down” typical of traditional urban disciplines such as urban geography. These disciplines routinely specify physical characteristics of territories (e.g., having dense built environment), social characteristics of the population (e.g., size, density, permanence, heterogeneity famously indicated by Louis Wirth, 1938), economic functions (e.g., predominantly industrial or service economy whether measured in terms of occupational structure or types of businesses), or similar characteristics that are located outside persons and are expected to project urbanism onto persons living in these conditions. In that sense, it fundamentally goes against the simple spatial determinism characteristic of some strands of urban planning (epitomized by utopian modernism of Le Corbusier) and conceptions of ideal city whereby “good” urban life is determined by and consequently is achievable through “good” design (Kharlamov, 2010).

Simply put, *the city is a meaning*—and therefore exploring *what is a city* entails exploring the diversity of meanings that ordinary people (rather than what planners, administrators, or even depersonalized sciences classified as “urban studies” mean by it) create that allow them to qualify certain places as urban places, as well as the process of emergence of these meanings itself.<sup>26</sup>

By bringing together the developmental nature of human psychic processes and the notion of place

as that which humans create through experiencing general and unspecified space, the humanistic perspective on space and place allows us to approach the issue of ostensiveness of the city in a person-oriented processual way. Human geography and urban sociology often work with defining the city in an “objective” fashion (thus working in “space over place” mode in terms of Agnew, 2005), through properties of physical distribution of things on a territory. The city thus becomes a sufficiently dense set of buildings, pavements, and human bodies. In contrast, from a humanistic standpoint, the urban is first and foremost a specific meaning attached to these things.

### **Conclusions: Situating Human Life in Settlement Space**

Luhmann (1984/1995) famously started his theorizing of social systems from the assertion that his “considerations assume that there are systems” (ibid., p. 12). His theory explicitly postulated that social systems have communication as their basic constitutive element—and that analysis of communication in social systems can proceed without considering persons—as individuals or as selves—at all. In fact, for Luhmann, social systems have nothing to do with people at all, even as groups or populations. His systems theory suggests that selves and persons do not exist—rather, the domain of psychic life should be reconfigured in psychology as a psychic system.

This radical formulation illustrates very well what all the traditional ways of looking at cities share:

the tendency to look at *wholes above individuals or wholes to which individuals are entirely irrelevant as the primary foci of inquiry*. Built environment, economy, community, neighborhood—all are examples of such wholes. At best, persons get reduced to being members of populations or communities.

Starting from the elementary encounter of an individual person with space requires reversing this kind of frameworks. This reversal task has particular salience for urban studies as they struggle with the evident failure of the rural–urban dichotomy on which they have constructed themselves. Presumably, urban geography deals with urban space, and urban economics deals with urban economy; however, in the world where regional economies take the form of urbanized regions without any discernible city center (Fishman, 1987; Dear & Flusty, 1998; Soja, 2000), this self-definition loses all utility and serves as a source of confusion.

In fact, there is nothing very new about this; in 1976 Castells was already questioning whether urban sociology had any salient subject matter. Thirty-three years later, Gans (2009) criticized the metro-centrism of American urban sociology, which concerned itself almost exclusively with a small number of iconic cities such as Chicago, New York, and Los Angeles. Gans' choice of the central organizing category to replace "urban" is settlement:

A focus on settlements would suggest examining and comparing the interactions, routine and unusual, peaceful and conflict ridden, and competitive and cooperative among and between all the various groups and institutions without concern as to whether they were urban or not but without losing sight of the fact that they are settlements.

(Gans, 2009, p. 215)

What this proposal best captures is that *wherever humans live, they appropriate environment around them as their Umwelt*. They settle—or, in Ingold's (2000) terms, *dwel*—in space: "it is through being inhabited, rather than through its assimilation to a formal design specification, that the world becomes a meaningful environment for people" (p. 173). Hence the issue is to put a more nuanced conceptual system in place of the old rural–urban dichotomy. In other words, it is necessary to de-essentialize spaces, or territories (Brighenti, 2010) as well as the notion of "amorphous, non-differentiated space," which could have no more salience to a non-geographer and non-psychologist than "standard metropolitan statistical area." What a psychology

of species of space (or settlement space, if we are to borrow Gans' term) could add to objectivist approaches that would classify places that people create and live according to their properties (social, economic, material, and other) is an insight into the ordinary meanings that people routinely employ to make sense of their surroundings. These might or might not correspond to "objective" dimension, and it is this domain of correspondence-non-correspondence where most fruitful transdisciplinary integration could be hoped for.

### **Future Directions: Integrating Cultural Psychology With Urban Sociology and Geography**

The proposed developmental-experiential perspective on human spatial life opens up a number of lines of future inquiry. At the center of this possible research program is, to draw on the title of Milgram's seminal article (1970/2010), the experience of living in spaces, or, in terms of Soja (2000), Thirdspace.

The first direction is to examine the *immense variety of settlements* that people create and inhabit. More specifically, the issue is what spatial signs define these settlements. Recent calls for de-metrocentrizing urban studies (Bell & Jayne, 2009; Bunnell & Maringanti, 2010; Gans, 2009) have forcefully argued against limiting inquiries to a small number of paradigmatic metropoli—a tendency that could be traced back to Simmel (1903/1997). A particularly important issue that emerges is to closely study "the city" as one of the most prominent and salient spatial signs, especially when it comes to differentiating cities. What could be "large" and "small" for urban geography may not be the same as large and small for many people who simply live in cities. Perhaps, personally and culturally specific taxonomies of settlements, dwellings, and other species of spaces could emerge as the outcome, *a la* the Linnaeus standard biological classification system.

Second, models of individual development are needed to account for the *immense intrapersonal variation* in these "taxonomies of spaces." In other words, on a mesogenetic and ontogenetic level, each of us develops our spatial taxonomies over time, and these taxonomies serve as further repertoires of spatial signs to regulate future experiences.

Third, on an interpersonal level, the important issue is how relatively *stable shared cultural complexes of spatial signs* emerge in communicative processes of collective cultures.

Fourth, it is important to understand what the *configurations* that spatial signs enter are and what are the regulative outcomes of these configurations (e.g., coupling “inner city” with “danger of crime” and the resulting affective reaction of “fear”). Further, it is important to study the specific characteristics of these signs and configurations, such as hierarchical organization and propensity to verbalization and expression in other forms.

Fifth, situations of *ambiguity and ambivalence* are an important area of research, such as when people employ different and/or conflicting spatial signs in their ongoing meaning-making. Study of boundaries (such as boundaries between different city areas or boundaries associated with different affective reactions—e.g., “ghetto begins on the other side of this street”), boundaries, and their maintenance and transgressions may be among the most fruitful areas in this respect (Brighenti, 2010; Kaganskiy, 1983; Rodoman, 1983). One interesting concept to develop in this way is Foucault’s notion of *heterotopias*:

real places, effective places, places that are written into the institution of society itself, and that are a sort of counter-emplacements, a sort of effectively realized utopias in which the real emplacements, all the other real emplacements that can be found within culture, are simultaneously represented, contested and inverted; a kind of places that are outside all places, even though they are actually localizable. (Foucault, 1967/2008, p. 17)

This notion has been developed in multiple ways to account for ambiguous spaces, including some of the spaces that writers such as Sorkin (1992) and Davis and Monk (2007) classified, respectively, as theme parks and evil paradises (*see* collection of applications of the concept of heterotopia in Dehaene & De Cauter, 2008). These spaces oscillate between different spatial regimes and functions and routinely misplace stable spatial orders in ways reminiscent of keying and rekeying in Goffman’s frame analysis (1974/1986). The enterprise of “heterotopology”, the science of heterotopias, (Foucault, 1967/2008), would benefit greatly from a personal perspective, a psychology of heterotopias and other strange places (cf. Edensor’s, 2005, analysis of industrial ruins as ambiguous spaces).

Sixth, the questions first asked by Antsiferov (1925), on what defines the *soul*, *the unique synthetic identity of the city*, and Milgram (1970/2010), on the atmosphere of great cities, could be fruitfully

tackled using this approach. Cities—and, for that matter, all places—have identities that we recognize as salient, and thus no matter how many skyscrapers are there in the world, there is only one Manhattan, and no matter how many cities were built around medieval fortifications, there is only one Moscow with its Kremlin and only one Warsaw with its fortifications built anew after it was leveled by bombs in World War II. Dresden, Coventry, Hiroshima, and Nagasaki, for that matter, did not lose their “souls” with the destruction of material built environment but, rather, solidified them and added new dimensions to them.

Seventh, the presented developmental-experiential approach to human spatiality should be taken further along the lines of accounting for time and sociality. The *temporal dimension* emphasized by Castells with reference to social life in network society (Castells, 1996/2010, Chapter 7) is fundamental for the approach and is reflected in the notion of irreversible time (Valsiner, 2007) in which development occurs. This dimension needs to be coherently and thoroughly conceptualized, including the personal perception of time and temporality and the role of time in organization of experience. The *social dimension* should be integrated with the spatial dimension, as many spatial encounters are also encounters with others (Amin & Thrift, 2002), and this bridging of the frameworks would allow accessing the rich theoretical resources such as the work of Mead (1934) and Goffman (1974/1986). In particular, these two dimensions are indispensable for accounting for the unique nature of city life understood so well by Simmel (1903/1997). These dimensions could also add to the understanding of new role of virtual worlds, these “new fractal social spaces” (Urry, 2007, p. 181) that are enabled by communicative technologies creating “connections and communities [that] are simultaneously private and public, intimate and distant” (*ibid.*). Indeed, whole new social realms emerge in the virtual worlds such as *Second Life*, and many of these at least attempt to simulate, emulate, and recreate the urban space and urban experience.

Eighth, *new methodologies* need to be developed that would grasp encounter in its microgenetic developmental unfolding. These methodologies might follow the track of controlled field experiments (Ittelson, Franck, & O’Hanlon, 1976) and more generally the recent trend toward mobile methodologies (Büscher & Urry, 2009; Fincham, McGuinness, & Murray, 2010; Büscher, Urry, &

Witchger, 2011) such as go-alongs (Kusenbach, 2003). The notion of non-representational theory (Thrift, 2008) captures very well the methodological necessity to go beyond assumptions of cognitive representations (and the corresponding empirical reliance on laboratory experiments popular in cognitive psychology) to grasp the affective, performative nature of experience. Thus, Urry reminds that the atmosphere of places is “in the relationship of peoples and objects. It is something sensed often through movement and experienced in a tactile kind of way, what Thrift terms ‘non-representational’ practices (1996)” (Urry, 2007, p. 73; see Jensen, 2009, for a conceptualization of ordinary urban mobility as a meaningful practice and a site for interaction). Although it may be wise—contrary to some proponents of non-representational theory—to retain the vision of theory as at least one of the outcomes of inquiry. These new methodologies could be fruitfully grounded in cultural-developmental psychology (Valsiner, 2007, Chapter 8).

Finally, integrative efforts should be directed toward recognizing the *complexity and emergent character of life in space*—which is impossible to account for from any one standpoint including the experiential standpoint. Rather, it is important to establish common grounds between different disciplinary efforts at understanding human life in space. Space, its use, and experience of it all come together in the complex interplay of affect, meaning, culture, social relations, technologies, and environmental settings that human living is about. Hence, urban psychology, or *settlement psychology* (not coterminous with either ecological or environmental psychology), could complement settlement sociology and settlement geography in exploring—*empirically* as well as theoretically—the personal, psychic, existential meaning of our habitats. This concerted effort is essential today if we are to revive utopian thinking and constructively assess what human life in spaces is and how to make it better and more just in face of the challenges of overpopulation, slumming, tensions and conflicts along identity lines, and global warming and resource exhaustion—challenges that target every city in the world today much as the individualist spirit of modernity, according to Simmel (1903/1997), converged on the fin-de-siècle Berlin.

## Acknowledgements

I am indebted to Svetlana Bankovskaya and Jaan Valsiner, who have supported the development of the ideas presented in this chapter in various contexts over the past 4 years. Alexander

Filippov and Nikita Pokrovsky helped me in many more ways than I can account for. I am grateful to the members of the Kitchen Seminar at Clark University, on whose cutting board I was a happy fish more than once. This research was presented at the Perceptive Minds and Affective Bodies in Urban Environment symposium at Aalborg University in October 2010. This research was supported by the Oxford Russia Fund Scholarship (2005–2007), Oxford Russia Fund Adam Smith Scholarship (2007), and Foundation for Urban and Regional Studies Studentship (2009–2011).

## Notes

1. I find strange the common (and dating back even to Simmel and before) use of the adjective “psychological” to denote mental processes, whereas the adjective “psychic” is reserved for weird things such as telepathy. This use essentially suggests that what is happening in our heads exists *only inasmuch as* it is accounted for by professionally trained people graduating with degrees in science of psychology. However, I am optimistic about the propensity of humans to maintain active and healthy psychic life without the intrusion of white-coated and/or tie-wearing professionals, at least most of the time—just as we seldom need sociologists to live active and healthy “social” lives. Hence, through this chapter the term *psychic*, with the exception of quotations, will be used to denote mental phenomena. The term *psychological* will be reserved for those phenomena that are made accountable for by means of the science of psychology, or for the concepts and standpoints used therein.

2. In fact, the original German title of Simmel’s lecture, *Die Großstädte und das Geistesleben*, could be translated as *The metropoli and the spiritual life*. Nikolai Antsiferov does not cite Simmel, but given that a Russian translation (using the word “spiritual” rather than “mental” in the title) was made shortly after the initial German publication, it is entirely possible that Antsiferov developed his notion of “soul of the city” and his proposal for urban psychology under Simmel’s influence.

3. Methodologically, the APA report hardly goes beyond calls for mixing qualitative and quantitative approaches as well as calls for interdisciplinarity and using methods borrowed from other disciplines (APA, 2005, pp. 45–48). One interesting proposal contained in the report is to adopt a “strength-based approach,” recognizing that urban life is not all about decay and disorder, and that in addition to infamous deficits and drawbacks, there are unique strengths that urban individuals, families, communities, and cultural groups have.

4. “Urban” is defined in the report as “Settlements or localities defined as ‘urban’ by national statistical agencies” (UNFPA, 2007, p. 6). Its authors immediately explain themselves: “since mindsets, planning efforts and data are still compartmentalized, the rural-urban distinction is still necessary, although imprecise . . . the deficiencies of . . . data are less significant when analyzing broad trends and prospects of urban growth at the world and regional levels” (ibid., p. 7). Thus, they imply that there is a tacit knowledge of what urban and rural means, shared by professionals and laypeople alike.

5. The paradigmatic status of Los Angeles has been largely crystallized through the efforts of the self-proclaimed “Los Angeles School of Urbanism.” Michael Dear and Edward Soja are the most prominent representatives of this group (the foundational works of the “school” are assembled in Dear, 2002, and Scott & Soja, 1996).

6. The great urbanist Jane Jacobs (1961/1993) called *diversity* the main principle of the city: “This ubiquitous principle is

the need of cities for a most intricate and close-grained diversity of uses that give each other constant mutual support, both economically and socially” (p. 19). “City diversity itself permits and stimulates more diversity” (ibid., p. 190), asserted Jacobs, and for her this was the diversity of uses of places coupled with the diversity of intentions people have for coming into a certain place (she was particularly hostile toward separating residential, leisure, and work functions of places). In the decades after her seminal book, *The Death and Life of the Great American Cities* (1961/1993), this diversity has received many interpretations. Thus, Iris Marion Young (1990), in one of the most prominent treatments of justice and social life, asserted that the good, just life is about elimination of institutionalized dominance and oppression, and affirming difference on multiple dimensions (such as race, sexuality, etc.). She had an urban vision: the normative ideal she suggested for human living was the “city life,” which she defined as the “being together of strangers” (p. 237). “Social justice in the city requires the realization of a politics of difference” (p. 240). In a way, the concept of diversity—more recently conceptualized as difference—is one of the most articulated ways of interpreting the old dictum that “city air makes people free.” Friedmann (2000) names, among other things, human flourishing as a foundational value and “multipli/city” as a primary good in a “good city.” Difference is also a founding element of Sandercock’s *Cosmopolis* (1998/2003; Sandercock draws on the work of Iris Marion Young, 1990, in discussing this concept).

7. “Moral” could be added, although this word has lately fallen out of fashion in human sciences, replaced by a blander notion of “values.” The word “moral”, however, links the concern with relations between people, the problem of social order, and the issues of justice and equity much better than “values” (but see Sandercock, 1998/2003, who names memory, desire, and spirit as important dimensions of urbanism—these three capture at least some of the spatial significance of moral orders of the city).

8. Cf. the works of John Urry (2000; 2007), who proposed “mobility” rather than “society” as the central concept of sociology concerned with social life today.

9. Highmore (2005) developed an interesting approach grounded in Henri Lefebvre’s notion of “rhythmanalysis.” He suggested that a study of urban culture could read the city as a text, but attempt first and foremost not to “make the urban legible” but to “declare its object to be the social anxiety caused by the city’s perceived illegibility” (ibid., p. 7). In this way, for example, he approached the material such as the movie *The Matrix* (1999) by reading it as a manifestation of network-connective urbanism. In Soja’s (2000) terms, however, this could still be considered a study of Secondspace.

10. It should be noted that von Uexküll’s conception is not anthropocentric. On the contrary, he powerfully asserts that Umwelten are species-specific, and therefore a dog inhabits a vastly different reality—and space—than a human. His *A Stroll Through the Worlds of Animals and Men* (von Uexküll, 1934/1992) is a picturesque statement to this effect, which, as Giorgio Agamben (2002/2004, Chapter 10) reminds, has the potential of stopping the “anthropological machine” that in our culture maintains the distinction between humans and animals. Accordingly, it would be interesting to extend the arguments presented in this chapter outside the domain of *Homo sapiens* to other species and to question whether city has phenomenal salience for those species’ relating to environments. For pragmatic reasons of simplicity, this chapter does not make this move, but such a move would entirely fit with the wide movement in human sciences

away from anthropocentrism, evident, for example, in “animal geographies” (Wolch & Emel, 1998).

11. It should be remembered that realities, in von Uexküll’s theoretical biology as well as in phenomenology in general, are *multiple* (Schuetz, 1945) and are different even in the subjective experience of one organism, as well as between organisms and between species.

12. This is broadly consistent with a definition for person–environment–behavior research perspective offered by Amedeo, Golledge, and Stimson: “either a focused level of cognition activated and reflected on by an individual . . . and/or . . . a particular reaction . . . undergone by an individual who may have been aroused or stimulated by some environmental and/or spatially related situation” (2009, p. 5). However, this latter definition gives primacy to environment and environmental stimulation, whereas, as von Uexküll’s framework suggests, the individual phenomenal world is *as much active as it is reactive*. It is nevertheless instructive in that it both brings in more traditional psychological concepts (cognition, reaction) and further reinforces the argument that experience is fundamentally related to situation and that situation always has an important spatial or environmental dimension.

13. Goffman continued this aim: “and to analyze the special vulnerabilities to which these frames of reference are suspect” (Goffman, 1974/1986, p. 10). Indeed, the bulk of his book is devoted to exploring how definitions of situations get transformed, “keyed” and “rekeyed,” such as when a legitimate game is subverted to become a set up. This focus will not be followed in the present inquiry, although it could serve as an inspiration for further exploration, for example, of the personal experience of “theme park urbanism” characterized by disguising consumption spaces as urban public space (Sorkin, 1992).

14. Goffman draws on Gregory Bateson’s (1972) notion of frame. In the present context, “sign” is the correlate of the concept of “frame” in relation to organization of experience.

15. Compare this to Herbert Gans’ “use-centered view” on sociology of space:

Natural space becomes a social phenomenon, or social space, once people begin to use it, boundaries are put on it, and meanings . . . are attached to it. Then the air-over-dirt becomes a lot or a plot, and if residential users obtain control over the bounded space, it becomes their place. (Gans, 2002, p. 329)

Gans’ use of “natural space” in this sense corresponds roughly to abstract space, although he leaves open the possibility that some space would be natural because humans do not (or even, for some reason, cannot) use it, rather than because they do not attach any meaning to it. Brighenti (2010) proposes a similar understanding, suggesting that the notion of “territory” could be an all-encompassing term to denote what happens to space when it is appropriated by humans and human social institutions. He also puts the notion of boundary forward as one of the crucial aspects of territory-making (cf. a cultural-developmental understanding of boundaries in Valsiner, 2007). Brighenti does not, however, provide a conceptual apparatus to approach the experience of territories and spaces. Nor this is a problem for Gans.

16. Simmel himself made a seminal contribution to the nascent urban studies in his *The metropolis and the mental life* (Simmel, 1903/1997), which, as Frisby and Featherstone remind, could be “read in the context of his more systematic explorations of social space and the social psychological impact of socio-spatial relations” (1997, p. 11). Simmel’s metropolis, the

spatial epitome of modernity (Kharlamov, 2009), was *the* form of modern social life:

An enquiry into the inner meaning of specifically modern life and its products, into the soul of the cultural body, so to speak, must seek to solve the equation which structures like the metropolis set between the individual and the supra-individual contents of life.  
(Simmel, 1903/1997, p. 175)

In that sense, Simmel's 'environmental-psychological' remarks on intensity of nervous stimulation that urbanites face, picked up by latter observers such as Milgram (1970/2010, p. 12) in form of concepts such as "overload," were only a starting position for a deeper philosophical inquiry into the essence of modern culture and its spatial condensation in modern metropolis.

17. Cf. the understanding of the "legibility of the everyday city" in the work of Ash Amin and Nigel Thrift (2002, Chapter 1) and the way Highmore (2005) discusses urban legibility and illegibility.

18. There are few axiomatic, conceptual, and theoretical differences between frameworks developed for environments on different scale, and their discussion falls outside the scope of this chapter.

19. Cf. the notion of encounter as used by Goffman (1961), whose focus is exclusively on *human interaction*, and more specifically, on focused interpersonal interaction with mutually sustained attention.

20. Von Uexküll's theoretical biology thus allows us to turn Amin and Thrift's concern with de-humanizing knowing the city (Amin & Thrift, 2002, p. 26) upside down—by asking whether there is, and could be, such a thing, or such a meaning, as "the city" in the Umwelt of dogs and ticks, instead of trying to suggest that human Umwelt is shared with them. Indeed—what is for the subway rat that environment, which humans call Manhattan, and attribute unique meanings, a "soul" (Antsiferov, 1925), to it?

21. Goffman's figure is illuminative in history of science and disciplinary traditions. Erving Goffman started his career *almost* as an anthropologist, defending his dissertation (Goffman, 1953) on patterns of communicative conduct in a rural community on the islands off the British coast. His dissertation—which was defended in Chicago as a dissertation in *sociology*—was completed under the guidance of William Lloyd Warner (himself an anthropologist and a student of Alfred Reginald Radcliffe-Brown) after 12 months of fieldwork using "observant participation" (*ibid.*, p. 2). Goffman's primary concern in his dissertation was with social order and social interaction. For him this was the beginning of a career-long conversation (cf. Goffman, 1983) with the work of Parsons (1951), back then the bible of theoretical sociology. However, his unique sensibility to the intimate complexities of human everyday life and to its immense variation across humanity—reflected in the methodology of his dissertation fieldwork—was unquestionably *anthropological*.

22. Erving Goffman, in an otherwise rare homage to early Durkheim's vision of sociology, did not cover *non-social experience*, and his primary interest in any situation was its social nature. Similarly, Mead (1934), whose rethinking of behaviorism introduced symbols and meanings as serving the mediating function between the mind and the environment, was mostly focused on *experience in social interactions* (starting with elementary analysis of gesture). This is the essential obstacle in applying their theories to spatial experience.

23. Behaviorist doctrine of mechanism excluding any notions of experience—especially private experience—"The behaviorist finds no evidence for 'mental existences' or 'mental processes' of any kind" (Watson, 1924, p. 2 n. 1)—was criticized by Mead (1934), for whom experience was the central matter of (social) psychology. It is, however, strangely re-enacted by contemporary cognitive neuroscience, which ideally would reduce all "internal" phenomena such as experience or consciousness to epiphenomena of neural processes in the central nervous system.

24. It should be noted in passing that such formulation, emphasizing the relative autonomy of personal cultures from collective culture (Valsiner, 2007, p. 61), avoids *reifying* the notions of group, community, and society, and assuming that there are cultures as bounded entities projecting their essence onto individual members of culture. As Urry (2000) shows, bounded "society"—and by extension "culture," usually coterminous in social and human sciences with "society" or even "nation-state"—is an inadequate concept for a highly mobile world of individuals constantly soaked in multiple settings.

25. Cf. the way Amin and Thrift (2002, p. 119 ff.) conceptualize night as one of "escape attempts" everyday life takes from the controlling forces of governmentality, and how it is in turn put back under control, for example through "theming" and consumerizing.

26. This is not to say that planners and architects are not people. Indeed they are—and it would be an interesting research project to see whether planners and administrators employ their "professional" notion of "the city" when they drive their kids to the doctor or leisurely walk in the city park.

# Modeling Iconic Literacy: The Dynamic Models for Complex Cultural Objects

Rebeca Puche-Navarro

## Abstract

Paradoxical objects are everywhere in human lives—and they are used as a cultural scenario to capture cognitive processes and trigger inferential operations. I look at how Nonlinear Dynamic Systems Theory can be used to make sense of cognitive processes, as these are embedded within the environment of cultural kind. Coordinating two different techniques—the *minimae* and *maximae* estimation, and the wavelet techniques—allow researchers to capture the dynamic nature of the mind. The discovered effectively inferential operations have a fractal structure. But perhaps more important is that the human mind in varied contexts and disparate perspectives may be studied by these techniques from Nonlinear Dynamic Systems Theory. The paradoxical objects—cartoons and other media—open a panorama for the study of the mind. The mind—through dealing with paradoxical objects—is sensitive and open to culture. It may be that cognitive and cultural psychology become united in the study of paradoxical objects.

**Keywords:** paradoxical objects, nonlinear dynamic systems, fractals

The purpose of this chapter is to illustrate the approach from nonlinear dynamics to human cognitive development by using paradoxical objects of an iconic nature in a cultural method. The emphasis here is based on the idea that **paradoxical iconic objects are by nature essentially cultural**. We encounter cartoons in everyday life, and we smile or laugh. Why? After all, these are merely some drawn graphic images that are not even—and purposefully not—adequate replica of the objects they depict.

The paradoxical objects with which our research program at University of Valle in California has worked are exclusively of visual and iconic nature. At the same time, we want to emphasize that not only verbal and argumentative procedures could get us closer to deciphering some thought processes. The key to this chapter is dynamic systems as a perspective that takes complex ideas into account.

Paradoxical objects can be understood through complex cognitive processes.

The choice of paradoxical objects for the study of development from a cultural perspective begins from the principle that these objects condense what is understood culturally. These are objects that “make sense” (in immediate encounter) they are not just perceived gestalts. Francastel argued that the arts in general are the result of a vision of an era, of a time, of a geographical moment, and of a world historically and culturally understood (Francastel, 1970)—an idea that captures the nature of paradoxical objects very well. In that sense, they constitute “a place of convergence” between the author and the world that is being re-created. Nonetheless, Barthes refers to some icons as representing a kind of hallmark, a celebration, a “spiritualization” of the object—not only as an object but as a sense.

Paradoxical objects contain another privileged relationship—that is, the relationship of the viewer with the work. In any artwork, be it iconic or not, there are converging perspectives coming from different sides, which overlap in shared meaning and significance. All art, says Barthes, has two dimensions: that of the work and that of the viewer. Effectively, the work is “a meeting place for the spirits of an era, they are a sign, not a building or a painting can have an existence independent of a double effort, that of the artist and that of the viewer that in meeting form it” (Francastel, 1970, p. 11). An exaltation is a joining “spiritualization” of the object that goes beyond it and returns not only as object but as a sense. From this perspective, the paradoxical object includes the future or a linkage of the past and future occurring in the present. In effect, the fact that the author and audience share the sense of perspective despite differences in eras, geographies, and cultures is a living example of a historicity that includes the future (Lyra & Valsiner, 2010). Needless to say, this intersection between cognitive development in a cultural approach, by using paradoxical objects, is not a usual way that cultural psychological studies are covered.

### **Nonlinear Dynamic Systems and Cultural Cognitive Development**

Nonlinear dynamic systems (NLDS) constitute neither a dominant approach in developmental psychological literature in general nor one in cultural cognitive development, in particular. It is an approach that, despite being new and promising, does not yet produce a large number of studies. The analysis of the comprehension of paradoxical objects as a way to integrate cultural aspects and do it from NLDS results in a doubly risky bet. Maybe these elements make the text provocative and then encourage the reader to become interested and join the discussion.

In recent literature there have been many authors who have claimed the use of NLDS for the study of cultural developmental psychology (Rose & Fischer, 2009; Fischer & Bidell, 2006; Lewis, 2000; Fogel, Lyra, & Lewis, 2000.) “Dynamic modeling offers tools to better understand development and learning in their full complexity, integrating influences involving person, context, and culture” (Rose & Fischer, 2009, p. 417). The position defended is that from nonlinear and open conceptions, one would be in better shape to decode and make sense of the complexity

of cultural objects. That position gathers strength when it comes to studying the cognitive processes involved in understanding doubtful ambiguities and evidently the little that is literal with paradoxical objects. The comprehension of paradoxical objects plays on the unpredictable, on uncertainty, and the transgressions of the conventional, and all of those are conditions for NLDS.

However, it is necessary to elaborate a bit more on the implications of working on cognitive development and specifically on the inferential elaborations involved in understanding paradoxical objects from the perspective of NLDS. The first argument rests on the idea that the chaotic phenomena studied with NLDS are of qualitative kind. They are characterized by being in the middle of the road between the periodic and a-periodic, between the predictable and unpredictable (although they are deterministic), between the regular and the irregular, and between the systematic and the random. It can be said that they do not conform to the distribution of the Gaussian curve, although they present a certain degree of consistency.

Working within the framework of these ideas, it is not risky to postulate that many cognitive and cultural processes, as well as cultural cognitive development, are phenomena of chaotic structure. They are unpredictable in the sense that the prediction thresholds are rather flexible and relative. As Rose and Fischer have outlined:

Developmental processes are highly nonlinear, heterogenous and dependent on a wide factors.

(Rose & Fischer, 2009, p. 417)

In the emergence of making inference, for example, we know that some categorical inferences must be present at the end of the first year, but the precise moment of their appearance is uncertain. They show great irregularity and variability (Rose & Fischer, 2009; Adolph, Robinson, Young, & Alvarez, 2008; Combariza & Puche-Navarro, 2009; Puche-Navarro, 2009b; Yan & Fischer, 2002). This irregularity that psychologists study under the concept of variability—behaviors that appear and disappear, breaking the image of stable growth that has always been taken as the rule in developmental studies—has caused nightmares to the developmental researcher (Smith & Thelen, 2003). In summary and generally speaking, recent research is increasingly insistent in providing evidence to confirm the chaotic nature of the operations and information-processing mechanisms in cognition.

## Some Terms of Dynamic Systems

Notions such as nonlinearity, self-regulation and self-organization, multilevel, attractors, and fractals then emerge as more appropriate and relevant to account for the nature of cultural psychological processes (Lewis, 2000; Thelen, 1995; van Geert, 1998; Smith & Thelen, 2003; van Geert, 1994, 1998, 2003; van Geert & Steenbeek, 2005a, 2005b). Taken together, these notions are information-bearing units on chaotic structure. Thelen, for example, approaches such developmental psychological phenomena in terms of components that interact with strong interdependencies among many variables, breaking with the simplified conception between an independent and dependent variable. Perhaps his most famous work is the illustration of the emergence of walking as a simultaneous interaction between multiple components with their respective covariance in self-regulatory processes (Smith & Thelen, 2003). Fischer, for his part, suggests an original reconceptualization of development called “dynamic theory of abilities,” from the NLDS. In that conceptualization, self-organization has a specific role in integrating the nonlinear dynamic with his own concepts of development and explains variability as an indicator of the complex organization of human activity (Yan & Fischer, 2007).

According to van Geert:

Non-linearity means, among others things, that the effect of a dynamic process differs from the sum of its parts . . . ( . . . ) An alternative and somewhat more intuitive understanding way of defining the property of nonlinearity is to say that the effect of a factor that influences the system is not (necessarily) proportional to the magnitude of that factor.

(van Geert, 2003, p. 657)

As is known, linearity supposes only one solution—the implied cause-and-effect relation only produces proportional effects. In contrast, in a nonlinear system, bifurcations occur as the causal relationships become more complex, leading to unexpected consequences and opening a range of possibilities with several possible alternative solutions. In the development of mother-child interactions, many studies show how in the observed trajectories, the emergence of patterns is not the result of accumulation, but precisely from the combinations among many variables that interact over time (Hollenstein & Lewis, 2006; Lamey, Hollenstein, Lewis, & Granic, 2004; Lewis, 2000; Lewis, Lamey, & Douglas, 1999). Other authors

have provided evidence on development and emergence of language in children. One such study reports on the individual pathway of Helen, who after little more than 1 year of follow-up, shows that her performance is not described by ascending, cumulative linear trajectories. By contrast, they take into account fluctuations that move within nonlinear dynamics and in which variability is always present (van Dijk, 2004). Studies such as these with clear empirical evidence constitute compelling reasons to consider that nonlinear systems are better able to access the complexity of cultural cognitive processes (for further elaboration of this point, see Cortés, Combariza, & Puche-Navarro, 2009).

The second argument is the questioning of linear methods for studying cultural cognitive processes. Those who make this criticism criticize linearity because it leads to a necessary simplification as opposed to the complexity of psychological processes, in general, and cultural cognitive process, in particular. The doubt that linear methods can preserve the basic properties of the complexity of a system such as cultural cognitive development is supported by accumulating developmental theories and methodologies that insistently raise this issue (Munné, 2005; Valsiner, 2004; van Geert, 2003). From linearity, it is difficult to capture the complexity of psychological processes, such as cognitive activity, and to obtain a meaningful understanding of the numerous relationships that hold in such a complex system.

## TOOLS FOR ANALYSIS

As van Geert has emphasized:

The adoption of linear statistical modeling enhanced the methodological rigor of research, but weakened aspects of comprehensiveness and mutuality from the oldest conceptualizations of development.

(van Geert, 2003, p. 643).

Without new tools, conceptualization from NLDS is not possible to study and to understand information from new perspectives. Concepts such as strange attractors, fractals, bifurcation, and iteration, besides being closely related, are the basis of techniques and tools for NLDS.

The classic definition of strange attractors considers them as a zone of turbulence (Combariza & Puche-Navarro, 2009). Hence their capture shows a set of paths characterized by not repeating themselves, by not crossing with each other, and not merging. Although it appears disordered, in reality

it is governed by an underlying order and regularity not visible at first sight (Smith, 1998). A good example is seen in the Rössel attractor (*see* [http://commons.wikimedia.org/wiki/File:Roessler\\_attractor.png](http://commons.wikimedia.org/wiki/File:Roessler_attractor.png)).

One of the growing possibilities that are very attractive to psychologists is to visualize the transition from one state to another. In that sense, the attractors are very useful in the study of cognitive change (Lewis et al., 1999; Spencer & Perone, 2008; Yan & Fischer, 2007). In addition to Fischer (Yan & Fischer, 2002), they have also been used by Lewis et al. (1999), Hollenstein (2007), and more recently by Spencer and Perone (2008). Studying cultural cognitive activity and other developmental processes starting with attractors has permitted a visualizing of the change between states in the processes of developmental change from cognitive activity (Lamey et al., 2004).

Fractals, in turn, are defined as established by Mandelbrot (2006) on the basis that they always repeat themselves on any scale. Munné (2008) relates this self-similarity characteristic of fractals to iteration to point out that fractals can be understood as generated by rules that produce self-similar phenomena in differing spatial and time-scales. Curiously, although attractors have been frequently used by psychologists, as mentioned before, this has not similarly occurred with fractals.

### **Paradoxical Objects and Cultural Development**

Any comprehension of humorous paradoxical objects constitutes a privileged scenario for capturing the historical nature of culturally understood cognitive development. Thus, the paradoxical objects are spaces in which, to paraphrase Francastel, culture and society enter and leave, and some of its features (geographical, scientific, economic, or of gender) establish themselves and leave traces, which is why time in art does not remain fixed (Francastel, 1970, p. 195). Obviously, the relationship that arises between paradoxical objects and their perceivers is not a new relationship; it was identified in the art world long ago. According to Gombrich (1997), for example, the entirety of visual contradictions suggested by paradoxical objects is highly illustrative of the processes of representation. For Magritte, they synthesize a “superposition from the thought exercise to the revealing exercise of his painting” (Meuris, 1992). Both make explicit and play on the

relationship between visual paradox and cognitive exercise.

One of the most appreciated benefits of paradoxical objects is precisely that they are just ineffable, they play in their own drawing, as Gombrich says, “the drawings (by themselves) get much more than the words would ever do” (Gombrich, 1997, p. 189). In the line of analysis of transgressions that embody different paradoxical objects, one can easily transform it into a review of how the subject knows. The diversity of paradoxical objects opens the spectrum of different inferential elaborations involved in comprehension.

The paradoxical objects are built on a transgression of the logical and conventional structure that subverts the shared meaning between those who produce it and those who read it. It demands the complicity of the spectator to be able to follow the traces of intermittent transformations and unexpected combinations before concluding and deriving consequences. Such a relationship between visual objects and the cognitive activity of those who read them perhaps have been clearer to drawing artists and art critics than to developmental psychologists. According to Gombrich, Steinberg was very conscious of this, as evidenced by the following quote: “I appeal to my reader’s complicity to transform the line into meaning by using our common cultural past, history, poetry. The contemporary, in that sense, is a complicity” (Gombrich, 1997, p. 192). It is therefore not surprising, although unusual, to argue that visual objects constitute an ideal scenario that fits well with the inquiry into the representational activity of the young child.

### ***Semiological Analysis***

One tool that has contributed to this work is semiological analysis of such objects that permit the establishment of distinctions among them while deriving important differences as to what is being referred to by the involved inferential elaborations (Puche-Navarro, 2001, 2004, 2009b). Semiological analysis of the paradoxical objects offers a rigorous examination of the necessary requirements for their understanding. The analysis of paradoxical objects discovers the contradictions in which they are based, as well as the conditions required by the subject to resolve the proposed crossroads. In other words, it allows for anticipating and controlling the explicit responses of the interrogated subject. A clearly subversive suggestion, even humorous, is to say that it is based on alienation and/or ambiguity.

Our previous studies have used semiological analysis as a tool to distinguish among different types of paradoxical objects. There is no doubt that differentiation between visual objects derives from the nature of transgression. The semiologic analysis could characterize very precisely if the display of distinctive inferential functioning already evolved is some kind of analyzing task used in psychology (Orozco, 2000; Pascual-Leone, 1991).

#### WHAT PARADOXICAL VISUAL OBJECTS MEAN?

The paradoxical object is presented as a problem to solve, a type of ambiguous enigma and at a crossroads for those observing it. Magritte refers to it as an ambiguity in which an object is transformed into another (Meuris, 1992). It is treated as a deliberately subversive suggestion that leads to an estrangement that produces an enjoyment of the humorous. There is some consensus that paradoxical objects combine possibilities for play, illusion, poetry, and humor. The work on the spatial aspects leads to traces of illusions and to geometric shapes that break with convention to open the door to the imagination and the unthinkable.

Perhaps the characteristics of uncertainty that surround paradoxical objects make them very diverse in nature and of different types. Magritte, for example, draws attention to the different types of transformations that lead to a wide heterogeneity of objects (Meuris, 1992). The nature of the subversive transformation (or of incongruence, as they're called by psychologists like Bariaud, 1983; McGhee, 1979; and Schultz, 1996) would define different types of paradoxical objects. Below is an incomplete typology that characterizes some of them.

In this classification, at a first and important place are Mutations, characterized by a transformation undergone by an object in front of the eyes of the spectator. A second type concerns objects that develop Recursions, which is the case for objects that break the distance between the author and his creation. Finally, there are the Mentalists: objects that play on the contradictions of content that take place in the mental states of the reader. Let us review them in more detail.

Magritte's work by itself constitutes an excellent overview of many of these distinct paradoxical objects. In this wide range, specific types of paradoxical objects are called mutations, named as such by Magritte to refer to those objects that undergo radical transformations. They are characterized as such because the transformation they undergo is of

such a magnitude that the objects cease to belong to one class or species, and, from the effect of that change, it becomes part of another distinct species.

"In the course of the inquiries I found a new possibility of things gradually becoming something different, an object becomes another (...) This means in my opinion, something very different from the coincidence between two objects because there is no break, no boundaries between the two materials." (Quoted by Meuris, 1992, p. 51; see illustrations of The Boots of Magritte in <http://cognitiva.univalle.edu.co/imagenes.htm>)

A second specific type of paradoxical object is when the drawing comes from the drawing, when the object is derived from the traces of the very act of drawing. Magnificent examples of that type of paradoxical objects are Escher's *The Drawing Hands* or Steinberg's *Passport*; the latter is certainly less transcendent but with a not insignificant dose of wit and humor. Steinberg puts it well when he says: "What draws is the drawing (and) drawing comes from the drawing. My line wants to be constantly reminded that it is made of ink" (Rosenberg, cited by Gombrich, 1997, p. 189). (See Illustration of Escher's *The Drawing Hands* and Steinberg's *The Passport* at <http://cognitiva.univalle.edu.co/imagenes.htm>.)

In the case of *The Drawing Hands* and *The Passport*, the author breaks down the barrier between that which draws and the action of drawing so that therein is the contradiction. A different thing occurs with mutations in that the transformation plays between two different objects, producing a hybrid. In the work *The Boots*, the feet turn into shoes in the presence of the spectator's eyes. That which characterizes this extraordinary mutation places it on the road to the metaphor. It is the same case as those paradoxical objects of Escher's that are half-bird, half-fish (extremes between two asymmetric animal species, one aquatic and one aerial—not in vain called Sky and Water) or as those found in *Meeting*, where he plays with the variation between ape and man.

Finally, other paradoxical objects are termed Mentalists. They have the specific feature of being psychological; in other words, they are anchored in mental states. This is nothing other than what is seen when a child interprets what occurs in the image that alludes a mental state of the protagonist and in front of which the viewer can situate themselves. Mentalist objects conciliate that early

capacity of children (or adults) to interpret and reproduce in their own emotional system the states, intentions, beliefs, and assumptions identified in the paradoxical object. That projection destroys the literal meaning of the object by discovering properties that it did not have, by creating ironies, and by opening other senses to the content acted upon. The dog sickness (Fig. 14.1) serves as a good example of this. The paradox is built on the fact that the reader has to know, that the dog “knows” what sickness means.

It is intended in those ways to better locate the class that we have named mentalists. It really is about these objects that our team has dedicated part of its work and has gathered much information. In fact, some of obtained results are used to account for the fertile and beneficial implications of returning to the iconic.

Paradoxical objects have a humorous side; in addition to being objects with meaning, they add an element of fun, which is also a cultural phenomenon. In a way of understanding the complexity of relations of development in a cultural approach, it is not surprising to come to a comprehension of them. No review of paradoxical objects would be complete without pointing out, if even briefly, the fact that humor plays an important role. Not all paradoxical objects are humorous, and not all visual humor proceeds from paradoxical objects. In this latter case, let’s just say, for example, a comic strip is some kind of iconic joke (Lozano & Puche-Navarro, 1998). In the first case, perhaps we can say that humor plays a fundamental role in understanding the greater part of paradoxical objects. Gombrich claims that “may be not other artist alive (referring to Steinberg) knows more than this humorist about the representation of philosophy” (Gombrich, 1997, p. 188).

The Mentalist class of objects may also include several different subclasses because they cover certain heterogeneity in the use of mental states. Consider some of the following subclasses.

#### *Mentalist 1*

When the transgressive relationship that is proposed transforms an object into another through projection that alludes to a desire or a sentiment of the protagonist. In the case of the object we have called *Cat in the Mirror*, subversion is defined by the functioning of a mirror that instead of reflecting (its fundamental property) transforms whoever is in front. What the reader must infer is the projection that is behind the relationship of “desired transformation.”

#### *Mentalist 2*

The contradiction that this object proposes is based on a clearly identifiable mental state but one that the protagonists cannot possess. It is clear that the television sets are discussing among themselves and that the reader can identify this directly and rapidly, but the contradiction is precisely that the television sets do not have the property for discussion among themselves (i.e., they “can” not do it).

Inferential demands that require an understanding of the evidence that mentalistic objects provide are not always the same. In some cases, the empirical evidence offered by this object is not direct (television sets), but they are necessary to deduce similar properties in the object. In the case of the *Cat in Front of the Mirror*, it is necessary to think and feel like the cat to understand the meaning of the lion in the mirror.

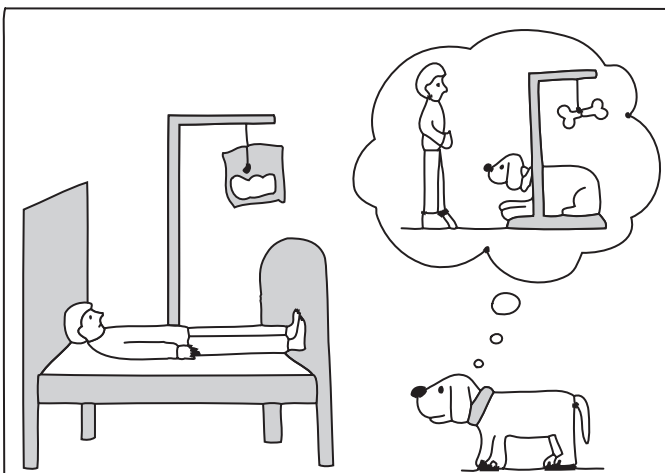

Figure 14.1 The Dog’s Sickness

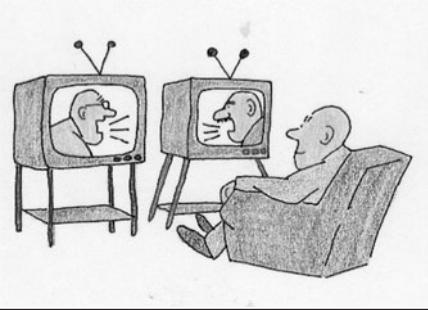

**HUMOROUS OBJECTS**

Perhaps it is time now to review some of the findings from our studies on understanding objects that have a clear humorous ingredient, to point out more precisely what is intended to be shown in this chapter. The spectators in our studies—the interpreters of paradoxical objects—are children. The age range used in the study was from 3 years to 4 years. Another element is that this child–spectator idea acts as a basic inquirer in the words of Karmiloff-Smith (2002), as a subject that raises questions and thus “reads the world.” It takes advantage of the paradoxical objects posed as a riddle, precisely to trigger the child’s abilities to discover what is being posed. In this exercise, one tries to understand what the posed object accesses from the inferential operations involved in such attempts at understanding. The results of previous studies (Lozano & Puche-Navarro, 1998; Puche-Navarro, 2001; 2002, 2004, 2009b) take into account such mental functioning required to make what is in the image explicit and find the original meaning that is implicit. The results are as surprising as they are diverse.

It is equally important to note that in the case of studies with children, the humorous ingredient of the paradoxical objects is a component that facilitates the child’s access to them. The young child’s ability to understand the meaning embodied in the subversion of the humorous visual object is necessary when it masters the double sense that it proposes. Such understanding assumes an inferential operation that when animated by the humorous ingredient moves the reader to decipher the meaning (see Table 14.1).

Table 14.1 shows that children of about age 4 years took the handling of mental states into account, which is the architecture required for understanding the mentalistic object. This fact by itself is surprising from the perspective of traditional child psychology. But equally interesting is the difference in the performance of children facing the mentalistic object 1 and the mentalistic object 2. Our semiological analysis of the requirements for understanding one and the other showed such differences. In one case the mental state is clearly identifiable, whereas with the other it is necessary to discover it. That discrimination that translates the different inferential operations

**Table 14.1. Comparison of the Understanding of Two Mentalists Jokes in Children from 3 to 8 years**

Mentalistic	Percentages of children that solve the problem
Mentalistic 1 (TV)	37/50 = 74%
	
Mentalistic 2 (Cat in the Mirror)	26/50 = 52%
	

shows them with relative transparency. Indeed, that the child discriminates between those two mentalistic objects implies that they require inferential operations at a different level of complexity.

One of the most important pieces of information collected shows that the understanding of different humorous objects of the mentalist type occurs quite early—that is, around age 4 years (Puche-Navarro, 2002). Precociously then, the children pass in a flexible and agile manner along the trajectory that separates the original representation of the subverted embodied in the iconic object. It is worth reiterating how humor plays an anchoring role in the reception that the child makes from the paradoxical object.

The very fact that the child discriminates between different paradoxical objects is a first-order fact to continue our study directed to delving deeply into the various classes of differential operations involved. It has been hypothesized that the understanding of paradoxical objects is played out on the unpredictable, on uncertainty, and on the transgressions of the conventional. These doubtful ambiguities and the little literal evidenced by the paradoxical objects should be enriched by taking up a larger class of them and adopting NLDS to try to explain the nature of the inferential operations that are derived.

In the subject's activity, one can then differentiate many kinds of inferences (although some of them are not included in our work). There are some that are of an inductive type (along the long-known ideas of David Hume), as are many of those working on children's ability to relate theory with evidence (Koslowski, 1996; Kuhn, 2002); there will be a relational or deductive type; and there will be the abductive, as those working in the emergence of metaphor (de la Rosa, 2006), to name but a few. However, the important thing to consider is that inferential operations cover a wide range. According to this idea, one of the most recent studies by our team worked on a task based on different objects requiring distinct operations. The study utilized conditions and the scenario favorable for differentiating them (Puche-Navarro, 2002, 2004, 2009b; Lozano & Puche-Navarro, 1998).

It is necessary to contextualize that traditionally the focus that has dominated the study of inferential operations has been that of pointing out an order of appearance (Mandler, 2007). Despite the importance of that work, and given the evidence that was just mentioned of the young child of around age 4 years, discriminating between various paradoxical

objects, it may also be relevant to question these facts differently. A very pertinent issue may be trying to find out what the structure is of the inferential operations that are involved and to investigate emerging alternatives that adopt the NLDS perspective to try to establish if they take into account a chaotic structure. Although the linearity of age-related behavior has been dominant, it is worth exploring what happens if one works from nonlinearity and bifurcation. The problem then would not be about the time of emergence of inferential operations nor stratification in relation to age. From nonlinearity the issue would be to explore what the paths of inferential operations over a span of several weeks involve to know what it is that these trajectories show. Paradoxical objects of the mentalistic type, others of the hyperbolic type, and, third, those of the substitution type are again taken into account. The paradoxical objects identified as mentalistic are characterized by a game of transgression based on the use of mental states. Hyperbolic paradoxical objects are characterized as such because the transgression takes place as a function of character exaggeration (e.g., a quiet fisherman in a small boat catches a fish three times the size of the boat). The transgression that gives rise to a substitution object is characterized by transposition of a structural element of the image that completely transforms the meaning of it (e.g., a cow with the head of an orchid).

The first objects that have been widely treated throughout the text (the mentalistic) are characterized from the standpoint of inferential operations as demanding deductive inferences that require a second-order intentional system (Dennett, 1995). That is, **the subject needs to think or feel what the protagonist thinks or feels**. The second objects of nature, hyperbolic, require inferential operations of the inductive type to the extent that they derive from direct and concrete indications of the iconic object. Finally, the third type of operations, the substitution, pose a transductive inference type, according to the classification of de Gortari (1969), who defines them as such for being of relational character given that they extract knowledge from among two or more elements. This can be seen in Table 14.2 with three paradoxical objects involving three distinct inferential operations (Combariza & Puche-Navarro, 2009).

On the one hand and from what can be seen in Table 14.2, it may be necessary to insist on the benefit of speaking of inferential operations in the plural and not simply of inference in the singular.

**Table 14.2. Relation between Paradoxical Objects and Types of Inferential Operations**

Paradoxical objects	Type of inferential operation
Hyperbolic	Inferential operations of the inductive type
Mentalistic	Inferential operations of the deductive type
Substitution	Inferential operations of the transductive type

In the given study, we worked with a paradoxical object situation on a problem-solving task with a branching structure. Faced with a board with three columns and four choices, the child could make three consecutive choices in sequences (which are given in the vertical columns) versus four options from the paradoxical objects (three distracters and a neutral option). In this way, we could keep itineraries of the choices for each child.

The study was carried out with a time-series design that allowed for obtaining 108 measures by presenting the subject 9 sessions where each experiment collected 12 data units (12 x 9 = 108). The data were treated with the graphic technique of *minimae* and *maximae* (van Geert & van Dijk, 2002) applied to the individual performances determined by the choices of the subject. The result is a band with observational measures. The *x*-axis represents the period of 108 observations and *y*-axis represents the scored choices of paradoxical objects (scale 1: control, 2: hyperbolic,

3: mentalistic, and 4: substitution). This technique, then, displays the temporal sequence of each choice among the four scores along the 9 repeated experiments (Combariza & Puche-Navarro, 2009).

In reality, rather than the technical specifications of the experiment that may be observed in the cited study, what we want to highlight here is that from the NLDS perspective, it sought to explore the performance of various inferential operations involved in the three paradoxical objects utilized. Let's look at some outcomes in an individual case (Fig. 14.2).

Juan's trajectory shows (Fig. 14.2) that much of the choices are scored as a 2. In the first 10 observations, the scores ranged among 2, 3, and 4 options with a wide bandwidth. The same thing occurred in the last 20 observations, a segment in which the largest number of option 4 appears. Between 10 and 45 the options are from 1, 2, and 3. A similar trajectory is presented between observations 47 and 64, as well as between observations 72 to 85. Another feature is that very few choices are recorded for option 4 because only 8 are counted. The bandwidth shows that Juan's scores range intermittently between the four options. The picture shown in these trajectories is a rather incessant oscillation of choices. This time-series technique results in highly irregular data showing variability as a recurrent and a-periodical process.

What these data reveal is that the choices of the subject are marked by oscillations. It would be expected that once the subject chooses the paradoxical mentalistic object, it would continue doing so. On the contrary, the study found that the next time,

**Figure 14.2** Juan's Performances of Various Inferential Operations Involved in the Three Paradoxical Objects along 108 Observations

a hyperbolic or a control may be chosen. There definitely does not seem to be an order or a sequence between the various choices.

These three types of inferential operations do not show sequentially among themselves. It is not recorded, for example, that the inferential operations of the inductive type (hyperbolic) precede the deductive (mentalist) nor those of the transductive type (substitution), following a growing line of progression. These three types of inferential operations do not evolve in fixed sequences, but their development is interdependent.

If there is no linear relationship among the various inferential operations, then the next step is to respond to whether they effectively have a fractal structure. To answer that question, it is necessary to identify whether they behave as a transition region and whether they might be treated as nodal points—that is, an area of attractors. This answer confirms the application of techniques such as the wavelet that was applied to the same data collected in the same situation and under the same conditions.

### ***New Methods: The Wavelet Model***

The history of this technique is in itself remarkable because it was rediscovered several times (Mackenzie, 2001). The name *wavelet* is first found in an article by Morlet in 1984 (Goupillaud, Grossman, & Morlet, 1984). Technically speaking, it is a transformed signal and of optimal visual representation with qualitative character and pattern productive. Its virtue is to identify within a cluster of data a code that allows for representing the facts in a simple manner. One of its great virtues is to identify a-periodicity in chaotic systems. In this regard, it is a privilege to know if the paths that make inferential operations in the selections of the different paradoxical objects correspond with chaotic systems.

Consider the wavelet of the same child, Juan, whose data were seen with the graphical technique of minimums and maximums in the Figure 14.3.

What does this image reveal? There are three characteristics: the vertical axes show shapes as arcs diffuse; these arcs are self-contained; they represent lack of symmetry. These three characteristics prove the multifractal nature of Juan's response pattern.

The wavelet produced by the set of inferential operations exposes a certain irregularity between different arcs that seem self-contained. These forms reveal the presence of different fractals in a multifractal space. Based on this information, it can be confirmed that the inferential operations studied mathematically correspond to a multifractal structure and to a strange attractor (Combariza & Puché-Navarro, 2009). The wavelet indicates that the trajectories studied belong to the same attractor.

The wavelet shows evidence that allows us to assume that the inferential operations constitute a system of coupled variables that control each other and that act simultaneously, formally demonstrating the nonlinear nature of the phenomenon under study. The three types of inferential operations belong to a region of attractors, which implies that they change each other in an interdependent manner. That is, if the inference involved in mentalistic object grows, then the inferential operations corresponding to the other two objects (hyperbolic and substitution) decrease. This type of interaction would respond in the game between the three objects in which one serves as a bridge between the two other visual objects.

The wavelet shows different patterns that emerge from the same model that underlies its functioning. Rose and Fischer pose the presence of “patterns of attractors” to refer to common values that would

**Figure 14.3** Juan's Performances Applied to Wavelet

account for the connections between these different domains (Rose & Fischer, 2009). These outcomes would show these patterns of attractors between different functioning of inferences, derived rising from the various paradoxical objects.

The passage between successive micro-attractors evidences that this is not a fixed sequence without uniform order. In terms of inferential operations, this implies that their evolution does not follow a pre-established linear process. Rather, it is on a somewhat illogical path with no apparent order, similarly to the passage from one memory to another, but that behaves much as dynamic systems and therefore has an underlying structure of a chaotic nature. As Rose and Fischer exposed: “Dynamic modeling offers tools to better understand development and learning in their full complexity, integrating influences involving person, context, and culture” (2009, pp. 417).

### **Conclusions: Toward Exploration of Nonlinearity in Mind and Culture**

One of the aims of this chapter was to demonstrate the virtuosity of paradoxical objects in the study of development from a cultural perspective. We believe that one is able to establish that they contain multiple paths of access to different levels for comprehension of the subject. The fact that a child can grasp the understanding of an object created in another distant place and in another century is, as we said before, as much surprising as revealing of the object’s ability to interface between perspectives and different times.

However, another important conclusion is the pertinence of NLDS to account for the complexity of inferential operations. Indeed, fluctuations and peculiarities of inferential functioning in understanding objects such as paradoxical ones requires a type of approach that is not schematic nor linear. In fact, methodologically employing our graphic technique of *minimae* and *maximae* and the wavelets technique, we have been able to establish that human cognitive inferential operations have a fractal nature. They belong to a *strange attractor* zone. We can show the path from one attractor to another—yet without a steady sequence. It breaks the idea of an order in appearance of inferential operations development complexity. Wavelet shows that the distinctive inferential operations evolve in an interdependent way.

Multifractality found in inferential operations leads to the issue of evolution of cognitive functions. This evolution is not necessarily from past–future relations as the sole and exclusive option—

in classical proportional or sequential relations between a previous element and a posterior one—but necessarily entails numerous bifurcated scenarios. Inferential operations fail to evolve in stages, and their levels of complexity do not appear in a stepwise fashion where the simplest precedes and is a condition of that which follows. Further, they do not necessarily follow an unequivocal form not a single cause and effect chain. The role of multiple interactions of the components that comprise the subject’s relations with its environment is very present. At least, perhaps the approach of Ilya Prigogine that can be found in the reconstitution of his conference, *L’homme devant l’incertain*, is perhaps very appropriate:

The vision of an evolving and bifurcating world requires a new rationality, a nature that invites us to wonder, and that wonder is the common source of the arts and science.

### **Future Directions**

Perhaps many more questions arise than answers that have been able to be established from this chapter. It is then worthwhile to focus on two issues on which this work is built: paradoxical objects, dynamic systems, and the role of both in a cultural approach to cognitive development.

Paradoxical objects constitute, in themselves, a great diversity and that diversity is what allows us to investigate the various kinds of cognitive activities, culturally understood. The semiotic analysis of paradoxical objects complements this form of inquiry by providing a map of the possibilities of the human mind in varied contexts and disparate perspectives. Being such a useful tool, the question is perhaps, “Why have paradoxical objects been used only by art critics and journalists, not by psychologists?” Perhaps the simplest answer is found in the weight of tradition. Psychologists are quite wedded to devices and tools that last and are reluctant to take risks. However, to innovate and especially refresh research when it offers interesting results is a task for everyone. In the agenda of researchers in developmental psychology from a cultural perspective, one must see the needs for innovation with the use of paradoxical objects (especially in a technological age where much of the information is imparted through images) as another road with fertile results.

It is also evident that there are not many authors who have adopted the NLDS as a conceptual and methodological perspective in the study of the

development as a system that evolves under a context. Why? It seems that this alternative is quite risky and requires the use of mathematical thought, which is a challenge for most psychologists. Nevertheless, in the future, there will be the capacity to build interdisciplinary teams composed by psychologists, anthropologists, physicists and mathematicians that will be suited to approach the problem from the psychology with the NLDS vision and methodology:

A dynamic approach can change the way you think about development and it can change the way you conduct research in development. Once we began to view development from a dynamic and selectionist approach, we found the ideas so powerful that we could never go back to other ways of thinking. Every paper we read, every talk we heard, every new bit of data from our labs took on new meaning . . . The final test of dynamics in development, of course, is in its usefulness to a wide range of scholars. We hope readers will accept the challenge of the new way of thinking and working and we look forward to the report card. (Thelen & Smith, 1994, pp. 341–342)

What Thelen and Smith raised here about the possibilities for the study of cognitive development from the perspective of NLDS can be applied with full force to the study of cognitive development from a cultural approach. Indeed, the dynamic model can reconcile what appear to be disparate aspects in development because of a whole range of influences, both cultural and otherwise. It is fairly safe to say that if psychologists look at the future, the latter provides new opportunities.

## Acknowledgements

The author wishes to express her gratitude to professors Ernesto Combariza, and Mariela Orozco members of the Centro de Investigaciones en Psicología, Cognición y Cultura, de la Universidad del Valle, for their help in for their careful, attentive reviewing, which allowed a significant improvement in the text. Much of the information contained in this chapter is part of an investigation project Cognitive development from dynamic non-linear systems. The empirical project was financed by internal resources of the Vice-Dean of research of Universidad del Valle, to the Center of Psychology and Cognition and Culture

# Existential Semiotics and Cultural Psychology

Eero Tarasti

## Abstract

Existential Semiotics is a new approach, or “school,” within the general semiotics and philosophy. It tries to renew the epistemic foundations of the theory of signs, inspired by rereading the classics of continental philosophy in the line of Kant, Hegel, Schelling, Kierkegaard, Heidegger, Jaspers, Arendt, and Sartre and, on the other hand, the whole tradition of classical semiotics from Saussure to A.J. Greimas. Yet, the new issue it offers is the revalorization of subject and subjectivity, and hence it opens the field to psychological explanation and application as well. It launches new notions to the field, such as transcendence, Dasein, modalities, values, *Moi/Soi*, and so forth. It constitutes a kind of ontological semiotics starting from the modality of Being and shifting toward Doing and Appearing, as well. Many concepts of various disciplines from representation and genre to dialogue and nature of communication can be re-interpreted in its light. Albeit it also takes into account moral and axiological acts, it emphasizes the transcendental aspect of value as virtual entities and hence does not belong so much to any post-modern or post-structuralist thought; rather, it aims for what is called “neosemiotics,” philosophy, and methodology of signification conceived in the 2010s.

**Keywords:** transcendence, subject, modalities, Being, Doing, Appearance (Schein), Dasein, *Moi/Soi*, sign categories: pre-sign, act-sign, post-sign, neosemiotics, existentiality

The mere notion of “existential semiotics” in the title evokes many issues in the history of ideas and study of signs.<sup>1</sup> As such, it is new theory of studies of communication and signification, as Eco has defined the scope of the discipline of semiotics (Eco, 1979, p. 8). But the attribute “existential” calls on a certain psychological dimension—namely, existential philosophy and even existentialism. In a broader sense one can ask, like once my publisher John Gallman from Indiana University Press: Is it something like existential life (this came to my mind since the American transcendentalist philosophers, Ralph Waldo Emerson, the writer Henry Thoreau and others can be considered a kind of pre-existentialist thinkers) On the other hand, it certainly carries a philosophical tinge at least and brings us back to German speculative philosophy, to the time

of Kant, Schelling, Hegel, and thereafter the existentialist line in the proper sense (i.e., Kierkegaard, Heidegger, Jaspers, Sartre, de Beauvoir, Arendt, Wahl, Gabriel, Marcel, etc.). However, albeit this new theory may get its inspiration from these classical sources, one cannot return into any earlier historic phase, the theoretical thought in 2010 is definitely philosophy in our time and in our case is enriched by the development of semiotic discipline through the twentieth century particularly.

## Return to Basic Ideas

These theoretical and philosophical reflections have started from the hypothesis that semiotics cannot forever stay as the classics from Peirce and Saussure to Greimas, Lotman, Sebeok, and others have established it. Semiotics is in flux and reflects

new epistemic choices in the situation of sciences in the 2000s. With existential semiotics, I by no means attempt any kind of return to existentialism or to some earlier historic thinker, like Hegel, Kierkegaard, Sartre, or Heidegger. I have felt entitled to search for inspiration in these philosophers because of the actuality of their ideas in the new context.

Existential semiotics aims for discovering the life of signs from within. It studies unique phenomena—unlike most previous semiotics, which have investigated only the conditions of such particular meanings. It studies signs in movement and flux, signs becoming signs (i.e., as pre-signs, act-signs, and post-signs), as I have portrayed this process (Tarasti, 2000, p. 33). It sees signs fluctuating between what I call by the German term *Dasein*—Being there (our world with subjects and objects) and transcendence. Completely new sign categories emerge in this tension between reality and being beyond it. We have to make a new list of categories in the side of that once done by Peirce. Such new signs so far discovered are a.o. trans-signs, endo- and exo-signs, quasi-signs (or as-if-signs), and pheno- and geno-signs.

In my own previous theory of musical semiotics, which is my special field of empirical research (Tarasti, 1994, pp. 27, 38–43), I came to the conclusion that the most important manner of music to signify comes from its modalities. This evokes the background of my theories in the so-called “Paris School of Semiotics,” and particularly its founder, the Lithuanian-born scholar Algirdas Julien Greimas. Before Greimas, I had studied with Claude Lévi-Strauss, but the Greimasian theory definitely brought me into the core of the European tradition of semiotics. Greimas started with his *Sémantique structurale* (1966) stemming from phenomenology, semantics, Merleau-Ponty’s phenomenology, and Levi-Straussian structural anthropology, not to mention Saussure and Hjelmslev. He launched new concepts such as semanalysis, actantial model, isotopies, and so forth. In the late 1970s, he put his thought into a generative course, fashionable model at that time (Greimas, 1979, pp. 157–164). However, the most radical of his innovations was just the discovery of modalities, to which he always referred to as the “third semiotic revolution” (the first being the invention of semantics by Bréal and the second the structural linguistics by de Saussure). Modalities remained probably the most durable and innovative aspect of the Paris school. By modalities, he meant the manners whereby a speaker animates

his/her speech providing it with his/her wishes, hopes, certainties, uncertainties, duties, emotions, and so forth. They meant, in fact, a psychological turn in the semiotics (even if it basically preserved its conceptual nature). Larousse’s French dictionary defines modality as:

Psychic activity that the speaker projects into what he is saying. A thought is not content with a simple presentation, but demands active participation by the thinking subject, activity which in the expression forms the soul of the sentence, without it the sentence does not exist.

(quoted from *Tarasti*, 1994, p. 39)

Modalities appeared in the grammar of some language as a special subjunctive verb form of subphrase. In French, one says: “Il faut que *j’aille à la banque*,” or “*J’espère qu’il vienne*” (so not: “Je vais” or “Il vient”). In Italian, one says: “*Credo che questa sia possibile.*”

### *Dasein*

Fundamental modalities were “being” and “doing.” Moreover, we can distinguish a third—namely, becoming, referring to the “normal” temporal course of events in our *Dasein*. Other modalities are, in turn, will, can, know, and must plus believe. Importantly, here modalities are processual concepts. Therefore, they are the element that is certainly preserved as valid from the “classical” semiotics, in the new existential semiotics, precisely because of their dynamic nature.

They are very apt to portray what happens inside what I call *Dasein* of the following model (Tarasti, 2000, p. 10) in Figure 15.1.

The concept of *Dasein* (which I have left untranslated because of its strong philosophical connotations) has been borrowed from German philosophy, Heidegger, and Jaspers (*see also* Jaspers, 1948, pp. 6–11, 57–66, 295); however, unlike in Heidegger, for whom *Dasein* in the first place meant **my** existence, here it does not refer only to one subject, Me, but also to Others and likewise to the objects that we desire. Yet, we have to notice that there is something beyond the concrete reality in which we live—namely, that which is called “transcendence.” The easiest definition of this intriguing notion, which certainly not all semioticians would wish welcome to semiotic theory, might be the following: Transcendent is anything that is absent but present in our minds. Furthermore, in the model, a new element is introduced—namely, the subject.

Figure 15.1 The model of *Dasein*.

There is a subject dwelling in the *Dasein*, who feels it somehow deficient, not satisfactory, and so negates it. This is what Sartre called *néantisation* (Sartre, 1943, pp. 44–45), the lack of the existence that forces the subject to search for something else and more. But in the model, there are two transcendental acts: first negation, followed by affirmation. As a result, we have the “existential style” in the *Dasein* x. That is what has been called also “existential move.”

First our subject finds himself amidst the objective signs of *Dasein*. But then the subject recognizes the emptiness and Nothingness surrounding the existence from which he has come—that is, which precedes him and comes after him. The subject makes a leap into Nothingness, to the realm of *Le Néant*, described by Sartre. In its light, the whole earlier *Dasein* seems to have lost its ground: it appears to be senseless. This constitutes the first act of transcendence, or the negation. Nevertheless the movement of the subject continues further and now follows the second act of transcendence: He encounters the opposite pole of the Nothingness—the universe that is meaningful but in some supra-individual way, independently of his own act of signification. The act can be called affirmation; as the consequence of this act, he finds what Peirce called the *Ground*. For me, it was first difficult to find a suitable concept to portray this state, before I noticed, after reading the Russian philosopher Vladimir Soloviev (1965, pp. 348–349), that it was the same as what in the Gnostic philosophy was called *pleroma* or plenitude. This again evokes *die Weltseele*, the world soul of Schelling (see also Ralph Waldo Emerson), which he defined as follows: “The soul of the world, anima mundi, is the unitary inner nature of the world, which is thought to be a living,

willing, conceiving, and feeling being.” Accordingly, what Schelling did was to portray the world soul as a “modal” entity, to use the semiotic vocabulary of the Paris School (Greimas, 1979, pp. 230–232).

As early as here I want to emphasize that the model is of conceptual nature and not of empirical one. This, of course, does not exclude any kind of subsequent psychological, anthropological, theological applications. Someone has proposed that “transcendental journey” means “a psychedelic trip,” some others have compared it to the act of a shaman in which his soul after he has eaten mushrooms, makes a transmundane wandering to other realities, and so forth. However, the scheme itself is philosophical and deals with what Kant called *transzendental* rather than *transzendent* (Kant, 1787/1968, p. 379).

We can, of course, provide the logical operations of affirmation and negation with a more psychological content and distinguish within them subtle nuances of these acts. For example, **negation** means:

- abandoning, giving up—that is, one is in a situation in which some x has appeared, the subject has taken it into its possession but now abandons it, and is “disjuncted” from it (formalized as S V O, in the Greimassian semiotics; see Greimas, 1979, p. 108)
- passing by: x appears but a subject passes by it
- forgetting: x has appeared, but it is forgotten; it does not have any impact
- making a counter-argument: x appears, but something totally different follows: y or x appears and it is followed by its negation (inversion, contrast, opposition or else) or this corresponds to Greimas’s semiotic square and its categories s1 and

s2, and non-s1 and non-s2 (Greimas, 1979, pp. 29–33)

- rejecting: x appears, but it is rejected
- preventing: x is going to appear, but it is prevented
- taking away the relations attributes: x appears, but one eliminates its seems x . . . xn where after only it becomes acceptable
- destroying: x appears, but it is destroyed
- collapsing, vanishing: x appears, but it then disappears by itself, without our ability or will to influence it
- concealing: the appearance of x is hidden, but altogether it “is” on a certain level
- parodizing: x appears, but it is not taken seriously; it is taken as an “as-if sign”
- mocking: x appears, but one jokes with it; it is ironized, made grotesque
- dissolution: x appears, but it is reduced to smaller parts; when its total phenomenal quality is lost, one does not see the forest from trees. Or, according to Adorno: “When one scrutinizes art works very close, even most objective works turn into confusion, texts into words . . . the particular element of the work vanishes, its abridgment evaporates under microscopic glance” (Adorno, 2006, p. 209)
- misunderstanding: x appears, but it is not interpreted as x but as something else.

#### Affirmation means:

- acceptance: x appears and we accept it without intervening it; for example, we rejoice in others’ success
- helping: contributing to the fact that x appears
- enlightenment: we see x in a favorable light
- revelation of the truth and disappearance of lie: x appears, it is recognized as *Schein*, lie, and as its counterpole we do so that, or allow that x’ appears
- beginning: we start to strive for, we undertake an act so that some positive, euphoric x appears
- duration: we attempt to maintain the appearance of x; for example, by teaching someone
- finishing: x appears as the end result of a process, as a reward of pain; the shine, the brilliance has been gained by labor (*see* later the modality of appearing)
- organic vitality: x erupts, appears as consequence of an organic process, as abandoning to it, as “striding at the top of a wave”

- transfiguration: x radiates something that stems from its background, not from its own power but as the weight of the invisible reality; for example, the bodies in El Greco’s paintings—in this case, we first encounter the negation: the body is portrayed as suffering, pining, but behind it looms some clarity
- victory: x appears as the end of a long struggle; for example, C major at the end of Beethoven’s Fifth
- opening: the appearance of x means a gate to the world of possibilities, new universes open for us
- liberation: the appearance of x signifies getting rid of the chains of y or x’.

However, one has to note two other aspects of this model of how our psyche is adapted to his/her existential situation and journeys. For the first, there is one thing that is evoked by pondering negation as a kind of **alienation**, estrangement. Namely, when a subject temporarily exits his *Dasein* in his transcendental act, he can naturally stay in this journey one minute, hour, day, week, year, decades. In the temporal sense, the journey can thus last whatsoever time span. Yet, it can occur that when he returns to the world of his *Dasein*, symbolized by a globe, it has changed, it has been all the time in motion by itself and completely independently of our subject, it has perhaps turned around to some directions so that our subject does not return any longer to the same world. There has been in-built in our model as a kind of solipsist idea that *Dasein* exists only for one subject and that it changes its shape because of **his/her** existential experiences. Yet it is not only so. During the transcendental journey, the world may have in the meantime developed into a new direction. Subject does not return at home but to a quite different world from that which he left. As far as we take *Dasein* as a collective entity, which consists of subjects and objects, of Others, we encounter the community and the autonomous development of the collectivity, the change brought by the history. Our subject can either accept this change and try to adapt to it or deny it. A special opportunity for semiotics of resistance emerges from the latter case. Progress does not mean to go along the normal course of the journey, but to look at other alternatives, or **what might have happened**, what might have been possible (*see* Tarasti, 2009, pp. 51, 61–65) as shown in Figure 15.2.

In addition, there is another aspect at our model, which opens new avenues after the previous one.

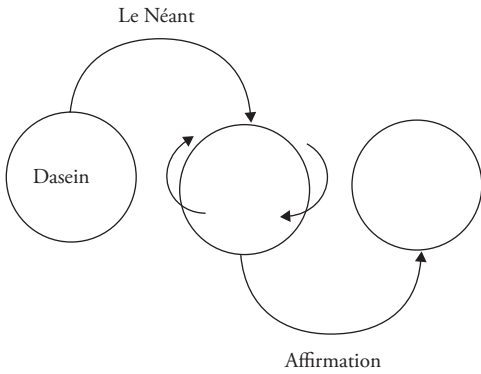

Figure 15.2 The turn-around of *Dasein*.

Namely, the arrows can go backward as well. Our subject recalls how *Dasein* was before and returns to it on the basis of his memory. His memory has kept still some images and ideas from these previous worlds and their phases, as we can see in Figure 15.3.

Some of them he may have already forgotten, and similarly the *Dasein* may have forgotten him. There is danger indeed that if he dwells too long in his position of resistance and outside the *Dasein*, then he is forgotten—like a text that has to be destroyed and ignored from the collective memory of a culture. This leads to strong social implications of our theory. Real thinkers of resistance are always forgotten and suppressed. If they were accepted, they would not be what they want to be. Thus, in our model the arrows go also to another direction: backward. This leads us to ponder the return of signs and problems of history, determination and optionality, causality, and communication.

### Values

In the existential theory, regarding semiotics (one may have already wondered what this has to do with the theory of signs), signs are in constant movement between transcendence and *Dasein*. Depending on their distance to *Dasein*, whether they are approaching it or distancing from it we indeed get new types of signs. For the first, we have pre-signs—that is, ideas or values that have not yet become concrete signs. Such signs are virtual. When they become manifest as a sign object or “vehicle” or an act, they become act-signs. Moreover, when they exercise their impact on receivers, they become post-signs. In their virtual, potential state as transcendental entities, they can be called *trans-signs*. These three or four phases correspond to three activities of the human mind: virtualizing, actualizing, and realizing—not only

Figure 15.3 The counter-current of the *Dasein*.

used by Greimas but appearing also in the phenomenological theories by Roman Ingarden.

Ultimately, this is an axiological problem of the existence of values. In the Saussurean tradition values are relative: they are determined only in their context as opposed to other values by the linguistic community (Saussure, 1916/1995, p. 116). In my theory, values are transcendental but become signs via the activities of the subject. In the aesthetic field such a view is of course problematic. How can we say that the value of, say, a Beethoven sonata existed before its creation? Was it looming somewhere and waiting for its actualization in the *Dasein*? We may say that transcendental values do not become a manifest reality without an agent who actualizes them.

When this occurs, such pre-signs can also become something different than they were thought to be before, as mere pre-signs (Tarasti, 2000, p. 33). Without the help of other modalities, know, can, must, and will they are never concretized. Signs can be also classified as endo- and exo-signs (Tarasti, 2000, pp. 37–55)—that is, either something internal to our subject’s world or external to it.

Let us scrutinize this problem regarding moral values. If we would like to abridge what was said above, then we could present the following figure:

The movement would be from the left to the right, when in the semiosis stepwise some abstract idea is condensed and crystallizes at the end into a sign (see Tarasti, 2004, p. 39). The psychological moment is situated at modalities and modalizations. But can we call this process a semiosis? Shall we then not commit the error that we consider signs not straightly as values but at least value vehicles, and then we would correspondingly keep values as signs? To some philosophers, to say that something

is “sign” is not any recommendation. But on which grounds could we reason that if something is of sign character, then it would be less “real” and valuable? Peirce’s way of thinking was that to become conscious of a sign is a second. The French novel writer Le Clezio said that as soon as when reading a novel, we exclaim: “Oh this was well said!” it is a kind of sign, and it does not function any longer. The functionality of signs has become almost an aesthetic slogan in recent years. But this is the same as stated above—namely, the value reality escapes our hold on it, and everything becomes only technical problems of functionality. Some may say that this was the fault of the semioticians! They taught us that all is only sign and semiosis: there can be disturbances in its functioning, but they can be corrected with the technical knowledge of dominance that we have of the functioning of text. Thus, values remain completely external, and transcendental, and one does not need to believe in their existence: There are only opinions, language, discourse, but no transcendental categories. Greimas (1979/1999) said: “*Il n’y a pas de vérité, il n’y a que véridiction*” [“There is no truth, there are only statements about truth”].

All moral philosophers have to deal with Moore and Hume. The latter proposed as his thesis that no values can be inferred from facts. From the state of how things are, we cannot logically infer how they should be. In my existential semiotics, I have defended the idea that values could be transcendental ideas in the side of other values that exist outside the *Dasein*. However, in some cases and under certain circumstances, they start to exercise their influence within the *Dasein*, when some living subject therein—individual or collective—feels such a value as his own, experiences it to oblige him/her into something and finally realizes this value as a sign. The British philosopher John Mackie in his work *Inventing Right and Wrong* (Mackie 1977), has represented extreme value nominalism. Views of different cultures of what is right and wrong are so different that no value facts exist. All moral statements are thus untrue. Mackie’s idea is that all objective moral theories make a mistake when they say that man cannot step outside and above morals if he/she wants to do so. In his mind, moral is a special form of social life, which man and his community creates and chooses. This sounds already rather existential. He says: “If moral leads into quarrel and dispute, then moral shall be forgotten!”

If, even after this, we keep on the point that moral values exist in transcendence, it remains on

the responsibility of the person of *Dasein* whether he/she believes in this and whether he/she lets them have any impact on his/her acts. This idea probably provides us with the key to the problem of how to fit values into modalities and furthermore into signs—that is, how to act. I offer you now such a proposal. No one can say that I pursue such and such an act because a transcendental value  $x$  requires me to do so.” When I select value  $x$  as my ideal, it is always my own choice for which I am responsible. This is my main argument against the argument most often used to attack the value realists—that is, who and/or what guarantees that some person does not start to enact some completely foolish transcendental value and even imagine to be right. However, when I have picked up the value  $x$ , it falls into the field of the modalities and passions of our *Dasein*, amidst our wanting, obligations, abilities, and knowing. Then I make the act,  $x$  or non- $x$ —that is, I fulfill an act following this value or I give it up, I do something against it, I negate the value by my act, see Figure 15.4.

Hence, the signified of the act is the transcendental value but only insofar as this, our subject, has the right value of competence for the code whereby he/she can connect such an act to the transcendental value under question.

At the same time this act further launches other acts, which either affirm or negate the act  $x$ /non- $x$ . Consequently, we can infer the crucial imperative for any moral activity: If the act  $x$ =/non- $x$ = causes in its *Umwelt* other negative acts, which are negative in relations to other transcendental values, then such an act should not be committed. In other words, we have to apply there the postulate by Mackie that says that we have to give up moral judgment and activity. We might, for example, imagine that we

Figure 15.4 The enactment of values.

have the transcendental value of being honest or keeping promises. However, somebody does something contrary (e.g., breaks a contract). This negative act enhances in its social environment reactions or other acts that can likewise be negative: non-y punishing, non-p abandoning, exclusion outside the community, non-q hatred. All these reactive value acts are, in turn, negations of some transcendental values, like indulgence, benevolence, abstinence from violence, charity, look at Figure 15.5, and so forth.

In other words, if the correction of a negative value act causes more negative acts in its *Umwelt* than the original negative act, then one has to give up such a correction, being morally right and displaying it.

Two kinds of modalities function in such a moral value act, like in any fulfillment of a value: (1) modalities that regulate acts and the behaviors of their agents in the *Dasein*, and (2) modalities that regulate the relationships of value acts to their transcendental values. This movement takes place in two directions: either it is manifesting, concretizing values or the process in which, as Greimas states, virtual act changes into actual and sometimes even real - this takes place when we 'return' to the value as it is in transcendence and compare the 'actual' value to the 'virtual value', hence the transcendental value serves as the source of the actualized value in *Dasein*. These two acts of metamodalization, i.e. making values concrete entities by actualizing them and by comparing them to their transcendental and virtual sources, presuppose a particular value competence. If our subjects do not possess the right codes to connect a potential, virtual value into an act that concretizes it and if they cannot decode from an act its value content and compare it to the

encyclopedia of values, then the reality of values is not fulfilled at all.

This model should likewise fit to other values, as said, like the truth or epistemic values and the beauty or aesthetic values. In any case, the subject of *Dasein* is totally responsible for his value choices—that is, which value he *metamodalizes* from the encyclopedia of values. Naturally when he is devoid of some value because of his education, for example, one can say that also his community, "senders" (school, parents, teachers), are responsible. Yet, he is existentially responsible for which transcendental values he selects, how he modalizes them into a value act, and which kind of value acts and modalities they bring about.

The intermediate phase of modalities is indispensable in making values and signs compatible. It also explains why some originally right value can, when it is transformed into a value act, get distorted into a caricature of itself: It is caused by modalization, or in the transformation of the phase of actualizing when the human passions intervene.

This explains the nature of meta-modalities: They are altogether activities of a subject. Yet, how then do meta-modalities distinguish from ordinary modalities? They contribute to the particular act of signification in which a value is connected to a physical act or object of the sign vehicle. That implies the following varieties of ordinary modalities:

1. want (*vouloir*): I want to connect value x to the signified of act x. If subject would not want it, this value could not manifest. But another concern is if such a wanting differs from that wanting and desire, whereby the subjects of *Dasein* look after each other or various value objects. Not even a supporter of the psychoanalytic theory would presume that the Freudian desire would as such explain for example, artistic activity, ethical choice or scientific theory. A special form of human wanting is involved.

2. know (*savoir*): I know that value x exists; without such knowledge I cannot even want to concretize it in my value act: But which kind of knowing is this? Is it quite similar information as the one we receive in our *Dasein* and that can be measured by the information theoretical concepts of entropy and redundancy?

3. can (*pouvoir*): I am able to connect a value x to an act x—for example, I want to help sick people but to do something I have to master medicine; I want to help the poor, but unless I am

Figure 15.5. Reaction to a value act.

able to provide a property, then I cannot do it; I want to transmit artistic experiences, but if I do not master good techniques, then I cannot produce any such emotions; and so forth.

4)=must=(*devoir*): *must* means the internalization of values, so that we could experience that a value obliges us. But even then the meta-modality *must* is our own existential choice.

## New Types of Signs

The traffic between these instances of signs—that is, between transcendence and existence—is taken care of by meta-modalities, as we would call them. Altogether, signs have their *situations*—an aspect found essential in the existential approach. If we take this first model as a narrative structure portraying human life, it radically differs from classical story schemes, which are symmetrical. Following Greimas, any narrative starts with a situation in which we are *hic, nunc, ego* (or here, now, me), but then something happens (the so-called “initial lack” in Vladimir Propp’s theory of Russian folk tales) that causes a “disengagement” from this prior state into there, then, others. Yet, normally in a classical storytelling, we return back to the initial state—that is, we are “engaged” with it, and so the syntagmatic line becomes symmetrical. However, in the existential semiosis, there is no return—what happens next is always unknown, unpredictable. This evokes the idea of Levinas in his theory of Totality and Infinite (Levinas, 1971).

Another new scientific paradigm that enters into existential semiotics—perhaps paradoxically to some minds—is the biosemiotics. Biosemiotics is one of the new schools that have emerged in the last 20 years within general semiotics, thanks to writings of Thomas A. Sebeok (*see also* Sebeok, 2001, pp. 31–44), and above all to the discovery of the founder of this doctrine, the Estonian Jakob v. Uexküll (*see also* Uexküll, 1940). For the first, the surprise with this new issue is that it does NOT mean that semiotic, symbolic processes and forms were reduced into something biological—for example, in sociobiological theories that say that society at the end is nothing but biology. It is the other way around: biology and vital processes are shown to be semioses. The son of Jakob, Thure v. Uexküll has said that his father’s doctrine is particularly well-compatible with Peircean semiotics (T. Uexküll et al, 1993), but nothing prevents us from using it in other conceptual frameworks as well. To illustrate

how such semiosis functions within an organism, Uexküll uses musical metaphors; he says that every organism surrounded by its *Umwelt* possesses its codes or something like a score, which determines which signs it accepts from *Umwelt*, and which it rejects. This principle is called *Ich-Ton*, Me-Tone (*see in music* Tarasti, 2002, pp. 98, 109). Moreover, Thure von Uexküll calls this process of signs intruding the organism and functioning within it on various levels from molecules to cells *endosemiosis*. On this basis, we can speak of two kinds of signs: endo-signs and exo-signs, in these two states of being either in or out (Tarasti, 2000, pp. 37–56).

I have tried to bring the wonderful idea of Me-Tone back to music and art by arguing that every composer, every composition, every artwork also has its Me-Tone that determines its characteristics. In this new framework of existential semiotics, and its fundamental notions of *Dasein* and transcendence, we can give it a Kantian interpretation so that *Ich-Ton* appears through Kantian categories of subject (actor)-time-space when some transcendental idea is filtered into *Dasein*.

Moreover, I distinguish as-if signs (i.e., signs that must not be taken quite literally in the *Dasein*, but rather as a kind of metaphors). All signs of artistic representation are of this nature any signs in cinema, theater that should never be blended with reality. Furthermore we can distinguish pheno- and geno-signs. This has nothing to do with Julia Kristeva’s geno- and pheno-text (Kristeva, 1969), nor with Barthes’s pheno- and geno-song (Barthes, 1977, p. 182). Pheno-signs are simply traditional signs that refer to or stand for something else. When referring or standing for, the sign remains what it is—it is only a tool, a window to the world of signified. Instead in the case of geno-sign, the entire process of signs becoming signs is included: the whole generation of the sign with various phases is vividly evoked by the appearance of such a sign. For example, when we listen for the first time to the overture to Parsifal by Richard Wagner, it launches with a motif raising from the depths, as something solemn, sad, appealing, longing for something. It is a pheno-sign that by its mere musical qualities evokes certain modal content (will, can, etc.). If one is a perfect Wagnerian, then one may recognize it as the *Abendmal* motif, referring to Amfortas. However, this motif, when heard at the end of the 6-hour-long opera, gets a turn into E-flat major with a cadence, and has become a geno-sign. We feel that it contains the whole growth of Parsifal

from a young ignorant foolish into the repemptor of the Graal knights, Kundry included. It carries the whole story in it. Here again the essential is that signs are nothing fixed; they are always in the movement of becoming something else.

However, in what follows, I want to scrutinize some new issues and concepts whereby existential semiotics tries to contribute to semiotics and humanities in general. These will be discussed under the headings of Transcendence, Subject, Being, Doing, and Appearing.

## Transcendence

Transcendence is not a concept we are used to encountering in the semiotic context. Dictionaries, encyclopedias and handbooks from Greimas and Sebeok as well as Posner, Nöth, and Bouissac simply exclude it from semiotic discussion. However, no one can deny its cogency and centrality in the German philosophy from Kant to Heidegger. As far as this philosophical tradition, its idealist nature, rejected by most of semiotic theories, is more and more seen as a fertilizing seed to contemporary semiotics (like the turn to phenomenology and hermeneutics in the European context and deconstruction in the American scene show), and we cannot any longer ignore its existence. In the existential semiotics, the life of signs is situated in their movement and traffic between transcendence and *Dasein*.

To some, the mere introducing of such a notion like transcendence has some kind celestial, almost theological tinge about it. If we go in this direction (which would also be very Heideggerian as far as he considered the ultimate goal of every being and *Dasein* its disappearance, *Sein zum Tod*), we can notice that within existential semiotics we are able to deal with even such profound and serious issues. In this framework, death means the disappearance of the boundaries of the *Dasein* and the blending of a subject to transcendence. There the juxtaposition of temporality of *Dasein* and atemporality of transcendence (i.e., time and not-time) is reconciled. All that has happened in the *Dasein* (according to certain narrativity, dynamism, and processuality) has accumulated into acts of this subject. They are signs left by him that fuse together with acts by other subjects who have already moved into transcendence. This is irreversible; nothing can be changed any longer therein. They can be naturally renarrativized and rendered to constitute a part of the pseudo-narrativity and temporality of history writing. In such a case, a subject is able to “remodalize” them

(I refer here to the modal logics developed by Greimas and angloanalytic philosophers and Finnish scholar Georg Henrik v. Wright). They are again subjected to communication process. Yet, transcendence represents pure signification **without** narrativization. Therefore, one can say that when the boundaries of the *Dasein* get vague or vanish, then starts the real semiosis without narrativity. There is narrativity only in *Dasein*. When, in turn, some transcendental idea intrudes to the *Dasein* of a subject, it becomes a sign, and it participates to the communication.

Now one has to ask, what is that force that makes a transcendental idea manifest in communication or incarnate into a sign? Signs have a certain imperishable part. Goethe said: *Kein Wesen kann zum nichts zerfallen* [No being can disappear], and he certainly meant this. Nevertheless signs also have a perishable, temporal spatial, and actorial part. From the viewpoint of a subject, the manifestation of content in the physical appearance of the sign vehicle is involved. The essential point here is thus the concept of a boundary. A transcendental idea has to transgress the limit to become a sign.

Ricoeur (1983, pp. 85–129) speaks about three kinds of mimesis. Could we not then say that the becoming of transcendence into a sign in a *Dasein* is the first mimesis? In other words, the *Dasein* of a subject can simulate transcendence: man wants by his act to change his *Dasein* according to some idea. Every action is based on this: a contradiction prevails between an idea and the reality of *Dasein*. Subject wants to intervene the course of events. Existentially he can do so—that is, he is free to do so. However, when a subject in his *Dasein* creates an artwork, which is like a model of his *Dasein* (in which case the world of a work imitates his living world), then the second mimesis occurs. In the theory of Ricoeur, the mimesis essentially belongs to the course of process of communication: mimesis1 = production of sign, and mimesis2 = the manner in which a sign simulates or portrays the living world (*Dasein*). Then, the third mimesis (i.e., mimesis3) would be the same as aisthesis, the interpretation of a sign.

Instead, in our own model, mimesis does **not** take place **horizontally**, in a syntagmatic or linear way as a kind of narrative course from a sender to receiver, **but vertically** as a movement from transcendence or a subject's inner consciousness, from a transcendental subject toward his living world, **Dasein** (by a transcendental subject, we then understand a subject who, by his thought, tries to conceive

the transcendence). Following this theory, I should make a slight correction to my earlier model of transcendental journeys and acts (see Tarasti, 2000, p. 10). There are no two different transcendences, one empty and anguishing nothingness (*le néant*), and the other rich and overwhelming plenitude, full with meanings or the “world soul,” as Schelling called it. There is only one transcendence, which the subject experiences as nothingness in his act of negation, when he clings to his *Dasein* in his fear of the experience transgressing the limits of the boundaries of his existence. This is caused by his unwillingness to give up the merits, achievements, and signs he has obtained and gained in the phases of his *Dasein*. In front of the unknown atemporal and anti-narrative transcendence, he experiences anguish, and he feels the nothingness threatens the significations he has made in his *Dasein*, which he believes he has created himself. All statements about the fact that life has went down the drain, the plans, and the noemas of a subject not being realized in the narrative processes of the *Dasein* result from this metaphysical attitude. Instead, when the boundaries of *Dasein* get blurred, the subject sees the connection of his signs and acts to their proper timeless transcendence and real signification. The subject has the liberty to pursue affirmation and negation as stated above. This means here that he/she can reject the processes of mimesis1 through mimesis3. When he opposes to mimesis1, he does not want to listen to the voice of the transcendental subject within himself and does not transform transcendental ideas into signs. His existence does not reach the level of sign; it remains a series of detached moments in the process of communication without a real content. The aesthetician Kierkegaard, who gets lost in his hedonistic life, is such a person rejecting mimesis1.

The models that keep within the *Dasein* and emphasize its immanency, which claim that the only reality is the *Dasein* itself, the body, the society as a continuous process, and that nothing else exists, is based on the rejection of mimesis1. However, a subject can also reject mimesis2 or the idea that he would create intentional objects in the course of *Dasein*. He can stay without realizing that he can, by his acts and signs (act-signs), imitate and simulate the narration of the *Dasein*. An artist again creates artwork, copies, and models of his *Dasein*, in which, however, one can try to see the existential in the narration of his proper life. Music serves as such a narration on a high level of abstraction.

Again, mimesis3 also may not be—that is, the subject does not accept the idea that he should give up the positions and signs he has gained during the processes of communication. Yet, unless he does not understand to make the limits of his *Dasein* vis-à-vis transcendence more transparent and thus experience the plenitude of the transcendence—what is nothing else but the encyclopedia of the acts and ideas in the entire transcendence—he is left without this essential deliberating and positive experience, which can also change his attitude toward death, the vanishing of his *Dasein*. In fact, in every temporal artwork, such disappearance already takes place, but still the subject is after such a mini-narration transfigured, because he has mirrored the imperishable transcendental entities of his living world to the aforementioned model and become aware of them.

In any case, there is only one transcendence, but the individual who has clung to the communication processes of his *Dasein*, as rich as they may ever be, is blinded to its contents, to the true semiosis of ideas and acts and significations, and believes it is empty. Therefore, only when he abandons the boundaries of his *Dasein* or via an act of conception and is able to step over this borderline, does he realize the true plenitude of the transcendence. This experience is connected with the existential experience that he is already waited for on the other side of the boundary. All that positive or negative, which he has left in his life, waits for him in the transcendence. Thus mimesis3 means transgressing the boundary, striving to get beyond oneself and its realization.

The continuous crossing-over limits of transcendence and *Dasein* is one of the most profound problems of existential semiotics. It manifests as many subproblems of the communication processes of the *Dasein*. Is it then so that it is not sufficient that a subject hears inside the voice of a transcendental subject that tells to him the right aesthetic resolution or ethical choice, but he has to manifest this voice to others in the world of communication (i.e., encounter a subject who is alien-psycho entity to him)? Such an encounter of the **alien-psycho** is again essentially an event of mimesis2—that is, our subject creates his model of “mini-*Dasein*” not to himself but in a dialogue with someone else, and this other influences it essentially. Our subject strives for anticipating such a transcendence of the other—for example, to please him, to get his message understood. But why is this so terribly important? Why does our subject want to communicate? Communication is always crossing over the

boundary, and in this sense it is a model of both mimesis<sup>1</sup> and mimesis<sup>2</sup>. The subject wants to show by it that his message goes beyond the boundary. It is supported by the authority of transcendence, but he also wants by this communicative act to abandon his own boundaries and taste in advance what the definite vanishing of such borderlines would mean. Communication on this level of transference or shifts of values and modalities means just such a fusion with the Other. It is anticipating the final blending with the Other or the transcendence in the proper sense.

In fact semiosis has two movements or “forces”: vertical and horizontal. **Vertical** force leads into the fulfillment of ideas of transcendence, to mimesis in the *Dasein*, in such a manner that they first become noemas of a subject. Thereafter the vertical movement continues within the *Dasein* as its modeling and simulating in various texts and narratives. This represents the second degree of mimesis. The third phase is, in fact, already a kind of de-mimesis, or the return of the ideas back to the transcendence, to which they are blended. Narrativity is a special kind of syntagmatic form, which appears first in the living world of the *Dasein* and then in the world of text. In other words, they at the same time get modalized and syntagmatized to participate to process of communication. This is the **horizontal** direction of semiosis, its temporalization. On this basis, I have argued that both aspects of semiotics are ultimately of transcendental nature: communication—every act of communication is the encounter of the Other, the alien psychic, a leap toward the unknown; and signification—by signs we talk about things that are not present. Therefore, both essential sections of any semiotics, communication and signification represent for existential semiotics the transcendental: when in Saussure’s picture of a dialogue, Mr. A sends signs to Mr. B, the latter is a transcendental entity to the former; there is a gap between them, but in human communication it is not empty: it is filled by **modalities** and modalizations by these subjects—that is, the destinator and destinee. Furthermore, the signs used and emitted here are transcendental entities because they are *aliquid stat pro aliquot*—something standing for something as the oldest scholastic definition of sign is put.

### Subject Reconsidered or BEING

In the structuralist phase, subject was eliminated in favor of systems and grammars that were talking

in us, like Lacan postulated: *Ca parle*. However, in poststructuralist and postmodern theories the subject re-entered. One may interpret existential semiotics as one of these new revalorizations of subjectivity in the history of ideas, but I would not call it any “post”-phenomenon any longer; rather, I would call it “neosemiotics.” This paradigm is setting forth something radically new, using freely from the classical semiotics what it needs and combining these ideas to what is the most inspiring in the speculative philosophy from Kant and Hegel to Sartre and Marcel. It never considers only the text but all its conditions, its whole *Umwelt*, its process of becoming a text, the whole act of enunciation. There has been much talk about subjects and subjectivity in many neighboring areas of semiotics, like in psychoanalysis, gender theories, and cultural theories.

However, without a more articulated vision of how a subject appears in the enunciation and our semiotic activities, such theoretical views remain at half of their goals, as laudable as their efforts as such might be. To do so, I need to make a short excursion to the roots of existential semiotics, which means to go back to Hegel and his logics. For some semioticians, Hegel is mere conceptual poetry, to someone he was only acceptable after a Marxist turn-around, but to some like Arendt he was the most central thinker of Western philosophy altogether, who had compiled phenomena of nature and history as a homogeneous construction, of which, however, one did not know whether it was a prison or a palace (Arendt, 2000, p. 111). To Arendt, Hegel was the last word of the Western philosophy. All that came after him was either his imitation or rebellion against him. The present schools of thought (i.e., in Arendt’s case, Husserl, Heidegger, and Jaspers) were the epigones of Hegel. They all tried to reconstruct the unity of thinking and being without reaching a balance when they either privileged matter (materialism) or mind (idealism). It may be that Arendt was right. I do believe that even the semiotic thought is indebted to Hegel, whose traces we can follow both in Peirce and Royce as well as in French structuralists, the Tartu cultural semioticians—particularly in existential semiotics. Therefore, I take as my starting point only one detail from the Hegelian logic, the principle by which we construct further our theory of subject—namely, his categories of *an-sich-sein* (Being-in-itself) and *für-sich-sein* (Being-for-itself). In the Hegel dictionary edited by Michael Inwood, there is an entry *in, for, and in and for, itself, himself, etc.* (Inwood, 1992, pp. 133–136).

Hegel used the terms *an sich* and *für sich* in their ordinary senses but also provided them with contrasting meaning. As finite a thing has a determinate nature only in virtue of its relation with other things, in negation of, and by, them. This is true not only of items within the world but also of Kant's thing-in-itself, as it, too, is cut off from our cognition. Thus, a thing as it is *an sich* has no overt determinate character: at most, it has potential character that will be actualized only by its relations to other things. An infant, for example, is *an sich* rational potentially, not actually. A tailor is tailor *an sich* in the sense of having certain internal skills that suit him for this role and of having certain overt features that distinguish him from e.h. sailor. Being a tailor, or musician, thus involves an interplay between being *an sich* and being for another. But a person is not simply a role occupant. He is also an individual "I," and as such can distance himself from his role and think of himself just as *me* or *I*. When he does this, he is no longer for others but *for himself*. For example, a bus driver has already left but notices one person still running to the stop. Against the rules, he stops and takes the passenger because he feels compassion for him. Although his self-consciousness may presuppose recognition by others, an "I" is not one of a system of contrasting roles: Everyone is an I.

Moreover, the idea that if something is for itself, it is aware of itself, leads to the further idea that an entity may have in itself certain characteristics that are not *for itself*. A slave is, as a man, free in himself, but he may not be free for himself. The student is future doctor and professor, but he does not know it. Finally, the terms *an sich* and *für sich* start to mean potential and actual and may be applied to the development. When a person becomes for himself what he is in himself, he usually recognizes his identity: he becomes meaningful to himself to use semiotic vocabulary. But before we make an existential-semiotic turn-around of Hegel, let us look what Kierkegaard did with the notions of *an sich* and *für sich*. In him, they turn into subjective and objective being. In his chapter, *Becoming a Subject*, in his treatise, *Unscientific Ending Postscript* (Kierkegaard 1993, the original in Danish *Afluttende videnskabelig Efterskrift* 1846), Kierkegaard speaks about an individual who is said to be a subject, or such an individual "who is what he is because he has become like it." In the existential semiotics, such a subject who has become himself could be considered a geno-sign. The advent of a subject from *an sich*

being to *für sich* being corresponds to his becoming a sign to himself, or the emergence of his identity. Kierkegaard says: the task of a subject is more and more to take off his subjectivity and become more and more objective. The objective being is the same as observing and being observed. But this observation has to be of ethical nature, in his theory.

The next careful reader of Hegel (as well as of Kierkegaard) was Jean-Paul Sartre, whose *L'Être et le néant* was, to a great extent, based on Hegelian concepts of *an sich* and *für sich* or: *être-en-soi* and *être-pour-soi*. According to Sartre, being only is and cannot but be. But it has as its potentiality the fact that it becomes aware of itself via act of negation. In other words, in Kierkegaardian terms the being becomes an observer of itself, and hence it is shifted into Being-for-itself. This is just transcending. The *pour-soi* as the outburst of negation forms the basis for the identity. It appears as a lack. According to Sartre, this is the beginning of transcendence (as said above): human reality strives for something that it lacks (Sartre, 1943, pp. 124–125). Man starts to exist when he realizes the incompleteness of its being. Via this effort also the value enters human life. Value is the one to which one is aspiring. Being-in-itself precedes every consciousness, Being-in-itself is the same as what Being-for-itself was earlier. The essential change in Sartre's theory regarding Hegel is the movement between these two categories, and a kind of subjectivization of them considering the existence.

Now we need still one modernization of Hegel and his categories. It has been offered by Fontanille in his study *Soma et séma. Figures du corps* (Fontanille s.d.). In fact, it deals with corporeal semiotics but presents the distinction between categories of *Moi* and *Soi* in a fresh manner. As a Greimassian semiotician, Fontanille starts from actant and his/her body. He distinguishes between body and form. We speak of body as such or flesh (*chair*), which is the center of all, the material resistance or impulse to semiotic processes. Body is the sensorial motor fulcrum of a semiotic experience (Fontanille, op. cit. p. 22). Yet, on the other hand, there is a body in the proper sense that constitutes the identity and directional principle of the body. Body is the carrier of the "me" (*Moi*), whereas the proper body supports the "self" (*Soi*) (Fontanille, op. cit. pp. 22–23). The *Soi* builds itself in the discursive activity. The *Soi* is that part of ourselves, which me, *Moi*, projects out of itself to create itself in its activity. The *Moi* is that part of ourselves to

which the *Soi* refers when establishing itself. The *Moi* provides the *Soi* with impulse and resistance whereby it can become something. Again the *Soi* furnishes the *Moi* with a reflexivity that it needs to keep within its limits when it changes. The *Moi* resists and forces the *Soi* to meet its own alterity. Hence they are inseparable.

Although Fontanille is a semiotician (and albeit he quotes here Paul Ricoeur), his reasoning fits well to the aforementioned Hegelian categories. A new interpretation to *an sich* and *für sich* is involved, the first corresponding to bodily ego and the latter its stability and identity and its aspiration outward, or the Sartrean negation. The *Soi* functions as a kind of memory of the body or *Moi*, it yields the form to those traces of tensions and needs that have been inserted in the flesh of the *Moi*.

In the light of Fontanille's concepts, we could change the Hegelian Being-in-itself or Being-for-itself, the *an-sich-sein* and *für-sich-sein*, into *an-mir-sein* and *für-mich-sein*—Being-in-myself and Being-for-myself. Nevertheless, before we ponder which consequences this has in our existential semiotics, we can scrutinize the principles of *Moi* and *Soi* as such. Then anything belonging to the category of *mich*, me, concerns the subject as an individual entity, whereas the concept of *sich* has to be reserved for the social aspect of this subject. When we think now again about Uexküll's principle of *Ich-Ton*, which determines the identity and individuality of an organism, we can distinguish in it two aspects: *Moi* and *Soi*. In "me," the subject appears as such, as a bundle of sensations, and in the "self," the subject appears as observed by others or socially determined. These constitute the existential and social aspect of the subject or, rather, the individual and community side of it.

### *Moi/Soi*

I can now put together the most important ideas presented above. My intention was to specify the category of being by providing this basic modality with new species from Kant and Hegel and to follow the phases of this concept further from Kierkegaard to Sartre and Fontanille. When one aims for more subtle tools in semiotics, one can still find basic innovations at classics of the philosophy. The Being-in-itself and Being-for-itself were turned into Being-in-and-for-myself in the existential semiotics. When these notions are combined in the Greimassian semiotic square, one gets the following cases like in Figure 15.6.

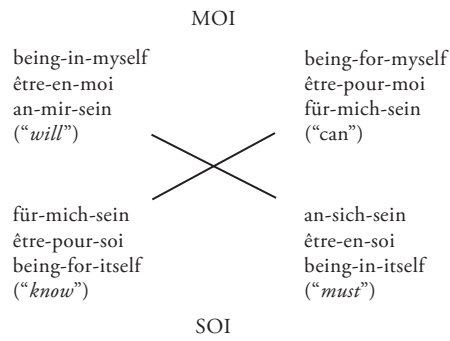

Figure 15.6 MOI/SOI

They can be interpreted in the following ways:

1. Being-in-myself represents our bodily ego, which appears as kinetic energy, "khora," desire, gestures, intonations, Peirce's first. Our ego is not yet in any way conscious of itself but rests in the naive Firstness of its being; modality: endotactic, will.

2. Being-for-myself corresponds to Kierkegaard's attitude of an "observer." Sartre's negation in which the mere being shifts to transcendence notes the lack of its existence and hence the being becomes aware of itself and transcendence. The mere being of the subject becomes existing. This corresponds to the transcendental acts of my previous model: negation and affirmation. Ego discovers its identity, reaches a certain kind of stability, permanent corporeality via habit; modality: endotactic, can.

3. Being-in-itself is a transcendental category. It refers to norms, ideas, and values, which are purely conceptual and virtual; they are potentialities of a subject, which he can either actualize or not actualize. Abstract units and categories are involved; modality: exotactic, must.

4. Being-for-itself means the aforementioned norms, ideas, and values as realized by the conduct of our subject in his *Dasein*. Those abstract entities appear here as distinctions, applied values, choices, and realizations that often will be far away from original transcendental entities; modality: exotactic, know.

The essential aspect of the model is that it combines the spheres of the *Moi* and the *Soi*, the individual and collective subjectivities. It portrays semiosis not only as a movement of the collective Hegelian spirit, but by adding the Being-in-and-for-itself the presence of a subject via Being-in-and-for-myself. Not only is the distinction of these four

logical cases crucial, but also the **movement** among them, the transformation of a chaotic corporeal ego into its identity, the becoming of ego into a sign to itself; furthermore, we have to take into account the impact of such stable and completely responsible ‘transcendental’ ego on the actualization of transcendental values, in which the ego becomes a sign to other subjects. In this phase, the Being-in-and-for-myself meets the you or Being-in-and-for-yourself, Others. Behind thus created social field looms the realm of transcendental, virtual values and norms, signs that have not yet become signs to anyone. So what is involved is also a psychological model portraying the varieties of our individual and social being **within** the mind of a subject. It shows how the social intrudes our innermost being and makes us social “animals.” In the classical sense, the semiotic sphere consists only of fields of Being-for-myself and Being-for-itself. The extremities of the semiotic square are the field of pre-signs, which surround from two sides the semiosis in the proper sense. However, in this semiosis, the process of act-signs cannot be understood without going outside of it, to the transcendence. The existential analysis hence becomes a Kantian transcendental analytics in these two phases.

Next we can start to elaborate this achronic structure, a kind of semiotic square in the Greimassian sense further. In fact, strictly speaking, it is no longer any Greimassian square with its rigorous logical relations of contrariety, contradiction, and implication. In what follows, I still go further away from the idea of such a square into a more dynamic and flexible model in which everything is in motion—as one of the fundamental theses of existential semiotics has tried to argue since its beginning.

We can now improve the model and make it still simpler by indicating those four cases of being by signs: M1, M2, M3, M4 and S1, S2, S3, S4. When

Figure 15.7 MOI/SOI

put in a semiotic square, they partly overlap as we can see in Figure 15.7.

These cases would contain the following issues, which are almost the same as above but are now seen from the standpoint of our semiotic subject in general and not as his acts embodied in texts or signs portrayed by Figure 15.8.

There are two directions in the model: one from the pure corporeality and sensibility, (M1; *le sensible* by Lévi-Strauss), to permanent, stable body (i.e. M2), and further to the social representation of the body in social roles and professions (M3), and to abstract values and norms of a society (M4; *l'intelligible, l'abstrait*). On the other hand, there is a movement from abstract norms to their exemplifications or representations in certain social institutions, and further their enactment via suitable personalities that these institutes recruit for their purposes, and ultimately certain corporeal entities. Therefore, there is in every form of square, at the upper side of the *Moi* (as we call that part of the “me” in the model), a tiny trace of the social; correspondingly in even most abstract social norms, there is a tiny trace of pure corporeality. The model itself takes place within the mind of a subject explaining how the social is internalized in it, and so, why we behave socially (i.e., obeying the laws and norms);

Figure 15.8. MOI/SOI

it explains how the society keeps us in its hold. To say it in the way of Adorno, what is involved is the juxtaposition of *Ich und Gesellschaft*. As to the idea that it would serve as a Greimassian semiotic square, I have already in my previous studies made efforts to temporalize it viewing movements among its members. So I would now rather call it a “Z” model, considering of its inner motions.

Nevertheless, the model seems to offer almost any possible type of theory or approach to human reality, depending on which aspect of the subjectivity, psychological, individual, or collective it emphasizes. For example, *L'esprit des lois* by Montesquieu (S1); *Culture in Minds and Societies* by Jaan Valsiner (2007; all M case in the light of the S:s); *Philosophy of Flesh* by Mark Johnson (M1); *Dictionnaire du Corps* (CNRS Editions 2008; all varieties of M); *Characters* by La Bruyère (M2); *Wilhelm Meisters Lehrjahre* by Goethe, *Dreams from My Father. A Story of Race and Inheritance* by Barack Obama (1995), and *Bildungsroman* in general shift from M1 to S1. We can also situate a lot of further central concepts of existential semiotics into these positions: dialogue, representation, and so forth. I leave the transcendence here out, because the model is still completely immanent—that is, it deals with phenomena of our empirical or phenomenal world, *Dasein* (it will be an essential addenda later).

However, the model evokes a lot of further elaborations. For example, it is about four stable moments of Being, but what if we consider the modality of Doing? Are the four instances there to represent a kind of “organic” growth from pure body to social norms? If yes, does this development take place by itself or by acts and activities of our subject? Is he/she able to promote or resist it—that is, affirm or deny it? As Schelling put it: either we are only looking at and observing this process (i.e., we are in a state of *Schauen*), or we can influence in it, cause it (i.e., we act via *Handeln*). How does the dialogue take place as an autocommunication among those instances of subject? Which signs and texts represent each moment? Which kinds of questions does our subject encounter in each stage?

### Questions by a Subject: From BEING to DOING

In the aforementioned scheme, man poses questions; in the cases of M, these questions are individual, whereas in cases of S they are collective. This is very typical of existential semiotics, which always tries to imagine and portray the life of signs from

within—that is how one feels to be in the position of S1 or S2, and so forth.

**M1:** In the case of M1 one may ask: Who am I in my body perceived in its chaotic and fleshly Firstness? “I wake up in the morning, I breathe, I do not feel in any pain, I exist, this is wonderful.” Avicenna, in his psychology, imagined a man floating in the air without any external stimuli, and still being sure of its existence, this would equal to the state of M1. Yet, as early as this primary being has been modalized, with euphoric or dysphoric “thymic” values as follows: which properties I have, what I am capable of, at which I am good—that is, what is involved is my sensuality, sensibility, my *Sinnlichkeit*, or to put it in terms of Lévi-Strauss, this is the “concrete,” *le sensible*, this is the case of being in archaic societies, like Suyu Indians in Mato Grosso, with a corporeal existence (but in direct touch with myths—that is, beliefs in the case of S1; see particularly the studies and video documents by the American anthropologist Anthony Seeger, 2004).

**M2:** How can I develop my properties so that I become a personality, I assume an identity? This is the idea of personality by Snellman (1848/1982), or Goethean *schöner Geist*; how I can get training and education whereby I sublimate my physical essence into a man/woman with a certain competence?

**M3:** How I can obtain a job, position, role in a social institute that would correspond to my personality, skills, and inclinations? How I become that and that, manager, artist, politician, administrator, teacher, professor, officer, priest, and so forth. How do I get a job and work that is equal to my capacities? How I can act in the community so that I become an accepted member of it and gain appreciation and success?

**M4:** Can I accept the value and norms that are dominant in my community and society—if yes, then how can I bring them on this level of ‘Fourthness’ into their brilliance, and efficiency. If no (as we can always either affirm or deny), then how can I become a dissident until the extreme negation and refusal, withdrawal from those values that I find unacceptable, and how can I then become a pacifist, ecologist, and so forth, with extreme attitudes?

Here we see that we are dealing with quite concrete cases and positions of our subject, not only with theoretical ontological varieties of different

kinds of “being.” However, from the standpoint of the society, its members, individuals (its *Mois*) are only carriers or vehicles of the *Soi*, its tools, and implementations.

Therefore equally from the *Soi* we can ask the following collective questions:

**S1:** It represents the voice of the society, its ideology, and its axiology, which appears in sanctified texts, myths. It represents the society as a virtual belief system.

**S2:** Here, the norms and principles are shifted into manifest laws, rules, and institutions. How are the activities of individual members of the society regulated, dominated, and ruled by norms and social practices; how are they channeled into acceptable form and genres of behavior? This is the same as Bourdieu’s notion of *habitus*.

**S3:** To which extent can individual personal properties and characteristics serve the society—that is, which personalities and person-types are proper material for its institutions? How are persons recruited into these practices? The interviews in job-hunting, for example, are functional here.

**S4:** How does the society penetrate even to the physical sensible behavior of an individual? How are even gender distinctions partly constructed? Here, we encounter those modalities whereby a *Soi* enacts its contracts, and those passions that make it real in the innermost individual core by emotions and feelings of guilty conscience, shame, glory, duty, and their quasi-physical counterparts of the behavior.

Involved here is the realization of *Moi* and *Soi* via four phases in two opposed directions, in the *Dasein*; the questions are linked to this movement and its goal-directness, Kantian *Zweckmässigkeit* (1790/1974, pp. 322–325), hence this constitutes the Schellingian action, *Handeln*. Yet each phase also has its existential side—that is, each phase can stop, it can cease moving automatically, organically forward by stepping into transcendence, by reflecting on each developmental stage from the viewpoint of its **essence** (i.e., that “idea” or “value” that tells us how things **should** be). However, as we know, from being itself we cannot infer in any way how it should be.

### **Consequences for the Varieties of Our Subjectivity**

I take the liberty to present these observations in the form of 17 “theses:”

**1. Every sign or text stems from its being, or a certain being behind it: ontological foundation.** Hence, the basis of this theory is in the modality of being or in the category of *Sein* in the philosophical sense. In this sense the theory proposed here is “realist” and not nominalist; the latter would mean taking into account only what is in the discourse, textual level, whereas here we postulate an agent, subject from whom these texts and signs originate. This means that we can somehow scrutinize every species and form of signs in this framework as well as we can interpret every scientific theory and discourse about human life in this context.

**2. Each sign or text is either done by a subject in a given state of being or it emerges “organically” from it.** This is one of the fundamental issues of any semiotic theory—that is, whether signs are just pragmatic, changeable, and variable tools that are all the time criticized and improved by our agents using them or whether they exist objectively and independent of choices and acts of our semiotic subject.

**3. One mode of being transforms, changes into another.** Hence, the shift from M1 to M4 can also be interpreted as a psychological development of a subject from childhood to adult. So it represents genetic course of it—noting, however, that no achieved stage disappears from one’s life anywhere when reaching a new state: man is constructed as a multileveled psyche in the course of the life. Even in the body, M1 changes physically when aging, and as Darrault has studied it, a young person or an aged one is anguished in noticing these changes and has to remodelize him/herself (Darrault & Klein, 2007). On the other hand, in a subjective microtime, within 1 day, one has to give one part of its to one’s corporeal existence (i.e., M1—eat, sleep, etc.), one part to personal hobbies in M2, one part for salary work in M3, and maybe one part for general interests, public life in a society of activity in some associations for universal values (i.e., in M4 = S1). Bertrand Russell recommended that with age the last part should become more and more prominent when M3 action is finished with a retirement. Yet this is valid in Western societies, in archaic communities the division of daily routine is different, and the same in postmodern, postindustrial society; an unemployed may be deprived of levels M3 and M4 but he can focus in his M1 and M2. Different profiles of lifestyles,

as Kristian Bankov has defined this concept in his studies on consumer society, can thus be sketched on the basis of our 'Z' model.

**4. Different modes of being are in a dialogue with each other.** So far existential semiotics has mostly dealt with only one solipsistic subject living its life in his/her *Dasein* and pursuing his/her "transcendental journeys." However, as much as on his/her own choices, he/she is formed and constituted by his/her communication with other subjects. John Dewey said that the mere communication is as such educative. Some scholars have even argued that such a dialogue is the primary issue; in other words, communication and mediation—all our ideas, concepts, and values—are nothing but absolutizations of these experiences of dialogue. The best known theory in this field is the one by Mihail Bakhtin. An entire school of psychology has been elaborated on his theory by Hubert J.M. Hermans, who speaks about "the dialogical self as a society of mind." To his mind, the dialogical self is inspired by William James in his classic distinction of "I" and "Me" (occurring also at George Herbert Mead) and by Bakhtin in his theory of the polyphonic novel. Thus, for Hermans, "Self and society both function as a polyphony of consonant and dissonant voices" (Hermans, 2002, p. 148). Other scholars of the school has confirmed this (Paul and John Lysaker in their essay "Narrative structures in psychosis: The self is inherently 'dialogical' or the product of ongoing conversations both within the individual and between the individual and others (op.cit p. 209).

The problem now here is whether we consider the dialogue as a disturbing element, ("noise") in our Z model that seems to be a relatively closed and autotelic process. Or, do we take dialogue as the precondition of any such process and shift from one phase to the other? If we adopt the phenomenological point, then the only certain thing is our own stream of consciousness; anything that happens in other's mind is only our hypothesis and constant source of frustrations in our lives when these others do not behave as we expected. Yet, the dialogue always constitutes the unpredictable element in our *Dasein*, it serves as the Freudian reality principle correcting our otherwise chainless and sometimes wild fantasies and conceptions. The other external provides us with standards, forcing elements is the transcendence.

**5. One mode of being transforms, changes into another.** This is the principle of "unfolding" development, history both in individuals and societies. There are two major narratives of such metamorphoses, one stemming from M1 toward S1 and the other from S1 reaching ultimately M1. The Finnish psychiatrist and writer Oscar Parland wrote a novel, *Förvandlingar* (Changes, Parland 1945/1966), in which he, with astonishment, scrutinized transformations of human life, in which new identities could emerge under the cover of the gastropod shell and a brilliant butterfly could come out. Or, as in Turgenev's novel, one person is portrayed in a heartbreaking incurable sorrow and anguish at one moment and appears in next, years after, talking and laughing cheerfully with others.

**6. Every mode of being has its history—that is, memory of what it was, and expectations of what it will be.** This means that the paradigms of memory and expectation are open at each moment of the process of the horizontal appearance, but in the existential sense we are not bound with them. In his speech at La Coruna world congress of semiotics (IASS), Salman Rushdie asked whether we are bound to our history or not. Expectation is again based on the modality of "believe" (Greimas) or the principle of hope (Ernst Bloch, 1985). These again are close to the modality of "knowing." Someone would say that hope is based on ignorance, the fact we do not know what will probably happen. The life is a determined semiosis in many respects; however, there is that *improbabilité infinie*, the infinite improbable that can happen and that in fact really happens, and causes huge empires to collapse; a person can achieve something against any estimates and evaluations. This was the idea by Arendt (1972, p. 221). If all the signs obtain their power in the Proustian sense in their reference to the past by functioning of the unvoluntary memory (Henri Bergson), they also can be re-articulated first by reflection and thought in our presence, and then in our textual and discursive activities, whereby these intuitions are communicated to others, and hence what was first totally private, unique, mental, becomes public, common, and ultimately a semiotic force in the sense of Umberto Eco reshaping our *Dasein*.

**7. Every sign or text is considered an appearance regarding its being; thus, being constitutes its truth.** Can we then say that the

Z model describes the essence of the world, what and how the life really is in our *Dasein*, some kind of ontological depth that then appears as our semiotico-symbolic activities? The whole theory of *Schein* is extremely important here. Yet here we speak of “vertical appearance.” To say that the truth is always conditioned by history would mean to deny this type of *Schein* (in the sense of Kant: “. . . so kann man nicht vermeiden, dass nicht alles dadurch in blossen Schein verwandelt werde”; 1787/1968, p. 116).

**8. Dialogue between two subjects carrying, “doing” them or how modes take place among their “levels” or modes.** Who speaks in a dialogue? A subject who consists of various portions or degrees of the principles M and S. That is why dialogue is transference (in psychoanalytic sense) and it is helped or obstructed by similarity, identity, or difference, strangeness between the *Moi* and *Soi*. We can say that a dialogue exists (*a*) when within the same *Dasein* the two *Mois*, *MoiA* and *MoiB*, share the same *Soi* or (*b*) when they share the same S and M (e.g., M = gender and S = values, and these two actors, x and y, in communication both have their own variants of M1, M2, M3 . . . and S1, S2, S3 . . .). For the first the Italian scholars Gino Stefani and Stefania Guerra Lisi have in their pathbreaking treatise on art therapy (*Globalità di linguaggi*, see Guerra Lisi & Stefani, 2006) have spoken about the principle of contact in all communication. How we get a contact with other persons is certainly a fundamental issue in our *Dasein*, and negatively if a speaker, performer feels he did not get a contact with his audience, or a teacher with his pupils, then the situation is lost.

Now following questions arise: (1) How does the dialogue intervene and influence our becoming and growth from M1 to S1? and (2) How does the dialogue intervene our becoming from the social man into an individual who has a unique destiny in the world, and who distinguishes him-/herself not only socially (Bourdieu) but also existentially? We can say that in the first case, our subject-actor externalizes him-/herself, becomes manifest; he/she explains himself by getting involved in broader and broader circles and contexts (explaining according to the genetic structuralist Lucien Goldmann), whereas in the latter case, it is the society, S, that understands itself by becoming more and more substantial and concrete. How does the subject in his/her state of M1 reach toward S1 in his/

her efforts to socialize, have a success in the social life, and in its desire to become accepted (i.e., in its social needs)? On the other hand, how is M1 manipulated by S1 and S2 (see theories on manipulation by Landowski, 1989, pp. 250–253) via its formation process, *Bildung*, *Erscheinen*, development?

Communication is a special type of appearance, *Erscheinen*. We have there, in an ideal case, two subjects, x and y (or Saussure’s Mr. A and Mr. B) in a dialogue. x sends a sign from his/her M1 and y answers from the position of his/her M2—for example, a young artist or student with full enthusiasm but without techniques shows something he has written chaotically by his intuition and the other answers from his/her S3: Do not try, you should first work and learn a lot! But the answer can also arrive from the destinee’s S2: you have to be first a professionally recognized artist. Or from S1: your expression has no aesthetic value whatsoever! The contact is not reached unless the subjects talk in the same level of their M/S modes. This is one source of misunderstanding among individuals and collective actors. In a therapy session, we listen to the signs of M in any case. In the real action in a society, we listen to the signs of S. If signs of M and S fall into conflict, how do we judge? This is analogous to Husserl’s distinction of two types of sign: *Bedeutungszeichen* and *Ausdruckszeichen*—that is, symbolic, conventional exo-signs as signs of S, and expressive, endo-signs, often iconic, organic signs of M. The third type of sign is transcendental signs, leading us beyond both *Moi* and *Soi*. By them we reflect on signs of M/S—that is, they form a kind of meta-language whereby we talk about our situation in the *Dasein* and transcend it.

**9. The real semiotic forces in the universe occur in the two opposed directions: from body to values, from concrete to abstract (M1–S1) or from values and norms to “khora” (S1–M1).** However, there the essential issue leading us toward semiotics of action, toward what Habermas called “*kommunikatives Handeln*” (Habermas, 1987), is whether we can trust that these forces function organically in any case, and look only if something goes wrong to correct the Z process in its right course like Zorro in the movies, or are we required in every shift from M1 to M2 to M3 = S2, and so forth, to do something, pursue a special semiotic act? If yes, what is the nature of such an act whereby we intervene in the course of the

events? Should it be studied like G.H. v. Wright following his logic of action—that is, considering how the world *p* becomes *q*? Or should we adopt the Heideggerian principle of *Gelassenheit*, or the principle of letting things happen put forth by Morris (Morris, 1956)? We can here turn to what Arendt and Schütz have said about this problem—without forgetting what Greimas first said in his Dictionary about the semiotics of acts.

**10. The encounter or touch between *Moi* and *Soi* or body and society takes place between M2 and S2.** Therefore, the essential shift is from social practices to individual or already half-socialized identities and personalities. Yet this “bridge” from M to S or from S to M cannot be separated from the whole “generative course” (NOT here in the linguistic sense!). We might say that there are two concepts that crystallize this encounter. One is “gesture,” which characterizes the cases M1 and M2, in M1 “gesture” is still only on the level of “behavior” or *Verhalten*, as Schütz and Luckmann have stated in their understanding sociology (*Verstehende Soziologie*). Yet gesture can become intentional in M2 when it is done by a person with an identity, and then we reach the phase of “acting” or *Handeln*. Nevertheless, the other important notion here is the one of “genre,” or *Gattung*, as a special type of social practice both in action and text. All genre scholars admit that it is essentially a social notion, based on a collective agreement, and presupposes a proper audience, receiver community. For example, TV, cinema, and mass media genres have been formed for special types of public, as Copley has emphasized (2001, p. 192). In literature it is constituted by readers, in music it is constituted by listeners. Therefore, the encounter of Me and Society, *Moi* and *Soi*, takes place as the meeting, blending together, or conflict between gesture and genre. Regarding gestures, Adorno has said that they cannot be developed, only repeated and intensified (1974, p. 32). They have to be sublimated into expression—that is, they have to be put in expressive genres to be influential in cultural sense, and not remain on merely the psychological, individual level. Sometimes it is the “me” who wants to impose its own new *Soi*; regarding avant-garde artwork, it is said that they create their own audience. However, this may be difficult because communication is possible only by accepting language (i.e., grammar as a social agreement and construction). A single *Moi* cannot decide it on his/her own unless he/she wants to speak an

idiolect language understood by one person only. On the other hand, genres need to be attractive for individual persons, M2s, which they try to recruit for their purposes. In this sense, genre (or *Gattung*) employs the third case of human activity called *Wirken* (impact), which means acting according to a certain plan (*Entwurf*; see Schütz & Luckmann, 1994, p. 22). This plan again is very much the same as what is called in semiotics a “narrative program.”

We might as well portray the phases leading our subject (internally) from one mode or phase to the others as: shift from S1 to S2 = virtuality; from S2 to S3 (M2) = passage to an act; and from S3 (M2) to S4 (M1) = achievement, applying the narrative theory by Brémond (1973). Here, we may only ask how this is related to the demand of existentiality? Is existentiality present in phases M1 and M2, giving thereafter a place for something “social”—that is, *Soi* that would be then the original of semiosis? Then a semiotic act would be essentially of social nature, and we would from those phenomenological adventures return to the Saussurean basis. However, if we conceive the semiotic act existentially as a transcendental act, we would rather think that our subject was able to distance from all those four modes of being, and even doings connecting them and putting them into a developmental scheme from M1 to S1 or vice versa, so to step outside of this process: Then the real leap is just based on the liberty of the subject to scrutinize his/her *Dasein* from a transcendental viewpoint and pursue thus what we earlier called a “transcendental journey.”

**11. In the analysis of subjects (of Being and Doing) and their representations (Appearing), the four modes can exist simultaneously; they are looming behind each other.**

Valsiner quotes Lewin’s comparison between American and German personality spheres and how easily its borderlines can be crossed. The structure of intrapsychological borderline system is involved. Layer 5 is the utmost subjective, deeply intrapersonal level. In the American U-type personality, it is strongly protected by resistance boundaries for outsider’s penetration, whereas the other layers (1–4) can be crossed in the interpersonal domain with relative ease. In German G-type only, the outermost layer is easily crossed; in other layers one is already more protected:

Valsiner has concluded that each person creates one’s own personal-cultural structure of the self-boundaries, and rules for entry into varied layers of

**Figure 15.9** Kurt Lewin's comparison of social relations in (a) America and (b) Germany. (Valsiner, 2007, p. 247)

**Figure 15.10** Boundaries of the self, according to Valsiner

one's self for his various roles (2007, p. 247). We could say the same about crossing the boundaries among M1 through S1 in circles.

Yet it is crucial to note that the boundaries are not necessarily fixed but vary in different situations of dialogue with other persons in the community. Signs are used to mark these spheres: clothes, such as uniforms, can signify the protection of the M1 and M2 in the social role of a priest, soldier, businessmen (nothing else but Georges Dumezil's [1971] three Indo-European mythological functions—war, religion, government—transformed into a myth of our time!). In the airplane, passengers quickly mark their spheres by leaving things around themselves. If one lets another person intrude into one's M2 or even M1, it does not hold true in another. Marshal Mannerheim could toast with a young soldier in evening party, but the next day he was again in his high position. However, the dialogical self model questions the idea of a fixed core—assuming that as Hermans defines it (Valsiner, 2007, p. 149): “The dialogical self is conceived as social—not in the sense that a self-contained individual enters into social interactions with other outside people, but in the sense that other people occupy positions in the multivoiced self. The self is not only ‘here’ but also ‘there,’ and because of the power of imagination the person can act as if he or she were the other.” This was evident as early as in the early works of Bakhtin, when he discovered the dialogical nature of any communication in the disputes in Nääveli, after the Revolution (see Erkki Peuranen: “Semiotics of disputes”; *Synteesi*, 1982, p. 45–46). This dialogical principle is organized into an “imaginary landscape in which ‘I’ has the possibility to move as in space. This is exactly what Proust said about music and its capacity to teach people to see unknown realities through others’ eyes. Bakhtin showed the polyphonic

consciousness in Dostoyevsky's novels based on simultaneity of its different narrator voices. However, I consider this view as additional to the basic phenomenological view of the fundamental nature of our stream of consciousness, as Schütz has proposed.

**12. Among the modes, there exists a process of learning from a subject's inner point of view (“know”) or of educating, teaching (“make known”).** Learning and teaching are essentially dialogue, but the problem certainly for every individual M1 is to become M2 and M3, and so forth, whereas from the viewpoint of culture, it is crucial that its values of S1 are adopted, assimilated, maintained, and renewed by institutions, personalities, and ultimately living experiencing human subjects. So, for example, if S1 = love for fatherland (*Heimat*), then S2 can = army, S3 = M2 = soldier and then S4 = M1 = a certain combination of qualities; or S1 = love for beauty in communication; S2 = theater, M2 = actor, M1 = certain psychophysical qualities (remembering that theater is always communication of communication; Ivo Olsobe); or S1 = love for beauty in sounds, intonations; S2 = orchestra, S3 = M2 = musician, M1 = certain ability to hear and for corporeal movement, kinetics, psycho-physical “harmony” (notion of the Russian school of music education). Whether teaching occurs as a dialogue between a Master with high competence and younger pupil imitating him/her or as a self-teaching process in a dialogical group or club (“*Du är själv din bästa lärare*” [You are yourself your best teacher], said the Swedish music pedagogue Gunnar Hallhagen) is an interesting educational challenge. On one hand, culture decides which texts and modalities are to be preserved and further transmitted to younger generations and which have to be forgotten. Ultimately the distinction between “culture” and

“civilization” (see Elias, 1997) concerns putting the emphasis either on S1 (as internal, interoceptive—like the Germans, *der deutsche Geist*) or M1 (as exteroceptive, sensual, pleasure—like the Mediterraneans, *die Lateiner*).

**13. Every mode of Being and Doing as well as becoming has its own ambiance, atmosphere, Stimmung, how they feel in their positions.**

Such an emotional atmosphere emerges from the isotopies, which are the basis of any action or decision making. The existential project just emphasizes this inner view of things.

**14. From every stage or mode, there are open possibilities for reflection (Schauen), distanciation, alienation, and existentiality, which means a shift to a metalevel, “meta-being” via affirmation/negation. Hence, the possibility of freedom opens in the side of necessity.** Here, we have to ponder how the transcendence appears and manifests in the *Dasein*; often, it occurs as a noise or disturbance in the communication. Let us think of such value as goodness. How can we explain that such things like goodness are a reality? Those who make good acts most often have to suffer from their consequences, not merely in the sense of ingratitude from the side of the objects of goodness, but even their hostility, and even becoming martyrs. Arendt has said that good acts have to be concealed, they can never be public. However, that cannot always be avoided. How can we explain that goodness makes people worse and not better? Because goodness means strength, by helping others, one shows he/she is stronger than the other, so it becomes a form of subordination that people consider unbearable. Yet one can argue. Goodness makes the evil appear, and when it is no longer imminent, when it is foregrounded, it can be more easily attacked and conquered. Goodness may thus seem an anomaly and disturbance. Very often transcendence is felt like that.

**15. One mode of being can compensate or sublimate another.** In the process of civilization, certain basic qualities are, via training and education, elevated from their merely physical qualities into most spiritual Thirdness-level phenomena and sign action. Yet there are limits: the lack of certain M1 properties cannot be compensated by any strong belief in certain values and cultural goals. A young person may hear in an entrance examination: “You will never become

that and that.” Prophecies often realize themselves but also cause counter-reactions that make an individual cross over his normal boundaries.

**16. Every mode of being is an actuality, but in a dialogue with others it becomes reality; yet, they originate from virtuality and they are aiming for virtualities.** Insofar as virtuality here is the same as transcendence, the problem is how do we communicate with such an entity as transcendence? Is transcendental journey or movement opposed to a dialogue in *Dasein*? Dialogue can strengthen or criticize or weaken *Moi*’s development. In fact, *Moi* is constituted by and in a dialogue only, but how can we be sure that there is a transcendental dimension in our whole existence? What we consider the voice of transcendence may be nothing but that impact of another subject on us, and via him/her the S1 what our surrounding community takes as transcendental—that is, true, absolute, under all circumstances. What is the difference and how do we distinguish between truth in *Dasein* and truth in a transcendental sense? How do we talk with transcendence? Via meta-modalities? If I want something in *Dasein*, how will that differ from the case where I want to strive for something transcendental? Does the latter mean an elevation of something into a general and universal principle for all others as well? Or if I know something in *Dasein*, how do I know in transcendence? The latter may seem irrational, absurd in the light of the former (*but: Credo quia absurdum*).

**17. Every mode of being has one dominant modality while organizing and subordinating others.** Thus, in M1 it is “will” that is the most important, everything is in a state of wanting to be actualized; in M2 “can” organizes all the other modalities, which find their place in the harmony or disharmony of thus organizing can—that is, what one realistically can do with one’s modalities, how they can be actualized. In M3, “know” gives further possibilities for enacting and actualizing and realizing modalities; the knowledge (*Wissen*) accumulated in a society in its institution provides persons with their proper position in a society. In M4, “must” operates (i.e., evaluates, orders, commands, subordinates, tempts previous modes—that is, sanctifies them). It seems to me that the modalities are built in order of their development upon each other so that they accumulate and remain valid. So essentially the “must” of S1 would never have any power

on subjects unless they would have internalized it in their own “will.” Jaspers has written about phenomenology of the “will” (Jaspers, 1948, pp. 423–435). Thanks to will, the *Dasein* is not closed in its own world but reaches beyond. There is illusion and reality. Will tries to make illusions concrete realities. Thanks to “will” the *Dasein* steps into history. With energy of will we strive in our imaginary directive of interiority toward real situations. So Jaspers conceives energy and power of “will as a kind thorough streaming force so that it connects various modes of being M1-M2-M3-M4. So will is not satisfied with satisfaction at one moment but it constitutes the ‘destiny’ and basis for the continuity of our existence” (Jaspers 1948, p. 425). On the other hand “will” is at the origin of our semiotic acts. It is as Jaspers well says: “Duration as continuity of the sense” [*Sie ist Dauer als Kontinuität des Sinns*] (Jaspers 1948, p. 425) Yet also the first sign of functioning of a “will” is bodily movement (gesture?), which should be seen as a continuation of our psychic events as it appears at a given moment (*Augenblick*). For Jaspers, this is a truly magic moment because there the spiritual directly intervenes the psychic and physical world and causes a change in our *Dasein*. Therefore, “will” is the moment that then recruits all other modalities for its fulfillment. It is the counterforce to the mere happening, organic, or automatic course from M1 to S1. So, on one hand, we have growth and becoming, full and force; on the other hand, we have doing and goals (*Wachsen und Werden, Fülle und Kraft; Machen und Zweck*) (Jaspers 1948, p. 429). In this aspect “will” might even seem to be something uncreative, it can only “want” such things that are given in that automatic process and set its goals according to the “know” of S2 and “must” of S1.

### *Appearance or APPEARING*

In the side of the fundamental modalities of “Being” and “Doing,” which we thus inherited from Greimassian semiotics, to conclude, I want to ponder the modality of “appearing” (*paraître*). One structuralist reasoning to which grand part of semiotics has stayed faithful—is that the true reality is not the one to be seen, heard, and felt, but the structure behind it, which causes it. The surface of the reality is only, as Greimas said “*effet du sens*”—that is, a meaning effect. In one word, the reality is only *Schein*, like as early as Schiller and Kant taught, or appearance or illusion.

### VERTICAL APPEARANCE

The idea of the appearance of the *Schein* is not quite a new finding; it dates back to German philosophy. Kant spoke about it in his *Kritik der reinen Vernunft* (1787/1969); in his *Briefe über ästhetische Erziehung*, Schiller spoke about it (1795/2000). Kant ponders *Schein* in critique of the pure reason in the chapter “Transcendental aesthetics.” He argues how space and time determine all our perception concerning both external objects and our own psychological states of mind; Greimas later coined terms interoceptive/exteroceptive (it is altogether not difficult to turn Kant into semiotics in the framework of Paris School). But then how do the external and internal world appear to our senses? From this, one cannot yet reason that they were mere *Schein* (*ein blosser Schein*). As early as this nuance represents the attitude that *Schein* is something less real than objects.

In any case, for Kant the term *Schein* always appears in the context of *bloss* or *falsch*—that is, something apparent in a negative sense. Adorno inherited this view directly from Kant, *Schein* was illusion, phantasmagory, which art paradoxically had to deny and abolish by its own *Schein*. Schiller became familiar with Kant’s thought immediately, and as one result we have his famous letters about aesthetic education. Yet, the radical difference to Kant was that he speaks about the **joy** of *Schein*. Savage men became humans when they were so detached from reality that they started to take it as a play and as a *Schein*, which could be appreciated as such. The dissolution from interests of the reality toward the world of *Schein* was a decisive step of progress for mankind. Consequently, we have two basic theories of *Schein*: one keeps it false, illusion, betrayal, and the other an independent, autonomous reality of its own, a great step of progress of humanity. How these theories have been inherited by later discussion about *Schein* soon will be seen. Similarly, the French phenomenologist Etienne Souriau, who also had an impact on early semiotic structuralism, like *Sémantique structurale* by Greimas, and whose monumental knowledge of the whole twentieth century was gathered in the collective work *Vocabulaire d’esthétique*, gives new meanings to the terms of *appearance* and *apparition* (Souriau, 1990, pp. 141–144).

The term *appearance* is defined by Souriau: an aspect whereby an object manifests, insofar as this representation then distinguishes itself from the object thus becoming manifest. From this definition,

furthermore, three different nuances open, which are: (1) the mere appearance of something to our senses (i.e., a phenomenon); (2) precisely the illusory appearance or illusion; and (3) the appearance that presupposes some kind of judgment (i.e., is the same as *vraisemblance*, verisimilitude). As far as what is involved is an illusion, we speak about the illusion of reality in painting or theater.

The truth of theater is based on three kinds of illusions: representation of emotions of men, the illusion of time and place or diegesis, and presentation of natural or supernatural phenomena to provoke strong emotions in spectator or to increase the credibility of the events on stage in general. The latter case also leads to the term *apparition*, which thus means appearance of something surprising to the spectator. What appears can be a real person who indeed appears at a right moment on stage—for example, the masked subscriber of *Requiem* in the movie *Amadeus* by Forman; but it can also be a real person who is imagined to be present, or it can be in reality a supernatural being, such as *Il commandatore* at the end of *Don Giovanni*. It is evident that *apparence* corresponds to the German notion of *Schein* and *apparition* to *Erscheinung*. Altogether these cases deal with *Schein* as a vertical phenomenon, in depth: it is something, somewhere, which then is elevated to the surface of reality and manifests. Also Greimas's theory of *paraitre* is of this kind. In his well-known so-called “veridictory square,” we act by categories of *être* and *paraitre* (Being and Appearing). When they are negated, we get four cases; Being, not-Being, Appearing, not-Appearing. When they are situated in the square, we get four meaning effects: truth, untruth, lie, and secret, always according to the relationship of these categories: truth is what appears and is what it appears; lie is what appears but is not that; secret is something that is but does not appear in any way; and untruth is something that neither is nor appears, as shown in Figure 15.11.

Figure 15.11 The veridictory square by Greimas

In fact, it is already on this basis that we can sketch a theory of vertical *Schein*. We notice how many topical problems of culture, art, and philosophy find their proper place in this framework. Regarding existential semiotics, a theory of *Dasein* is involved. Lehto has proposed that *Dasein* is characterized by its particular *Da-signs* (2010, pp. 156–165). But to what extent are they in reality *Da-shine* in the sense of brilliance, virtuosity, and bravura of this term? Although in *shine* there is always the same danger (as with *Schein*), or it is always under certain conditions the same as fake and illusions, the lie: Not all is gold that glitters. Without love the words are empty as it is said in the Bible.

Thus one has to distinguish between *Pseudo-shine*, which belongs to the category of vanity, and the authentic shine or brilliance, which is always based on the truth of being. What is involved can be shine, which has been gained by work according to the protestant ethics. We accept richness if it has been obtained by striving or overwhelming talents but doubt *nouveau riches*. On a symbolic level, in a symphony the law of thematic elaboration prevails: the victory finale of the end has to be earned by the struggle of thematic actorial forces in music in their *Durchführung* and in the whole structure; if in music there is shine without this work, it is entertainment, lower level shimmer. Yet there is also brilliance that is like a gift of nature, proof of vitality, overwhelming energy, like in the case of Australian aboriginal handicraft studied by Hénault (2002). The problem of shine remains in the aforementioned distinction: from which signs can we distinguish between pseudo-shine and real, good shine?

To do this, we need to compare *Schein* to *Sein*—to continue our playing with words. The appearance and being manifest in many forms and variations in the history of ideas. First, we have a pair of concepts referring to this: *structure* and *ornament*. One thinks that structure “is”—that is, it is really, is something permanent, whereas its decoration is merely the quality of surface.

Moreover, the whole theory of simulacra, copies of reality as *Schein* belongs to this category. Here, the doctrines of Jean Baudrillard get a new dimension, just as Eco's theory of forgery. The problem of a forgery is not only in comparison of two objects on the same level but in the shift of levels—in the dialectics of appearance and being, in the Kantian sense. The whole network of these concepts can be seen in Figure 15.12.

SEIN	SCHEIN	SHINE	SIGN
ETRE BEING	APPARENCE (APPARITION)	BRILLIANCE	
ERSCHEINEN PARAITRE APPEAR		ÉCLAT VIRTUOSITÉ BRAVOURE	
morality:			
GOODNESS EVILNESS	EVILNESS GOODNESS		
	ILLUSION IMAGINATION ORNEMENT		
STRUCTURE	SIMULACRA FAKES/FORGERIES		
SUBJECT OBJECT CULTURE KULTUR GEIST (MIND)	DREAM OBJECT or: SUBJECT (depending on epistemology) CIVILISATION  MATERIE (MATTER)		
life style:			
IDENTITY SPIRIT (Earth spirit)	FASHION BODY	KITSCH	STYLE
communication:			
PHRASE	GESTURE		
TRANSCENDENCE (distinction) PROFOUND	DASEIN (being-there) SUPERFICIAL	DASEIN	TRANSCENDENCE.
		either: PSEUDO-SHINE: vanity, illusion or: AUTHENTIC SHINE referring to the “truth of being” SHINE as earned (Protestant ethics) SHINE as gift of nature	

**Figure 15.12** Categories around the appearance

### HORIZONTAL APPEARANCE

Nevertheless, in the aforementioned dictionary by Souriau is a passage that opens a different view. Namely, we find the following definition for the term *appareance*: “Certain art works never appear to the spectator entirely and by all parts simultaneously. The temporal arts like music, theater and cinema, are all based upon successive appearance” (Souriau, 1990, p. 140).

Hence, when we join the idea of temporality—of succession, linearity, syntagmaticity, seriality, unfolding, developing—to such a static concept like *Schein* or being, we are lead to a radically new theory. A naive fact is that we can live our lives only one moment at

a time. So the reality all the time *appears* to us temporarily, it has a certain rhythm, which we can neither retardate or accelerate, but which altogether proceeds irrefutably. We are all the time going toward something unknown and imprevisible; we are all the time transgressing some boundary or moving toward transcendence. Schutz and Luckmann considered just such an idea of borderline essential in the idea of the transcendence. The thought could be resumed in one phrase: the appearance (*Erscheinen*) is becoming of transcendence (*Werden der Transzendenz*). Yet not whatsoever becoming is an existential revelation or realization of the transcendence—that is, existential choice. There is also blind becoming, without any

Figure 15.13 Existential appearance

chosen direction, the principle of *laisser-aller*, which means throwing and abandoning into the power of uncertain future, perhaps its narrative course leading assumingly into good. The situation could be illustrated with the scheme in Figure 15.13.

The modalities of existential appearance are: becoming (necessity) and doing (freedom) and their alternation or balance.

One could say that the existential appearance is directed only by the *Ich-Ton*, the identity of a subject (the concept has been borrowed from v. Uexküll's biosemiotics), but we cannot know in advance how it reacts in each situation. Therefore, the *Schein*, which manifests the truth of being as a kind of figuration of a structure, its ornamentation, is not yet existential *Schein* in this new sense. Similarly, the brilliance of the appearance, which is realization of the structure of being, is of course a kind of brilliance but one has to distinguish from it the *shine*, which occurs in the choice at every moment, and the fact that we are truly free to choose and not as predetermined by any structural or ontological principle.

These starting points have immediate consequences, even to such a far-seeming theory as semiotics. Namely, when in semiotics communication is the only properly dynamic temporal process in the mediation of message from destinator to destinee, we have here found a completely new deeper epistemic level: appearance.

Appearance as the existentiality of subjects and appearance in general is a still more fundamental category as communication. Which kind of semiotics might emerge if we would take this principle of horizontal appearance as our fulcrum? Which kind of theory, which methods, which analyses? I already referred to the new research program of Eric Landowski, the semiotics of life and irregularities, which are analogous to existential semiotics. But also new approaches may emanate.

Transcendence as nothingness is just such in which the appearance has stopped, the time has been finished, one is in a totally achronic state and one could not even imagine anything more anguishing

for a subject. Instead transcendence as a plenitude means the virtuality of innumerable possibilities, omnitemporality (a concept by Karsavine, 2003), which only artists have been able to conceive and simulate: Wagner in the networks of his leitmotifs in his operas and Proust by the time dimensions going to all direction in his novels. These simulacra models are *Schein* that correspond to the truth of being. Its modus is appearance, linear and horizontal.

## Conclusions and Future Directions

Existential semiotics emerged from several sources, both semiotical and philosophical. If we would try to situate it in the panorama of recent trends in these fields, one might be tempted to classify it among the so-called "post-structuralist" and "postmodern" issues. It is true that the heritage of French semiotics has been so modified there that it is in this respect a "post-Greimassian" theory. Also the concern of human subject and its living and acting in the world with all of its moral issues provides it with a certain tinge, which some others have called "semio-ethics" (like Deely, 2008 Bonfantini, Petrilli, & Ponzio, 2009). What it attempts to underline in this debate on the nature of values is that values are not relative as Saussurean linguistic theory proposed—that is, completely determined by the position of a sign in a certain system. Rather, values are considered virtual and transcendental entities waiting for their actualization in our living world. Altogether, the theory is definitely a product of our time, which perhaps is no longer any post issue but rather something neo.

Yet, it preserves the ties with the long tradition of Western thought and has not thrown itself into purely contemporary doctrines of so-called "innovation"—with commercial and technological usefulness and direct applications. However, amazingly even in this respect already existential value aspects are applied to the study of consumers' values or comparison of law systems of various kinds.

We could say first that the theory is not yet ready and completed at all. But then, to what directions should it be developed further? Should it become a complete, coherent, maybe even axiomatic system of human mind and its various activities in the world? Then the goal of such science would be a kind of system, or generative construction in which concepts and levels are derived from each other, so that it seems as if they were logically and organically growing from the basic hypotheses. That would be something like Hegel Science of Logics

of McTaggart's Nature of Existence (McTaggart, 1927/1988). On the other hand, one would then easily argue that the time of such big narratives has passed away and that the human mind, history, and experience in all its complexity and diversity cannot be any longer captured into one unified system of thought. In such a case, the theory should unfold into a more fragmentary treatise, something like Schlegel's *Athenäum Fragmente* or Ruskin's *Modern Painters* (Ruskin, 1843–1873/1987) as its goal. Perhaps such a presentation would better do justice to the contradictory nature of the world or *Dasein* that it tries to portray and mirror. The time of clean and rational generative courses has gone. One would also develop it as a discourse into more figurative expressions, supposing that meanings are created in the language and texts. Yet, the great difference to this structuralist views is that the origin is definitely a theory of subject and a kind of psychology.

In this aspect, one should think that it would grow into a direction of collective subjectivities reaching the level of communities and cultures. For any cultural theory, it would provide a new type of approach. It would, in this respect, have its impact, not yet tried, on gender theories as well. Yet keeping ourselves in the social sphere, it might next focus on the modality of Doing if so far the being and appearing have been focus. It might develop into a theory of action, and even in its radical and political sense, telling us What We Have To Do, like Leo Tolstoy once asked. However it could also flourish in the field of such an indefinable notion like transcendence. Even if this concept were originally conceived here as something purely conceptual and philosophical, it can certainly have psychological, anthropological, and even theological repercussions, like the Rumanian mathematician Solomon Marcus, who has connected it to divinity (at a roundtable on existential semiotics in Paris, October 27, 2010). I am also convinced that once having reached such an epistemic status, the theory would proceed into a new methodology of human sciences and into a new type of analysis of human mind and its various signs. As one of the most tempting fields here, it offers the artistic texts and signs, such as, say, music: after the existential approach, one could not imagine any musical or any aesthetic utterance but is simultaneously corporeal (M1), expression of human personality (M2), manifesting certain genres (S2), and fulfilling aesthetic values (S1). Accordingly, I believe the avenues opening from

existential semiotics may lead not only the semiotic theory to new configurations but also change our basic understanding of mind and culture leading perhaps into new discoveries.

## Notes

1. Since fifteen years ago I launched a new theoretical project to renew the so-called classical semiotic approach and to rethink its epistemological bases. So far I have published on this topics a monograph *Existential Semiotics* (Bloomington, Indianapolis: Indiana University Press 2000), and in addition several articles in various journals and anthologies. Moreover the Belgian review DEGRES published in 2003 a special issue on *Sémiotique existentielle* with some international reactions to these new theories. Yet recently there have appeared two other volumes in Italian and French in which the theory has become remarkably larger and aspired towards deeper epistemic levels. These were *Fondamenti di semiotica esistenziale* transl. by Massimo Berruti (Bari: Laterza Editore, Tarasti 2009a) and *Fondements de la sémiotique existentielle* transl. by Jean-Laurent Csinidis (Paris: L'Harmattan, Tarasti 2009b)

## Culture: Result and Condition of Action

Ernest E. Boesch

### Abstract

How to use human potentials constructively will be a major problem for a science of culture. This chapter covers the key issues that follow from its author's Symbolic Action Theory. That theory (which has been developed since the 1960s) has been rooted in the work of Jean Piaget, whose constructivism has opened my eyes for human creativity; Pierre Janet, whose theory of feelings started me on action theory; Sigmund Freud, whose use of free association became an important method for the study of symbols; Gaston Bachelard, with his books on the symbolism of the house, the Earth, the air, and fire; Claude Lévi-Strauss, by his studies of South American Indian myths; Raymond Firth, whose work on symbols was a great help; and the anthropologists Mary Douglas and Victor Turner, who contributed importantly to the symbolic side of the theory. Gaining multiple insights into traditional Thai customs provided the cultural contrast for the development of the holistic theory.

**Keywords:** culture, self, action

For one who has lived the horrors of the twentieth century, it is not easy to write about culture. We tend to think of culture as a special, positive endowment of the human species, and if we say that a man or a woman are cultivated, we mean that they show endearing human qualities. Yet, the deprivations of the past century were, indeed, also a product of culture. The systematic killing of 6 million Jews, Gypsies, invalids, and others were committed by science and weapons produced by our culture, applied by its members and justified by a cultural ideology. And so were the Stalinist mass killings, or the extermination of almost half of the Khmer population. Deeds, perhaps less striking but still horrible enough, have accompanied the history of culture: The burning of heretics at the stake or the stoning to death of a woman presumed to be adulterous are cultural, as are the modern terrorist killings of women and children in market places.

The writing of the Bible was a cultural feat, but using it to justify expulsion, slavery, executions, and torture was no less cultural; the extermination of whole non-believing communities of men, women, children, and cattle had been at the origin of Jewish civilization, a biblical command, contrary to the ten commandments demonstrating the Janus face of culture. The atomic bombs of Hiroshima and Nagasaki were a feat of science and a crime in the name of culture. The large depletion of forests for oil rather than food production is done with cultural techniques and for cultural purposes. Religion, of course, has benefited culture in many ways but has also brought intolerance, war, cruelty, and suppression. Science, equally, has largely improved human life; yet, it has also produced weapons with more and more destructive power and sophisticated poisons and, intentionally or not, a misuse of medical knowledge; even art had to serve ideological indoctrination and commercial seduction. Culture shows

a double face. It is man-made and as conflictual as the man himself (Boesch, 2005).

### A Terminological Note

In the following, I will often speak of *experience* and *action*, so it might be helpful to explain from the outset my use of these terms. “Experience” is the larger one. It means everything that enters our senses and our mind, be it conscious or unconscious. I consider it as equivalent to the German word *Erlebnis*, meaning what we live.

“Action” means striving for a result, therefore not all we experience is action—we perceive or feel the sun, the wind, the heat, the cold, the rain, sounds and noises, and the smile or anger in the face of a person. All these are not actions but influence our mood and our awareness of reality, and thus they may instigate or at least influence actions.

By action we experience our world, its attractions or threats, but at the same time we experience ourselves, our strength, our abilities, and our weaknesses or vulnerability. This twofold experience makes action particularly important. As a student, I learned from Pierre Janet that emotions and feelings were regulators of action, which, by making actions as frequent as emotions, required us to define them anew. If even dreams were actions as Sigmund Freud had taught us, then we would have to accept also unconscious actions, but what, then, were their goals? I finally concluded that all we do for regulating our relationship with the environment and ourselves, be it physical or mental (with the exception of reflexes), is action. Thereby action became one of the two main sources of self-evaluation (the other one being social feedback). The term, in this large conception, allows us to better understand self-formation in relation to culture (Boesch, 1975, 1976, 1991).

In the following, the word *meaning* will also be used frequently. Meanings can be public and private. Public meanings concern generally accepted purpose, function, or sign quality of a thing or an event. Private meanings consist of subjective evaluations such as beauty or ugliness, attraction, repulsion, hope, or fear. The distinction between public and private meaning is not always easy, as they can blend, and language lacks sufficiently subtle terms. We will meet enough examples for illustrating both, but I tend to use the term *meaning* mainly in its private sense. As to the term *symbol*, also frequently used, it is explained in the text.

### Culture: Basic Functions

Culture is man-made, of course, but for each newborn child it is the existing world, firm but strange, full of things to discover and explore progressively. At first a child will discover persons, the mother and other caretakers as sources of gratification and pleasure. During the first months, the child will smile at any face entering its field of vision; later, distinguishing between familiar and strange faces, it will show pleasure seeing the first and will reject the second. This is a distinction between the familiar and strange, which, however primitive, tends to remain with most people all their lives. Of course, the number of familiar and strange faces will increase, and the child will learn to differentiate between persons—yet the basic distinction will remain.

The child’s world, of course, consists also of objects, an unending realm of discovery. Objects form its space by their shape, color, weight, sound, smell, and taste; by variable illumination; and, of course, by their different use. All this the child discovers by acting on objects, experiencing curiosity and pleasure related to attractive things and places, but the child learns also to be cautious with unknown, possibly dangerous objects. Thus, the child first structures the world along dimensions of attraction or avoidance; it starts being a valence world (1963). This first organization of the environment is not yet culture—every animal also structures its surroundings along the places and objects of positive or negative valence.

Yet, this world of valences—including objects, people, and events—will soon be connected with rules: “Do this, don’t do that.” The child will discover such rules by his/her own action, which reveals the quality and function, the use, and the beauty or danger of objects. But rules result also from adults or older children, who demonstrate or teach appropriate behaviors. Important rules concern property: “No, you can’t play with that, it belongs to your sister!” Property rules emphasize the I-vs.-you distinction, and thereby the possession of things will soon manifest self-value. Although the correct use of objects requires knowledge and skill, the rules concerning property limit one’s action in a way that cannot be overcome by skill. They demand new kinds of action obeying other social rules—begging or borrowing will have to replace the act of simply taking. The child will have to learn that, which is not easy, and so property will also give rise to new emotions, jealousy, greed, and aggression. Conflicts

about property tend to be most frequent already in kindergarten and probably occupy the major time of civil courts. Without that, these conflicts can easily turn into hostility, with the loss of property felt as a threat to one's self.

These initial actions, of course, are accompanied by words. The child's world soon will become a *named* world. Mother tells her boy: "Go to the baker to buy bread." Here, the object is classified by naming, integrating it into a category of similar things, separated from "no-breads" as, for example, from cakes. Or during a walk in the woods, the mother might instruct her boy who collects berries: "Take only blackberries, leave raspberries, they are infested with worms." She classifies not only with relation to other berries but also to clean or infected ones. Thus, naming facilitates orientation within one's known and knowable world. It refers to a structure existing prior to individual experience. Even should a name be forgotten—for example, as with a technical term—we still know that the thing belongs to a named category. Language, a collective system of signs, orders the world. Yet it does so only to the extent that it is understood, understanding language is as much part of cultural learning as is naming correctly. Both are needed for useful orientation.

Words do not simply classify things and events—they also include qualities. "Don't eat these black berries, they are poisonous nightshades, you might die of them", the mother would warn her son. Words establish relationships between thing and actor—perhaps correctly, perhaps erroneously, but in both ways they constitute reality. Soon the world of the child will be somehow doubled by language, which defines qualities, and thereby conducts action.

There exists a further basic aspect of culture. Soon children will start acting on objects. As a boy, my grandfather taught me how to fashion a kind of flute from a hazelnut twig. Such transformations of reality may begin even early in phylogeny. When a chimpanzee mother takes a big stone, places on it a nut, and knocks it open with a strong truncheon, she uses elements present in her environment in a novel way. In other words, she *transforms* nature to conform with her subjective intentions. Culture starts with such transformations, subjecting nature to the wants and needs of individuals, for limited purposes at first, sometimes for mere curiosity or play, but it will become more and more complex with individual growth or social development. The baker transforms natural products into bread by making use of fire, whose destructive power he tames and

controls; cotton wool is spun, woven, and sewn into shirts, and the construction of automobiles is only a more complex transformation of natural materials and utilization of natural powers.

These transformations often require interaction and cooperation, and this, too, the child will meet early. Wanting to construct a toy, the child will have to ask for the help of an elder brother who then will need material or tools from their father. Depending on the cooperation of others, the child discovers the need for action chains. In fact, culture consists of a dense and complex web of action chains, of cooperating actors. This, besides the coordination of competences and means, also requires mutual trust. Trust is an emotion without which no culture can exist.

These are the basic functions of culture: structuring the environment along positive and negative valences; inventing language to classify things and events and to communicate about them; establishing rules for regulating action and interaction; and transforming nature to meet the desires and needs of people. And, finally, there is cooperation of actors with different competences and means for pursuing common goals. These functions, of course, engender consequences. The monkey who discovers the breaking of nutshells instigates a corresponding rhythm of seasonal behavior and fosters new habits of eating and sharing; the baker who transforms wheat into bread initiates a new breakfast culture and, as a consequence, also transformations in the environment—for example, wheat fields replacing woods. Even more so the automobile makers, by introducing new habits and skills, have altered individuals, society, and even nature and climate. The hunter who blows into the hollow leg bone of a deer or perceives the humming of the bow string discovers new sounds and, playing with them, develops musical instruments, which, simple at first, engender progressively an almost entirely non-natural musical culture (Boesch, 1998). All that, from primitive beginnings, led to increasingly complex transformations of nature, accompanied by new habits, increased skills and knowledge, new social formations, and even a change in mentality—to our benefit and peril as well.

### **Objective and Subjective Culture**

All this relates to actions by which the child structures his/her world. Such actions not only form the environment but acquire meaning themselves—actions have their significance, otherwise one would

not perform them. There is nothing invented, constructed, sold, bought, used, exchanged, borrowed, given, stolen, or destroyed without a meaning to the actor. By their meaning, things and actions become subjective realities.

Yet, meanings can be expressed by language, and then they belong to a mental system different from the inside experience. In other words, meanings named differ from meanings felt. The sentence “I am walking” says only that I move by feet somewhere in space, in a way different, for example, from running. It does not say how I walk, where to, why, nor what I see or feel while walking—language points at categories of reality, not at specifics of experience. Adding more details, such as, “I am walking from home to office,” would clarify where I walk but still nothing of the experienced meaning.

Indeed, the experience of walking implies a number of proprioceptive, physical sensations, and it includes the anticipation of a goal, related to expectations, hopes, or concerns, and it is colored not only by perceptions of the surroundings I pass by but also by a general feeling of idleness or haste, by the weather, or by unarticulated memories of other walks, and even, unconsciously, by the style of my walking—the gait of a soldier or the ambling of a sightseer are obviously felt differently, but so are, even less consciously, the walking styles of a German or of a Thai. In other words, naming the act places it within objective categories, whereas performing it relates it to a net of connotations. Let us not forget that this applies also to the very action of saying something; this, too, is subjectively experienced and has its own meanings, which, of course, differ from the content expressed: saying something addresses a person, with expectations and feelings of sympathy or unease, we try to form our speech accordingly, being aware at the same time whether we do it well or not. The addressee, on his side, will try to guess the intentions behind the words. Language has to be understood semantically *plus* the meanings connoted by the words spoken *and* by the act of speaking them.

This complexity of meanings, of course, is true for actions as well as for objects. By saying that in the center of my hometown stands a Baroque cathedral, I mention a specific category of buildings, and even adding more descriptions, my explication still remains limited to the architectural structure and objective function of the church. Although in the individual experience, the cathedral relates to religious teachings and rituals at home, in church, in

school, as well as to cathedrals seen elsewhere, it reminds of sin and merit, of guilt and atonement, of anxiety and hope. The cathedral, far from being simply a particular building, becomes a symbol for a whole complex of memories, feelings, and expectations. And, of course, why, when, and to whom I speak of the cathedral has its own symbolic meanings. Let me emphasize, these meanings are not just appended to an object, an action, or a situation: they change its quality.

The two kinds of meaning determine the relationship of citizens with their culture. The objective meaning concerns material structure, factual events, shared customs, myths, ideologies, and theories. Objectively, the Baroque cathedral stands for religious services, rituals, sermons, and their performance—in short, for customs and creeds an anthropologist might neutrally observe. The subjective meaning just described relates somehow to identification with the place and to feelings of belonging, of being at home, or, contrarily, of strangeness, even adversity. I may describe my culture, may enumerate its characteristics, but I also feel at home in it, identify with its customs and values; identifying with one’s culture is very different from factual knowledge.

All this leads to the conclusion that the term *culture* has two meanings. On the one hand, it is objective. Our surroundings are factual. Of course, most of it is created by individuals at a certain time. Yet, once produced, these creations become public facts of generally accepted qualities. Houses, individually built, become parts of the common landscape; laws, individually conceived, regulate public life. Even a poem or a painting, once published or exhibited, belongs to the factual culture. Language, man-made too, is a pervasive element of objective culture.

But how about genuine nature—the hills and the forests, the rivers and lakes, the birds, wind, clouds, storm? Although not man-made, they are given a cultural significance by classification, use, and interpretation. Trees are named, used for specific purposes, they may be inhabited by spirits one must placate before falling them; wind, clouds, thunder, and lightning may be attributed to gods or explained by science—both of course, being objective culture.

These factual elements of culture are connected with rules determining their use and function. Those rules, too, are objective facts. Shops are for selling and buying, offices for working, schools for learning, hospitals for curing, churches for services, and so on; tools have to be used correctly, traffic

codes have to be obeyed, and even forms of greeting and other social rituals are objective culture.

Objective culture shapes the person to a large extent but not exclusively. Mountain peasants may be different from seaside fishermen, yet in each of these groups individuals differ, too, and will, as far as circumstances allow, tend to select or shape their own environment—their culture will turn subjective. “My home is my castle” goes the British saying—the home area is the center of each individual’s subjective culture, from here she or he will branch out and return again. Here, the objective constraints are minimal; the individual enjoys freedom of action much more than in the outside world.

Yet, this points at a subtle balance. The inside of the home may be a place of maximum individuality, yet it is nevertheless also controlled by objective culture. Furniture, decorations, curtains, and even small gadgets in most homes correspond to public taste and fashion. Common rules of doing and acting also considerably influence personal behavior at home. On the other hand, the outside world is structured and interpreted subjectively, sometimes minimally, at other times considerably. The individual strives continuously at establishing his or her balance between subjective and objective culture. My Swiss dialect, for example, sounds typically San Gallese, yet it still retains my own personal tone and rhythm, distinguishable from other San Gallese speakers. My language, which is objective, of course, still retains a subjective flavor. How such balances are achieved remains enigmatic. The process is mainly unconscious, but usually so are the rules along which an individual realizes the subjective–objective balance in his home.

Let me try a more detailed look at this subjective–objective relationship. The pond in our garden is surrounded by a lawn, and the whole site is enclosed by big trees of various kinds. They somehow close off our private area from neighbors, and I enjoy the quiet privacy and the soothing green scenery, but I have apparently not much interest in details; I never can remember the names of many trees, cannot distinguish their foliage or bloom, and tend to confound, when mowing the lawn, kitchen herbs with weeds. My wife, obviously, also enjoys the green surroundings, but in addition she observes each smallest plant, watches their growth, knows almost personally the frogs and the newts in the pond, and distinguishes not only the song of different birds but even its change when a cat prowls in the garden.

In other words, she not only enjoys the garden, but she lives with it. Her and my objective reality are, of course, identical, yet subjectively they differ. This difference is not easy to define, because it is not simply conceptual but implies, more importantly, a difference of identification. For her, she looks at plants, birds, or frogs with a kind of spontaneous empathy. I envy her, and I might, of course, try to live up to her knowledge of the garden, but it would remain a mere cognitive competence, devoid of the feelings of identification and empathy. Her culture and mine, objectively similar, differ subjectively.

This difference, of course, has its history. My wife spent her childhood and young years in a tropical country, surrounded by a nature full of life, with plants growing almost at sight, producing fruits for food or enjoyment, with all kinds of animals, snakes, geckos, bats, rats, fishes, birds, insects—in short, a nature that required continuous attention but provided also a multitude of pleasures. And by her Buddhist education she was taught since early years, too, that all this life surrounding her was, essentially, a life similar to ours. Animals were our relatives, and plants possessed a power of their own—not simply medical but magical, too.

This difference in subjective meanings can be shown in more details with every object. Take the water lilies in our pond. For me, they are somehow imbued with my recollection of the lotus flowers in the pond near the house in which I lived for a time in Bangkok; less consciously, they also recall the beautiful reflections of the evening light on the water surface. They might surreptitiously call up other memories, such as the strange snake with tentacles like a snail I had seen swimming there or the nightly concert of frogs and toads around the pond. Occasionally, the water lilies remind me of Buddha’s parable of the lotus bud striving out of the deep water mud toward the sun. Unexpectedly even, I think of the lotus song my mother sang while as a boy I sat listening under the piano of my father. And, of course, the water lilies imply not only memories but also future anticipations—for example, the hope to re-experience such beauty.

For my wife, our water lilies also remind her of the lotus in her home nature, but her recollections are much richer, including her swimming in the nearby canals and the life of animals she observed there, but they refer also to very different lotus flowers, related to myth stories of Hinduism and Buddhism, as well as to religious rituals—lotus buds were offered to the Buddha and to monks during religious ceremonies.

In other words, lotus plants were holy plants, and therefore even the view of our water lilies appealed to very private religious feelings. Their subjective and public meaning blended inextricably.

One might object that such memories connected with the garden in no way alter its factual reality. One can enjoy it, can work in it, but always only as far as its size, structure, and content allow. Whatever the different past experiences, action still remains determined by the objective reality. This is true only if one neglects the very different garden behavior of my wife and myself. Objective reality determines our action, but we select its relevant contents, which thereby receives a meaning that is both subjective and factual. Again, the manner in which this blend is achieved remains a puzzle.

Our life does not consist of disconnected events. We want ourselves to be a consistent continuity. Therefore, what I experience now will color coming moments. While driving, I pass near the scene of a car accident, with police and ambulances. Will that not affect the style of my further driving? The beatings I received as an unruly boy still somehow influence my adult behavior, and the stories I was then told even today color my imagination. To be a permanent self implies that experience, as different as it may be, be tied by a thread of continuity—what this thread is, is difficult to tell; it corresponds to our continuous construction of the self, but we ignore what directs this construction.

Thus, it is this thread of continuity that affects the different garden behaviors of my wife and myself. Yet, these differences remain at the subverbal level. The thousand and thousand impressions that constitute a life will only rarely be present in our mind; yet, there are reasons to presume that, although latent, they still remain active. An apparently long forgotten memory may suddenly re-emerge at a particular moment, not in all details probably, but in some of its personally relevant features. Unnoticed, it was here all the time and must have melted somehow into the totality of our experience and view of life, I tend to think that this totality in some way constitutes a prism through which we perceive reality, thereby contributing to our action tendencies. According to the angle through which we look, the image perceived may change, but it still results from the same prism. Of course, that is only an image, but it allows me to understand the continuous integration of experience in an individual's life. We not only act with regard to an actual situation but continue always the thread of our life.

The example of the garden is a simile for the intimate blend of objective and subjective culture, but it demonstrates also another important aspect. When we built the house, the garden area was an uneven terrain of dirt and rubble. We had it leveled and planted the saplings with a vision of their growing big. Saplings, of course, symbolize the trees, but they symbolized as well a life in nature, with all that implies in memory and hope. Thus, we created objective culture, yet with a view on future subjective options. Those would be many years ahead—action is future-oriented. It may welcome immediate reinforcements but as a confirmation of hope.

Such distant goals require imagination, which, of course, is fed by previous experience. Imagination, however, is not simply repetitive: it expands or strengthens our action potential and can do so in quite novel ways. When we built the garden as an objective structure, we imagined it to offer not only different but also new opportunities to our every action—to anticipate newness can particularly animate imagination. Thus, a concrete situation is always open; it allows individuals their private interpretations.

### **Factual and Imagined Reality**

Action, I said, is both real and symbolic. Besides its specific goal, it always pursues other related interests—the polyvalence we already have met. We have also discussed the overdetermination, meaning that past experiences also enter the present motivation of action. Polyvalence and overdetermination constitute a major part of the symbolic variance of action and experience. Symbolism enriches the actual experience by relating it with outside contents. Those may be directly tied to present action (as polyvalence and overdetermination), may be connected with conventional beliefs (such as the lotus buds), may recall some recollection, or may be result from private imaginations, some or all of those in combination. Symbolism, thus, is complex and polyvalent itself. Although mostly unconscious, it serves an important function: to relate actual with previous experience and to thereby guarantee the continuity of our self and cultural belonging.

By its symbolism, action necessarily includes imagination. Imagination, therefore, is omnipresent. It may confine itself to the already known, but it can also reach toward the unknown. Even when weighing alternatives of an intended action, we

imagine possible outcomes, some never experienced before; imagination is a creative function.

For me, the creation of language is a striking example. Indeed, linking a sound with an object establishes a connection not present in reality. The phome “fish” has nothing in common with the animal; the sound “table” nothing with the material object. Therefore, to believe that imagination results from language puts the cart before the horse: the invention of language requires imagination.

However, language progressively becomes a major vehicle for imagination. It opens, as I have said, the realm of the unreal. And the unreal is present at every moment. Whatever somebody says refers to meanings that have to be imagined. But imagination extends further. It works already in the simple contemplation of a flower, an insect, or a bird; it colors our perception of a person, and from anticipating the results of an action it leads up to the most artificial and abstract constructions of mind. Facts, I said previously, become real only through the meanings attached to them, which implies that it is imagination that constitutes the reality of facts.

Therefore culture, consisting of meaningful facts, is also always imagined; it operates constantly on the two levels of concrete facts and imagination—the two, of course, being inextricably interrelated. This relationship constitutes reality. Each factual creation results from imagination, and for achieving its effect, it needs imagination, too. On the other hand, imaginations strive at material reality. Artists paint or sculpt their inner images, the founders of religion mold their spiritual inspirations into words and materialize them in innumerable ways. Yet, despite their close alliance, concrete action and imagination have to observe different rules. Objective action requires close observation of matter and compliance with its qualities. For imagination, on the contrary, anything is possible; even the rules of consistency, logic, and truth may often be disregarded.

Language, opening the dimension of the unreal, permits invention and fiction but also lie and deceit. Although invention and fiction enjoy much prestige and lead to the highest creations in art, literature, religion, and science, the ever-present possibility of untruth introduces suspicion and distrust. This ambivalence plays an important role in culture. Imaginative creations, like religion or political programs, may positively influence culture, but they can also mislead and provoke dissent or even deadly conflicts. Therefore, any culture invents rules that try to guarantee trust. These are not always

successful—lies can be profitable. Yet trust, necessary for any cultural community, is itself a belief based on imagination.

Trust is not only concerned with possible dishonesty; one must also trust oneself. Let me recall an aspect of language touched upon earlier. A meaning said and a meaning felt, we found, are not identical. Expressing a thought or a feeling by words unavoidably curtails or even distorts them. Therefore speech, for being understood, requires completion by imagination, and one must be able to trust it. The speaker, on the other side, needs to trust that his words truly express his intention. Both may be wrong, their trust unfounded—a cause for much misunderstanding, possibly even conflict.

Thus, pure imaginations, apparently unrelated to facts, are more than ineffectual creations of mind; they can persuade and can give rise to hope or despair, which gives them a strong emotional appeal. Imaginations not only make facts real, as we already found, but may constitute facts or suggest their existence. Aware of that, perhaps unconsciously, we often tend to believe imagination more than facts. Love relationships, financial investments, down to the preference of certain foods rely extensively on imaginations, and multiple are the conflicts resulting from imagination more than factual reality. Indeed, in Europe, religious wars were probably more passionate and cruel than territorial ones. The bloodiest war in history, World War II, had many causes, but the ideological ones were prominent. That was true as well for the crusades or the 30 Years War. In the United States, the Civil War was fought over racial ideologies, and in our days religious zeal creates bloody terror. To fight and kill for religious or ideological reasons seemed, up to our days, to many people legitimate, or even required. Cruel punishments for real or suspected heresy were widely acclaimed, and lynch justice persisted until recently. Now merely fictive imaginations can engender violence that is real.

The relationship between imagination and violence leads to two overarching concerns of human beings: To know who we are, what is the meaning of our life, and in what kind of a world we live. These are strange questions. Animals live from day to day without ever wondering about the sense of their existence. Mankind, from as early times as we know, unceasingly asks these questions. Dryness and floods, thunder, lightning, earthquakes, or diseases disturb the routine of their lives, and they start wondering about their causes. The world

seems to be full of enigmatic powers—and how to deal with them. This is an issue that appears to be the root of culture formation and has directed our evolution up to modern science. Our curiosity, the drive at increasing the transparency of our world, has brought us down to the depths of oceans, up to the expanses of the universe and into the microscopic insides of matter. It has not only immensely increased our knowledge and mastery but also our feelings of security—the enigmatic occurrences that had threatened us have largely lost their power, whereas the one of mankind has increased.

Yet, the question—*Who are we?*—still remains. We may live a longer, easier, and more pleasant life, but we still die, and for most of us, life still consists of struggle more than of pleasure. With luck, we will reach an age of pension, allowing us (again with luck) a carefree life for a few years, not enough to compensate the toil of the preceding decades. What then were all our efforts and pains for? Some of us may have the means to eschew this question—at least for a time—by accumulating pleasant experiences. The meaning of life, they may find, is to enjoy it. However, for the majority, even nowadays, this remains utopian. So what, then, was the meaning of life?

It is one of the main functions of culture to provide answers to these questions. I don't know of any culture that did not try to explain the world and the universe and to define the role and destiny of human beings. Mythology, religion, philosophy, art, science—they all compete to offer answers. These are manifold, varying from superstitious beliefs to Indian cosmology, from Egyptian religion to Greek mythology, from medieval religions to modern science. They may stress the worldly role of individuals, their social contribution, and responsibility, or they may link man's fate to metaphysical powers. Such answers, whatever they say, turn to be collective creeds; they dispel doubts, provide security, and thus induce strong feelings of belonging. Although pure imaginations, devoid of empirical proof, they tend to be taken as factual truths, strengthening the self and its social bond. This explains why any attack on such beliefs appears as an existential threat and risks to provoke violent reactions. Imaginations, not only establishing the reality of facts, gain tremendous power by constituting also our self.

Of course, the impact of factual conditions on human beings is evident. Poverty creates frustration, and frustration engenders anger and aggression. True. Yet, there exist people living in what we would call

stark poverty who are apparently content with their sort. The impact of factual conditions varies according to the meaning we attach to them. This meaning results, of course, from previous experiences, meaningful in their own way but no less from the cultural answers to the existential questions. External objects and events are real as well as symbolic.

The cultural views on life and the world take form in myths and theories; in minute details of fashion, taste, and customs; and, most strikingly, in concrete creations. A temple, a mosque, a church are not only material manifestations of cultural beliefs, but by their size and magnificence confirm them impressively. The same is true for sports stadiums or race courts, for hospitals or universities—they all resulted from a cultural ideology. Imaginations respond to facts and want to turn into facts themselves—facts, as I said, become real by imagination, but imagination strives at factual concretization. Thus, facts and imagination form that symbiotic unity that we call culture.

### *A Note on Cultural Differences*

Cultures are different. That is a truism. But how and why do they differ? Not an easy question. The usual answer is that, living in different ecological surroundings, populations are forced to develop different ways of coping. That is true, yet not a sufficient explanation. Of course, peasant cultures in moderate climates, for example, resemble each other, without, however, being identical. Or let us look at an even more instructive example: the male and female cultures, which obviously differ all over the globe. Men and women tend to differ in language, movement, taste and body care; in social and sexual behavior; and in emotional reactions, religious inclinations, art preference, and probably many more ways. Ecological conditions, being identical for both sexes, can of course not explain their difference. Therefore, it is usual to see the reason in their unequal anatomical and physiological constitution. That seemed plausible until recently but now appears less convincing. Women enter professions and occupations previously reserved for males; they compete successfully in science, sports, and other fields. Of course, child bearing will necessarily remain female, but it seems to hinder less and less their full participation in the hitherto male world. The difference between male and female culture is on the wane, because of, let us not forget, the creative opposition to the prevailing order by individuals, both women and men.

## Future Directions

The conclusion appears evident: The difference was to a large extent ideological. Cultures gave men and women a different answer to the basic question “Who am I?” Without denying the importance of ecology in forming cultures, we have to accept, too, that ideologies carry considerable weight. Why?

The question “Who am I?” asks for evaluating oneself. Self-evaluation derives mainly from two sources: action potential and social feedback. The action potential results, as we know (1976, 1991), from previous successes and failures, allowing the individual to conceive future actions – the action potential is prospective. But what is a success; what is a failure? We need criteria to evaluate them, and apparently it is social feedback to our behavior that mainly provides these criteria. Yet, social feedback is multiple and often contradictory, the one may praise what the other blames, and they may also differ from own evaluations. Therefore, the individual will select among social reactions and form personal criteria of success and failure. Those, however, will still result from cultural inputs. Thus, action experience blends intimately with cultural evaluations.

Let us look again at female culture. Cultural imprinting starts early. Soon the child will exhort: “No, that is not for girls”; or “Don’t act boyishly”; “A good girl will behave this way” and so on. Advice and examples will lead the growing girl to identify with her female belonging and its appropriate behaviors. She will learn sewing, knitting, and cooking rather than working wood or metal. She may rebel occasionally, may reject certain constraints, but on the whole will accept being a woman to be one of her tribe with its particular culture. However, only to be a woman is no sufficient answer to the question “Who am I?”. The individual wants to know “What kind of a woman am I?”. Within the confines of their culture, each person seeks to form and define their particular identity. This may be easier in some cultures than in others because cultural constraints vary. The cultural ideology provides security but limits also the individual’s personal way of life. To some, security counts more, for them culture is a welcome stabilizer, which lets us understand that many women at first resisted the feminist revolt. It threatened their self and the gratifications related to cultural identification.

We all belong to many cultures—national, sexual, religious, professional ones—each with their conditions for membership, their rules, benefits, prohibitions, rituals, even their particular language.

They are subcultures within an all-encompassing cultural field with its own opportunities and demands. How can we maintain an individuality in balance with such diversity? Some may choose to howl with the wolves, to bark with the dogs, and to sing with the birds, being content to be simply what each situation requires. Himmler was, without qualms, a family man, an amateur musician, and a killer of Jews. Others may strive at an independent self, consistent over variable situations. Such a self will, of course, not be culture-free but will integrate creatively diverse cultural elements. For those, to maintain a balance between self and diverse cultures requires creativity, critical understanding, and empathy. Such individuals, history tells, can influence their culture in important ways, but on a more modest level, everyone may contribute to shape their close or even distant world. Each of us leaves his or her traces wherever we dwell and act—it is worth pondering about what kind of traces we wish to remain. Human beings, although products of their culture to a major degree, still also shape or even transform it—some minimally but some also with considerable impact. Science may often prefer to neglect human creativity, looking at individuals as mere results of outside forces. Yet, without considering the balance people create between mind and culture, we would never understand the emergence of cultural differences. Let us, however, remain mindful. Human creativity, history tells again, can benefit as well as harm our lives and world. How to use human potentials constructively will have to be a major concern for a science of culture.

# Culture-Inclusive Action Theory: Action Theory in Dialectics and Dialectics in Action Theory

Lutz H. Eckensberger

## Abstract

The following chapter deals with the concept of Culture-Inclusive Action Theory (CIAT) and research the author and his coworkers conducted primarily in Saarbrücken (and later in Frankfurt) over the last 35 years in two (complementary) subject areas, which also form the roots of the chapter: cross-cultural research and development of moral judgment in the tradition of Piaget/Kohlberg. In cross-cultural psychology, the duality “person versus culture” is unavoidable. In moral development, the dualities “content versus structure,” “facts versus norms,” and “affects versus cognition” are likewise unavoidable. In both research fields, the assumption of a dialectical relation between these dualities and the role of action theory in relation to dialectics was and still is attractive. In the following this role is interpreted also within Dynamic System Theory, by the concepts of upward emergence and downward selection, which are synthesized by the human action. This theoretical orientation from the very beginning called for its justification vis-a-vis mainstream psychology by implying meta-theoretical reflections. After a short introduction into dialectics and action theory in psychology, a more detailed treatment of the two research subjects are presented. The first step in both topics was (biographically) a systematic theoretical analysis dealing with the meaning of culture for psychology and the deep structure of moral development. In both topics the (descriptive) application of action theory and the (interpretative) appropriation of dialectics was productive and lead to contextualized research by conceptualizing a “regional cultural identity” on the one hand and formulating “types of everyday morality” on the other. This cultural contextualization is the reason for calling our approach *Culture-Inclusive Action Theory* (CIAT). A later study on the process of coming to terms with cancer was based on the same theoretical model; developed in both fields (culture and morality), it was also methodically contextualized from the very beginnings.

**Keywords:** moral judgment, culture, action, dialectics, cross-cultural research

In cross-cultural psychology, the duality “person versus culture” is unavoidable (e.g., Eckensberger, 1979, 1990a, 1990b, 1996a, 1996b, 2002a, 2010a; Krewer, 1990). It has a long tradition in culture and personality studies (for an overview, see Eckensberger & Römhild, 2000; for an early critique, see Shweder, 1980). In moral development, the dualities “content versus structure” (Eckensberger, 1986; Eckensberger & Reinshagen, 1978, 1980; Eckensberger & Burgard, 1986), “facts versus norms” are likewise unavoidable

(Breit & Eckensberger, 2004b; Eckensberger, 1993a; Eckensberger, 2006a), as is the duality of “affects and cognition” (Eckensberger, 1989a; Eckensberger & Emminghaus, 1982; Villenave-Cremer & Eckensberger, 1985). In both research fields, the role of action theory in relation to dialectics in dealing with these dualities was and still is attractive.

The first step in both topics of research was a systematic theoretical analysis dealing with (1) the meaning of culture for psychology and (2) the theoretical

foundation of moral development. Both topics lead to contextualized research by conceptualizing a “regional cultural identity” on the one hand (e.g., Krewer & Eckensberger, 1990; Krewer, 1990) and formulating “types of everyday morality” on the other (see Breit & Eckensberger, 1998; Breit, Döring, & Eckensberger, 2003; Döring, Eckensberger, Huppert, & Breit, 2008; Eckensberger, 2006; Eckensberger, 2010b; Eckensberger, Döring, & Breit, 2001). A later study on the process of coming to terms with cancer was based on a theoretical model, which was developed in both fields of research (culture and morality) (e.g., Eckensberger, Kreibich-Fischer, Gaul, & Schnurre, 1990). However, this study also contributed to the model itself, although it is not closed yet. The following chapter rests upon these studies. But the action-theoretical orientation from the very beginning forced me to justify this approach in the context of mainstream psychology by “meta-theoretical” reflections (Eckensberger, 1979, 2002, 2003, 2006, 2010a, 2011a, 2011b). This work will also be summarized in the following. Molz (2010) has recently reconstructed my work also by comparing it with the theories of Yrjö Engeström and Jacques Demorgon.

Although the Culture Inclusive Action Theory (CIAT) is genuinely developmental, the chapter does not intend to give an overview of action theory in developmental psychology in general. Examples for such overviews can be found in Brandstaedter<sup>1</sup> and Lerner (1999) and with reference to social cognition in Eckensberger and Plath (2006a). Rather, the chapter by necessity has a historical (autobiographic) dimension, which implies (1) that it not only rests on my recent work, but it also starts with its root in the 70s; (2) it also sometimes refers to unpublished work like reports; and (3) to save space, sometimes larger chapters I contributed to handbooks or reviews are referred to, which contain detailed literature dealt with in the following.

### Multiple Views on Dialectics in Psychology

The term *dialectical/dialectics* has a long and complex history. Briefly characterized, dialectics can be regarded as (1) a basic principle in dealing with dualities in development/progress (often) in form of a spiral (not helix), also known as the negation of negation; (2) dealing with (overriding, synthesizing) dualities, or contradictions (thesis, antithesis); and (3) the transformation of quantity into quality that implies nonlinear concepts of development. Often it is understood as a principle of interpenetration or interdependency between dualities. Furthermore a

distinction is made between dialectics as an inherent aspect of things or thought (although this distinction is difficult to maintain under a constructivist perspective), but dialectics is also considered an assumed relation between concepts and an operation.

Dialectic thought exists both in the West and in Eastern philosophies—for example, in Taoism (Lin Yuang, 1948). In the West it goes back to classical “old Greek” philosophy (Aristotle, Socrates, and Plato); it was a topic in medieval philosophy but primarily in the modern philosophy of the nineteenth century. Here the outstanding figures are Hegel and Marx, whose political impact certainly did not contribute to an appreciation of dialectics in science. Yet, later it played a role in the Frankfurt School (Horkheimer & Adorno, 1969). These authors already indicate that dialectics was/is not only relevant for psychological theorizing but also for sociology and, in fact, for all sciences that deal with development/change and with dualities (e.g., nature vs. nurture; individual vs. society/culture; norms vs. facts; theory vs. practice, etc.) and thus also for biology (Levins & Lewontin, 1985) and even physics (Cross, 1991).

### *Dialectical Thinking and Developmental Psychology*

As the work, summarized here, began in the 1970s, a word about the “Zeitgeist” of that decade is in order. During that time, dialectics received considerable attention in *developmental psychology* (e.g., by Riegel, 1979; Rychlak, 1976; Schmidt, 1972; Datan & Reese, 1977; Buss, 1979). But the reception of dialectics in psychology was also quite critical. Psychology was—and still is—heavily influenced by Popper’s (1959) critical rationalism, in which the principle of falsification is crucial. It is plausible therefore that for Popper, contradictions (antithesis in dialectics) cannot be *logically* accepted as valid. This argument is explicitly formulated in Popper’s early criticism of dialectics in a paper entitled “What Is Dialectic?” (Popper, 1937/1963). There, he concludes that “two contradictory statements can never be true together” (1963, p. 5). It is important to realize, however, that basically Popper evaluates a “newly formulated” perspective by using traditional criteria of Boolean two-valent logic—which the originators of dialectics Hegel and Fichte had left behind more than a century earlier.

Baltes, Reese, and Nesselroade (1977) stated: “What the basic metaphor of dialectics is, is open

to question” (p. 26), and in the same year Baltes and Cornelius (1977) speculated that “many developmentalists . . . are attracted to dialectics as a philosophical theory or as a theoretical orientation . . . however, whether the convergence of research issues in developmental research with the proposition of dialectics is more than a temporary courtship is another question” (p. 123). Hook (1957) and Mehlberg (1955), like Popper, evaluate dialectics in terms of a traditional scientific method, when Hook states:

“the dialectic method can claim to have meaning and validity only when it is understood to be synonymous with scientific method, and that therefore there is no need to talk about dialectic method at all.”

(Hook, 1957, p. 27, quoted by Baltes and Cornelius, 1977, p. 126)

In contrast, Baltes and Cornelius (1977) have discussed different aspects and levels of the principles of scientific method much more moderately and in more detail. They claimed pragmatically or strategically: “In order to implement a dialectical perspective, pluralistic but systematic methodological procedures are necessary” (p. 130). This argument is based on their effort to break the associative link between the dialectical perspective and paradigm as well as between paradigms and the scientific method. They argue, “A dialectical perspective need not be linked with a specific metaphysical . . . paradigm nor with a specific epistemological model, but may be better implemented by the utilization of multiple world views or meta-paradigms” (p. 130). The same is true for “lower-level research methodologies” (p. 130). So these authors somehow tried to eat the cake (take a dialectical perspective) and keep it too (by sticking to traditional scientific methods). In other contexts Baltes, Reese, and Nesselrode (1977) used the term *dialectics* at the same formal level as “mechanistic” and “organismic” (p. 23 ff.), thereby suggesting a specific paradigm (see p. 877 ff.). Yet, as will be shown, I have not only argued slightly differently (see Eckensberger, 1979), but I am still convinced that the assumption of dialectical relations is productive in science and psychology in particular.

### The Action Theory Enters the Scene

Important aspects of action theory can be summarized as follows (Eckensberger, 2001a): Action theory is not a formalized and unitary theory agreed

upon by the scientific community but, rather, a *family of theories*. Like dialectics, action concepts also have a long and complex history, again going back to the “old Greeks” (Aristotle) and existing since the very beginning of the formal discipline of psychology in the last century both in Europe and North America, although it varied in saliency during its history. In the psychology in Germany in 1874, Brentano, a teacher of Freud’s, focused on *intentionality* as a basic feature of consciousness, leading to the concept “*acts of consciousness*.” Ten years later, Dilthey (1894/1968) distinguished between the *explanation of nature* and *understanding the mind/soul*, a duality that paved the way for the ongoing discourse on the *duality of explanation and understanding* (v. Wright, 1971). At the turn of the twentieth century, Münsterberg, a disciple of Wundt and one of the founders of an applied psychology, proposed *action as the basic unit* of psychology rather than sensations. In North America, James developed a sophisticated theory of action at the end of the nineteenth century, which anticipated a remarkable number of action theory concepts (see Barbalet, 1997). These early traditions were, however, overruled by the neo-positivistic *logic of explanation*, expounded by the Vienna circle in philosophy that was quite in line with behaviorism in psychology. They were taken up in philosophy by Wittgenstein’s “language games,” which are assumed to be different in natural science and the humanities. In 1920, Stern criticized the mainstream psychology of the time because it neglected *intentionality* and also *cultural change* as a framework for human development. And it is probably no wonder that Bühler (1927) and Vygotsky (1927) both published on a crises of psychology in the very same year.

### Action As the Basic Unit of Analysis

When seen from our contemporary vantage point, action theory terms have increased in importance again during the last three or four decades. Bruner’s (1991) “acts of meaning” elucidated the difference between meaning and information and focused on contexts. Freese and Sarbini (1985) published on goal-directed behavior, whereas Martin, Sugarman, and Thompson (2003) discussed the question of agency in psychology. In Germany, Boesch (1991) published a remarkable introduction to his Symbolic Action Theory (see also Boesch, 2011). Its development was recently carefully reconstructed by Lonner and Hayes (2007). Groeben

(1986) analyzed the relation between the concepts of action, doing, and behavior (historically as well), and Straub (2006) discussed action theory from a linguistic and cultural point of view and published an interdisciplinary discourse on action theory (Straub & Werbik, 1999), to mention but some of these developments. In fact, the term *action* also has a long and controversial history in philosophy. At least Juarrero (1999) and her discussion of action as a complex system is to be mentioned here, also because some of her concepts will be used in the following as they are quite compatible with my own theoretical orientation.

### ACTION THEORY IN DIFFERENT FIELDS OF PSYCHOLOGY

Although not a focus of mainstream psychology, action theory is also applied (implicitly or explicitly) in a variety of its subfields. This is true for basic science—in theories of motivation (e.g., Heckhausen, 1989; Gollwitzer, 1990; Kornadt, 1982)—problem solving (e.g., Dörner & Kaminski, 1988), ontogenetic *development* (e.g., Oppenheimer & Valsiner, 1991; Brandtstaedter & Lerner, 1998), social psychology (von Cranach, 1991), and particularly cultural psychology (Boesch, 1971, 1991; Cole, 1990; Eckensberger, 1990a, 1990b). It is also true for educational psychology (Bruner, 1996), organizational psychology or psychology of work (Hacker, 1986) sport psychology (Kaminski, 1982), and “applied domains”—for example, in clinical psychology or counseling (Janet/Schwartz, 1951; Eckensberger & Kreibich-Fischer, 1994; Eckensberger & Plath, 2006b; Plath & Eckensberger, 2008).

Particularly the applied domain is of central importance here, because since the very beginnings there has been a conceptual split between general nomothetic psychology and psychology as a means to solve individual and social problems. This tension is one reason for the development of an “ecological orientation” of the 1970s focused on the issue of “two realities” (Boesch, 1971) of real life and the laboratory. Therefore, I have proposed (Eckensberger, 1995a, 2003, 2004) to allocate two different types of actions to these fields (theory building and problem solving) that have quite different criteria and implications. A similar distinction has been made recently by Smedslund (2009), who additionally called for taking problem-solving strategies more seriously in science. But basically I (Eckensberger, 1989a) interpreted action theory as a bridge between theory

and practice, between general laws and contexts (*see also* Eckensberger, 1979, 2003, 2004). In addition, an action-based cultural psychology, for example, becomes an integrated enterprise that is developmental as well as cognitive, affective, and motivational (cf. Boesch, 1976, 1991; Cole, 1990, 1996; Eckensberger, 1990a, 1990b).<sup>2</sup> Considering the breadth of action theoretical frameworks, it is not surprising that neither are the issues studied similar nor is the terminology coherent or fully agreed upon by different authors or traditions.

From an analytical perspective, to *act* does not mean to *behave* (although some authors consider actions as a particular subtype of behavior). To speak of an *action* rather than of behavior implies at least the following features:

1. Broadly speaking, it means that sentences, symbols, but also mental states *refer to* something in the world (Searle, 1980). *Intentionality* basically means *that a subject* (called *agency*) *refers to the world*. Intentionality, therefore, is intrinsically a *relational* concept. Agencies refer to the world by *acting* with reference to the world, by *experiencing* it (they think, feel, perceive, imagine, etc.), by influencing it (actions are genuinely contextual), and by *speaking* about it. The latter is called *speech act*. An *intentional state* thus implies a particular *content* and a *psychic mode* (a subject can *think* that it rains, *wish* that it rains, *claim* that it rains, etc., where rain is the *content* and thinking, wishing, and claiming are *modes*). The *intent of the action* is the intentional state of an action; the *intended consequence* or *goal* its content. This implies what is also called “futurity” (Barbalet, 1997) or future orientation of an action. It follows that actions are not necessarily observable from the outside. If they are, one also uses the term *doing* (Groeben, 1986). However, *intentionally allowing something to happen* as well as *intentionally refraining from doing something* are both actions (von Wright, 1971; Janich, 2006).<sup>3</sup>

Furthermore, it is assumed that action involves the subjective *free choice* of alternatives to do something (A or B), to let something happen intentionally or to refrain intentionally from doing something. This condition is closely related to the (subjective perception) of *free will*. Although the control aspect is sometimes also expanded to include the *intended effects* of an action, these two aspects should be distinguished, because the effects of an action can be beyond the control of

the agency, although the decision to act itself was controlled by intentionality.

2. Actions in principle are *potentially conscious activities* of an *agency*. But the consciousness of actions is discussed differently by different authors. Whereas some authors claim that consciousness is a necessary aspect of an action (which also implies the methodical possibility of asking actors about their actions), I have claimed that only the *potential* self-reflectivity of an agency (and a specific action) is crucial (Eckensberger, 1979). This not only implies that a self-reflective action may be a rare event (e.g., during a day) but also that actions can turn into automatisms or habits, yet still remain actions. This rather tricky issue was a problem in action theory from the very beginning. In Paris, Pierre Janet wrote his dissertation about *Automatisme psychologique* (Janet, 1889) to deal with non-consciousness in actions. This was the beginning of an elaborated action theoretical system of neuroses (see Schwartz, 1951). Freud (1923) of course chose a different solution of non-conscious actions in conceptualizing a dynamic unconsciousness, but he also postulated a “descriptive unconsciousness” (habits). This implication, however, calls for the analysis of the *development of single actions*. That is one reason why *development* is a genuine and crucial dimension in many action theories (as *micro-process* or *actual genesis*, as *ontogenesis*, and as *social/cultural change*; see Fig. 17.1).

3. Back in 1979, I therefore proposed interpreting action theories as a “theory family” (Eckensberger, 1979) based on the *potentially self-reflective subject or agency* (see p. 881). This position relates to the basic issue of whether *Homo sapiens* have a *special position in nature*, because this species is, as far as we know, the only one that can decide to a certain extent *not to follow natural laws in their actions* but can intentionally and reflexively follow *cultural rules* (e.g., of prudence, of social/cultural conventions, morality, law, and religion) as well, which (s)he also “created.” This intentional rule following implies that although an agency is in principle considered autonomous, actions are not arbitrary. It is important that the term *agency* is not restricted to a single subject here, but it may also include others or even groups (Eckensberger, 1990b, 1996b). Therefore we sometimes speak also of co-agencies or co-actions, which imply shared goals and/or coordinated actions.

4. The tension between autonomy (free choice) and heteronomy (intuitive<sup>4</sup> rule following) is basic to many action theories and is therefore also the focus in the social/cultural context of actions (cf. Parsons, 1937/1968). One can try to resolve this tension, however, by assuming that cultural rules and their alteration are also man-made, although the implied intentionality of cultural rules/norms may “get lost” over time. This is why Smedslund (1984) can understand culture as “the invisible obvious.”

In principle within this theoretical frame, an action links the actor/agency and his/her environment (see James, 1897). Intentionality is not only a core concept for understanding the individual/agency (Eckensberger & Meacham, 1984), but at the same time it is also possible to conceptualize culture as being the result of actions and co-actions (Eckensberger, 1979, 1990a, 1990b, 1996b) or as an intentional world (Shweder, 1990).<sup>5</sup> We (Eckensberger, Krewer, & Kaspar, 1984, p. 99) elaborated on this issue by claiming that actions result in material social and symbolic changes of the environment on the one hand (this is why culture is sometimes understood as “the man-made part of the environment,”; Herskovits, 1948), and they result in the development of cognitive and affective schemata in the subject on the other hand. The specific cultural contents and rule systems constitute both the cultural context, the external medium (Cole, 1996) in which development occurs, and what is in the minds of members of a concrete culture (D’Andrade, 1984). Most importantly:

Both processes are preconditions, which are contextual conditions for further acts. It is this *dialectical interrelational process between material and ideal action contexts* that is the key to understanding cultural change.”

(Eckensberger, Krewer, & Kaspar, 1984, p. 99, italics LHE)

We sympathized then with the work of Berger and Luckmann (1966), who relied extensively on human action to explain (or speculate about) the development of society (culture). We specified:

(1) Every human act is subject to habituation and each action solidifies into a model; (2) this habituation of actions is standardized reciprocally in the fundamental dyadic face-to-face situation with two actors; (3) if this standardization is communicated to a third member (e.g., socialization), this makes it possible to distinguish

types of actors as well as types of actions and this in turn results in the formation of institutions. Thus institutions have a history, which creates them . . . (but) the logic of institutions does not consist in its external functionality, but rather consists in the way it is reflected by their participants.

(Eckensberger, Krewer, & Kaspar, 1984, p. 100)

Similarly, White (1959) understood culture as a set of extra-somatic symbols (symbolates), which are ossified forms of human activities. This does not mean that all historical changes are intended; they can, of course, also be unintended—an aspect that Graumann (1996) underlined when he interpreted Wundt's early ideas on historical change. So, cultural psychology does not focus on concrete cultures but on the general *concept* of culture and its relevance to psychology.<sup>6</sup> And, as proposed, thereby psychological and cultural concepts are intrinsically and mutually inter-connected.

Of course, this perspective poses a serious problem for understanding psychology as a natural science based on functional or (efficient) causal processes. It was again Boesch (1971) who aptly pinpointed this tension when he formulated: "It is the dilemma of psychology that it deals as a natural science with an object that creates history" (p. 9, translated by LHE). It is evident that this leads to serious (epistemological and methodical) problems, as long as psychology is understood as a natural science, which basically tries to interpret events/processes in terms of causes and/or functions. No wonder that this general action theoretical perspective (in my version of 1979) was strongly criticized. Malpass and Poortinga (1986), for example, argued like Popper (1937) and Hook (1957) by basically understanding psychology as a natural (nomothetic) science and likewise by evaluating the self-reflective paradigm from a mainstream perspective. Consequently, they first claimed that action theory concepts have to be "formulated in *causal* terms." And, in fact, also some philosophers try to explain actions by interpreting beliefs and desires as *causes* of actions (e.g., Goldmann, 1970). But there is more or less agreement at present that actions cannot epistemologically be *explained* by (efficient) *causes* but have to be *understood* in terms of their *reasons* (cf. Habermas, 1984; von Wright, 1971). Juarrero (1999) also criticizes the attempt to apply the deductive-nomological model to understanding actions. Additionally, I (Eckensberger, 1996) have argued that *causality* usually is *empirically defined* by *intentional actions*

(variations in experiments), implying that the relation of causality and finality is exactly the other way around: finality is the precondition for defining causality (von Wright, 1971). But actions cannot be explained by the same rational. Second, Malpass and Poortinga (1986) have argued that "culture as the product of human actions transcends behaviour as studied in psychology" (p. 29). I also have refuted this argument (Eckensberger, 1996a) by showing that behavior alone is too narrow an object of psychology. Even in cognitive anthropology, culture is located in the heads of people (D'Andrade, 1984), and behavior never occurs without a context.

The *course of actions* is particularly relevant in empirical contexts. Analytically, actions are divided into *action phases*. The number and features of these action phases differ, however, according to one's issue of concern. Whereas Boesch (1976, 1991), in following Janet (Schwartz, 1951), distinguishes three main action phases (beginning phase, its course, and end), others (e.g., Heckhausen, Gollwitzer, & Weinert, 1997) later propose four phases (a pre-decision phase, a pre-actional phase, the action phase [doing], and a post-action phase) for Heckhausen's work on motivation. Here, the decision to act plays an important role (Heckhausen uses the metaphor of crossing the Rubicon). We (Eckensberger & Emminghaus, 1982) distinguished a total of six action phases in dealing particularly with "action barriers/impediments" (perception of the situation; attribution of the origin of a barrier, attribution of responsibility for the barrier; estimation of action possibilities; decision to act; post-decision). Kornadt (1982) also used six quite similar phases for analyzing aggressive actions (analysis of the situation, activation of the aggression motive, evaluation of the action, decision to act, act, and action result). For a critique/refinement, see Eckensberger (1988). Within all these phases, there is an *interplay between cognitive, affective (motivational), and energetic aspects* of the action.

## Dealing With the Duality Personality and Culture *Toward a Dialectical Relation Between Personality and Culture*

The sub-branch in psychology that dealt with culture in the 1970s was cross-cultural research. The International Association of Cross-Cultural Psychology (IACCP) was founded in 1972. Its members followed the experimental logic, which was the methodical ideal of mainstream psychological

research at that time. Therefore, cross-cultural differences were considered a consequence of an experiment in nature. Consequently, culture was understood as an independent variable having (a causal) influence on practically all psychological constructs. Cross-cultural psychology was thus understood primarily as a method (Berry, 1980; Boesch & Eckensberger, 1969; Eckensberger, 1969; Eckensberger, 1973; Whiting, 1954). My own (contextualized) research in a foreign culture (Afghanistan) was also at first undertaken from a mainstream (nomothetic) perspective (e.g., Eckensberger, 1968, 1972, 1973). However, in the long run it resulted in critical reflections on this mainstream approach (Eckensberger, 1979), because I learned more about the limits than possibilities of the traditional research strategies (for a summary, see also Eckensberger & Plath, 2003) in dealing with foreign cultures. So fairly early, I came to the conclusion that to really understand the meaning of data collected in a foreign culture, one should develop a theory *that not only explains ontogeny of an individual but also culture and its development* (Eckensberger, 1979, 2003, 2010). This was in line with Riegel's (1975) demand that developmental psychology should aim at analyzing "the changing individual in a changing world," but it was more than that: it called for a *theoretical inclusion of culture into psychology*—particularly called for also by Boesch (1991), Cole (1990), and Valsiner (1987), whose biographical examination of the culture concept in psychology was carefully reconstructed by Mey and Mruk (1998). He was probably the one who most explicitly argued that culture was not an independent variable (Valsiner, 1988).

To check whether existing theories can meet this demand, I followed and extended the meta-theoretical perspective Reese and Overton (1970) introduced into developmental psychology. It was based on Kuhn's (1969/1970) ideas on the development of science, which is well-known today (see Frezzo, 2004) but was new in those days. Kuhn assumed (based on the reconstruction of physics) that science did not develop by a continuous process of upholding or falsifying hypotheses/theories but rather by a radical change in the perspective (worldview) on the subject matter of the theory. The underlying worldviews in theories define the qualitative features of theory development as well as the questions that can be asked and the methods that can be applied (exemplars). The scientific community follows this paradigm. Kuhn therefore claimed that science evolves by discontinuous

"revolutions" because newly developed paradigms are qualitatively different from or are incommensurable with the former. The same applies to theories, formulated on the basis of the new paradigm. Different theories can therefore not easily be evaluated comparatively; they also cannot be evaluated (traditionally) in terms of being right or wrong from this perspective but, rather, as being more or less fruitful, depending on the issue of concern. It is important to note that the core of Kuhn's argument, the *change* of paradigms in psychology, was neither followed<sup>7</sup> by me nor by Reese and Overton (1970); rather, it was assumed that psychology is a multiparadigmatic science. But the idea of the internal relationship of *model*, *theory*, and *methods* was maintained as well as the notion that science is a *social process*. Therefore, at first more attention was directed at the relationship/incommensurability of paradigms, which were all evaluated according to their fruitfulness in allowing the inclusion of ontogeny and cultural change, and of culture into psychology in the sense that they could be explained by the same theory. In the early analysis, I proposed five paradigms that more or less covered psychology (Eckensberger, 1979). Three paradigms (quantification or multitude and extent [use of measurements and statistics], system theory [e.g., sociobiology], and the model of the potentially self-reflective individual [Boesch's action theory]) were added to the two Reese and Overton (1970) distinguished (mechanistic [learning theory] and organismic [Piaget's genetic structuralism]).

Many of the following arguments basically *start* with the notion of a dualistic position. Therefore, at least a few sentences are necessary to justify this decision because it is true that it became rather unpopular in science for some time, particularly after Dennett published "Consciousness Explained" (1991), in which he even accused the dualistic position of being antiscientific. A similar position is held by Bhaskar (1999), who also "argued against the dualism and splits that dominated the ... contemporary human science", and he proposed to look for "a third subsuming position which could reconcile these stark polarities and oppositions, and which could situate the two extremes as special cases of the more general subsuming position," thereby proposing in principle a dialectic (Hegelian) procedure. Yet, I argue that this does not mean that dualities are generally not a fruitful *starting point* in science. It may be sufficient in the present context only to refer to the detailed discussion of psycho-physical duality

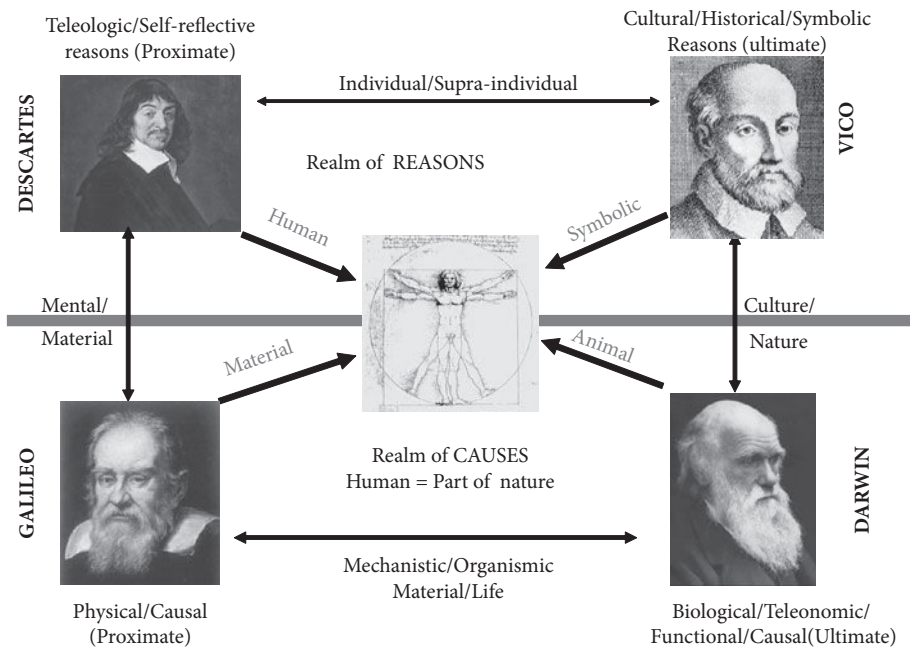

by Meixner (2004). He has even distinguished 11 arguments for dualism (pp. 122–158). Beyond that, the four perspectives in psychology later proposed by Eckensberger (2002a, 2008a, 2009) were compatible with Rychlak's (1993) four “groundings” of *Physikos, Bios, Socius*, and *Logos* in psychology.

So it seems to be quite productive to start with the assumption of dualities and to discuss their inter-relationship by some general principles but by at the same time also keeping them (see p. 930). Beyond all efforts either to overcome dichotomies by *reductionism* or *incommensurability* and *complementation* (Eckensberger, 2002a) or to *eradicate* them by either subsuming one dichotomy under the other by formulating a “more general sublimating position” one easily runs into the danger of getting a solution that in a way is *ontologically empty*. Quantum Theory may serve as an example that demonstrates the attractiveness but also difficulties and dangers in that approach. Quantum Theory seems only to work as a *regulative idea* but not in the reality of science (Görnitz & Görnitz, 2010). I will return to this central problem later.

Figure 17.1 illustrates particularly the four perspectives distinguished as well as their inter-relationship.

- *The physical perspective:* Most historical reconstructions of psychology underline that physics was the most attractive model for this emerging new science at the end of the nineteenth century. This was strongly supported by Kurt Lewin (1931), who, in a classical paper entitled “The Transition from an Aristotelian to the Galileian Worldview in Biology and Psychology,” called explicitly for defining psychology as a *natural science* and choosing physics as the proper model for psychology. To represent this perspective, he chose the Italian mathematician, physicist, and astronomer Galileo Galilei (1564–1643), who not only came into conflict with the church because he argued for a “heliocentric” worldview but also discovered the law of “free fall.” Reese and Overton (1970) named it the “mechanistic worldview” (e.g., Learning Theory). It represents the *homo mechanicus*.

- *The biological perspective:* In 1980 Norbert Bischof, in his inaugural address at the German Congress of Psychology in Zürich, agreed that psychology is and should be a natural science, but he accused Lewin of having selected the wrong science to overcome Aristotelian thinking. Instead of physics, he proposed *biology* as the proper

**Figure 17.1** Distinguishing the four perspectives in psychology and their inter-relationship. (after Eckensberger 2010a, 2010b, 2011b)

model for psychology and used Charles Darwin (1809–1882) as the key thinker, who published the “Origin of Species” in 1859, in which he claimed that the existence of different species was not the act of God’s creation but the result of a long process of natural selection. Interestingly, Bischof did not refer to the discussion of Reese and Overton (1970). But both perspectives represented a natural science perspective, both of its representatives were involved in conflicts with the church, because their theories and empirical work contradicted the worldview presented in the Bible, and therefore both contributed to the Enlightenment (e.g., the organismic worldview/ Piaget, sociobiology; Eckensberger 1979, 2002a). It represents the *homo sapiens sapiens*.

- *The socio-cultural perspective:* In an earlier paper (Eckensberger, 1979), culture was used simply as a concept that had to be integrated into psychology. Later (Eckensberger, 2002) it seemed justified or useful, even necessary, to distinguish a *cultural perspective* in psychology as a perspective in its own right. This resulted from the conceptualization of a (sub)discipline *cultural psychology* and the emergence of culture-bound *indigenous psychologies*, which became salient in the late twentieth century, although their roots go back to the foundation of modern psychology at the end of the nineteenth century (Eckensberger, 2010a). Ng & Liu (2002) have even spoken of a cultural revolution in psychology. I have chosen Giovanni Battista Vico (1668–1744) as a representative of this perspective, because he is considered one of the first to have developed a systematic methodic approach to history. He called for an analysis of the “birth” and development of human societies and institutions; proposed the study of language, myths, and tradition; and underlined the symbolic meaning of words. For Vico history was already a source to help understand humans because humans are the ones who *create* history and *form* human rule systems. This is in line, for example, with the anthropologist Geertz (1973), who understood culture as “a set of control mechanisms—plans, recipes, rules, and instructions for governing behaviour” (p. 44). This understanding also defined the centrality of morality (our second concern) as one important rule system of culture. It represents the *homo symbolicus* (Cassirer, 1921/1922; Deacon, 1997).

- *The perspective of the potentially self-reflective human being:* The French philosopher,

mathematician, and natural scientist René Descartes (1596–1650), who counts as founder of modern rationalism (Cartesianism), was proposed to represent this perspective on humans. He is famous for his dictum “*cogito ergo sum*” (“I think, therefore I am”). Clearly in the present context, his dictum is used because it underlines the importance of the principal ability of humans to be *self-conscious* or *self-reflective*. Although it is argued (Fischer, 2003) that the famous *cogito ergo sum* is logically not compelling because thinking as such is arbitrary in content like meditating or walking. The reflective action should therefore not be thinking but *doubting*. Although one can doubt everything, one can not doubt that one doubts. It is interesting that according to Fischer (2003), Descartes first used the phrase “*dubito ergo sum*” (“I doubt, therefore I am”). It is claimed that under a dialectic perspective, only this self-reflected negation leads to a logically compelling new stage of self-assurance. This topic also led Descartes to distinguish two different substances: material substance (*res extensa*) and mental substance (*res cogitans*). He is therefore often referred to as one of the founders of the duality of mind and matter (thus called “Cartesian dualism”). In any case, Descartes is responsible for an understanding of human nature as radically reflexive, meaning that we are not only self-conscious in the usual sense but uniquely conscious of the fact that we are able to reflect on the contents of our own minds (Taylor, 1989). (Example: action theories, Eckensberger, 1979, 2002a). It represents the *homo interpretans*,

Figure 17.1 summarizes not only the four models of man relevant to psychology but also distinguishes the general relationships between the four perspectives, particularly highlighting the classical splits or incommensurability based on them. The upper and lower parts represent the two cultures, differentiated by Snow (1959/1963) in his famous Cambridge lecture (see also Frezzo, 2004). Whereas the human/cultural perspectives basically deal with created personal and *cultural rules* and therefore constitute the “realm of reasons,” the natural sciences perspective is based on *natural laws* and the “realm of causes”. Mack (2006), with reference to Dilthey (1894/1968), recently distinguished between an “**e**- and **u**-type of thinking” (**e** is based on explanation, and **u** is based on understanding). Within these two domains, in the realm of reasons the split

between individual (agency) and supra-individual (aggregate/culture) objects is evident, and in the realm of causes the difference between a mechanistic and an organismic worldview is illustrated. Additionally, one can see the splits between nature and culture but also the Cartesian split of mind and matter. It is evident as well that the ontologies of the perspectives themselves differ: material (physical) versus symbolic (cultural) and the basic distinction between human (self-reflective) versus animal (biological).

Because the perspectives themselves are understood as ways of looking at the world, they are considered epistemological. Therefore one can, at present, not argue that they represent the *sciences* of physics, biology, psychology, and anthropology/sociology, which are primarily or historically defined by ontological categories, like the three worlds distinguished by Popper (1977). Rather, the productivity of the argument is that one can, in principle, take all perspectives in each science (*see*, in detail, Eckensberger, 2002). Whereas in earlier times ontology was considered to lead epistemology in theory construction (because in empiricism the results of research corrected theories), nowadays, with the increasing relevance of constructivism (Mahoney, 2004), epistemology *leads* ontology in a way, because *theories* determine data collection to a great extent and therefore the data themselves. One can even argue that ontology and epistemology are no longer separated (Gülerce, 1997). As will be seen, however, in the following a contextual constructivism (Eckensberger, 1990) is advocated.

### **Personality and Culture: Action Theory in Dialectics**

In the early paper on the integration of culture into psychology, I argued (Eckensberger, 1979) along the lines of the transformative method formulated by the post Hegelian Ludwig Feuerbach (1804–1872) and described by Buss (1979). Feuerbach's method was developed within his critical thinking about religion.<sup>8</sup> It basically entails reversing the subject and object of a statement, thereby hoping to get closer to truth. I basically used the transformative method in saying that the person is shaped by culture and culture is shaped by persons. So this duality was framed as a *dialectical relation* and it attempted to integrate person and culture. Similarly, Bandura (1997) claimed later that “people are both producers and products of social systems” (p. 6).

The earlier (Eckensberger, 1979) as well as the much more sophisticated later analysis (Eckensberger, 2002) showed that if the inclusion of ontogeny and cultural change as well as the interpretation of agency and culture within the same theoretical framework is aimed at, then only the paradigm of the potentially self-reflective subject seems to meet both criteria, when normative concepts (like morality) and the meaning of culture and cultural rules are of interest. In that early paper, not only the relation between person and culture was called a *dialectical* one because they were interpenetrating each other, but *the human action was located between the subject (agency) and culture*, thereby qualifying what dialectical meant in this duality. Dialectics in this sense means that neither exists without the other. It has been proposed that human action mediates between the individual and culture as a synthesis of that duality.

In doing so, I also chose the *intentional and potentially self-reflective agency* as the *model of man*, which is fundamental to the psychological understanding of the subject as *agency* (Eckensberger, 1979). This qualification of the human being is nowadays called “the human kind” (Danzinger, 1997; Martin, Sugarman, & Thompson, 2003; Martin & Sugarman, 2009). Also Smedslund (2009) has recently elaborated a similar model of man that is unique to humans. So intentionality and self-reflectivity were considered the characteristics of the model of man, which I later (Eckensberger, 1993) called the “*homo interpretans*.” Differing from Baltes and Nesselrode (1977), I considered dialectics methodologically as equivalent to causality and functionality in the mechanistic and organismic paradigm (*see* p. 868) inter-relating culture and personality (agency) and not as a metaphor or paradigm.

The relationship of the potentially self-reflective and socio-cultural perspective, just elaborated, is illustrated in Figure 17.2 by using human action as the genuine *unit* of psychology that mediates agency and culture in both directions and thereby synthesizes them. The ring structure (Leontiev, 1977) of Russian activity theory is based on the same theoretical model (Eckensberger, 1995), as is Haste's (2008) theoretical position, which also relies very much on Vygotsky.

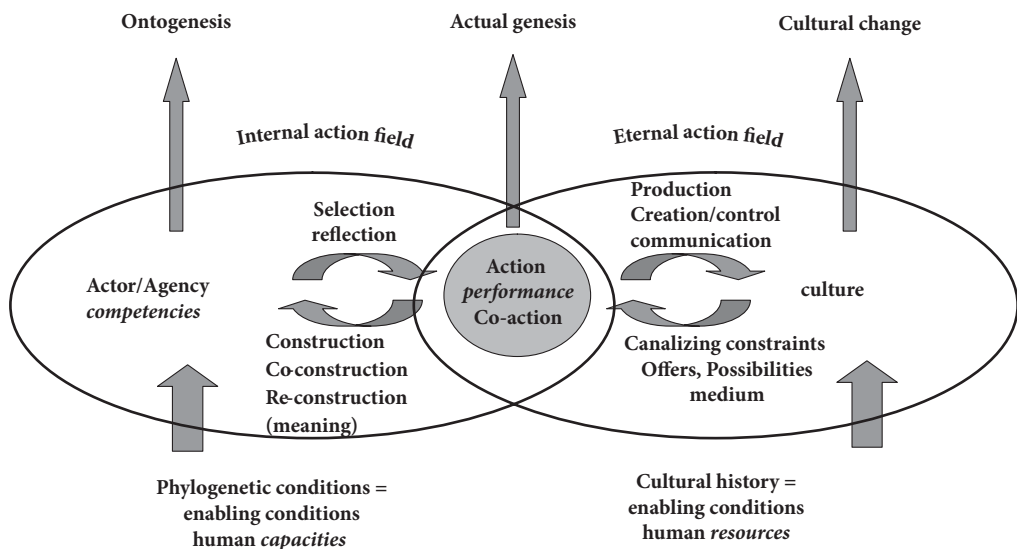

The *interpretation* of agency as a potentially self-reflective being who, in addition to reconstructing the world (*homo interpretans*) and constructing culture (*homo faber*) to a certain extent, also “creates

him- or herself” (thinks of the person he or she wants to be, develops norms about right and wrong, which more or less implies upholding one’s character) calls for the integration of individual as well as cultural *rule* and *interpretation systems* (Eckensberger, 1993a, 1993b, 1996a, 1996b). Humans create and shape culture (material, symbolic artifacts and social rules), which are in turn preconditions for their actions. This is why these conditions are always saturated with teleological structures. This perspective also implies that they can be altered to varying degrees. As mentioned, an action theory that includes culture quite naturally implies a genuinely developmental perspective, because the interrelationship between culture and individual is based on *intentional processes over time*. But development is conceptualized on different levels: On the phylogenetic level (phylogeny), the individual level (ontogeny), the action level (actual genesis or micro process), and the cultural level (history and cultural change). These developmental levels are illustrated in Figure 17.2.

By placing action (co-action) between the subject (agency) and the context (culture), two action fields are formed: the external and internal action field (Boesch, 1976, 1991; Eckensberger, 1990a, 1990b). They overlap and are interconnected by the action, which is part of both, and which therefore acts as a bridge (or a pivot) between them. The internal action field encompasses the subjective

meaning people attribute to a situation, and the external action field or cultural factors include existing shared cultural concepts such as shared interpretational patterns, scripts, and expectations. It is this conceptual status of culture and human action that justifies the term *culture-inclusive action theory*.<sup>10</sup>

This approach not only results in constructions and co-constructions of cognitive and affective (evaluative) schemata in subjects but also implies results in symbolic, material, and social structures in a culture, which in turn form canalizing constraints (ranging from inhibitions to taboos) and/or supporting encouragements or *selective* pressures (ranging from support to duties) given in the cultural context or action possibilities (Eckensberger, 1990a, 1990b; Martin & Sugarman, 1999), which also become part of the schemata. Also Poortinga recently (e.g., 2002, p. 327) formulated this model by distinguishing constraints and affordances quite in detail, although he does so in a different paradigmatic context. Yet in the following the term constraints is kept and the term “affordances” is “adopted” because of its semantic convenience. But these aspects of culture are understood here as parts of a dialectical relation of *emergence* and *selection*: The basic idea is that culture *emerges* on the basis of *human actions* and *reflections* (upward emergence) but also has a *selective function/effect* via actions on humans and their development, which are called “downward selection” in analogy of *upward* and *downward causation* in<sup>11</sup> in

**Figure 17.2** Different kinds and levels of development in an action theory framework. (after Eckensberger, 1979, 1990a, 1990b, 2010a, 2010b).

Complex System Theory (Campbell, 1974; Juarrero, 1999). These terms are avoided here; rather, the terms *upward emergence* and *downward selection* are preferred because the former still suggest a reductionist worldview, which is, however, not intended (Murphy, 2010, suggests *downwards constraints*, but we want also to include downward affordances from the culture point of view, hence we use the more comprehensive term *downward selection*). But the basic dialectical ideas formulated in my early writings are quite compatible with this terminology, which we therefore consider as being more precise than just interpenetration or interdependence. But we are also aware of the fact that both (emergence and downward causation) are not fully agreed upon (Davies, 2006; Stephan, 2002). A detailed discussion of this discourse is, however, beyond the scope of this chapter. We will come back to this terminology and its usefulness later.

### CULTURAL PSYCHOLOGY

In trying to integrate these concepts, one simultaneously ends up understanding psychology in general as *cultural psychology*, a concept that has regained importance in the last decades. As mentioned, this new branch of psychology (better: renewed branch; see Stern, 1920) is partly rooted in the socio-historical school (e.g., Branco & Valsiner, 1997; Cole, 1990, 1996; Ratner, 1991; Rogoff, 1990; Valsiner, 1987; Wertsch, 1985 and Holzkamp<sup>12</sup> in Germany), and it is partly based on Piaget and Janet and even Lewin (Boesch, 1976, 1991; Bruner, 1990; Eckensberger, 1979, 1990, 1995, 2002; Greenfield & Bruner, 1966; Krewer, 1990; Straub, 2006) as well as on some other traditions (Allesch & Billmann-Mahecha, 1990; Gergen, Gülerce, Misra, & Lock, 1996; Price-Williams, 1980; Shweder, 1990). So I have already argued for some time that action theory is not just the most adequate theory for the perspective of the potential self-reflective agency but for cultural psychology *in general*, precisely because it allows one to *synthesize* agency and culture in time (ontogeny and history).<sup>13</sup>

After having examined the role of action theory in the dialectic inter-relation of agency and culture, the role of dialectics in Culture-Inclusive Action Theory will now be elaborated.

### *Person and Culture: Dialectics in Action Theory—Action Levels*

It has been argued that the potential self-reflectivity of the agency as well as internal (individual)

standards and external (cultural) rules are critical attributes of action theory. It is postulated that both are inter-connected in this perspective by the *culture-inclusive action*. In doing so, one also integrates Shweder's (1980) proposal of cultural rules and research on the domain specificity of human cognitions (differentiated by authors like Nucci, Smetana, and Turiel; for an overview, see Eckensberger & Plath, 2006a), which constitute individual standards. They both shape the normative frameworks for actions in the internal and external action fields (Eckensberger, 1990, 1993, 1996a, 1996b; Eckensberger, Kapadia, & Wagels, 2000). It is claimed that both emerge from the same type of action, although culture is ontologically often understood as a supra-individual phenomenon (White, 1959), it is saturated with intentionality. Things are, however, not only more complex but also more productive, because by partly following Janet (Schwartz, 1951) and Boesch (1976, 1991) different *action levels* are distinguished. Not only *primary* and *secondary actions* (Janet, Boesch) are differentiated but also *tertiary actions* (Eckensberger, 1990, 1996, 2003, 2006a, 2010a).

These levels come about because it is quite normal that barriers/impediments occur in every action. One can almost regard them as the condition for or initiator of development (see particularly Boesch, 1976; Eckensberger & Emminghaus, 1982; Eckensberger, Breit, & Döring, 1999; Martin & Sugarman, 1999; Ulich, 1987). These can only be experienced, however, because every action already implies normative frameworks, which serve as standards<sup>14</sup> for determining whether or not the action was adequately accomplished. These barriers lead to reflections, which by necessity occur from a higher level, which *itself emerges through this very reflection*. This is the basic idea of Piaget's (1970) proposal of the notion of reflective abstraction,<sup>15</sup> which is a genuinely *dialectic operation* because the same phenomenon (the action) is at first the subject ("in operation") and then is reflected on as an object (see Kesselring, 1982; Vuyk, 1981). Through this operation, existing structures (levels/stages) are transformed into new ones. So the same phenomena are at first *structure* and then *content*, which is logically contradictory but developmentally plausible. But the three action levels do not only emerge through abstractive reflections (which could end up in an infinite regression), but they additionally have different orientations: *primary actions* are world-oriented, *secondary actions* are action-oriented, and

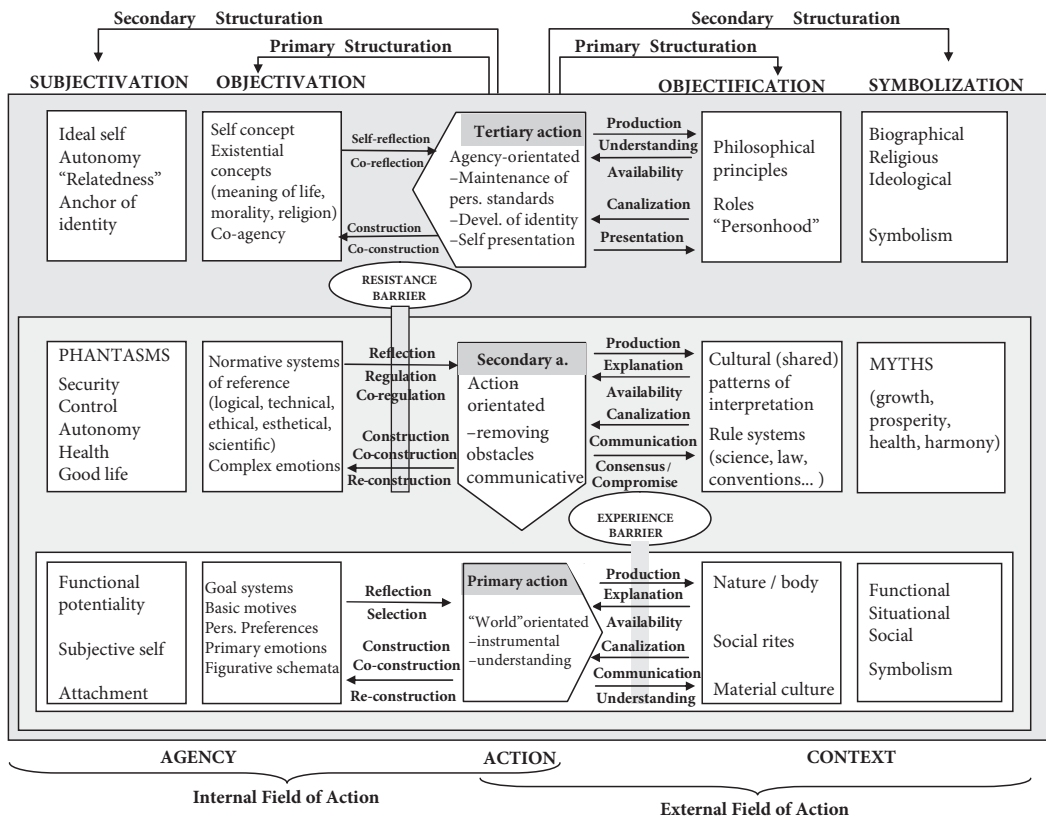

*third-level actions* are agency-oriented. This is the reason that action barriers are of utmost importance for the emergence and development of the action levels (this issue will be taken up in discussing moral development). However, it is again assumed additionally that new action levels do not just emerge through the process of *reflective abstraction* (upward emergence) but that these influence the lower level via downward *selection processes* (constraints and supports) rather than by causal processes. But a possible misunderstanding has to be clarified: As in the case of agency (see p. 873), the reflective abstraction should not be understood as being “firmly fixed on the organism side” and therefore being “fundamentally a-cultural” (Glick, 1985, p. 106). To clarify this point, I tried (Eckensberger, 1990b, p. 48) to apply this term to co-constructions by proposing a reflective understanding and co-reflective understanding, thereby making it cultural or social.

This developmental principle is proposed for both ontogeny (particularly the third level emerges later in development) as well as for actual genesis. Although the action levels are formed in this sequence, it is assumed that the older one gets, the more of these levels are more or less simultaneously active. In general, it depends on the number and kind of barriers that occur in an action. The genesis of the levels is bottom-up, but the interpretation process has to be top-down because all levels are necessary to understand a human primary action. To understand a simple act (primary action like writing a chapter), one has to know the immediate intentions of the writer (to make a particular point within the time span of the deadline given) but also the standards or conventions (secondary actions) in which the chapter has to be written (length, APA format) as well as the fact that the writer is aware of deviating from some other theoretical positions. In addition, this may be essential for the self-identity as a psychologist, and so forth. (tertiary actions). *Therefore CIAT not only helps to understand the proposed dialectics between the subject/agency and culture, but dialectics also help to understand assumed relations within action levels.*

The standards themselves that are the preconditions to experiencing barriers are not only developed during internal processes in ontogenesis, but the experiences of barriers also take place in a specific cultural context, in which different expectations—technical, social, or belief systems (customs, logical, and ethical principles)—set the stage (Eckensberger, 1979, 1985, 1996, 2003, 2010a, 2010b). Thus the

Piagetian model of an active subject is still considered productive, but it has to be complemented by cultural content that appears to become ever more important as the concept of standard increases in complexity in the course of development, as research on Piaget’s and Kohlberg’s theory shows (e.g., Dasen & Heron, 1981; Eckensberger & Zimba, 1997, Snarey, 1985). There is an urgent need to complement Piagetian developmental concepts with more content-orientated concepts of development. This is aimed at particularly by Boesch’s concept of “secondary structures” (see p. 896, but it is also called for by Krishnan’s (1999) proposal to complement it by research in the tradition of socialization processes. These should particularly include cultural rituals of various kinds that are all normative in character.

In the following, the action levels will be described according to their implied structure, interpretation, and experience of standards as well as their concomitant emotional processes. Although the methodological status of the action levels is primarily theoretical they also represent a productive framework for empirical work. They provide a psychologically useful scheme for organizing and inter-relating a variety of psychological concepts; they therefore also enable links to concepts that have not necessarily been defined originally in an action theory perspective. This is not only true for many cognitive constructs but also for motivational and emotional processes and their interrelation (like motivation, emotion, control theories, or self-concepts; see Bettingen, Eckensberger, Gaul, Krewer, Madert, & Prowald, 1993). The reflected action levels were particularly productive in the contextualized research on regional culture (Krewer 1990; Krewer, Momper, & Eckensberger, 1984; Krewer & Eckensberger, 1990), on moral development in the context of education (Breit & Eckensberger, 2004a, 2004b; Eckensberger & Breit, 2003, 2006; Eckensberger, 2002b; Maslowski, Breit, Eckensberger, & Scheerens, 2009; Eckensberger & Chang, in press) and ecological issues (Eckensberger, Döring, & Breit, 2001; Döring, Eckensberger, Breit, & Huppert, 2008; Eckensberger, 1993; Eckensberger, Kasper, Nieder, Schirk, & Sieloff, 1990; Eckensberger Sieloff, Kasper, Schirk, & Nieder, 1992), and particularly on coping with cancer (Eckensberger & Kreibich-Fischer, 1993, 1994; Eckensberger, Kreibich-Fischer, Gaul, & Schnurre, 1990, Eckensberger, Kreibich-Fischer Gaul, Bettingen, Madert, & Prowald, 1993). But these studies also fed back into further developments of the theoretical structure of the CIAT: Figure 17.3 presents an overview of the three action levels distinguished.

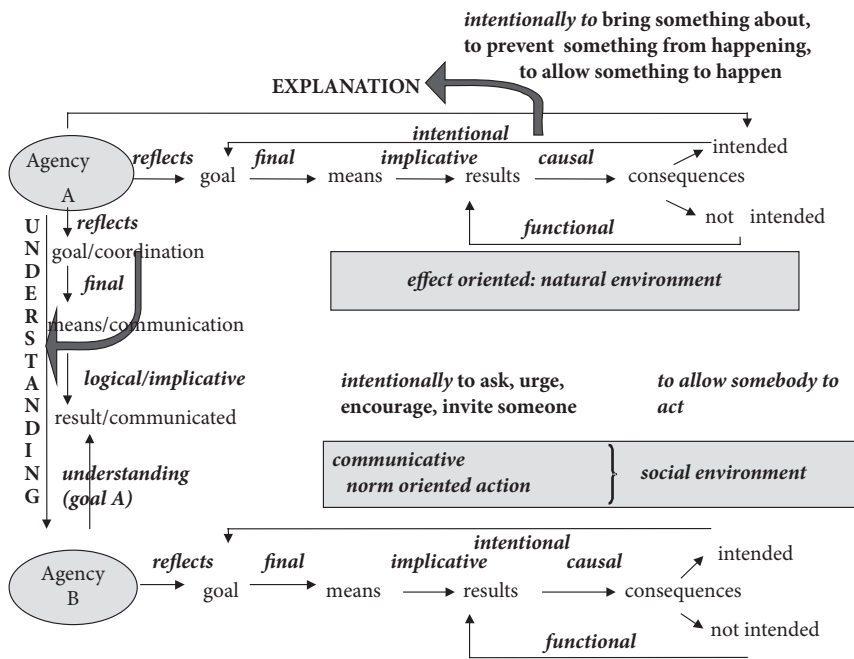

**Figure 17.3** Three action levels: primary (world-oriented), secondary (action-oriented), and tertiary (agency-oriented) actions. (after Eckensberger, 1989, 1990a, 1990b, 2010a, 2010b).

### PRIMARY (WORLD-ORIENTED) ACTIONS

Analytically, the *basic structure* of instrumental primary action aims at some *effect* (to bring something about). It is assumed that the *means applied to carry out an action follow rationally (not causally) from the intentions*—that is, they can be justified or made plausible by the agency. They are chosen on the basis of *finality (to reach a goal)*. If they are carried out, the *result* is some change, and this change leads *causally* to some *consequences*. Those consequences of actions that represent the goal are *intended*, others are unintended (to let fresh air into a room [intended goal], one opens the window [does something], after having opened the window it is open [result] and lets [causally] fresh air in [intended], but the room may become cold [unintended]; see Fig. 17.4).

It is useful, however, to at least differentiate *two types of primary actions*.<sup>16</sup> If directed at the *physical/material world*, and aimed at bringing about some *effect* (also “letting things [intentionally] happen,” von Wright, 1971) or *suppressing some effect*, they are called *instrumental actions*. But if

actions are directed at the *social world*—that is, at another *agency B or group*, they cannot (causally) bring something about in *B*, but it is *B* who has to decide to follow or not follow a request/demand by agency *A*, which implies that *B* also has to understand *A*’s intentions. So *A* has to coordinate with *B*’s intentions, means, and even with evaluations of consequences. Thus agency *B*’s intentions have to be *understood* (interpreted) by agency *A*. This presupposes a *communicative attitude* (Habermas, 1984). This type of action is consequently called a *communicative action*. If this orientation not only implies understanding *B*, but also *respecting B*’s intentions, means, and consequences, then this is clearly a *moral action*. Interestingly, in non-Western philosophies/religions (Taoism, Confucianism Hinduism, Buddhism<sup>17</sup>) this adaptive attitude and respect for the non-*A* is extended to include the plant and animal world or even the cosmos. So one can distinguish between two action types that aim at *A*’s *control* of the environment (instrumental and strategic) and two action types, in which *A* aims at

**Figure 17.4** Two main action types: instrumental- and social/norm-oriented action (after Eckensberger, 1993, 1996, 2010b; Eckensberger & Plath, 2006).

*harmonizing* with the environment (communicative and adaptive actions; Sinha, 1996).

This clearly shows that *understanding does not refer to causes but to reasons*. So, basically understanding or communicative actions are appropriate for the social world.

This distinction, however, also depends on the relationship between the agencies **A/B** as defined in the cultural context. If there is no mutual respect (e.g., if agency **B** is a servant who has to follow orders), then this can lead to an instrumental interpretation of agency **B** by agency **A**, called a strategic action by Habermas (1984). In other words, agency **A** interprets **B**'s behavior as something caused by the order, like a natural law without any possibility of deciding not to do it (**B** has to do it). This means that agency **A** treats agency **B** as if(s)he were a part of nature that is governed by causal laws. But the reverse can also occur: a person may speak to his car that is broken and *ask* it not to fail him but to make it for some more miles. Then, in a way, the person treats the car as part of the social world. Hence, the world is *constituted* by the application of the respective action types. Whether or not something is part of the social or natural/causal world is thus a matter of *interpretation* on the part of the agency. Clearly the methodological

status is primarily analytical again. So, agency is characterized by four relations: by being (1) *reflexively* tied to one's goal in the physical environment; (2) orientated at the social world by *understanding* the actions of others; (3) *self-reflexively* related to itself (the "Innenwelt" or "inner world"); and (4) it is related *contemplatively* to some transcendental or ultimate phenomenon (see Fig. 17.4).

In empirical research, these action types enable a methodical distinction that is quite productive for the analysis of data (see Bettingen, Eckensberger, Gaul, Krewer, Madert, & Prowald, 1993, for a manual of data on cancer patients; Eckensberger, Karpadia, & Wagels, 2000, for rules in marriage in India). Empirically these two action types often occur simultaneously (e.g., if somebody asks someone for help), particularly in early childhood, when the physical world and the social world are not totally distinct yet. In developmental psychology, particularly in early childhood, the concept of theory of mind (TOM) is highly relevant to the development of social cognition. Premack and Woodruff formulated this concept in 1978 for chimpanzees, to study the question of whether chimpanzees understand *intentions* or actions of another chimpanzee (see also Boesch<sup>18</sup> & Tomasello, 1998). This concept not only triggered much research with primates other

than humans but also became a broad research program for human infants (understanding intentions of another person is clearly an operation that is the precondition of primary communicative actions; for more detailed information, see Eckensberger & Plath, 2006a).

Actions (goals and means) are selected by the agency from all possible actions on the basis of their personal preferences, called personal concerns in social cognition (proposed particularly by Nucci and Smetana; for detailed references, see Eckensberger & Plath, 2006a). Primary actions form schemata (standards) of technical, logical, and (instrumental) action competence as well as social competencies (social actions). Additionally, they are based on content *knowledge/facts* (what effects can be produced) as well as the effectiveness of means (how can they be produced). So in primary actions, *standards* exist in preferences of goal and means and, of course, in the expectation of action outcomes. Although people relate directly to their nonsocial, material, or natural surrounding, this process also takes place *in a cultural context and/or together with other subjects*. Writing, for example, is inextricably linked to the script that comes with a language—Latin letters differ strikingly from Hindu scripts, both diverge from Arabic ones, and they are all totally different from Chinese characters. Thus, the cultural context already provides shared schemas of writing, including the semantic meanings that refer to the world. On the one hand, these schemas serve as a sort of template for individual and collective experience; on the other hand, humans themselves constructed and modified them in the course of history or, rather, cultural history (upward emergence). They therefore represent the cultural *resources* (cf. Fig. 17.2) individuals can rely on or choose from (fashion, rationality, logic, technology, and economy and their implied standards), which again form the “downward selection” processes of canalizing constraints and affordances (Eckensberger, 1993a, 1993b, 1995, 1996a, 1996b, 2008a, 2010a, 2010b).

There is considerable agreement among researchers that empirically actions do not just have one goal but many. They can be seen as forming a chain or a hierarchy. To write an article may have the goal of understanding and describing a particular problem and may be considered part of a primary action. Writing individual characters on paper may be taken as subaction or elements of an action (called *actemes* by Boesch, 1991). Yet, writing the article

can also be embedded in a larger set of goals (e.g., to get ahead in a career). These hierarchies are particularly elaborated in instrumental contexts, but they are also relevant to communicative actions.

The following discussion makes use of Boesch's (1976, 1991) distinction of *primary structurations*, which are cognitive, and *secondary structurations*, which represent affective structures/schemata. Yet again this distinction is primarily analytical. But in fact the issue of how cognition and affect interact or merge is probably more important. He presumes that an action (he usually refers to instrumental actions) has *two* components: first, the instrumental component usually studied (e.g., one uses a hammer to drive a nail into the wall) and second, the subjective functional component. Here, Boesch (1976, 1991) applies Lewin's (1951) concept of valence to action elements. Hammering may also be fun—one can let off steam or be proud of being able to hammer successfully. Therefore, Boesch proposes that action results (nail in the wall) lead to two simultaneous feedbacks: one—like in Piaget's theory—is *descriptive* and leads to *cognitive structures* (schemata, formal condensations of similar actions), which represent primary structurations and therefore an objectivation of the action in the agency and of material consequences of actions in the real world (culture), which he calls “objectification” (Boesch, 1991). The other form of feedback is *evaluative* and leads to *affective structures* (*secondary structurations*). They are basically threefold: At this point, he talks about the subject's *functional potentiality*, which is the positive valence for the agency itself. Second, a goal valence is also established, and finally the action means (hammer)<sup>19</sup> acquires an object valence and thus an *idiosyncratic meaning* for the subject, a process called *subjectivation*. However, at the same time, these valences virtually symbolize the action and the *situation*, a process that is therefore called *symbolization*. This topic of *personal meanings* (valences) of objects is notoriously undervalued in psychology, because of its more or less exclusive focus on general laws and principles. Not surprisingly, suppositions in this domain are still rudimentary and have to be developed in more detail in future. But to me the *secondary structurations* and its implications are the core of Boesch's Symbolic Action Theory (1991), and they are probably his most important and unique contribution to the field.

It is evident that these secondary structurations are derived from a depth-psychological body of thought, which is the second source of Boesch's

theory besides Piaget (*see* particularly Simão's [2002] comparison between Boesch, Freud, and Piaget). Therefore, it is also evident that their empirical confirmation presupposes some psycho-analytical competence and should be done cautiously and checked particularly by the inter-rater reliability of competent raters. Boesch's examples mostly refer to successful, positively experienced actions, which are also emotionally balanced and imply emotions of joy and triumph (pride). Eckensberger and Emminghaus (1982) and Eckensberger and Kreibich-Fischer (1993) called these emotions, which are closely related to the flow-concept (Csikszentmihalyi, 2000), emotions of fit between the expectancies of the course of action and action experiences (internal equilibrium). But again it is productive to follow Boesch by assuming that actions are also affectively structured and lead to individual superordinate affectively structured goal systems of actions, which Boesch calls *phantasms*. These are not only affective but also content-oriented normative frameworks. On the first action level, they include notions of *functional potentiality*, which means the feeling of being the cause of some event, which not only forms the basis for a subjective self but also for the subjective valence of places and objects. Therefore, this concept goes beyond the concept of self-efficacy that Bandura (1997) coined.

But Boesch's (as well as Bandura's) proposals primarily relate to instrumental actions because his analysis of subject–world relations primarily relates to subject–object relations, which are not communicative/normative but can be interpreted as being instrumental/strategical. Therefore, Simão (2001, p. 487) tried to add *interaction* to Boesch's theory, by treating Boesch's object as a subject (p. 488). But in a way, through this substitution, she remains on the level of instrumental co-actions: coordination and cooperation with others (p. 490). Only the *normative coordination* of actions for the benefit of (all) others would imply true interactions and fall into the moral domain. This leads to my research on morality (which particularly in the beginnings focuses primarily on *primary structurations*) by distinguishing different barriers and reactions to barriers and by reconstructing Kohlberg's moral theory by action theoretical terms<sup>20</sup>. I have also argued in two contexts (Eckensberger, 2001b, 2007b) that, to increase the fruitfulness of Boesch's concept of the *secondary structurations*, its general idea, should also be applied to communicative actions, in which other *persons* obtain their

*idiosyncratic* symbolic meaning for an agency and through which the *affective core* of the agency itself is also developed. This phenomenon is classically explained in psychology by the concept/theory of attachment (e.g., Bowlby, 1969; Ainsworth, Blehar, Waters, & Wall, 1978),<sup>21</sup> which has explicit roots in phylogeny but also in psycho-analysis. I have speculated how attachment to a specific person can also be reconstructed in terms of action theory. Since the beginnings of depth-psychology in the nineteenth century, the empirical status of hypotheses on the dynamics of early child development and mothering has changed dramatically. This can be credited to researchers like Beebe and Lachmann (1994) and Stern (1985, 1995), who all have a depth psychological background, as well as Trevarthen (1993), who is a child psychologist with a biological/systemic approach. Their research and theorizing has focused on early child–mother interactions. They have developed concepts, which can be understood as aspects of *secondary structurations* in early communicative actions. First, all of them do not see the child in isolation; rather, all communicative principles are *mutual* between a caregiver and a baby. Second, they focus on the *course* of the communicative activity (temporal feeling shapes; Stern, 1995). Third, they *integrate* cognitive and evaluative (emotional) aspects of the processes. The “schema of being with” (Stern, 1995), or interpersonal timing as matching and being matched (Beebe & Lachmann, 1994), or the term *affect attunement* (Stern, 1985) between a child and a mother may serve as examples. Fourth, they study children before they are able to speak, beginning shortly after birth. Yet they interpret early gestures and mimicking as communication (Trevarthen [1993] speaks of proto-conversation). At present, the early proto-conversations on the basis of gestures—particularly pointing—are interpreted as the basis for communication and also as foundational for the uniqueness of humans as a species, because great apes generally fail to do that (Janik & Zuberbuehler, 2009; Tomasello, 2001; Tomasello, Call, & Hare, 2003; Tomasello, Carpenter, & Liszkowski, 2007).

These mutual communication processes in a close relationship not only reduce negative emotions (prominent in attachment theory) but also maximize positive feelings, which represent happiness or mutual fit of emotions (not just security), if the attunement/mutual regulation of interaction rhythms works. So the constructed schemata are not

only cognitive but also evaluative and should lead to attributing a *valence* to a *particular person* within an interaction in a situation.

Of course, emotions that accompany actions after early childhood can also be positive or negative, and they occur in different phases of the action. It is interesting in this context that positive emotions are mainly characterized as happiness and being satisfied, but they are not as differentiated in language as negative ones (*see also* Smedslund, 1988).

#### SECONDARY ACTIONS: ACTOR-ORIENTED

As mentioned, during the course of primary actions, almost inevitably obstacles or barriers occur that are accompanied by negative emotions and provoke control efforts and reflections. It is of utmost importance to remember that every definition of a barrier or obstacle in the course of an action implies (analytical as well as psychologically) some *standard* about how an action *should* be carried out. We call these phenomena “action-guiding frameworks” or “normative rule systems” for actions. In conceptualizing the relationship between the objective world (ontology) and the subjective understanding of the world (epistemology), I claimed, however Eckensberger (1985, 1993a, 1995, 1996a), that these barriers (like the interpretation of the world in first-order actions) are intuitively and objectively given in primary actions, but in secondary actions they are reflected and come about through *interpretations in action contexts*. Therefore, these standards are not only preconditions for defining the barriers *as barriers* but also imply different ways of overcoming them that are more or less adequate. Additionally, the different interpretations of barriers also imply different types of *emotions*: Although all these emotions relate to frustrations in a general sense, manifold shades of affects/emotions that emerge as reactions to differently interpreted barriers or experiences are distinguished (cf. Eckensberger, 1993, 1985, 1996; Eckensberger & Emminghaus, 1982). It is not so important that the chosen terms reflect everyday language exactly; the central point, rather, is to distinguish various emotional reactions to frustrations by using different emotional concepts, depending on the barrier’s interpreted source or origin.

To give some examples from the cancer research: These standards may be *technical* (e.g., during the process of cancer, some body function may be at stake or some kind of prosthesis should work), then barriers are called *problems*, and the accompanying

emotion is *anger*, *wrath*, or *fear* and one adequate regulation is to *remove* the problem. But they can also be social; then the standard is social functioning (an unfulfilled expectancy concerning individual or conventional behavior of the social support system of the family, the staff of the hospital, or doctors), these barriers are called an *interpersonal conflict* or *disagreement*, and the accompanying emotion is *embarrassment*, *shame*, *rage*, or *disappointment*.<sup>22</sup> The adequate regulation is *conflict solution* or *communication*. In the domain of *logic*, the standard is *consistency*, the barrier is *contradiction*, and the emerging emotion is *insecurity*. The adequate solution is searching for a *new logical path*. In case of *personal concerns*, the standard is *goal hierarchy*, the barrier is an *intrapersonal goal conflict*, the corresponding emotion is *dissatisfaction*, and the regulation is *subjective re-evaluation*. In case of *morality*, the standards are *duty*, *respect*, and *fairness*, the barrier is an intrinsic (or intuitive) *conflict between different interests, values, or principles*, the corresponding emotion is *guilt* or *shame* (in case of observing a *moral transgression*, it would be *indignation*), and the regulation is *avoidance of harm* or *consensus-orientation*. Although the emotional terms suggest that they are situational, this is not intended; on the contrary, elaborating emotions in action contexts implies that they are automatically understood in time, and they can easily change if the interpretation/meaning of the situation changes.<sup>23</sup>

So secondary actions serve as frameworks to regulate barriers in primary actions, which means they re-establish an equilibrium between the agency and cultural standards. They are formed by *upward reflection* (reflective abstraction), but they also form a *downward selection* of primary actions. Following the fruitful terminology of Janet (Schwartz, 1951) and Boesch (1976, 1991), these regulations are called *secondary actions* because on the one hand they (just as primary actions) basically also have the formal structure of actions—they are future-oriented and have a basic teleological structure (they are goal-oriented because they are supposed to re-establish and adapt primary actions, and they involve decisions and evaluations of outcomes). On the other hand, however, they are not oriented toward the world but toward primary actions. Hence, they are also called *action-oriented actions*. They form normative schemata (conventions, morality, and law) as regulatory rule systems in the agency as well as rules in culture.

A systematic depiction of the most important types of rules, their distinctions, and inter-relationships

is presented elsewhere (Eckensberger 1993b, 1995, 1996). More recently, a systematization in terms of *action types* was even proposed (Eckensberger, 2008, 2010b; Eckensberger, Kapadia, & Wagels, 2000).<sup>24</sup> In a later section, the development of moral judgment in action terms will be considered in more detail.

Of course, action regulations (secondary actions) are not new in psychology; rather, they are similar to coping processes (cf. Lazarus & Launier, 1978; Haan, 1977) or control theories of primary or secondary control strategies (e.g., Heckhausen, 1997). But the control efforts distinguished were internally more sophisticated. Hence, a detailed internal structure of these processes and a scoring manual to define different cases based on the internal structure of actions was elaborated (Bettingen, Eckensberger, Gaul, Krewer, Madert, & Prowald, 1993). To at least give a rough idea, some examples are in order: First, intrapsychic and actional regulations were distinguished. Both can apply to goals and/or means. The regulation of means can involve representations, evaluations, or reflections; they can refer to the social or material world. The goal is either reset or not. Actional regulations apply to doing or not doing something; they also refer to the social or material world. Additionally, it is useful to differentiate whether regulations are orientated *toward* the barrier or *away from* it.

The “social world” certainly also initiates co-regulations (support, help), which in turn influences the emotional evaluation of the success or failure of a regulation (e.g., if one succeeds, one feels pride or triumph, one feels grateful toward others or appreciates their help, etc.; cf. Valsiner, 1987). Apart from knowledge systems, however, among other things, fashions, conventions, morals, and laws as outcomes of time-tested ways of solving problems/conflicts in a culture also exist. For example, in some parts of Africa, local chiefs decide and moderate social conflicts, the West has developed a written law, Islamic cultures operate with the *Sharia* law system, whereas in China a written law also exists, but conflicts there are preferably regulated by mediation (Ma, 1998).

Again in following Boesch, it is assumed that secondary actions are also affectively structured and lead to individual superordinate affectively structured goal systems called *phantasms*. They include general notions of control (or harmony), security, health, and good life. The corresponding *myths* in culture (in the West) are the well-known ideals of

growth, wealth, and health. In the cancer research (Eckensberger & Kreibich-Fischer, 1994), these phantasms are, for example, individual overarching affectively satiated goals of *health*, which are embedded in a whole pattern of subjective theories about one’s own illness (e.g., Phillip & Ferring, 1998) and (corresponding) ideas about the proper means to re-establish health. They are also embedded in the immediate social context (social support system) as well as in cultural myths about cancer, its development (who gets it, and why), and proper treatment (what to do). Thus, all regulations aim at re-establishing or coordinating actions—whether to continue or give up an action and/or how to reinterpret the situation, and so on. Apart from this, as outlined above, secondary actions also differ (just as in case of primary actions) in the affordances and possibilities a culture provides as well as in the canalizing constraints, prohibitions, and taboos (the normative rule systems) that already exist. In cancer, for example, culture offers (besides the traditional medical treatment) a variety of alternative treatments that promise healing. In the cancer study (Eckensberger & Kreibich-Fischer, 1983) practically no patient did without them. So, quite generally, with reference to the social world, phantasms like *security* or *ideals of love* develop.

#### TERTIARY ACTIONS: AGENCY-ORIENTED

It is only consistent to presume—especially when postulating that humans are “*potentially* self-reflective beings”—that impediments to or disturbances of secondary actions inevitably compel the person to reflection or, rather, to *self-reflection* (see Piaget, 1974). One asks questions like, “What goals do I really have?”; “How important is a particular action outcome for me?”; “What does some moral insight mean to me?”; or “Is it important for me to ‘uphold’ my personal convictions or character?” which finally raises the question “Who am I?” or “What is the meaning of my existence?” Once again, the barriers of actions (this time in secondary actions) provide the developmental potential for such questions. They again emerge from upward (abstractive) reflection, and they form downward selection processes onto secondary actions. At the level of tertiary actions, the process of primary structuration leads to role expectations or stereotypes of persons in a culture or society (personhood) and to the development of the subject’s identity and how he or she presents his- or herself to the outside world. These identity structures also possess an action-guiding

potential. They can be considered as developmentally organized types of identity (stages), as outlined by Kegan (1982), Blasi (1985), Erikson (1959), and others. It is the ability to rise to a higher level of evaluation to evaluate possible actions and the motives, emotions, and so forth, involved that allows for the development of moral responsibility, character, and eventually free will. For example, Kane (1989) has argued that when two possible courses of action conflict, the resulting destabilization of brain states allows for genuine free will and that when we act on the basis of such deliberation, we are engaged in self-forming actions that create our character and thus make us responsible in the long run for the people we are.

In the present framework, the *development of agency can itself be considered an action* as a project of identity development, which has a goal and which may fail (Clemens, 2007; Brandtstaedter, 1998; Eckensberger, 2007; Krewer, 1990; Krewer & Eckensberger, 1991). Also Simão's (2005) discussion of self-formation from the perspectives of Gadamer, Boesch, and Valsiner is relevant here. This implies that individuals constantly reconstruct and renew their understanding of their *relationship* to themselves and to the social and material world and thus the relationship between autonomy (independence) and affiliation (interdependence) in the social world. Essentially, the subject reconstructs the balance between fulfilling personal needs and those of others. The relation of the subject to the natural world (aspects of culture) is also located here.

Methodically, it is important to note that individual goals are not as conscious as seems to be suggested here, and they are therefore sometimes rather naively investigated by applying questionnaires that ask explicitly for goals. In the longitudinal cancer research study (Eckensberger & Kreibich-Fischer, 1993, 1994), using the action framework, it became evident that the significance of barriers/impediments is also methodically highly relevant: people do not speak as *spontaneously* about their goals as much as they do about barriers. Empirically their goals, in that sense, often have to be reconstructed from the barriers the subjects experience.

The research on regional cultural identity and cancer may serve as examples for the productivity of the proposed action levels. Although quite different in detail, both tackled the problem of identity development. Usually, in those days, theories on ego, self, or identity development (Fillip, 1980; Habermas, 1976; Kegan, 1982; Lapsley & Power,

1985; Leahy, 1985; Loevinger, 1976) shared the common feature of conceptualizing "the process of identity formation towards higher or more mature stages as a process reflecting increase in abstract and formalized competences or structures" (Krewer & Eckensberger, 1990, p. 216). The other side of becoming more and more complex (structurally) implies, however, that one loses more and more (everyday) content. This assumption not only contradicts daily life experiences, but it also somehow neglects the fact that identity is rooted in the specific biography and cultural context. So our goal was to contextualize identity formation by means of the elaborated three-level action scheme,<sup>25</sup> which included daily life activities (primary actions) as well as action control (secondary actions) and reflections (tertiary actions).

The German region in which the University of the Saarland is located was ideal for such effort, because it has a unique history (at times it belonged to France, at other times to Germany, and it was even a European protectorate), and hence developed a unique regional culture. So daily life contexts relevant for that culture were investigated by my coworker Bernd Krewer in his dissertation (Krewer, 1990): language (dialect) use, preference of regional food, humor, and meaning of historical events of the region. A whole variety of methods was used to really capture the daily life context (biographical interviews, diaries, group discussions, video tapes of language use). On the basis of this research, Krewer (1990) formulated the term *cultural identity anchors* for these cultural features of the region and a *regional cultural identity*, which used these features as symbolic representations of one's identity; this was particularly true for the regional dialect.

The importance of the particular role of self-reflections (third action level) in cancer was quite different. The study was triggered by the observations of a practitioner (Kreibich-Fischer) that many of the cancer patients stated sooner or later, and more or less pronounced, that *becoming ill was good or beneficial* for them. At first this was shocking, but then it was not really so, as it seemed to result from the increased self-consciousness and awareness of the value and importance of every minute of life under the threat of a limited time perspective. Hence, the goal of the study was twofold: to understand this increase in self-reflection (acceleration of self-development) in more detail and to examine whether healthy people might be able to learn something from this attitude.

None of the research programs mentioned was cross-cultural<sup>26</sup> or done in another culture than Germany, yet culture served as a necessary context—that is, a cultural psychology was followed. Rychlak (1993) saw no methodical implications in his distinction of the four groundings, but we disagreed explicitly with this (Eckensberger, 2002). In the contrary, in the cancer study we refused the demand by the Ministry of Technology and Education to use scales and questionnaires; instead we tried to take the *self-reflective active model of man* as seriously as possible also methodically, by treating the subjects with respect, care, and understanding. This was exactly what Smedslund (2009, p. 792) also called for recently. Although data collection and interpretation varied between studies, data collection (sampling) basically followed the model of theoretical sampling (Glaser & Strauss, 1967) and ended up in formulating psychological types (Werbick, 1985). But differing from these authors, the resulting types did not simply emerge from the qualitative data collection; rather, they were, like the sampling, (action-) theory-driven. In this sense, every new person was included in a sample with the aim of testing and, if necessary, correcting the theoretical framework. Data collection allowed the interviewees as much freedom as possible to keep data as authentic as possible. Data analysis was qualitative (hermeneutic), but it was also guided by the action theoretical psychological framework.

To be methodically as unobtrusive, contextualized, and as respecting of the patients as possible in gathering data, no questionnaires were applied; rather, normal counselling sessions were taped and only short (selective) interviews were performed. Of course, the patients had to give their consent and could stop the taping whenever they wanted. But that was extremely rare. The study lasted about 3 years, and in the end, up to 30 tapes existed for every patient over different time spans. Because the patients themselves decided what to talk about (a medical or practical or financial problem, a problem with the family, etc.), the scoring manual had to cover an extremely broad range of topics and yet had to be structured in great detail (Bettingen, Eckensberger, Gaul, Krewer, Madert, & Prowald, 1993). The three action levels served as a framework, and it was, of course, complemented and improved content-wise during the project. The particular question of self-development was mainly covered by an adaptation of Kegan's (1982) theory on the evolving self, which also makes use of Piaget's reflective abstraction.

Although data from 30 patients were collected, only 6 of them were analyzed because the analysis of the material was extremely time-consuming and thus expensive (s. Eckensberger & Kreibich, 1993). But the results were quite promising. First, it was in fact *possible* to score free utterances for every patient in terms of the theory of developmental types and to reconstruct possible qualitative change (this was quite unclear in the beginning). Second, four of the patients oscillated between stressing intimacy and self-control, only one manifested the over-adapted picture, which was drawn about cancer patients (mamma carcinoma) in the literature of the 1980s (Vetter, 1989; Lerner, 1987; Canakis & Schneider, 1989). Third and most important, two of the patients exhibited different developmental changes: one patient, in fact, within 3 years, developed from an intimate self to a reflected egoistic and then to an autonomous self (which was particularly interesting for the question at hand). The other, however, first had an intimate, relational self-concept, but *regressed* to an expressive egoistic self-orientation, which demanded support and attention from her partner (social support system). In both cases, the support systems (cultural setting) were attuned to these structures of the patients. These differences were also discussed in terms of their implications for therapy (Eckensberger, Kreibich-Fischer, & Gaul, 1998), but this discussion is again beyond the scope of the present context.

Secondary structurations were also relevant to the results of both studies: affective bonds were formed to the regional (concrete) culture. This was true for the landscape (homeland), the food, but particularly for the regional dialect. On the other hand, the cancer patients formed phantasms of autonomy and relatedness, which became part of their identity. Although investigated primarily in early mother–child contexts (*see* p. 898), it is productive to assume that these affective structurations are relevant during the entire lifespan (e.g., in love relationships) but also in therapist–client relations (the counsellors in the cancer project remained close intimate friends with the patients for as long as they lived).

One barrier is of utmost importance on the third level, and this is, in fact, the other side of the coin of self-reflection. It is the knowledge of the end of this process—that is, of one's death or existence on earth. Most religions (on the cultural side) offer the hope of an existence beyond biological death (although this may differ qualitatively and quantitatively in

various religions, it can be paradise [Christianity/ Islam] or rebirth [Buddhism/Hinduism] or only moderate pronouncements as in Judaism), thereby outwitting death. Religion thus can be regarded as what most individuals believe so as to create hope for a better state of existence after death. But all religions also encompass rituals and have prescriptive components that regulate social life on Earth (Kimmel, 2010). This is actually an interpretation scheme in its own right; it usually implies an entire theory of the structure of the world (relations among men, animals, and plants) and its creation (created and governed by one or more ultimate beings). It also entails rules of conduct (what is right or wrong, what is a sin). Some kinds of regulation are even prescribed in or afforded by a religion. These may be purifying rituals, prayers, and so forth. Since the Enlightenment, these knowledge and rule systems compete with science. And they still do, as we know from the discourse between evolutionism and creationism. As noted by Oser and Gmünder (1984) or Fowler (1991), religious structures are of an *existential* nature and can also be described as stages (developmental types) that represent human's relation to the ultimate (*see also* Eckensberger, 1993b).

But again, a word of caution is in order: It is not proposed that these various rule systems are reconstructed or detected by the agency alone. Although single agencies can create rules for themselves, they inevitably do so in a cultural context. In our research on the development of understanding precursors of law in children (Weyers, Sujbert, & Eckensberger, 2007), we created group situations (with restricted action means), which by necessity had to end up in distributive justice problems. In an analysis of literally hundreds of video-taped action episodes, only *two* situations were found in which only *one* child created a rule (upward emergence) that was immediately followed by the group (downward selection). But not all rules are created or detected by children alone—to a great extent, most cultural rules are co-constructed in the enculturation process (Glick, 1985) and happen to be reconstructed under “adult guidance or in collaboration with more capable peers” (Vygotsky, 1978, quoted in Valsiner, 1987, p. 107). A very similar concept can be seen in Feuerstein's (1989) proposal of mediated learning, which according to him is even constitutive for humans and forms the essence of culture (*see also* Bruner, 1996). This viewpoint is also supported by psychologists working with chimpanzees, like David Premack (personal communication, 1984) and by

Tomasello (2001). Greenfield's (2002) ingenious work on hand-loom in the Zinacateco Indians, which are *offered* to children in an *age-related increasing complexity* and can be understood as adaptations to the sequence of the ontogeny of cognition *a la* Piaget, may serve as an example.

This kind of theorizing may look idiosyncratic at first glance, but it is not. As mentioned, Russian activity theory also uses action levels (but with a different rationale; *see* Eckensberger, 1995). Recently Molz and Edwards (2011) gave an overview of altogether 11 meta-theoretical approaches that use three hierarchical levels. Those of Bateson (1972), Christopher and Bickhard (2007), Gülerce's (1997), Kitchener (1983), and Sorokin (1958) come close to my distinction of action levels. But Martin, Sokol, and Elfers (2008) also distinguish three levels of reflection in social cognition (from prereflective interactivity through reflective intersubjectivity to meta-reflective sociality). However, here is not the place to elaborate on similarities and differences of these approaches in more detail.

### Dealing With the Duality “Content versus Structure”<sup>27</sup> in Moral Development

If one defines the importance of a theory in terms of the amount of theorizing and research it triggers, then Kohlberg's theory clearly is an important one. Although things have changed much since his death in 1987, his theory is still very much alive and productive (*see* the Association of Moral Development, AME, and the affiliated *Journal of Moral Development*). The amount of work, enthusiasm, as well as criticism this theory provoked (*see* Modgill and Modgill, 1986; Latzko & Malti, 2010 for the German context) is immense. But there is no need to summarize it here. Instead, only our own engagement with the theory will be focused on, which also began in the middle of the 1970s (Eckensberger & Reinshagen, 1978, 1980) and continues (e.g., Eckensberger, 2006a, 2010b). In this domain, the relation of action theory and dialectics was and is also crucial.

The interest in moral development from the very beginning was also part of my interest in the role of culture in psychology. Morality is clearly one of the most important *cultural rule systems*, and its development in the individual therefore has been central for a psychology that tries to include culture (Eckensberger, 2006b, 2007a). Kohlberg's theory was particularly appealing in this regard, because he claimed (Kohlberg, 1958), during the

value-relativistic orientation of the 1950s, that morality (as *the* exemplar of cultural relativism at that time) itself is a universal phenomenon in that it develops in a transculturally invariant sequence. He holds that developmental progress always occurs in a *non-reversible order*—that is, no stages should be skipped and regression to former stages is theoretically excluded (e.g., Kohlberg, 1976, 1986). This strong claim is not only a strength of his theory but also the Achilles' heel and a challenge. Even today it is difficult for many cross-cultural psychologists to accept that this claim is not based on a biological model (i.e., on biological universals) but rather on the assumption of a developmental *logic* that should apply cross-culturally (i.e., it is based on structural universals; cf. Eckensberger & Burgard, 1983). And this claim came under attack again in the postmodern orientation of the late 1980s.

This assertion was at all possible, however, because Kohlberg sharply distinguished between *content* and *structure* of moral judgments and because his universalism claim referred to structure. This perspective was derived from Piaget's structuralism, which is also not at all agreed upon in social sciences, where values and norms are still understood as content or normative orientations (Nauck, 2010)—these are either assumed as universals or as culture-specific frameworks. Because of its importance, in the following, reference will mainly be made to the content versus structure duality. But it will be shown that this duality has many implications for the whole theory.

### ***Toward a Dialectical Relation Between Content and Structure in the Development of Moral Judgment***

Before starting, it should be noted that it is extremely difficult to do justice to Kohlberg's theory, because it has been modified several times over the last 30 years of his life.<sup>28</sup>

1. *From independence to dialectics between content and structure.* Over time, not only the definitions of *structure* (form) and *content* changed but also the assumptions about their *inter-relationship*. Originally, the stages were defined primarily by the chosen *content*. Structure was only inferred as an ideal type, which connected the normative content favored by the stage (Kohlberg, 1958). Later, Kohlberg was convinced that he differentiated between the form of moral judgments and the content norm chosen. He

applied the complexity of *role-taking* (egocentric perspective, perspective of another, of a group, generalized role taking) as stage *structure*, and decisions in a dilemma as representing *content* (values/norms: life, property, authority, law, etc.). Additionally he distinguished further *ethical positions* (elements like egoistic consequences, utilitarian consequences, ideal or harmony-serving consequences, fairness) as *content*, which also entered the scoring manual (although differently over time). When talking about "holding content constant" so as to examine structure (Kohlberg, 1978, p. 55), structure and content were viewed as independent from one another. In fact, in the final versions of the theory, Kohlberg (1986; *also* Kohlberg et al. 1983) again followed Piaget (1932) by assuming some *mutual reference between content (values/norms) and structure*; thereby he, in fact, assumed a *dialectical* relationship between both.

2. *The centrality of the justice principle:* Beyond this, justice as the chosen ethical principle that guides the theory also came under attack. Gilligan's (1982) formulation of an ethic of care and responsibility has to be mentioned, a criticism which in some sense was supported and even expanded later by cross-cultural research and theorizing (for an overview, *see* Eckensberger & Zimba, 1997). A variety of culture-specific perspectives and principles have been proposed that appear not to be covered by Kohlberg's justice perspective, which also cast doubts on the proper conceptualization of content and structure as well as their operationalization in the manual—for example, the Confucian principle of *giri-ninjo* (obligation), which seems to be close to the Indian *ethic of duty* (Miller, 1994; Shweder et al., 1987). Huebner and Garrod (1991) have pointed out that in some Hindu and Buddhist cultures, morality is embedded in conceptions about the nature of human existence itself. There, especially the law of *karma* (i.e., the adding up of good [*dharma*] and bad [*adharma*] actions that may also have been committed in earlier lives) is regarded crucial. It leads, according to the authors, to types of moral reasoning totally different from the ones defined in Kohlberg's stage theory and manual. The Javanese/Indonesian principles of *hormat* (respect for older people) and *rukun* (harmonious social relations; Setiono, 1994) and the principles of *collective happiness* in the kibbutz (Snarey, 1983) require mentioning. Lei and Cheng (1984) noted that some of their Taiwanese interviews were difficult

to analyze, because their subjects referred to different types of *collective conflict-solving strategies* not mentioned by Kohlberg. Tietjen and Walker (1984) were faced with similar problems in Papua New Guinea. Similarly, Ma (1988) pointed to the Chinese (Confucian) principle of *jen* (love, benevolence, human-heartedness, man-to-manness, sympathy, perfect virtue), and the Indian principle of *respect for all life* (Vasudev, 1986), which lead to the principle of nonviolence (*ahimsa*) in Hinduism.

In fact, a long-enduring discussion exists on the relation between justice and care (Kohlberg et al., 1983) as well as between role-taking and empathy. Here it may suffice to say that one can interpret the tension between both as constituting a thesis and an antithesis. From this perspective, it is productive that Kohlberg, Boyd, and Levine (1986) discussed integrating (synthesizing) both orientations in a new formulation of stage 6, although that theoretical work did not have any consequences for Kohlberg's method either.

3. *Beyond justice operations and A/B – substages:* Additionally, Kohlberg added two concepts that also blurred the relation between structure and content. First he added justice operations (equality, equity, reciprocity) and the balance between the perspectives as a further criterion for structure (Kohlberg, 1985), which is analogous to a synthesis. Second, in following Piaget's (1932) notion of the development from a heteronomous to an autonomous orientation, Kohlberg (1976) elaborated on **A**-/**B**-substages. He saw them "as laying intermediate between content and form" (Kohlberg et al., 1983, p. 43). They referred to the equilibrated (**B**) use of a justice structure. Without going into details, substage **A** was more intuitive, and **B** was reflected and equilibrated. He first distinguished these types by means of elements (egoistic and utilitarian consequences counted as **A**, ideal or harmony serving consequences and fairness as **B**). Later Kohlberg et al. (1983) explicitly used "Kantian" and "Piagetian criteria" (which were not quite independent from one another) to score substages. If most criteria applied, it was **B**; if not, it was **A**.

By doing so, he somehow constructed two developmental paths of moral development (Eckensberger & Burgard, 1986; Eckensberger, 1986): one stage structure in terms of socio-moral role-taking (a *Meadian* path), the other in terms of **A**- and **B**-substages (a *Piagetian* path). But

the status of these substages was rather unclear from the very beginning (cf. Eckensberger & Reinshagen, 1980; Eckensberger 1984, 1986). And although some researchers (Tappan et al., 1987) later seemed to conceive these substages as a further refinement of the theory, Gielen (1991) rightly stated that Kohlberg's moral types (**A** and **B**) "*do not exhibit the same logical tightness and inner consistency that his moral stages do since the types intermingle structure and content to a considerable degree*" (p. 34). I have demonstrated (Eckensberger, 1984, 1986) that the substages in the manual are highly correlated with main stages (**B** substages increase and **A** substages decrease continuously with main stages), and I have pointed to the fact that the substage **B** criteria are barely discernible from criteria that define principled (post-conventional) stages. Hence, both the main stages as well as the substages represent an increasing trend toward *autonomy* (see also Tappan et al., 1987), which serves as an integrative concept. Moreover, the incitement conditions for substage **B** development are difficult to discriminate from the ones hypothesized for conventional and post-conventional development (institutions and societies emphasizing democracy, equality, cooperation, and mutual relationships; see Gielen, 1991).

4. *Stages and levels:* As is well-known, Kohlberg not only proposed development of moral judgment (structure) in six (later five) empirical stages but also organized these stages into three levels (stages 1 and 2: pre-conventional; stages 3 and 4: conventional; stages 5 and 6: post-conventional). If this classification has a developmental psychological meaning, then development between and within levels should differ in speed of development or in difficulty. Given the state of the empirical data in those days, this was, however, rather doubtful. The main difficulty in progress seemed to exist from stages 3 to 4—that is, it cut the second level of conventional thinking. In stage 4, a system perspective was involved (Selman, 1974; Kohlberg, 1976); formal logical operations seemed to be a necessary condition for stage 4 rather than for stage 3 (Kuhn, Langer, Kohlberg, & Haan, 1977). The known cross-cultural data (summary in Eckensberger & Reinshagen, 1980, p. 100 ff.) of the time suggested that stage 4 was difficult (improbable) in "face to-face cultures", whereas stage 3 was common (particularly Edwards, 1975).

Edwards (1986) and Ma (1988), for example, raised questions about the strict definition of Kohlberg's stage 4 in terms of *law and institutions*. From her investigations in face-to-face societies, Edwards concluded that the *social perspective of an informal understanding of roles should be sufficient for a scoring at stage 4*. Nisan (Nisan & Kohlberg, 1982) also proposed guess scores for a transitional stage between stages 3 and 4 for subjects' reasoning based on either family tradition or relatedness of the actors. Ma's (1988) formulation of Chinese stages of moral development interestingly only began with stage 4 (the first three stages were assumed to be identical in the West and in China) and ended in higher principles of harmony. Later, in following the German sociologist Toennies (1887/1957), Snarey and Keljo (1991) distinguished a community perspective (Gemeinschaftsperspektive) from a societal perspective (Gesellschaftsperspektive).

5. *Stage 4 ½*: Finally, two studies (Kohlberg & Kramer, 1968; Haan, Smith, & Block, 1968) led Kohlberg to formulate a stage 4 ½ (between stages 4 and 5). The reasons were different (regression from 4 to 2, and rescoring of stage 2 as a stage that was post-conventional but not yet stage 5). It was defined in terms of relative egoism and as representing a "personal and subjective choice (which) is based on emotions and hedonism, since conscience is seen as arbitrary and relative, as are terms like 'duty,' 'morally rights,' etc.," (Kohlberg, 1976, p. 17). As similar structures had also been found in studies of adolescence by Döbert & Nunner-Winkler (1975), there was no reason for treating this structure as an abnormality, as was done in the tradition of Kohlberg (cf. Colby et al., 1983), but they could be included in the main-stage development.

6. *Scoring*: Finally in scoring, it turned out that it was not difficult to differentiate between the adjacent stages; rather, sometimes stage 1 was similar to stage 4 (both have a heteronomous core), similarly stage 2 and stage 4 ½ seemed to imply similar structures (after all, stage 4 ½ was the result of rescoring some stage 2 answers in the Haan, Smith, & Block [1968] study). They both had a liberal relativistic core, either regarding actions means (stage 2) or personal choices in values (stage 4 ½). Stages 3 and 5 also had a similar core: focus on common interpersonal expectations (stage 3) and social contracts based on common values (stage 5), so both referred to

harmonious structures but on different levels of social abstractions.

Based on these ambiguities in Kohlberg's theory, we speculated about a different internal order of the stages. Partly following Piaget, we assumed that instead of a one-dimensional order of six stages in three levels, moral development happens like a spiral in two levels of social spheres. The first sphere is called the "personal" or "interpersonal sphere." Here, agencies or conflicting parties are viewed as concrete, more or less real people or subjects. This social sphere encompasses stages 1, 2, and 3. A second sphere, which developmentally follows the first, is called "transpersonal sphere."<sup>29</sup> Here, conflicting parties are primarily understood in terms of roles or functions or even general positions (abstract principles). This sphere encompasses stages 4, 4 ½, and 5. Beyond these social spheres, we have proposed a philosophical sphere of ethical positions. Instead of one post-conventional stage, we (Eckensberger & Reinshagen, 1980) have proposed three ethical positions: rule ethics, act ethics, and consensual ethics. We have also speculated about *decalages* between these stages from a lower social sphere to a higher one and have assumed a dialectical relation among the three stages on each level (1 and 4 thesis; 2 and 4 ½ antithesis, and 3 and 5 synthesis). But we first did not have a plausible reconstruction for this assumption.

#### CONTENT VERSUS STRUCTURE IN MORAL JUDGMENT DEVELOPMENT: ACTION THEORY IN DIALECTICS

Although some of the cited data were published later, they support the problems we (Eckensberger & Reinshagen, 1978, 1980) ran into with Kohlberg's theory (in fact, only the last three problem areas—numbers 4, 5, and 6—formed the basis of our earlier discussion). A better understanding particularly of the role of dialectics in moral development was (and still is) called for: (1) a possible *spiral in stage development*, as well as (2) the *dialectical relation* (mutual reference) between *structure* and *content*.

We began (Eckensberger & Reinshagen, 1978, 1980) with the choice of the structure of an action to define a new criterion for the structure of moral arguments. So a "paradigm shift" from *role-taking* (Kohlberg's criterion of structure) to *goal-taking* was proposed (Eckensberger, 1977; Eckensberger and Plath 2006a). *Instead of the classical social perspective taken on each stage, the perceived complexity of*

the actions involved in a conflict were applied as the leading criterion of stage structures, thereby applying action theory to dialectics. Later it was discovered that in analytical philosophy, a similar logic is applied to the concept of understanding another person, when, for example, Meggle (1993) elaborates “to understand a person means to understand his/her actions.” Meanwhile this paradigm is also increasingly being used in the context of social cognition, where the concept of TOM refers precisely to understanding others’ actions (see p. 893 and, for an overview, see Eckensberger & Plath, 2006a).

We (Eckensberger & Reinshagen, 1978, 1980) first analyzed Kohlberg’s manuals<sup>30</sup> (which later became the standard issue scoring; cf. Colby & Kohlberg, 1987) and then collected empirical (cross-sectional) data (Eckensberger, 1984; 1986; Eckensberger & Burgard, 1984, 1986). The justification of the choice of human action as the candidate for defining the structure of moral arguments was, in fact, simple. It was first based on the fact that the human action is the only way of defining and conceptualizing morality, because it implies a choice between alternatives and therefore a subjective decision, which is the precondition for the conceptualization of *responsibility* as a central moral category (Eckensberger, 1986; Eckensberger & Reinshagen, 1980); this is not true for role-taking. Second, it was based on the assumption that the human action is *intrinsically a universal framework* (Eckensberger, 2006b).<sup>31</sup> It is assumed that all humans experience agency, have goals, choose means, produce effects and results by acting, and coordinate actions, although these activities may be context- or culture-specific. So we still imply a *universal framework also for comparison*, which again implies that action theory is a culturally informed theory.

Generally speaking, *any structure consists of elements and their inter-relations*. If this notion is applied to the human action, then the most simple structure of an action can be defined by the *elements* of goals, means, results, and consequences and by different thought processes that form the *relationship* between these elements (see Fig. 17.3): *final* thinking (a means is applied in order to reach a goal), *logical* thinking (the choice of a means implies the result), and *causal* thinking relate the result with the consequences of actions. Additionally, consequences can (at least) be differentiated according to their *intentionality* into intended and unintended ones, and both are also *functionally* related to the results. Last but not least, it has to be remembered

that actions themselves are reflectively tied back to an agency, which is itself potentially self-reflective.

Actions can now be evaluated *in two regards* (see Fig. 17.3). First, they can be evaluated in view of their instrumental/functional adequacy. This means analyzing whether the chosen means are instrumentally adequate to realize a certain end or goal. Actions can, however, also be evaluated from a moral point of view. This is primarily made possible by the criterion of a potential *self-reflexivity and reflection* on the means. Although trivial, it is the principle choice of the means, which implies responsibility for the outcome. Second, the moral evaluation of an action implies analyzing whether different aspects or elements of an action (goals, means, or various consequences) possibly could or, in fact, do interfere with other actors’ interests (goals).

Thus, to define the structure of a moral judgment in this framework:

1. a given moral reasoning was analyzed in the light of the *complexity and comprehensiveness of the action structure* elaborated by a subject (e.g., whether a quasi-mechanistic relationship between ends and means is assumed, or whether the choice of means is considered to be a question of personal choice, and hence, of personal responsibility, etc.).
2. This reasoning was analyzed with reference to *where the subject locates the main conflict* (whether the conflict is located between the goals, means, consequences or entire actions, and/or an existing external rule).
3. A given moral reasoning was analyzed in view of the *standard* (or normative claim) being used by the subject either to prevent, to circumvent, or to solve a given or possible conflict.
4. In addition, to define the two levels, the action elements were generalized to values and principles, partly using Linton’s (1954) distinction between conceptual values and instrumental values or Rokeach’s (1969) distinction between terminal values and instrumental values, the former representing classes/abstractions of goals, the latter classes/abstractions of means. It is important to realize that within this approach, content and structure was not assumed to be independent but norm/value preferences were *intrinsic* to structural (stage) development.<sup>32</sup>

The subsequent higher stages can be reconstructed accordingly with the same dialectical relationship (Eckensberger & Reinshagen, 1980). At the first (stage 1), actions and action rules are

primarily interpreted intuitively and as being quasi-mechanistic. The conflict is located between existing norms and action means, Consequently, unilateral respect is expressed in the moral standard. The moral standard (content) that represents *unilateral respect* and an intuitive *rule orientation* on stage 1 can be understood as a *thesis*. Next (stage 2), the conflict is located between intentions and means, all intentions involved become important, and hence, means to realize all goals are focused on. The standard to *realize all goals* of the agencies and an *instrumental* and *outcome orientation* implied in a dilemma can be understood as the *antithesis*. It is only thereafter (stage 3) that complete actions are analyzed and integrative moral standards are developed. These standards imply mutual respect and *shared goals*. *These integrating* moral standards, which imply like harmony or consensus orientation, represent a *synthesis*.

The subsequent (transpersonal) stages can be understood as follows: First, the concrete social interactions are transformed into a group structure that is regulated by social norms/laws as means (stage 4, thesis). Then this stage is replaced by a standard that calls for efforts to order hierarchically the values involved in a conflict. It is this hierarchical order of the value system as super-individual goals that are used to define what is ethically right or wrong (antithesis). As before, the final stage (stage 5) is basically characterized by mutual respect, which, at this point, is now generalized to all rational human beings and to abstract positions (synthesis). So, altogether both dialectically interpreted internal relations in the stage structure have been plausibly reconstructed by action theory structures: (1) the spiral-shaped development (repetition of a dialectical sequence of thesis, antithesis, and synthesis on two levels of social reality) and (2) an internal mutual reference of action structures and normative orientations (values) in stages.

But these early proposals were supplemented by additional stages between these Kohlberg-related stages that we (Eckensberger, 1984, 1986; Eckensberger and Burgard 1986) formulated on the basis of their own data. They ended up with 11 stages, which, however, did not destroy the basic dialectical relation between the stages.

These data were collected using a different method than Kohlberg's hypothetical dilemmas. Rather than presenting the whole text of a Kohlberg dilemma (e.g., the famous Heinz dilemma), only the nucleus or core of a dilemma is used. For example, "There

is a young man who asks a druggist to get a drug, but the druggist refuses to give it." Then the interviewee is requested to ask more questions about the situation, because not much information has been given yet. Then he may ask, "Why do I need the drug?" It is not immediately explained that his wife is ill (like in the Heinz dilemma), but he is asked in return "Why is that important?" He may now answer, "I am ill," or "I am an addict." Again, one inquires, "Where is the difference?" and so forth. So the subjects *create* their own normative framework and make-up cases, which are all highly relevant for scoring. Only the highest score (in terms of action elements) counts as a stage score. This procedure was developed on the basis of the underlying model of man, the self-reflective human being. By doing so, we again admit Smedslund's (2009) later claim of taking this model serious also in methods.

Mainly for empirical reasons, the 11 stages were "condensed" into two levels on both spheres, which represent a development from heteronomy<sup>33</sup> to autonomy. Therefore, an interpersonal trend from heteronomy to autonomy is distinguished from a transpersonal one from heteronomy to autonomy. There are good reasons to argue that the second dimension of transformation of moral judgments is still best summarized as a move from heteronomous (intuitive reference to external behaviors, rules, simple interests of people) to autonomous moral judgment (mutual respect), as proposed by Piaget as early as 1932. This becomes obvious when looking at the standards (now called norms); the subject applies when discussing a moral conflict. So the claim that in moral development a "horizontal decalage" also occurs between the stages 1 and 4, 2 and 4½, as well as between 3 and 5 on the two levels has been supported. The notion of a horizontal decalage implies that it is not assumed that two different dilemmas are discussed on the same stage, and hence stage regressions from the higher to the lower levels may also occur (Burgard, 1989; Eckensberger, 1989), implying also a weakening of strict (internally consistent) level/stage concepts. We also argue that we escaped the problem Kohlberg ran into with his distinction into moral stages and **A-/B**-substages. The two developmental paths (Mead and Piaget) are integrated in this model.

#### **DUALITIES IN MORAL DEVELOPMENT: DIALECTICS IN ACTION THEORY**

Again, the role of dialectics in action theory as applied to moral judgments will be discussed, first

with reference to the action theoretically reconstructed stages, then for the contextualized everyday types of morality.

#### *Dialectics in Stages Defined in Action Terms*

First, in a later paper (Eckensberger, 1984), a *dialectical relation between the three levels* was even proposed in following Piaget's proposal to interrelate cognition and affect. We interpreted concrete action elements (personal social realm) as a *thesis*, the values on the transpersonal realm as *antithesis*, and principles on the philosophical level as a *synthesis*.<sup>34</sup>

There is, however, a second aspect in which dialectics contribute to the action theoretical reconstruction of moral stages (Eckensberger, 1986). This is, as in the case of action levels, the concept of the principle of *reflective abstraction (upward reflection) that explains the emergence of the stages that can also be applied here*: Every new standard (n + 1) emerges from a reflective abstraction triggered by impediments/problems/conflicts of the standard (n) of the previous stage. Every standard (*structure*), x, is therefore first operative on stage (n) then *content* of the abstraction (n + 1). Again, this is logically contradictory but developmentally plausible. However, once more also the complementary process of a downward selection process is assumed that regulates (re-evaluate) lower stages. These processes were not only speculatively assumed (after all, our data were cross-sectional) but also validated in interviewing. The content of lower stages is explicitly discussed by the interviewer and critically reflected on by the interviewee (Nieder, Sieloff, Kasper, & Eckensberger, 1987).

#### **CONTEXTUALIZATION OF MORAL JUDGMENTS (MORE DUALITIES—FACTS VERSUS NORMS; AFFECTS VERSUS COGNITION)**

Contextualization is one particular feature of dialectics because contextualization can be understood as environment (*Umgebung*) coherence (*Zusammenhang*) (Graumann, 2000). Basically, Kohlberg (e.g., Kohlberg et al. 1983) was a Kantian because he, like Kant (1966), wanted to keep morality free from empirical facts. Kohlberg constructed *hypothetical* moral dilemmas, which were intentionally *decontextualized*, whether he succeeded in doing so or not.

#### *Contextualized "Everyday Types" of Morality: Action Theory in Dialectics*

So, in following dialectically thinking, we also tried to contextualize moral development

(Eckensberger, 2010). After having defined what can be called a *deep structure of the development of moral judgment* by action theory structures, we turned to real-life contexts step by step by analyzing ecological issues (building a coal-fueled power plant, water consumption, following conventional or "green" farming methods) but also issues of education of democracy. In a way moral judgments were re-contextualized in this research. This was realized by the CIAT perspective, which theoretically allows the integration not only of the subject (agency) and context (culture) but also of norms and facts, as well as cognition and affect, because these dualities are part of the three action levels.

In doing so, methodically *biographical data* rather than the dilemma core or hypothetical dilemmas were used as a source of the data. Theoretically the four moral levels (derived from the 11 stages defined by action structures) were combined with the three action levels described above. The results were interpreted in terms of four *types of everyday* morality, which were still prescriptive (deontological) in nature but at the same time they were embedded in the everyday reality of the subjects. Two interpersonal types (heteronomous and autonomous) and two transpersonal types (heteronomous and autonomous) were defined (Breit & Eckensberger, 1998). The definition of these types was based both on the theoretical model and the analysis of data obtained from 180 subjects, who were intensively interviewed about ecological issues in their daily lives. The core of morality was defined by the complexity and normativity of the implied action concept. Additionally the kind of respect implied was used as a moral criterion as was the appreciation of rules (see Table 17.1). Because of the combination of the four types with the three action levels, normative concepts on the three action levels were also added: *risk-taking* on the first level, *responsibility* on the second, and *solidarity* on the third. Additionally, on the first action level (world-oriented actions), the perceived *efficiency* of actions as well as the *perception of facts* was analyzed.

On the second level (action-oriented actions), understanding of *control* in moral contexts was analyzed as well as the dominant usage of *coping* or *defence styles* (Haan, 1977). This was established using a particular text-analytic method (Sieloff, Schirk, Kasper, Nieder, & Eckensberger, 1988). Finally, on the third action level (agency-oriented actions), the basis of *identity* and concepts of

*solidarity* were analyzed. Beyond that the dominant *affects* were reconstructed within the four everyday types. Because affects exist on all three action levels, they differ in complexity. Hence, the dualities of facts and norms, cognition and affects, as well as content and structure were not defined independently (and related to morality in a second step), but from the very beginning they were defined *within* moral structures of the four types. Hence, content and structure were conceptualized as being mutually interdependent: content feeds back into structure (Eckensberger, 1986; Piaget, 1932)—that is, the understanding of facts also contributes to morality, and morality contributes to the understanding of risks (Döring, Eckensberger, Huppert, & Breit, 2008; Eckensberger, Döring, & Breit, 2001). Particular emotions also occurred (dominant) within the types: rage and wrath in Type I, indignation in Type II, the absence of affects (objectivity) was the ideal in Type III, and hope was dominant in Type IV. Hence, the normative structure (morality) shapes/influences the descriptive cognitive structures, but emotions also support both and are themselves triggered by them (Eckensberger, 2006a). In that sense, all these dualities form dialectic relationships, which can be understood in terms of a CIAT. Table 17.1 describes the four types and should be self-explanatory.

#### *Contextualized “Everyday Types” of Morality: Dialectics in Action Theory*

Empirically, the “everyday types” of morality were defined on the basis of data from adults. To be able to claim that they yet can be understood developmentally in terms of an increase in complexity or maturity, again the concept of the reflective abstraction (upward reflection) as a dialectical principle was applied in this context analytically as well as methodically. It is assumed that every type  $n + 1$  *emerges* on the basis of *reflections* on type  $n$ . Also the *downward selection* processes are assumed in type-development by devaluating type  $n-1$ . Additionally in this research, this assumption is used productively in the process of interviewing in that the interviewee is confronted with “lower type” ( $n - 1$ ) arguments as well—that is, s(he) is forced not only into reflection processes but also to re-evaluate the lower type. This method supported our developmental understanding of the types. This is illustrated by the backward arrows in Table 17.1.

## **Future Directions**

In closing this chapter, two aspects of action theory will be discussed, which are quite basic. I will argue that the concept of CIAT is relevant far beyond psychology. Therefore, the arguments would deserve a much more detailed treatment, which would, however, demand a second chapter. Yet, I at least intend to point to possible directions of thinking. The following arguments will be developed on two levels: one that focuses on the epistemological power of the human action (and therefore of CIAT) for *science in general*, and the other that focuses on the four (ontological) perspectives.<sup>35</sup> It will be shown that CIAT not only allows one to synthesize the self-reflective and the cultural perspective within psychology but also allows one to inter-connect all four perspectives, which is not the same as integrating them but is more than treating them as complementary (Eckensberger 2002).

## **The Epistemological Power of the Action Concept**

The first level, from which the four perspectives can be inter-connected by CIAT, may seem a bit exaggerated and rather psychology-centered at the first sight. But, in fact, the argument is quite simple yet also quite evident in the present context: as culture is understood as unique to humans and not only created by human actions but also transmitted by human actions, the same is true for science, because science is part of culture. This is true for the interpretation of nature and culture (*homo interpretans*) as well for the creation of culture (*homo faber*) as *man-made*. Hence, the different sciences can be elaborated on the basis of different aspects of actions (Eckensberger, 1993, 1995, 1996). This idea is not new, however, it is elaborated in detail by Holzkamp (2006) in his book *Science as Action*. During recent years it has been explicitly elaborated in the program of a “methodical culturalism” by the philosopher Peter Janich and his group as well (Hartmann & Janich, 1996), called the Erlangen school. Finally, the “constructive realism” of the Vienna group of Fritz Wallner (Wallner & Jandle, 2006) requires mentioning. They all rest on the early work of Dingler (1936/1987), who differentiated between *pool* (*Bestand*) of knowledge (*Erkenntnis*) and *acquisition* (*Aneignung*) of knowledge, a perspective that is equally central in Piaget’s theory. It is compatible with the definition of causality by having an impact on something by actions too, which von Wright (1971) has convincingly demonstrated

Table 17.1 Four Types of Contextualized Everyday Moral Judgments

Morality	Interpersonal heteronomous autonomous		Transpersonal heteronomous autonomous		
<b>Action concept</b>	Intuitive, external flexible understanding and acceptance of other's intentions	additional evaluation of action consequences/ shared goals	Laws as means to secure morality (flexible rule, exceptions)	Consequences for upholding self-respect; consequences for values, recognition of principles as goals	morality and rights are complementary
<b>Appreciation of rules</b>	intuitive acceptance of rules	shared rules	rights and exceptions	Universalized respect (respecting human-kind <i>per se</i> )	
<b>Respect</b>	one-sided	mutual	respecting social and legal systems		
<b>Identity</b>	based on similarity	relationships, tradition	functional roles	good life (virtues)	
<b>A III Solidarity</b>	shared interests	preservation of group standards	experts, power structure	world of potential moral patients	
<b>C Affects</b>	not articulated	not articulated	not articulated	<i>hope</i>	
<b>T Control – cognitive – affective</b>	external, conformity, defense > coping	co-control coping > defense	technological realizability defense > coping	reflection of interests/goals coping > defense	
<b>i II Responsibility</b>	delegation of power	individual responsibility for the group	legal responsibility of "expert-power"	moral responsibility of all people	
<b>N Affects</b>	not articulated	<i>indignation/guilt</i>	"objectivity" (not articulated)	not articulated	
<b>L Perception of facts</b>	important, individual	dependent on group interests	objectivity	reflection of limitations of knowledge	
<b>E Facts/norms</b>	norms as given facts	norms reconstructed as norms	facts dominate norms as institutionalized facts	Facts as such hardly exist, norms dominate and evaluate facts	
<b>V I Risk</b>	individual, to lose property/advantages	to lose one's reputation, lifestyle, group-related	to lose wealth or the power of society	loss of justice for all	
<b>E Efficiency</b>	maximization of benefits, adaptation	exchange, reciprocity	functionality of the system (market, technology)	self-commitment	
<b>L Affects</b>	<i>rage/wrath</i>	not articulated	not articulated	not articulated	

(see p. 876). Causality as one of the core concepts of *natural sciences* can best be determined by producing effects through systematic *intended* variation of conditions or by *intentionally* preventing things from happening *by means of human actions*. So *intentionality* (as a central concept in action theory) is the

*precondition for defining causality* (Eckensberger, 1996). In that sense, the physical as well as the biological perspective are *constructions* based on and derived from *human actions/co-actions*. It is non-trivial that the development of science is marked by outstanding humans (here by Darwin, Galileo,

Vico, and Descartes). That the entire discourse in science nowadays is based more on teamwork and interdisciplinary efforts (co-actions) is not a major argument against the present point of view: human action *creates* science.

Although there is much commonality among the underlying action concepts, there are also differences among the mentioned schools—particularly to CIAT. (1) The culture concept is not as elaborated as it should be, and (2) communicative actions are not considered as important as the instrumental ones. These, however, immediately connote *human science* and *hermeneutics* and *understanding*, rather than explanation and experimental strategies. Symbolic dimensions (secondary structurations) are not part of these theories, hence aesthetics are also not really part of the discussion. (3) Particularly, the three action levels are not distinguished. But doing so would be productive for reconstructing science as well. After all, *all scientific theories* are formulated by humans on the basis of *empirical activities* (primary actions) and their *reflections* (secondary actions), but *self-reflective processes* (identity questions of scientists and *responsibility* in science, tertiary actions) are also highly relevant. This aspect particularly is often neglected or even denied or avoided when psychology is considered a natural science (Smedslund, 2009). But within that perspective, no “research just for the sake of research” exists, because science has a purpose that is bound to human (autonomously chosen) goals, which means that science defined as action by *necessity* implies responsibility. On the other hand, there are good reasons for being cautious about going from “is” to “ought” transformations (called the *naturalistic fallacy*; see Eckensberger & Gaehde, 1993). A good example for holding psychologists responsible is Narvaez, Panksepp, Schore and Gleason’s, (in press) demand for taking an *ethical responsibility* based on the *factual* knowledge on early child development, including brain development. In addition the normative consequences Narvaez (2008) draws from her proposal of *triune ethics* can serve as an example. However, it calls for a note of caution as well because she draws normative consequences from empirical facts that are themselves of a *functional kind*—but functional norms are not ethical norms/principles. It is therefore important that within all action theoretical frameworks, the relation between facts and norms can be fruitfully discussed (Eckensberger, 2006) just as that between application (praxis) and theory (Eckensberger, 1989, 2003, 2004; Plath & Eckensberger, 2008;

Hartmann & Janich, 1996), and this may be symbolized by Dingler’s notion that “*in the beginning was the act*” (Dingler, 1928, p. 73).

Of course, this program is also criticized by critical rationalism (Albert, 1991), which only means that at present, the ongoing discourse is necessary and hopefully fruitful.

### ***Focus on the Four (Ontological Perspectives in a Relational Meta-Perspective***

Overton (2007, p. 156) elaborated on the necessity of relational meta-theory recently when he stated:

“relational metatheories are post-Cartesian and inclusive. Relational metatheories aim to transform classically fundamental dichotomies into dissociable complementarities through the relational principles of holism, identity of opposites, opposites of identities, and syntheses of wholes ( . . . ) Relational metatheories support holism, analysis in the context of synthesis, ontological spontaneous activity, dialectic and necessary change, necessary organisation, additivity/non-additivity, and linearity/non-linearity ( . . . ) there is no privileging of one side or the other, and no privileged explanatory base; inside and outside, and, efficient, material, formal, final explanation all play necessary, not epiphenomenal, roles in the full understanding of any event.”

But as mentioned earlier, these relational meta-theories cannot be formulated easily, because of the danger of their becoming ontologically empty (as already argued with reference to quantum theory). Therefore, the goal of this final section is rather ambitious despite its brevity. In a way, it attempts to square the circle because it tries to *retain all four perspectives*, yet to *inter-connect them by* CIAT as a *synthesizing principle*.

The basic assumption is first specified by the two mutually interacting concepts already developed and applied in many sections of the text. (1) Emerging upward processes (in human competencies the reflective abstraction) and downward selection processes, compatible with Dynamic System Theory (Juarrero, 1999), will be applied to the relationship among *all four perspectives*. (2) Again it is proposed that the *human action* can be *understood as the general synthesizing agent* in these processes. (3) Yet, it is of an utmost importance that one *not* assumes that these processes are of the same kind or ontological nature

(Emmeche, Koppe, & Stjernfelt, 1997). Rather, all four perspectives have a particular *inherent basis for the kind and range of possibilities/facilities, that enable and limit development*. They are therefore characterized by different possibility-concepts or “attractors” (Eckensberger, 2010a, 2011a, 2011b: The species (gene pool) provides the *capacity* inherent in this pool for phylogeny, which was already conceptualized by Mead (1934). But we distinguish additionally the individual body (particularly the brain) by its *potential* for ontogeny. The agency develops *competencies* (cognitive, energetic, and affective) underlying its performance, and culture has *resources* to offer, developed throughout history that can be used in actions. The four perspectives also imply different kinds of interpretations: The species is reconstructed by *ultimate causes*, the body by *proximate causes*, the agency – by *proximate reasons*, and culture by *ultimate reasons*. (4) From every perspective there exist mutual arrows toward the neighboring perspective, which are mediated by human action showing the emergence of these perspectives and a downward selection process.

This argument transcends earlier proposals (Eckensberger, 2002) that treated the different perspectives just as complementary<sup>36</sup>. In a recent paper, Martin (2003) has come close to our intentions.

Figure 17.5 tries to illustrate the assumed inter-relationships.

Figure 17.5 once more shows the splits between the four perspectives and the two cultures of humanities and science. Of course, humans cannot escape being dual creatures, belonging to culture

and nature. This is so because culture is explicitly understood as an *achievement of humans* that transcends their mere nature, it is built onto nature, but is not nature itself (Gehlen [1978] therefore called culture the “second nature” of humans; Dux [1994] speaks of culture as a “connecting organization” to phylogeny). For this reason, the classical perspectives, which represent the natural science perspectives, must also be maintained.

In Figure 17.5, the action (or resp. the co-action) is (like in Fig. 17.3) located in the center but between all four perspectives. This means that the action/co-action is assumed to *inter-connect all four perspectives*, thereby forming a *meta-system* or a *dynamic whole*, in which (upward) emerging processes and (downward) selection processes are active between *all* perspectives. To paint an admittedly speculative picture, it is assumed in Figure 17.5 that no single perspective can be used as a “reductive explanation” for any other perspective; rather, they emerge from each other and feed back into each other, and they do so *via* actions/co-actions.

The relation of the self-reflective and the cultural perspective *via* actions/co-actions has already been described (p. 880). So I will begin with the relation between nature (species) and culture (cultural rules).

Although it is often argued that it is not fruitful to separate culture and biology because they interact, it is not explained how this interaction is to be understood. Instead, cultures are often interpreted in biological terms and are explained by their *biological* adaptation as “man’s peculiar elaborate way of

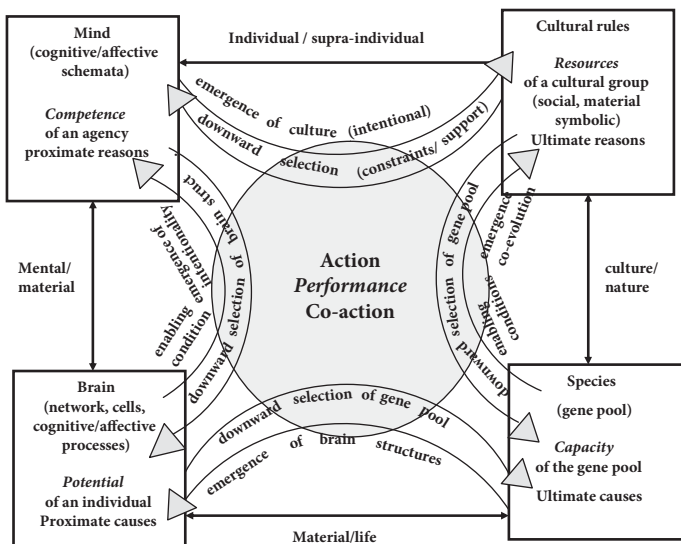

Figure 17.5 Action Theory as conceptual link between all four perspectives.

expressing the vertebrate biogram” (Count, 1958, p. 1049) or as an “epiphenomenon” and as “a product of selfish individuals, who are forced to live in groups” (Chasiotis & Keller, 1994, p. 77, translation LHE). Thereby the specifics of culture(s) as unique to humans is lost. In contrast, it seems to be more fruitful to argue that despite phylogenetic continuity in species, there is a qualitative shift in phylogeny, when it comes to humans (some behavior patterns in animals that look like cultures are rather proto-cultures from this point of view). Although there is no doubt that humans possess a phylogenetic continuity with other species, this does not imply that humans’ achievements and potentialities can be explained sufficiently by ultimate causes, by phylogenetic explanations. In fact, *logically* epistemological continuity does not follow from *empirical phylogenetic* continuity (that humans can be explained on the same level and by the same mechanisms as other species; see Eckensberger, 1978). Whether this qualitative shift is characterized by tool use, language, teaching, or empathy is at present a matter of debate. Even if some of these criteria can be shown to exist in a simple form in animals (Boesch & Tomasello, 1998; Janik & Zurbuehler, 2009), their *quantitative* developments in humans represent a *qualitative* change. Even Dawkins (1976), who can be considered one of the fathers of socio-biology, realized the danger of an exclusive application of this approach to humans, when he wrote at the end of his book *The Selfish Gene*: “Be warned that if you wish, as I do, to build a society in which individuals cooperate generously and unselfishly towards a common good, *you can expect little help from biological nature*. Let us try to teach generosity and altruism, because we are born selfish” (p. 203). Some time later, he formulates: “We, alone on earth, can rebel against the tyranny of the selfish replicators” (he obviously refers to the genes here) (Dawkins, 1989, p. 201). Psychologically the biophysiological processes as well as phylogenetic processes obtain their relevance only through their meaning in actions, developed and existing in cultural contexts.

So, at some time during phylogeny and the history of the species *homo sapiens sapiens*, killing became homicide, reproduction strategies became romantic love or arranged marriage; eating was cultivated by table manners and cultural styles (like using forks, spoons, and knives, chopsticks, or eating with hands); and simple nourishment was transformed into “nouvelle cuisine” and McDonalds. Yet the species survived and species-specific conditions

were maintained, but killing, reproduction, and nourishment were transformed by culture although nature forms the *enabling conditions* for cultural transformations and variations (upward emergence). However, culture also works on the gene pool by downward selection processes. This not only happens because of human actions of selective mating strategies (based on affiliation to social structure, caste, or religion; Eckensberger, Kapadia, & Wagels, 2000) but also by the process of industrialization and work distribution between man and woman and emerging (intentional) family planning and establishing (intentionally) a legal framework for family responsibilities, marriage and divorce, and by various means (actions) of birth control in history (from killing offspring’s to religious rules/prohibitions and different kinds of contraception strategies, family planning, genetic counseling, etc.). “Culture–gene–pool co-evolution” can only be understood from this point of view.

When we examine the relation between the mechanistic (here restricted to the neurophysiological perspective)<sup>37</sup> and phylogenetic perspective, then it is first clear that the phylogeny of the human brain is a complex process, and its understanding is by necessity still speculative (Learey, 1994). It can neither be separated from environmental conditions like climate change (Calvin, 2000) nor from the development of the body (blood vessels, shape of the skull) nor from the development of the upper limbs—particularly the hand (instrumentality and expression in gestures, leading finally to language; Rizzolatti & Sinigaglia, 2008)—nor from cultural achievements like hunting and use of fire nor from the development of agriculture and a more and more complex tool use, ending in industrialization (Learey, 1994). The assumption is that these physiological developments probably *emerged on the basis of the increasing flexibility of human actions/co-actions in context* (their biotope and culture) representing the “upward emergence” principle.<sup>38</sup> Davies (2006) considers natural selection in evolution a prominent example of downward causation: “Selection takes place at the level of the organism, but it is the genes (or base-pair sequences) that get selected” (p. 33).

Beyond this, the development of the human species is not only supported by brain development but also by social coordinations via language (communicative actions), which in themselves were probably triggered and supported by cultural development (Deacon, 1997) It is an empirical datum that, apart from a basically similar structure of all

human brains, at present not two brains are identical. In recent discussions in neuroscience, it has therefore been understood that cultural content (experiences of meaning and rule systems) leads to changes in the brain from the very first second of life, which creates the differences in single brains. Therefore, in that sense physiological processes in the brain cannot be separated from culture, and at the same time they are conditions for actions. Even the neurophysiologist Singer recently spoke of the brain as a *social organ* (Singer, 2008).<sup>39</sup> So the *potentialities* of humans allow them to create conditions of living that may or may not be biologically (!) adaptive. In other words: The focus on culture as a unique human phenomenon does not deny the utmost importance of biological- and neurophysiological-enabling conditions for human actions and therefore also for culture.

Consequently, within an action theory approach, I propose that the physical perspective as well as the biological perspective in particular also form the roots as *enabling and limiting conditions* for human actions. These conditions can also be understood as *potentialities* and *capacities*, which set limits and can be exhausted by humans. On the other hand, they can also be controlled and intentionally changed to a certain extent.

Recent neurophysiological interpretations of actions in the context of new brain research, which refer to (biological) proximate causes for human activities (Singer, 2000; Roth, 1997), therefore do not explain cognitive processes as such, although they clearly form their basis. Physiochemical (brain) conditions as *enabling conditions* can also be fruitfully discussed within this scheme—for example, the heated debate on the existence of free will (already mentioned) and its relation to brain structures in physiology (e.g., Libet 1999; Baumeister, 2008; Habermas, 2004; Singer, 2000). Particularly Gustafson's (2007) discussion of Wegner's (2002) book, *The Illusion of Conscious Will*, formulates the important insight that the fact that the subjective experience of will (conscious decision) seems to come *after* physiological activities in the brain (and therefore is not assumed to be the real cause of an action) would only be a problem for action theory, *if actions are interpreted causally*.<sup>40</sup> This is, however, not what I consider as productive: Self-reflection and the free will are, in fact, assumed to emerge from complex brain structures (upward emergence), but they are not of the same kind as the physiological structures (Murphy, Ellis, & O'Connor, 2009).

They form an emergent meta-structure with a unique ontology, which, however, also influences the brain *via* actions in a cultural context (Singer, 2008). In a similar vein, Narvaez (2008) recently discussed the neurobiological roots of moralities and even related these to present moral developmental theories, including Piaget and Kohlberg. Narvaez' paper is remarkable because she first reminds us that physiological brain development leads to a *hierarchical system that is maintained*. In fact, evolutionary older brain structures (reptiles, early and late mammals) are still present (and working) in the human brain. According to her theorizing, they imply particular behavioral systems, which she calls triune *ethics* (*reptiles*: the ethics of security; *early mammals*: the ethics of caring and bonding; *late mammals*: the ethics of imagination). She secondly clearly applies the process of *emergence* (Varela, 1992/1999) to the development of human conduct, and she thirdly very creatively draws *analogies* even to stages of Kohlberg's theory (cf. also Krebs 2005). It remains unclear, however, what these analogies represent *ontologically*. It is claimed here that the causal influence of these ancient brain structures may only dominate in doing, under highly existentially threatening conditions and time pressure (Eckensberger & Emminghaus, 1982), and that they are ontogenetically *transformed* into a qualitatively different ontology by the upward emergent principles. In fact, the present discussion is really only at its beginnings.

## Acknowledgments

The chapter is dedicated to my teacher and "intellectual father," Ernst E. Boesch. Since it deals with the development of Culture-Inclusive Action Theory and research that I conducted during the last 35 years, first in Saarbrücken and later in Frankfurt many colleagues contributed to its theoretical and empirical basis over these years (in alphabetical order): Judith Bettingen, Heiko Breit, Peter Burgard, Thomas Döring, Gabriele Gaul, Elisabeth Kasper, Renate Kreibich-Fischer, Bernd Krewer, Anita Nieder, Heidi Reinshagen, Ulrike Sieloff, Susanne Villenave-Cremer. Heidi Keller and Ype Poortinga basically took a nomothetic perspective on Psychology in long discussions and thus forced me to qualify my arguments in favour of action theory tremendously. I thank Ingrid Plath for her constructive criticism of the chapter and for improving its English, as well as Jaan Valsiner and Nancy Murphy for their very constructive critical comments.

## Notes

1. These authors—particularly Brandtstaedter—also incorporate the cultural context into their theoretical arguments. But this is not accidental, because Brandtstaedter also was a student of Boesch and obtained his degree as well as his PhD in Saarbrücken. But he only turned to action theory in the 1990s.

2. One should remember that a “second tradition” of *Russian activity theory* exists, with Vygotsky, Luria, and Leontiev as its most famous representatives, which overlaps with Action Theory to a great extent, but also has specifics. This relation cannot be elaborated here (for details, see Eckensberger, 1995).

3. This attitude is particularly cultivated in Taoism.

4. An intentionally *reflected* rule following would be autonomous. Narvaez (2009) recently discussed the role of intuitionism in moral theories and actions critically. I basically follow her criticism. But in following Bastik’s (1982) definition of intuitive judgments as immediate, spontaneous judgments that are certain but not based on substantiated thinking, then our theory allows for intuitive judgments in lower “stages” that are justified (if forced to in interviews) with reference to rules. And additionally we assume that in adults intuitive decisions/judgments also exist, but adults *can* reflect on them (see model of action). In fact, one can also argue that even Piaget describes a lot of intuitive thinking on higher stages of cognitive development as well.

5. Without going into any detail, it may be noteworthy that in the 1970s, German psychology also discussed the emerging field of an “ecological and/or environmental psychology”. So the reflections summarized here, went hand in hand with the discussion of “ecological” approaches in psychology and of the status of “ecology” as *human context*—particularly the tension between ecology (as a biological approach) and culture (Eckensberger, 1976, 1979c; Eckensberger & Burgard, 1977). The paradigms distinguished were also applied in later discussions of environmental psychology (Eckensberger, 2008a). Biological perspectives in ecology were distinguished from human action theories (Eckensberger, 1978, 1979, 2002a; Vogel & Eckensberger, 1988).

The fruitfulness of Action Theory in this context was based on the “fact” that human environment cannot be described solely by “if-then conditions” (causality) but also requires “in order to” conditions (finality). The (cultural) environment is build or influenced by humans with a *purpose*.

6. Later I tried to differentiate indigenous psychologies systematically from cultural psychology within this theoretical frame, although this cannot be elaborated here (Eckensberger, 2010a).

7. This is more or less agreed upon today also in science of science (Nancy Murphy, personal communication, She also pointed to Conant & Haugeland [2000] for this discussion).

8. Feuerbach transformed the statement “God created humanity in his/her image” into “Humanity created God in its own image” (Buss, 1979, p. 3).

9. Of course, this distinction is not commonly agreed upon by all social scientists and philosophers. Martin and Sugarman (2009) summarize and reflect on that issue in a detailed paper and basically agree that the subject matter of social science is unique. Without going into details here particularly the argument that not all actions are reflective, and therefore a legitimate demarcation between natural and social sciences concepts cannot be drawn. Kuhn (1991) is the reason why I speak of the “potential” self-reflectivity of the agency. But I also insist that natural science need interpretation (Eckensberger, 2011).

10. In fact, the decision to use that term is rather recent. Earlier we also used the term *cultural action theory*, which sounds rather clumsy in German. Hence, we borrow this term *culture inclusive* from Valsiner’s (1987) concept of a “culture-inclusive psychology,” which is conceptually equivalent and can also be used in German.

11. In our earlier analysis, we did not accept system theory as a solution to integrating agency and culture, because it contains functional but not intentional processes. Since then, I have come to know “Dynamic Action Theory”, which particularly Juarrero’s (1999) also applied to action theory and *intentions*. Heylighen (2011) even argues that the basic ontological categories for systems theory are *agents* and *actions* (pp. 6–8, italics LHE). It was particularly the discussion with Nancy Murphy on an International Symposium «Research across boundaries. Advances in Theory-building» University of Luxemburg, June 16–19, 2010, which encouraged me to propose the following arguments.

12. Although most of these authors are now known in the English-speaking community, Holzkamp probably is not. But Tolman (1994) provides a good introduction to his work.

13. This basic *integration/synthesizing* of agency and culture *through action* has been pursued in my writings since 1979, but Kim, one of the leading figures in the movement of indigenous psychology, also follows this interpretation now (Kim & Park, 2006).

14. Boesch uses the term “should values” in this context. He kept this term from his early cybernetic orientation. We avoid this term because of its “mechanistic” connotation.

15. So I make extensive use of Piaget’s (1970) theory—particularly reflective abstraction (but also to a certain extent the implied processes of assimilation/accommodation and decentration) is advocated as developmental principle or process that leads to a qualitative transformation of these standards during development in the sense of levels. Reflective abstraction is not just a speculative construct but can be discovered in “real” cognitive transformations; see the documentary movie by Thiel & Schönbein (2000).

16. For pragmatic and methodical reasons, we only apply two types of primary actions in our research. The philosopher Peter Janich (2006) is much more differentiated.

17. Taoism: Lin Yang (1948); Hinduism and Buddhism: Sinha (1996), Ohashi (1994); Confucianism: Ma (1988), Hwang et al. (2003)

18. Christian Boesch, the son of my teacher Ernst E. Boesch (see also chapter on Primate Cultures in this volume).

19. In interviews of 30 hunters, I analyzed whether the gun (which is proverbially the “bride” of the soldier) also has a personal symbolic meaning for hunters that goes beyond its instrumental purpose by asking them what they would do and feel if the gun were damaged. *All of them* would simply get a new one without emotions of sadness or a sense of personal loss. However, they would have exactly these feelings if they were to lose a trophy (deer head or fur). So the emotional personal attachment (in this case) does not develop toward action *means* but rather toward the symbolic representation of action *results*. Much more research is necessary to understand these processes of subjectivation.

20. It is not by chance that Boesch dealt only peripherally with symbolism in ethics (Boesch, 1998), rather emphasizing it in aesthetics (Boesch, 1983, 1993).

21. For a basic critique of the underlying assumptions from a cross-cultural perspective, see Rothbaum, Weisz, Pott, Myake & Morelli (2000).

22. Depending on the situation and cultural meaning: Bedford & Hwang (2003) with reference to guilt and shame. Kornadt, (2002) with reference to shame/guilt and anger.

23. Imagine a boy sees that his girlfriend is kissed by another guy. This would immediately trigger jealousy. But imagine that he learns that this other guy is the brother of the girl. The emotion would vanish.

24. An elaboration of these recent proposals is beyond the scope of this chapter.

25. The action levels of those days differed slightly, but the foundation of the later scheme was laid.

26. This is one of the misunderstandings of some discussions in cross-cultural psychology: Cultural psychology is not restricted to that sub-branch but represents a different psychology. For a distinction and interrelationship of cross-cultural psychology, indigenous psychologies and cultural psychology see Eckensberger (2010a).

27. The duality facts versus norms and cognition versus affects are only mentioned here shortly; they are extensively dealt with elsewhere (Eckensberger, 1993, 2006).

28. Whereas the stage descriptions published in various tables were hardly altered, central theoretical positions have undergone remarkable changes (Kohlberg, 1976; Kohlberg, LeVine, & Hewer, 1983; Kohlberg, 1986). With respect to the stage assumptions, Kohlberg in a way became more Piagetian than Piaget himself, because in the course of time, his stage concept grew more and more strict. Therefore, deviating from Piaget, a very important criterion for the validity of theory and method is the *internal consistency* of the stages (Colby, Kohlberg, Gibbs, & Lieberman, 1983).

Also with reference to his *methods*, he became more and more strict: Although he began with an interview following the clinical method of Piaget rather closely, his interview became more and more standardized over the years, as did his scoring procedures (Colby & Kohlberg, 1987a, b).

On the other hand, his theoretical arguments, clarifications, and corrections over the years somehow did not “get through” to the empirical level—for example, the *justice operations* that serve to define the structure more precisely in Kohlberg’s later writings did not enter the logic of the scoring manual, nor did the distinction of A- and B-subtypes of stages; they were first included into the manual than removed again.

29. Although this term triggers different associations of transcendental level (Kochetkova, personal communication), this is of course not intended. It was taken from Burgards (1986) reconstruction of Piaget’s terminology to the elaborated stage model of Eckensberger & Burgard (1986).

30. Mainly translated by Uta S. Eckensberger into German.

31. This aspect is interpreted differently by different “schools” (for example, see Wallner & Jandle, 2006). However, we use the structural aspects of actions for humans as *axiomatic*.

32. A similar logic was applied later by Keller & Reuss (1984), but for the first three stages of moral development only.

33. Autonomy and heteronomy are strictly connected to free choice or absence thereof. This implies that heteronomy is not understood as some enforcement by an authority or an external rule. Instead it is the absence of autonomy. This implies that intuitive judgments are also heteronomous because they do not represent reflective free choices. But decisions that follow external rules by free choice can also be autonomous.

34. Much later, this dialectical interpretation of the development of moral judgement was taken up by Minnameier (2001), who based his argument on Piaget and Garcia (1989) distinction of “intra, inter, and trans” (which is quite similar to our dialectical position). But he used perspective taking rather than action structures.

35. This term looks like an oxymoron, but the expression is intended to keep a constructivist attitude (perspective) while holding onto the assumption that the four perspectives differ in their ontological presumptions.

36. It was particularly the discussion with Nancey Murphy on an International Symposium «Research across boundaries. Advances in Theory-building» University of Luxemburg, June 16–19, 2010, which encouraged me to propose the following arguments.

37. I restrict my argument to the neurophysiological perspective, characterized as “physical/causal (proximate)” in Figure 17.1 and summarized as “brain” in Figure 17.5 because also classical learning theory as an example of the “mechanistic perspective” is increasingly interpreted in terms of neurophysiology. A more basic discussion of the principles that explain the “self-organization of matter and the evolution of biological macromolecules (Eigen, 1971) which nullifies the distinction of matter and life is far beyond the scope and level of this chapter. By applying the Darwinian principle of selection to matter, life is explained (reduced) to matter.

38. The anatomist Rolshoven, for example, in explaining the morphological change/development of the tegmentum argued already in the 1960s: “What happens in the periphery [in body activities], you will recognize it in the centre” (personal communication).

39. “Wir müssen das Gehirn als Teil seines soziokulturellen Umfelds verstehen. Unser Gehirn ist nicht nur von genetischen Dispositionen geprägt, sondern auch von unserer Erziehung, den Werten und moralischen Kategorien, die uns vermittelt wurden, und der Wechselwirkung mit anderen Gehirnen. Das Gehirn ist ein soziales Organ – man kann es nicht isoliert von der Umwelt verstehen” (Singer, 2008). [We have to see the brain as part of the social environment. Our brain is not only shaped by genetic dispositions, but also by our education, values and moral categories that we were taught, and the interaction with other brains. The brain is a social organ—one cannot understand it in isolation from the environment.]

40. Where else should free decisions be prepared for, if not in the brain?

## The Other in the Self: A Triadic Unit

Lívia Mathias Simão

**Abstract**

In this chapter, the notion of the *other in the self* is proposed as a *triple holistic developmental structure*. This proposal aims to account for aspects that have not been considered for understanding the constitution and maintenance of the self–other–culture processual structure yet. The structure here proposed is a derivation of Herbst's (1995) model of co-genetic logic. Additionally, it takes the self as an actional self (Boesch, 1991) dialogically oriented by the other (Marková, 2003; Linell, 2009). From this perspective, self–other interactions are approached under the focus of how the *triple holistic developmental structure* tacitly (Polanyi, 1966/2009) constrains (Valsiner, 1998) them in a feed-forward process. In this dynamics, new forms of cultural fields for symbolic actions (Boesch, 1991) can emerge. Some concluding issues, an illustrative analysis, and some future developments concerning the *triple holistic developmental structure* approaching the *other in the self* are also presented.

**Keywords:** triple holistic developmental structure, self, other, culture, actional self, dialogism, constraints

“(..) Triste noção tem da realidade quem a limita ao orgânico, e não põe a idéia de uma alma dentro das estatuetas e dos labores. Onde há forma há alma”

“(..) Gloomy notion about reality have those who limited it [only] to what is organic, not putting a soul inside the statuettes and handcrafts.

Where is a form, there is a soul”

—(Fernando Pessoa, 1997, “Livro do Desassossego” [Book of Disquieting], 416)

The main proposal of this chapter is to discuss the psychological notion of “the other in the self,” arguing that it embraces a threefold relationship among *self*, *other*, and *culture*. This relationship takes the form of a holistic developmental structure. As belonging to the realm of developmental phenomena, this structure is characterized for an

ever-changing movement, which makes it an always re-emerging structure.

### **The Threefold Relationship of Self, Other, and Culture**

The notion of the self has a very broad and long history in philosophy and psychology. The

vagueness and ambiguity of this notion can be considered very useful for heuristic purposes. However, precisely because of its fuzziness, it is necessary that one makes explicit the theoretical–conceptual frame in which the term is being used (Stam, 2006). Usually, in the domains of philosophy and human sciences, the notion of self leads implicitly to the notion of someone else, the non–self, who maintains some relation with the self. However, although conceived as partners in a relation, self and other are usually treated as if they were independently separated instances at the organic and/or psychological levels.

Besides, the socio-cultural aspects of the self–other relation is conceived as a something outside of them, as if culture were a kind of independent variable directly influencing self and other, which are consequently taken as dependent variables. Synthetically speaking, this view posits a dyadic relationship among the elements (e.g., self and other as dependent variables, and culture as the independent one); or even a triadic relationship (e.g., self and other immersed in culture; or self and other creating culture as well as being constrained by it). However, none of them accomplish to consider self, other, and culture in a co-genetic threefold relationship, as I am here proposing based on Herbst’s (1995) co-genetic logic.

Taking into account the psychological notion of “the other in the self” requires consideration that the relationship among *self*, *other*, and *culture* is conformed according to one of the main characteristics of the dynamically contextual human functioning. This dynamics can be accounted by a derivation of Herbst’s (1995) model of co-genetic logic. This logic, maybe as an alternative to the classical one, has not been considered for understanding the constitution and maintenance of the self (other) culture processual structure until now. This alternative logic, by putting in relief the distinction among the parts of a structure while, at the same time, keeping them joined as a triadic unit, may give us new ways of understanding the relationships among self, other, and culture.

According to Herbst’s (1995) co-genetic logic, any structure is formed, from its very origin, by a primary process of differentiation among its future compounding relational parts. According to him:

When a distinction is made, a boundary comes into being together with the inside and the outside of a form. What is generated in this way is a triadic co-genetic unit consisting of the inside and outside

**Figure 18.1** The form of primary distinction (extracted from Herbst, 1995, p. 68).

and the distinction made that is represented by the boundary. At this stage, we have nothing more than a form in an empty space. In most general form what has become generated in this way is a unit consisting of not less than three elements (...) In this case, primary distinction that generates the form (the inside) together with the empty space (the outside), and the boundary separating and distinguishing inside and outside, is only one particular realization of the primary distinction (...).

(p. 67)

Figure 18.1 shows Herbst’s form of primary distinction.

The triadic unit so formed has the following properties:

1. *It is Co-genetic*: The three elements that are generated come into being together.
2. *It is Nonseparable*: We cannot take the components apart (...) we cannot have them initially apart and then put them together” (...).
3. *It is Nonreducible*: There cannot be less than three components. If any one component (...) is taken away, then all three components disappear together”.
4. *It is Contextual*: None of the components have individually definable characteristics. In fact, they have no intrinsic characteristics that belong to them. (...) the components are individually undefined, but each is definable in terms of the two others. (Herbst, 1995, pp. 67–68)<sup>1</sup>

## The Threefold Co-Genetic Relationship of Self–Other–Culture

### *The Actional Self*

Instead of being a static, crystallized entity, the notion of self will be taken here as an actional self, who is always in interlocation with someone else: the other, or the I itself, in the I–myself interactions. Therefore, there will always be someone else for me as an actional self: the one who has created the masterpiece that disquiets me, the one who has composed the music that now delights me, the one

who directed the film that made me so anguished yesterday, the one who gave me a gift, who made me angry, who sheltered me. The actional self is, then, someone who is always in companion of someone else, co-creating their cultural world in both time and place. Of course, as highlighted by Boesch (2011), unfortunately this does not always happen in an ethically promising world.

Fortunately, the companionship between self and other keeps the proper tension of relationships among different participants, even when the involved persons can neither realize nor admit their differences, nor feel the thusly created tension. I am using the term *fortunately* in aiming to highlight the fact that thanks to the tension caused by the difference, the other may subvert the self's symbolic actional contribution, and vice versa, may be preventing each one of the presumptions of being the only and sovereign actor in the process of the meaning-making of personal and collective culture (Simão, 2011, in press).

#### CULTURE AND OTHER IN THE SELF

Culture, on its turn, is taken here in a sense that channels our sight to some specific aspects of the social life, which are directly related to the dynamics of the I–Other relationship. The notion of culture is concerned with the interactive social field, which, par excellence, modulates symbolic actions in contextualized time and place. Culture allows some persons' symbolic actions, and prevents others, so engendering a myriad of tensional situations in the symbolic world. In such an extent, the self–other relationships are understood as they act as modulators, and are modulated by, the experiences of the actional self in its cultural field. These formulations are based on Boesch's (1991) notion of culture, which clearly and consistently backgrounds and pervades all his oeuvre (Boesch, 2011).

The relationship between culture and self occurs through the figure of the other, this other being concretely present, distant, or even imaginary but, in any case, always the figure who makes remarks, sings praises, reproves—in sum, acts in a multiplicity of contextual ways, verbally and nonverbally, directly or indirectly. In so doing, the other becomes the representative of, as well as the one who renders concrete, in each particular moment, the affective and cognitive possibilities and limits for the actional self in a given socio-cultural constellation (Simão, 2000, 2008). All this is possible thanks to the nature of the dialogue as an intersubjective field of

similarity and difference, even under the perceptive human laws we are submitted to as belonging to the same species (Crossley, 1996; Boesch, 2011).

The perspective of the dialogism, which presupposes *the other orientation of the self* as a basic assumption in human sciences, is certainly also implied here:

A definitional point in dialogism is the assumption that human nature and human life are constituted in interrelations with “the other,” that is, in *other orientation*. Humans are always interdependent with others, although the degree and kinds of interdependence will of course vary with individuals, cultures and situations.

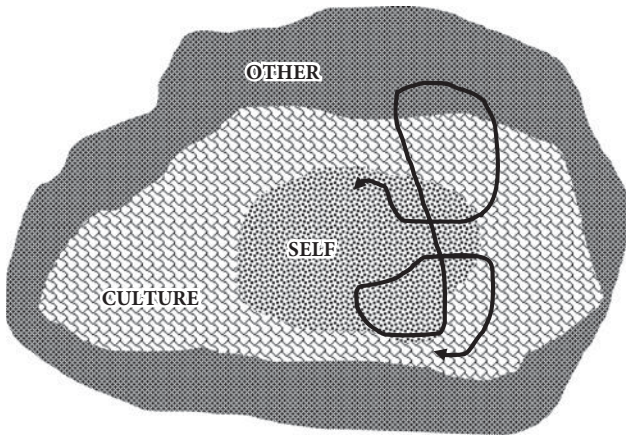

(Linell, 2009, p. 13)

Thus, a relationship of mutual constitutive interdependence is configured among the self, the other—as representative of their culture—and the expectations they have one about the other, their experiences diverging from the expected and the relational meaning among them. In this dynamic field of relationships, the self's and the other's meaning-making will occur according to the extent to which they can position themselves in respect one to the other as someone who gives opportunities for constructing new meanings, as well as supporting them in the social milieu (Simão, 2003).

In such a co-genetic emergent processual structure, the relationships are engendered thanks to the I's symbolic actions in its I–I and I–Other interactions in each particular and temporary socio-cultural milieu. The I's symbolic action, by selectively making distinctions from its experienced world, generates, at each moment and place of its life, diverse triadic units formed by the three elements that come into existence jointly and inseparably: the self, the other, and the relationship between them. *It is in the core of this third element—the relationship between self and other—that cultural objects (in the Boeschian broad sense) are engendered, through negotiations in face of the tensional difference realized by the self and the other as differences between them, as represented by Figure 18.2.*

As far as the social interaction is one of the main sources of self-formation in culture (for example, see Boesch, 1991, 2011; Simão, 2005), and assuming Herbst's co-genetic logic as the way of functioning of the triadic processual structure of self–other–culture here proposed, I will now approach some ways by which this process works in the dynamics of self–other interactions.

**Figure 18.2** The triadic processual structure of self–other–culture, as it emerged according to the co-genetic logic proposed by Herbst (1995), at each time and place in lifetime during self–other relationships.

### *How the Other Orientation by the Self Happens*

By proposing to discuss some ways of other orientation by the self, I will take into account some inheritances from the tradition of Ancient Greek thought, believing that these inheritances are nowadays present in our personal process of *Bildung* (Formation) in Western tradition. As any inheritance, it is not now present in its identical Ancient form but in a transformative way. This presence can be found in the ways we aim and try to establish our interpersonal relationships, as well as in the ways we evaluate and try to change them in everyday life. The same applies to our psychological understanding and explanation about them (Gadamer, 1959/1985; Taylor, 2002; Simão, 2005, 2008).

Among the Ancient Greek philosophers, one of the most disquieting aspects in the nature was *movement*. When they were trying to understand it, they arrived at distinguishing categories that made their conception of movement simultaneously more specific and broader than our modern conceptions of movement. Not one, but four categories of movement were conceived by the Ancient Greek philosophers:

1. the *local movement*, concerning the movement of things from one place to the other;
2. the *quantitative movement*, concerning the increasing or decreasing of things;
3. the *qualitative movement*, responsible for the changes in the nature of things; and
4. the *substantial movement*, concerning the generation and degeneration of things (cf. Mariás, 2004, p. 14).

As far as relationships involve changes (i.e., movement), the quest for comprehension about movement and the consequent differentiation according to these categories by the Ancient Greek philosophers interests us because they can raise some reflections concerning the apprehension and transformation in I–world (other) relationships. These aspects, by their turn, are linked to two inter-related aspects about the triadic structure of self–other–culture here proposed: (1) the ways by which it is formed and tacitly (Polanyi, 1966/2009) constrains (Valsiner, 1998) the self–other interactions in a feed-forward process, and (2) allowing the emergence of new forms of fields for symbolic actions (Boesch, 1991)—that is, new cultural processual structures.

### **The Issue of Transformation and the Self–Other Orientation**

Differentiating movements assumes that things may transform themselves during time, presenting themselves differently than they were. In such an extent, things *are not* (as if they had an *intrinsically immutable state belonged to them*), but they *are temporarily in this or that way*.

Among the categories of movement already mentioned, those referred to as the *qualitative and substantial movements* (more than the other two) lead us toward reflections about temporality, multiplicity, and contradiction inhabiting the self–other relationships.

Moreover, the category of *substantial movement* puts in focus the generation and degeneration of things during time. Differentiating and recognizing this category ends in bringing uncertainty over to the very and real nature of things, also carrying

the issue of how to state relationships with them. Recognizing the inconstancy of things in the world brings disquieting feelings, preventing oneself of ruling lines for self–other relationships that otherwise would be coherent with the tacit belief of stability. Generation and corruption imply that if there will be rules, they can only be addressed to the processes of understanding transformation.

In the ambit of self–other relationships, a relevant issue for human affairs shifts its terms from *what is the real and veritable knowledge about ourselves and the other* to *what kind of relationship we can develop with ourselves and the other at the present circumstances*. This issue poses the incessant quest for disclosing what is believed to be true behind the appearances of the other, who always seems changeable. All this means putting under suspicions the adequacy of self’s and other’s ways of acting, as well as the possibilities of a “real” apprehension of the one by the other. The expectation about the stability of the self–other relationships becomes, then, groundless.

*In the presumption that interpersonal relationships are not safe and regular as they wish or expect, as for the true person’s thoughts and desires may be hidden behind their appearances, self and other try to create relationships that will be patterned and ruled by ways of discovering and holding the unrevealed truth. Culture, as a field is created at the frontiers of self–other relationships, will be then less flexible and more ruling to guarantee the aims of safety in interpersonal relationships.*

In sum, as the self does not quit pursuing the *true knowledge about the other*, aiming to act on an ever more safe ground, the person will then be faced with one of the most important antinomies about the self–other relationships, the one of *stability versus transformation*.

From this antinomy, we can differentiate two versants of *other orientation in the self*. In the first versant that springs from the whole Ancient Greek thought, the *other orientation channels the self*—tacitly or explicitly—according to the conceptions of *illusion, uncertainty, and imperfection* as the hallmarks of self–other relationships. This channeling, as we will discuss, are linked to Plato’s and Parmenides’ philosophical inheritances. The second versant of *other orientation channels the self*—tacitly or explicitly—according to the conceptions of *potentiality and becoming (the time to come)*; it can be linked to the inheritance of Aristotle’s and Heraclitus’ philosophical ideas.

### ***Transformation As Illusion, Uncertainty, and Imperfection***

The pre-Socratic philosopher Parmenides (515–440 BC) was intensely dedicated to the fundamental issue of the *thing-in-itself*. He argued that acting in a twofold way is inherent to human kind when surveying the nature of things. Both ways of acting are not excluding each other, leading to different places. On the one hand, there is *the method of thought, the only way for capturing the being in its certitude, uniformity, unity, and veracity*. The way of thought is, however, counterposed by that of the senses, *leading to the uncertain, changing, mutable, heterogeneous, and multiple things*. The way of the senses *leads to grasping the things* as if, simultaneously, *they are and are not*.

For Parmenides, the perception of the aforementioned movements of generation and corruption of things are originated by the apprehension of things through the senses; these kinds of movements are, however, mistakenly understood as true attributes of things, as if one were grasping their *come to be*. It is a way of apprehension that is inherent in the human condition, making the pursuing of the thing in itself tricked by the senses. However, it is an inescapable condition of human beings. In conclusion, for Parmenides, via the senses, the human being goes pursuing something that can be rightly done only by the way of thinking (Marías, 2004).

Putting these ideas under the focus of self–other relationships, the quest for grasping the other in his permanence and unity (i.e., in what that other is in his essence) should be done through the self’s rationality, as the senses would only lead the person to encounter the inconstant and liable character of the other. *Thinking the other, rather than feeling the other, would be the “golden rule” for the other orientation in the self aiming to grasp the other’s essence behind its appearances*. This is the hallmark of a conception of self–other relationship settled in the dualism between *what is* and *what seems to be, but is not*; between *reality* and *illusion, veracity* and *falsity*; a dualism between *relationships ruled by the reasoning of thought* and *those ruled by the emotion of sensibility*. *The cultural field so engendered will value reason to the detriment of emotion*.

Moreover, one of the consequences of this kind of dualism is tacitly creating a synonymy between *transformation and nonessentiality* in the ambit of the other orientation in the self. It is a dualism that opens the ground for self–other relationships exclusively settled in rationality, taken it as the only

essential and desirable via for self–other relationships, whereas those involving feelings and emotions are considered as labile and less desirable. It is worth noting that the desirability of the former seems to be due to the fact that they intuitively believe in the possibility of objective interpersonal relationships, letting self and other free from the onuses of taking different perspectives as valid. Considering the assumption of the impossibility of the complete objectivity, the situation would require negotiation for creating a third or recognizing and validating its impossibility. These situations that imply negotiation would also probably interfere in the already stated knowledge about the state of affairs, which is in focus during the interaction. In other words, the path of negotiation requires recognizing that there is not only one valid apprehension and comprehension of some reality, but many. If so, the co-genetic unit of *self–other–culture* is kept, or is even unfolded in other co-genetic units, by distancing and polarization of its compounding parts. The non-negotiation method, on the contrary, puts the interlocutors in the territory of the emblematic and chimerical world of no tension. It is a world without place for the creative symbolic action as the movement, par excellence, of solving tensions (Janet, 1928, 1929; Boesch, 1993). *In such a way, the co-genetic unit of self–other–culture is broken down, and cultural innovation is prevented.*

The impasses created by the interplay of forces between both ways can be viewed as a inheritance of the *aporia* concerning making compatible the *unity, immobility, and eternity of the thing in itself* with the *multiplicity, variability, and perishing of the being* in Ancient Greek philosophy. This can be viewed as a good inheritance, as for Aristotle suggests that the very point of departure in any inquiry should be an *aporia* (Aristotle, 1979, p. 139, *Metafísica, Da Geração e Corrupção*, I, 8, 325 to 13).

#### THE PERFECTION–IMPERFECTION DUALISM IN SELF’S SEARCHING FOR THE IDEAL OTHER

Concerning the *aporia* here in focus, we can now turn ourselves to Plato’s (427–348/347 B.C.) philosophical ideas. Synthetically, they can be understood as a permanent quest for complementing *the world of things, which is never perfect*, to the *ideas of things, in their perfection* (Simão, 2010). Brought to the issue of the self–other relationships, Plato’s perspective points to the fact that we are always relating ourselves with a world of imperfect others, as the perfection is not lodged in the beings that inhabited

our world; perfection inhabits only in their essence, the ideas of others. The essence dwelled by the ideas are, however, inaccessible through via the I’s experience in our world, so remaining outside the ambit of the self–other relationships.

Moreover, in Plato’s philosophy, the entity—understood as the *thing in itself*—is not only perfect but also independent of its circumstantial predicates, what makes it not changeable according to them. If self–other relationships were framed accordingly, we would have a self that would not be altered by its past or present experiences with the other, nor by its future expectations about the other. The same would be the case for the other. In this respect, self and other would be above of their mutual interference and evaluation; they would be entities exempted from imperfections and differences predicated by their mutual relationships. Here, we have the emblematic perfection in the relationships to which the common sense wisely gives the label of “platonic.” There would be no tension, no necessity of negotiation—in sum, no actual interactive contact. Again, and consequently, the co-genetic unit is broken down; also there is no place for movements of differentiation, preventing cultural innovation in the sense here assumed.

But there is something more to be said: in Plato’s philosophy, perfection exists only in the realm of the ideas, not in the mundane real world of personal relationships. In such a way, self and other can then be mutually affected in their actual relationships. However, this affection still remains captive of the *thing in itself*; as the self will forcefully depend on some previous idea of the other, in expectation or imagination, for realizing its mere presence, the condition for any possibility of relationship. In such a way, the self should act symbolically at the level of the ideal anticipation of the other’s actions, thoughts, and feelings (i.e., at the level of the perfect entity), for having the opportunity of encountering the real other (i.e., the imperfect being). All this leads to the following consequence: what the self apprehends in its relationship with the other is not *what the other is* but only *what the other almost is*.

However, in Plato’s philosophy, the distance between the idea of the other and the real other as encountered by the self gives rise to a further *aporia*: if, on the one hand, for realizing and relating with anything we need previously have some idea about it and, if on the other hand, the idea is an event that cannot come from direct experience in the world, then we will always have access just to things as

imperfect instances of the ideas, never to the entities in their perfection. In such a way, the terms of our former issue derived from the platonic aporia are shifted: Even without the possibility of having access to the other as an entity in its absoluteness, the self needs to track the other at least as an idea in its perfection. This is the only possible way for the self to try grasp the other. As far as it is impossible for the self reaching the other in its absoluteness, it will forcefully reach the other only in its aspect of an imperfect other.

In other words, the quest for perfection, for the essence (the entity), remains conditional to the imperfection of the self–other relationship, the only via for its access to the world, through the I’s symbolic action. It will always be, then, a distance between the idea of other, in its perfection, and the other as the self can encounter it, what gives place to the tension between *what is planned, expected, and desired* and *what is effectively encountered* by the self concerning the other and their relationship. *As culture is a field originated from the core of self–other relationship, it will be always a real (imperfect) construction of the humankind, aiming to solve the gap between perfection and imperfection through symbolic action.* In such a case, the self–other–cultural co-genetic processual structure here proposed could be kept and will always involve a struggle for perfection.

However, as in the Platonic philosophical context, the major issue is the possibility of the human being reaching Perfection and True, the other enters then only as an instrument for the I reaching those absolute values, rather than being the other—interlocutor. This is, indeed, the main role of the other in platonic dialectics (Voelke, 1961; Szymkowiak, 1999; Marková, 2003a).<sup>2</sup> In this frame, identifying and recognizing differences among beings, as between self and other, will only account for displacing them from the ambit of the essentiality of the entities and not for approaching the subject of differences concerning the “real and mundane world.”

#### THE TRANSFORMATIVE CONSTRUCTION OF ERNST BOESCH FROM A PLATONIC INHERITANCE: AN ILLUSTRATION OF CULTURE IN PSYCHOLOGY

In this section, I will work mainly with two aspects of Plato’s philosophy inheritance, trying to illustrate the transformative and creative psychological thought about the self–other–culture structural

process. For this purpose, I will analyze some of Boesch’s proposals, as I understood them from my own perspective, taking them as a transformative intellectual construction that contemplates aspects of Plato’s philosophical conception.

At this point, it is worth recapitulating two of the main tenets of Plato’s philosophy as we have brought to our focused subject. First, the I–world relationship happens at the level of *imperfection of things*, if considered the *perfection of the absolute of the ideas*. This means that the self can relate itself just with a world of imperfect others, as the perfection of the essence of beings is not accessible to its worldly experience. Second, as far as the I is imperfect in its humanity, because not naturally provided of the Goodness and the Beautifulness, the self will try to accomplish Perfection through its relationship with the other.

At this point, it is important to listen to Gadamer. He points out that delineating the historic-cultural place of the concept of Beautifulness in hermeneutic (among other aspects) to the tightly relation between the ideas of Beautifulness and Goodness in platonic philosophy, which are sometimes even interchangeable. Moreover, Goodness and Beautifulness are beyond the circumstantial conditions of the things, concerning what is unitary and unconditional in their whole essence. Goodness and Beautifulness are above all world circumstantialities (Gadamer, 1959/1985).

Nevertheless, Gadamer also warns that in platonic philosophy, there is a deeper distinction between Goodness and Beautifulness, as only the latter has the property of being showed by itself. This differentiated character gives to Beautifulness the most important ontological function, that of mediation between idea and phenomena (Gadamer, 1959/1985).

If brought to the focus of the semiotic–cultural constructivism (Simão, 2005, 2007, 2010, in press), these aspects of platonic philosophy appear in important transformative conceptions that are present in Boesch’s thought.

#### *The Beauty of the Sound*

The human experience of questing for perfection is clearly approached by Boesch in his *oeuvre* as, for example, in one of his most important papers entitled *The Sound of the Violin* (Boesch, 1993). Boesch reconstructs there the filogenesis and ontogenesis of the violin and the violinist in their intimate relationship. At the very beginning of his paper, Boesch

explains that the understanding of the term *ontogenesis* he invites us to take in its original sense—that is, the sense of “what comes to be.” This means to take the term in the sense of *potentiality* and *coming to be*, one of William James’ impacts on Boesch’s thought (Simão, 1999; Simão, 2002). In his own words, “Indeed, a violin becomes really a violin only on being played” (Boesch, 1993, p. 72). The potentiality, the come to being of the symbolic object, in its function and meaning, is then actualized only through the relationship with the subject.

But this is not only for the object: the apprenticeship himself has also his genesis as such. The eventual future violinist, through a challenging and painful process, faces himself, at once, with the difference between *the sound he desires the violin produces* and *the sound he realizes he reached that the violin has produced*. The violinist is so confronted by the distance that separates him from *what he is, in his actual relationship with the violin*, from *what he is not yet, what he desires to be and may be will never be*. In such an extent, the relationship with the violin, in the perspective of the violinist’s *comes to be*, confronts him with his own limits, transforming him in some way. Therefore, Boesch brings to discussion the issue of the emergence of symbolism through the subject’s action in his relationship of tension and distension with the object. This is a process where the I (the violinist) searches in its relation with the other (the object violin) for the Beautifulness as near as Perfection, although never reaching them at all.

Boesch enters, then, in a Janetian way (Simão, 2003b), where the antagonism between perfection and imperfection experienced by the self is clearly present. From here comes the micro and ontogenetic value of the quest for perfection, as it instigates the self for continuing to want to be. For Boesch (1993), the reason for the maintenance of the young violinist, usually a child, in the activity as a violin apprenticeship is her *search for her sound*, that sound that *only she can extract from the violin*, that she can *recognize as her sound*; it *affects her, touching her heart in an indefinable way*, producing a *contentment and fulfilling* in the few and liable moments she reaches the violin produces that sound (cf. p. 74). This means, in Boeschian terms, the real cultural quest for perfection, which is always a step further from where we presently are (cf. Boesch, 1993, pp. 76–77).

We are here clearly facing the human search already announced in Plato’s philosophy: the Beauty,

in its perfection, bringing Goodness together; neither, however, is ever attained in their plenitude. On the other hand, in Boesch’s semiotic-constructivist contemporary ideas, there are at least three reconstructive aspects that are far away the strict Platonism, clearly illustrating the transformative process of creation in tradition (Gadamer, 1959/1985; Taylor, 2002), as I would like to bring here in focus.

First, in Boesch, the search for perfection is explicitly recognized as a transformative cultural process in the self, putting the things nearer to Gadamer’s (1959/1985) conception of self-relationship with masterpieces. In Boesch (1983), the violinist’s search for the Beautiful Sound requires a complex and subtle imbalance between the *is value* and *should value* (Boesch, 1991). Managing this requirements will challenge the self (the violinist), if he lets himself be challenged in the process of making art. In a similar vein, for Gadamer, the horizon of the masterpiece *interpellates* who really looks for its comprehension, who lets it be interpellated by it, in ways that the self went out transformed in this dialogue.

Second, the necessity and feeling of fulfillment, which is experienced in the process of a constant search for perfection, is eminently dependent on self-subjective processes. In this sense, Boesch’s propositions seems nearer to the primacy of the self’s inner resources than the mundane-ideal imbalance of forms, maybe putting his/her propositions nearer from Augustine’s than Plato’s inheritance.

Third, according to Boesch’s Symbolic Action Theory, in the self-other relationships, the self not only continuously reconstructs the symbolic objects (the other here included) but also transforms itself, as in this process it experiences its action potential—that is, the experience of can or cannot reaches its covet personal patterns (Boesch, 1991). This aspect puts Boesch’s reconstructive propositions about Beautifulness and Perfection closer to the real self in its lived world. This keeps, at the same time, the self’s present experiences and the desire for transcending its experience at the heart of the self, not in an external world. In such a way, Boesch reaches to keep both worlds—the present and the desired, imagined—together inside the self, rather than platonically interdicted in their communication.

### ***Transformation As the Potentiality of Coming to Be***

In the domain of Ancient Greek philosophy, it will be Aristotle (384–322 B.C.) who refused the

synonymy between transformation and nonessentiality, inherited from Parmenides' thought, attributing a special place for the issue of mutability of the natural phenomena.

Nevertheless, as highlighted by Marková (2003), it is important not to forget that despite the fact that it was Aristotle who opened the place for the pair of opposites *potentiality and actuality* in Ancient Greek thought, he still remained faithful to the canon of non-contradiction in Ancient Greek philosophy. In such a way, potentiality and actuality remain as mutually exclusive in Aristotle's philosophy, an inheritance that will preponderate in European thought until the advent of Hegel's dialectic but has never completely disappeared until now (see Marková, 2003, pp. 34–37).

Although keeping this aspect in mind, we can reflect about some particular implications of Aristotle's philosophy for the understanding of the self–other–culture processual structure proposed. The character of the other enters in Ancient Greek philosophy only when Aristotle takes the phenomenon of friendship as paradigmatic for the comprehension of human relations. For Aristotle, friendship is an event that touches the live beings (humans and other animals). The condition for considering that friendship exists in a particular relationship is that the involved persons should be capable of recognizing that they are the objects of the other's attachment, as well as being capable of retribution (Szymkowiak, 1999; Voelke, 1961). Therefore, Aristotle's conception of friendship implies a preponderantly symmetrical self–other relationship. It is settled in the equalized apprehension of the nature of the ongoing relationship by the involved persons, as well as their explicit reciprocity.

This conception of friendship is clearly founded on the Aristotle's *Metaphysics*, in which he postulates that for each category of entity there is a set of essential properties and availabilities without which that entity ceases to exist. Variability from the essential properties is, by its turn, assumed as the different circumstantial modes through which essentiality can concretely be effective in each particular case. Among these modes by which variability can express itself, two pairs of modes are especially important for our discussion: first, the pair *veracity* and *falsity* (respectively, when the being shows his own nature and when it shows a nature that does not belong to it); second, the pair *potency* and *act* (respectively, when the being manifests something

about its come to be or when it manifests what it presently is) (Marías, 2004).

The importance of these pairs of modes to our focus is that they address to dual forms of self–other relationships as, for example, the true versus false friendship. These pairs of modes also address, consequently, the self's acts aiming the construction and maintenance of the true friendship, which according to Aristotle's thought, is the main way for accomplishing the human potential of being happy in life.

In fact, the Aristotelian most important moral value is the human constant search for the sovereign Goodness of happiness. In Aristotle teleology, this is the supreme goal, under which all other are subordinated as means for reaching it (see Voelke, 1961). Searching for happiness, in Aristotelian terms, should be understood not as if it were an exceptional occurrence but a natural one. It is the natural way destined to the existence of the human beings in their world, which should be reached through their effective actions. Bringing this philosophical frame to the self–other relationships, the cultural value of friendship will be the principal method for the self's attainment of happiness.

The range of uncertainty will, then, fall over the issue of skillfulness and perfection in the search for happiness—in other words, I's virtue in acting for the perfect self-realization of coming to be happy, the natural way for the human beings. However, according to Aristotle's philosophy, even the virtuous person is not self-sufficient for her self-realization in happiness, as the self never can prescind from the other in this pursuit. In self's search for being happy, different interconnected roles are reserved for the other.

Insofar as the attainment of happiness depends on a continuous activity of the self in searching it, as uninterrupted as possible, its questioning is at the level of the self virtues. According to Aristotle's philosophy, it is easier to be virtuous in companionship than alone, as the other, through its actions, feedbacks the self's attitudes and paths.<sup>3</sup> Besides, as far as the other is someone who is demanding in the very convivial relationship, the I needs to make use of his virtues for being convivial with the other, what makes him better by practicing a more enriching activity concerning social interaction. Last but not least, the relationship with the other allows the I to exercise him-/herself in love. In Aristotelian philosophy, love is a Good in itself, as it touches to happiness and self-accomplishment, natural destinies of the human beings.

As should be expected, in face of the weight of the other's role, this other must be someone who fulfills some requirements to give the best opportunities for the exercise of virtues by the self and should be someone who can give the best opportunities for a virtuous self–other relationship. As such, the other must also be virtuous.

At first sight, then, the undifferentiated and, in some sense, self-centered figure of the other, that one who is “someone but not me” will become, in Aristotle's proposals, a very special other, the fellow. However, the other as friend is still a self-centered figure, as he should be “someone as similar in Virtues as possible to the self,” an alter-ego. The other as friend will be, indeed, reduced to a subcategory of the self, a kind of self detached from the I, with whom the relationships must be similar to those hold by the I with the self.<sup>4</sup>

In sum, according to the Aristotelian philosophy, the human life is something naturally good and nice. It consists of feelings and thoughts that are actualized in activities, especially those about which the human being is conscious. We will desire to live if our consciousness is informing us that we are accomplishing our natural function of having a nice and good life. The conscious activity is, however, more difficult when turned to oneself than when turned to another, to the friend, that “myself detached from the I,” with whom the relationships are very similar to those of the virtuous I with himself. The friend, the alter ego who amplifies the self-consciousness and its living, will be, therefore, so necessary to the self-accomplishment (Voelke, 1961).

Besides, and maybe more relevant for our discussion, the person's consciousness about that alter ego allows him/her, by contemplating the other's virtues, to contemplate the virtues in his-/herself easier than he/she could do if he/she had only him-/herself for contemplating; to see oneself in the mirror is easier than without it. In few words, the virtuous man will need friends who resemble him in virtues to contemplate himself.

If the self needs the other for activities that allow him the search of Perfection in living—that is, for his self-accomplishment—this other should be a virtuous friend as the self, an alter ego to whom the self can have a perfect and veritable friendship. Therefore, in the Aristotelian philosophy, the access to Goodness does not happen against a background of diversity but of similarity with the other; does not happen against the background of difference and alterity but against that of the other as an alter ego.

Moreover, if the other as an alter ego is the mean for knowing oneself, then that other must be similar and apprehensible by the I— as much as it is, the best the I can fully know and feel itself and fully live. Happiness, then, is brought by similarity with the other, accompanied by its consciousness.

These possibilities of self–other relationships as a way for the self-awareness and self-accomplishment is settled, in a great part, on the Aristotelian metaphysics about knowledge, where the fundamental character of *empeiria* is to allow a kind of knowledge that cannot be taught to another by the knower; the one who knows can only give conditions for the other to have similar experiences. Brought to our context of discussion, the self–other relationships would allow the *empeiria* to the self, through the individual, particular and circumstantial experience of getting knowledge about oneself in the familiarity with the other. It will be, then, through the mediated experience in self–other relations that the human being will search for the wisdom about himself, for the *sophia*.

As already noted by Cuvillier (1938), the basis for the Aristotelian conception of friendship is analogy in its strict sense of the mathematical proportion. However, in its extended sense, it concerns a kind of reasoning in which one goes across some established similitude to other not yet established. Additionally, Marías (2004) explains that in the Aristotelian sense of analogy, many different things are connected thanks to a common aspect in their nature.

In fact, for Aristotle, in a perfect friendship the attitudes the self has toward the other are analogous to those he would have toward himself (cf. Voelke, 1961). This means that I would not conceive the other as identical, but analogous to itself; anyway, it would always be a process of construction of self–other relationship by similitude, not by contraposition. Besides, as the direction of the process is preponderantly from the self to the other—and not bidirectional—it transpires some omnipotence of the self in the course of the relationship.

In Aristotle's view, individualism and utilitarian attitudes make unviable the attainment of the perfect friendship. However, friendship can embrace imperfect aspects. In this case, because of its combination with altruism, the result will be that the very friend would like to be useful and give pleasure to the other (Voelke, 1961).

The perfect friendship will also embrace the interplay between altruism and individualism in the

context of approximation or distancing from suffering. The paradigmatic situation in Aristotelian terms is the one in which, if Friend 1 is suffering, the other (Friend 2) will try to share such a suffering with him (Friend 1), believing that his attitude can relieve his friend's pain. Almost paradoxically, Friend 1, on his side, trying to be a real friend of Friend 2, would try to avoid that such sharing because it could bring pain for his Friend (2).

In a coherent way, in the Aristotelian solution for this impasse, reason must prevail upon feelings. According to this criterion, the very friendship among human beings will be distinguished from the vital communality among other animals, as well as from the loving relationship. The way of reason will allow that the very friendship constitutes itself not through the identity fusion, but through rational reciprocity. Reciprocity presupposes the vice versa, whereas rationality presupposes the awareness of reciprocity in the relationship. As such, the very friendship, although lived at the affective level, will be known at the thought level (Voelke, 1961).

Aristotle gives, then, an integrative destiny to the dichotomies of *perfection–imperfection* and *individualism–sharing*. The attributes that make the friendship perfect or imperfect (altruism vs. utilitarian feelings and self-pleasure) become, through the way of rationality, a whole hierarchically more complex than the former forms of relationship, which preserves the primordial character of perfect friendship. This, however, makes it something hybrid, less pure, and maybe more real, as it also embraces some utilitarian attitudes and the pleasure in the relationship with the other. Imperfection, by its side, becomes less imperfect in this new arrangement, because it is at the service of a virtuous relationship, through altruism.

This reorganization may open the doors for transformation of the self and other involved in the friendship. However, in face of the Aristotelian presumption of the other as an *almost myself*, where the pleasure of the self and the other are barely distinguished, that process, in principle a reorganizing process, ends in configuring a situation where, if no one loses, also transforms himself.

About equality and inequality, the Aristotelian perspective is that of proportional equality, in which the merits of each person involved are contemplated: the most powerful, for example, should receive honors proportional to the extent he/she has helped the weakest (Voelke, 1961).

It is, then, a conception of self–other relationship where complementarities become synonymous

of symmetry and equalization, and the purposes of each one should be convergent to the other's. Divergences will be indicative of imperfection and lack virtuosity in the symbolic actions that construct the *self–other–culture* relationships.

### *Heraclitus and the Unity in the Tension*

Heraclitus' (approx. 550–480 B.C.) philosophy inherits mostly the issues brought about by Parmenides' philosophy, which had installed the antinomies of *being* and *not being*, *unity* and *plurality*, *stability* and *changing*. As we already mentioned, these antinomies touch to another issue, that of the transformation of things, *to the one that becomes the different*. Heraclitus' metaphysics relies on the idea of movement, of mutable reality, according to which everything flows. This mutability expresses itself in the duality of the being, who, as a creature of the world, *while actually being, is already in a movement of coming to be, of being no more what it just was*.

According to Bréhier (1931/1988), there are four basic and inter-related themes in Heraclitus' meditations. These themes are directly related to our discussion about transformations in the processual triadic structure of self–other–culture.

The first Heraclitean theme is war, attributed by Bréhier to the fact that Heraclitus lived in a time of great civil catastrophes in Greece. In those times, the birth and the conservation of beings were dependent on an imbalance of opposite forces in conflict. In such a perspective, the absence of conflict would cause the cessation of the universe. Conflict, therefore, is taken in its aspect of fecundity, where opposite forces harmonize, "as the forces that maintain the tension of the strings of a bow" (Bréhier, 1931, p. 62). We are, then, by other ways, very near to Boesch's *The Sound of the Violin ...*

The second theme in Heraclitus' philosophy is the unity of nature and of everything that inhabits it. This unity is, however, hidden behind an appearance of multiplicity, making the former evident only through the intuition of the laws that rule transformation. In such a sense, wisdom means to grasp the general formula of the world changes, especially the ones related to the temporal cycles (see Bréhier, 1931, pp. 62–64).

The third Heraclitean theme—and probably the most known—is the perpetual flowing of things, from which the being cannot be divorced. Bréhier (1931) explains it by giving its paradigmatic circumstances of manifestation: "[T]he young becomes aged; life gives place to death, the

vigil to sleep; cold things come to be hot and the wet dries” (p. 63).

Finally, the fourth theme of Heraclitus’ philosophy concerns the fact that the things embrace the opposite of what they reveal about themselves. Grasping their opposite side depends on the perspective according to which one’s take them (Bréhier, 1931, p. 63).

Among the fourth themes, it is the second that interests us, especially in the present discussion. Apprehending cyclical changes involves more challenges in approaching the phenomena than could appear at a first glance. It involves the conception of the Cosmos, which is a constant come to be and perishing, a kind of primary background from which everything comes and returns to. However, the so conceived Cosmos is not something out of the being, as a kaleidoscopic spectacle to be watched. On the contrary, the Cosmic event passes throughout the being, it is linked to its soul. The human being is a Cosmic being that should orient its life according the Cosmic spirit—that is, the logos (cf. Jaeger, 1933/1942). In such a case, the constant mutability of the human life is not a matter of individual option but an unavoidable natural fact, as the being is part and parcel of the cosmic whole. The issue to be put is, then, about the orientation the person can or cannot give to her life toward the logos, integrating herself more or less harmoniously into the Cosmic unity.

Orienting one’s life toward the logos cannot be reduced, in Heraclitus, to the sense of logic-rational understanding concerning some phenomenon external to the self, relating to which the self should take a position. Orienting oneself toward the logos is, otherwise, a constant movement of fighting between *being* and *coming to be*. This movement can be done only through self-investigation. It is, indeed, an inner movement. In other words, aside from sensitive intuition and rational thought about the world perceived as external of the self, the investigation toward the logos means a self-investigation about inner experiences. To apprehend the logos is, therefore, mainly of an *imagetic* nature (cf. Jaeger, 1933/1942). However, although it requires turning to oneself, contemplating the self’s particularities, the way toward the logos cannot be tread out as an idiosyncratic individual search. As the logos is unity and communality, this kind of search would end in putting the self away from the logos, breaking the unity of the Cosmos (cf. Jaeger, 1933/1942).

Among the philosophical perspectives here focused, Heraclitus’ philosophy is indeed the one that opens possibilities for thinking the self–other relationship as a dynamic structure between genuinely different parts producing a third member, the cultural field, which will be also active as symbolic field for action. The metaphor of the intense and conflicting relationship in war is paradigmatic; there, tension and conflict have a restructuring power, generating a new relational unity. Moreover, Heraclitean ideas also point to the fact that the relationship among different beings installs itself in the core of the proper I as a dual being in a constant movement of coming to be. This is the natural condition of the self in its constant flow. Simultaneously and successively, the self *is* and *it is not*; it is *itself now* and *its come to be*. The impossibility of such a duality is the impossibility of the existence itself.

The same is true for the relationship among different selves in the self–other–culture triadic processual structure: the relational unity depends on the duality, without which the proper sense of relationship is voided. The conception of duality in Heraclitus’ philosophy also has important implications for the issues of meaning-making and contextual understanding in self–other–culture relationships. Hans-Georg Gadamer approaches this issue in his reflections upon aesthetic and religious experiences, when talking about his comprehension of *sign*:

[A sign] is not something that everyone has been able to see, not something to which one can refer, and yet, if it is taken as a sign, there is something incontestably certain about it. There is a saying of Heraclitus that illuminates this matter very well: “The Delphic god neither reveals nor conceals, but gives a sign”. One needs to understand what “giving a sign” means here. It is not something that takes the place of seeing, for what distinguishes it precisely from all reports or from its opposite, silence, is the fact that what is shown is only accessible to the one who looks for himself and actually sees something there.

(Gadamer, 1977/1986, p. 152)

In such a way, the constructive character of duality in Heraclitus allows us to think that a message is born from something that, at the same time, *is not* (*does not reveal*) and *is* (*does not conceal*), generating a third thing, the meaning (the sign). Maybe it is not a coincidence that, curiously, Heraclitus was called, at his time, *the obscure*.

But in Gadamer's Heraclitus, there is something more: The comprehension of the sign will be possible only if, at the beginning, the person who is faced and confronted by the duality quests the unity of the meaningful third in her horizon; in other words, only if the self has the unity of the meaningful third as a pre-comprehension. *If we take this third part as the cultural productions emerged from the core of self-other relationships, cultural demands, prescriptions, and possibilities should be, by a process of Bildung (Formation, Gadamer), as personal pre-comprehensions. In short, living in culture, as living in the level of self-other core productions, demands the person's availability for relationships with the other, which will be, of course, always selective relationships according to the person's ever reconstruction in culture.*

### Some Concluding Issues

From what we discussed until now, one main issue emerges—that of the conditions under which self-other relationships can develop. This main issue, by its side, unfolds in other that of the possibilities for relationships among different selves, which allows cultural diversity.

From Parmenides' and Plato's philosophical conceptions, as here discussed, emerges the suspicion about the possibility of real relationships among different selves. Even if this possibility is admitted, it still remains the question of the validated status of the ways by which that relationship happens, touching the status of the proper relationship. In this scenario, thought and rationality appear as safer ways for the self apprehending the essence of the other, whereas senses and sensibility would allow the self to apprehend the other only in its inconstant and runaway character. *Culture will be, in very schematic ways, a predominantly rational matter.*

In such an extent, a dualism between *true* and *false* in the apprehension of the world and, more particularly, the other, is then installed. It means a dualism between *what is* and *what appears to be, but is not, because inconstant and mutable*. In such a way, some questions can arise as, for example, "When I have a relationship with myself as well as with other person, am I relating myself with the essentiality of the other, with my essentiality, or just with something transitorily?" or "Can interpersonal relationships be real, truthful, or just illusory?"

The already mentioned synonym between *nonessentiality* and *transformation* pervades the self-other relationships, in which core cultural objects (in Boeschian sense) are engendered. From Aristotle's

and Heraclitus' philosophical conceptions, as we have discussed here, the conditions for self-other relationships will happen in very different ways.

From what we discussed about Aristotle's philosophy, we could say that the idea of the "good form" (in the very later Gestalt sense) prevails. The self-other relationship will reach the "good form" if there is reciprocity between self and other. In the symbolic action field (culture, Boesch), engendered in the core of self-other relationship, the alter ego will be the ideal other, with whom the self will preferably develop symmetric and virtuous relationships. *In very few words, culture will be the field of harmony and virtuosity.*

With Heraclitus other possibilities for considering self-other relationships were opened. The unavoidable tension between opposites, which can be co-present or successive, allows a self-other relationship that is in itself a process for solving that tension. In this process, self and other transform themselves in their search for mutual understanding in an always nonsymmetrical relationship (Marková, 1997; Rommetveit, 1979, 1991; Linell, 1995). It is the self's search for the unity of *the time to come* in its relationship with the other, never reached at all.

Talking about self, other, and culture can bring in its core a tricking statement. As far as culture is understood as people meaning constructions, which channels the person's symbolic actions, we fall in a vicious cycle, instead of arriving to a productive circle, as we can arrive through the ideas of the hermeneutic circle (Gadamer), as well as in the idea of the circle of knowledge (Boesch). The idea notion of a productive circle includes a movement of interchange among self-other and culture from which a new structure or state of affairs emerges. This new structure can be more complex than the former or not; the important feature is, however, that there is some change. In this sense, the productive circle involves—and makes more dynamic—the process of differentiation and de-differentiation according orthogenetic principle proposed by Werner and Kaplan (1956).<sup>5</sup> According to this principle, human development happens in ways of formerly nondifferentiated elements to their differentiation. Such a process of differentiation produces systematization, integrative hierarchical transformation and articulation among the involved parts, giving more autonomy to the system as a whole respect to its context. This process is possible only through movements of distancing and polarization of the involved parts. All this means that development

implies de-contextualization, concerning a multi-linear process, resulting in qualitative reorganization of the whole.

Bringing to the frame of the subject's relationships in culture, the proposition here developed not only keeps the advantages of above referred models, even because it is in part based on them, however strengthening more the figure of the other. This alternative puts culture as a co-genetic construction, avoiding explanations that can fall into a vicious cycle. Thanks to the premises of the co-genetic logic (Herbst), the unity of self–other–culture comes to the existence at once, by the relationships among the three elements, so preventing that one can explain the other in terms of its previous existence.

Besides, the co-genetic model here proposed allows for understanding how different relationships can bring about different cultural constructions, from the self–other feelings of great similarities between them to the self and other feelings of dissimilarities that can cause stress, pain, and disquieting.

In sum, the possibility of relationship between self and other, mutually perceived as different one from the other, allows the eternal mutability in the search of the unity, bringing the constant re-creation of their relationship, from which core culture emerges. Difference, tension, polarization, and distancing should be part of the processes of social life, requiring negotiation in self–other relationships, which opens doors for cultural channeling and cultural innovation (Boesch, 1991; Valsiner, 1998)<sup>6</sup> In schematic terms, from the core of this nature of relationship emerges some unity, a provisional solution for the tension that can be understood as

a momentary field for symbolic action—that is, a cultural field—in Boesch's sense. This is what was intended to be represented by the Figure 18.2 presented at the beginning of this chapter.

### *An Illustration of the Character of the Triple Processual Structure Here Proposed*

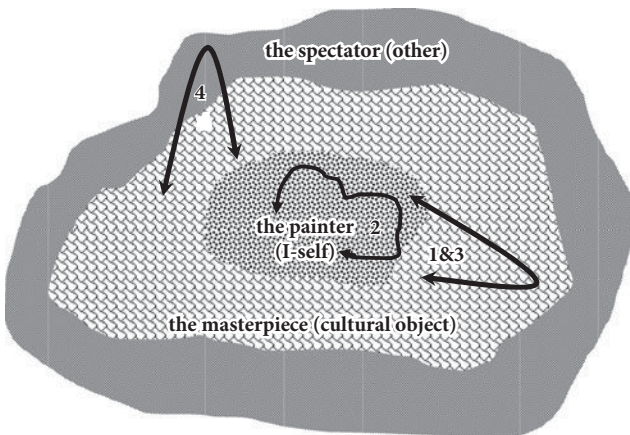

In what follows, I present an illustrative analysis of a specific context of cultural production, taking advantage of some reports by the French plastic artist Pierre Soulages, when he talks about some aspects of his own work (Soulages, 1950/2009). Soulages' reports were chosen for mainly because they offer a rare and consistent published material of self-reports by someone who creates culture through reconstructions of a tradition in which—as all of us—he is immersed, and most importantly, which directs him to the other as an active fellow in his cultural construction.

It is worth emphasizing that the aim of this illustrative analysis is not to access or analyze Soulages' reports about his creative process in itself but to offer an opportunity for thinking about if and how the triadic processual structure of self–other–culture here proposed (Fig. 18.3) can help to highlight some important aspects of the psychological process of cultural creation emerged from I–self and self–other relationships.

#### **Excerpt 7:**

*(1)8 The problems posed for a painter do not precede their solutions. They are born from the oeuvre, together with it.*

*I do not believe that I can learn what I look for but by painting; (2) this does not exclude that my painting*

**Figure 18.3** Representation of the analysis of the excerpt according to the proposed triple holistic developmental structure.

can be preceded by a desire, a need of some kind of form more than other, (3) yet it is not but in painting that those forms let me know about that desire. It is the moment when I draw the changes, the details that seems to me necessary, and also the next forms that oblige me to replace the former in question again. As an artist, I believe in a continuous intervention: the artist comes and goes of his creative impulse to the interrogation about the form presented by his creative impulse to himself. Truly speaking, the matter is not the isolated forms which are added one to the other, but the elements that takes, step by step, the non disso- ciable character of a synthesis: the accomplished canvas.

(4) In this way of painting, in which the artist's liberty is each moment at stake, the canvas itself is a whole engagement, a poetic testimony of a world where the validity is abandoned to the spectator. He is not asked for re-finding a history, a landscape, a still life, characters, animals or fragments of them; not even a state of soul experienced by them in front of the canvas, in brief a romantic or an expressionist anecdote, or whatever. (5) There is nothing required from the spectator: a painting is proposed to him, which he sees all at once according to his whole liberty and necessity. (6) Yet, in this painting the spectator also finds himself naturally engaged as a whole. The position adopted by him in front of this kind of canvas depends on and answers his general attitude in the world; and this is so much strong that the painting does send him to nothing that is external to himself.

N.B.: The painting as the highest I see it is not a «pure art» opposed to a «realist art». There is no gratuitous art; moreover there is no pure play of forms. It is a walk that engages all at once the man and the world. The man as the spectator and the artist as well. (Soulages, 2009, pp. 12–13)

The triple holistic developmental structure here proposed can be circumstantiated in **Excerpt 1**, as well as the Excerpt can us to understand the dynamics of the structure functioning.

In (1) Soulages put the métier of fine arts at the level of the artist's quest, in which there is no precedence of the problem or the solution either. They are born together, and the solution comes as far as he searches for it. This way by which things happen in everyday life of people interacting to themselves and others (as Soulages' report clearly illustrates) is what I am proposing to grasp and trying to understand (at the psychological level) with the above presented and discussed triple holistic developmental structure.

In (2) we see a proactive symbolic action from the artist's self, settled in its desires and necessities, which gains clearer contours while the self acts; yet, these contours are always changing and never completely achieved in the sense of completely fulfilling the artist's desires and quests (remember here Boesch's *The Sound of the Violin . . .*).

In (3) Soulages interacts with a cultural symbolic object (the canvas) at two intertwined and mutually feeding levels. There is an objectified level of the canvas, the *tempera*, or whatever he will use as instruments in their materiality for working. Yet, Soulages uses them for producing his work that which makes them subjectified in his canvas, his *tempera*, and so forth. On the other hand, the subjective level in which the painting comes to the existence by the artist's symbolic actions, becomes objectified in its materiality, allowing some relationships between him and his ongoing painting. During this relational process, insofar as he is painting, changes may happen in the artist's self. In such a way, there is a symbolic personification of the white canvas, as it asks for a symbolic action from the artist's self, the very condition for the dialogue between the artist and the canvas. This means a circumstantiation of the self–other relationship with the unknown (the white canvas asking for some action on it), which becomes, step by step, more familiar (less unknown) while the artist goes on painting in it. The canvas is then becoming transformed in a painting. A symbolic cultural object emerges, then, from the heart of the relationship between the artist's self with the canvas as other (a symbolic object) in the perspective of the artist's *come to be*. The noncompleted painting channels the artist's self-symbolic actions, in a back-and-forth movement, as referred by Soulages himself (remember here Boesch's *Culture–individual–culture: the cycle of knowledge*).

Passage (4) gives us the report of the unavoidable moment in which the artist abandons his painting, in a kind of donation to the spectator. Here (as we also see clearly later), the matter is not the self getting rid of its symbolic production but allows it to try to survive outside the isolation of the self–myself relationship. It is “as . . . if” the artist's self knew from the beginning that there were always a third person (Marková) waiting for acting in their horizon (Gadamer): the spectator. It will be him, by his interactive symbolic action with the painting, that can validate it—or not—as a cultural object in its full sense. This requires an openness from the painter's self to the otherness of the spectator, letting him

talk to the former through the art object. In such an extent, the spectator is, in fact, a participant. Besides, as we shall see below, the artist's self can move—and usually does—from the author's self-position (Hermans, Kempen, and van Loon, 1992) to the self-position of a privileged spectator of his own painting.

However, I will keep here the term *spectator* to avoid diverting our attention from the main focus of this chapter.

Letting the spectator's self talk requires neither talking for him nor inducing him to talk. It implies a necessary but not easy attitude of leaving aside the idea of asking someone for symbolically acting in this or that way. This is the attitude reported by Soulages in passage (5). He wants to let his painting say something—if it can—to the spectator, which depends on the spectator's willing of being touched by his painting.

In terms of our proposal, a painting is a potential cultural field for channeling symbolic actions. However, as Soulages' himself suggests in passage (6), the real symbolic actions will depend on the spectator's self ongoing constructions about and in the world. In other words, we have here a circumstantiation of the process of bounded indeterminacy (Valsiner) in self–other–culture relationships. What will really happen in this relationship varies not only from one spectator to another but also from the different moments or occasions for the same spectator.

Being the painter consciously of all that, in the sense that his self-report is a testimony of his concerns and even provisional answers about the process of art creation, we can say that it indicates the ways in which the *other in the self* is present in the process of cultural construction. Here also is involved the process of distanciation and polarization in development, allowing the emergence of more complex structures (Werner & Kaplan, 1956). This more complex structure, in the present case, is the proper emergence of the masterpiece from the painter's production through the symbolic action of the spectator. *The painted object will come to be art only when interacted with the spectator.* In Soulages' own words:

I am the spectator of what I do. I do realize that I am a very particular spectator, very committed to what I do. Yet I paint firstly for myself; I have no fear to say that; it is what makes my life possible. I paint because I need to paint. But I consider that my

painting does not become art but from the moment when it is viewed, it is saw by others; it is how it becomes a masterpiece, that is, a thing that others see and live in their own way.

(Soulages, 1973/2009, pp. 41–42)<sup>9</sup>

## Future Directions

Some future directions for semiotic-constructivist research in psychology can be foresighted from the ideas here proposed and discussed.
