First, we need to develop theoretical-methodological ways of better apprehending and comprehending the dynamics of how cultural constructions emerge in the core of the relationship between self and other, according to the co-genetic model here proposed. This involves accounting for, among other aspects, the great diversity and differentiation in the contemporary societies (Simão, 2010). In face of what we already have discussed about Herbst's co-genetic logic, and also considering that social interaction is one of the main sources of self-formation in culture, it may be productive pointing to some further implications of the self-other-culture co-genetic process here proposed. As culture is a field originated from the core of self–other relationship, it will be always a real (imperfect) construction of the humankind, aiming to solve the gap between perfection and imperfection through symbolic action. In such a case, the self–other–cultural co-genetic processual structure here proposed could be kept and even increase in complexity, according to Werner's and Kaplan's (1956) orthogenetic principle.

Lawrence's and Valsiner's (2003) metaphorical model of "membranes of meaning transitions," accounting for the intra- and interindividual selective movements of meaning-making in psychological process should also be very promising integrated in the theoretical-methodological framework here in focus.

Second, we cannot lose our ethical sight from the discussions that can be unfolded from the proposal here focused. As already noted, the main characteristic of the structure here in focus concerns the fact that, from each instance of its occurrence, other more complex structures can unfold from the present one. These new structures are never identical to the former, not even necessarily similar, but more complex in some sense. Their greater complexity, however, does not mean that self, other, and their cultural co-construction will allow accounting for values and goals that are more engaged with

ethical and social issues than the former structure (see Boesch, 2011).

Third, the issue of temporality is now accounting for the co-genetic model here proposed for the self–other–culture relationships.<sup>10</sup> Temporality embraces a movement of dual interplay between the intersubjective time and the subjective duration, bringing about by the other to the self. In such an extent, it brings in its bulk the dual co-presence of the I and the other, in which the other inserts itself in the I's subjective life, demanding the duration to be transformed in time and vice versa, in face-to-face relationships and through cultural traditions as well. In such an extent, otherness requires changes in the mediational strategies of expression and communication by the subject, pushing him to create alternative forms for expressing his new experiences about temporality. These latter, on their turn, are partially created exactly by the new forms of mediation brought about by the otherness.

## Notes

1. Concerning this fourth characteristic stated by Herbst (1995) it is worth noting that I am using the model of his co-genetic logic respect to the *self* as one of the elements of the triad. I am not referring to the *I*. The discussion about the relationships between I and self according to Herbst's co-genetic logic certainly also merits to be done, but should be kept for other opportunity.

2. This point is related to the important issue of Love in Plato's philosophy which, however, will not be approached in this chapter.

3. Being alone with oneself, however, is not the same of isolation, as in Aristotle, existence includes the companionship of oneself, which means otherwise the complete accomplishment of living in Virtue (cf. Aristotle, *Ética a Nicómaco*, Nicomachean Ethics, Book IX, 4, 1166a-b).

4. In the symbolic action space of culture, the value of the "selected friendship" and the friend as alter-ego will lose importance during the Middle Ages for regaining its strength in the Renaissance period, especially in face of the increasingly rupture between public and private spheres (Ariès, 1986 / 2006, p. 12).

5. For a discussion about the genesis of Werner's ortho-genetic principle, remounting to Goethe's biological ideas, see for instance Valsiner (2005) and Van der Veer (2005).

6. About the relationship of the issues here put in discussion to some of our proposals about the notion of otherness, see, for instance, Simão (2007); Simão and Valsiner (2007); Simão (2011, in press).

7. The original text in French is:

« Pour un peintre les problèmes que se posent ne précèdent pas les solutions. Ils naissent de l'oeuvre, avec elle. Je ne crois apprendre ce que je cherche qu'en peignant; cela n'exclut pas que ma peinture soit précédée d'une envie, d'un besoin de certaines formes plutôt que d'autres, mais ce n'est que peintes que ce formes me renseignent sur cette envie. C'est à ce moment-là que j'en tire les modifications, les précisions qui me paraissent nécessaires, et aussi les formes suivantes qui m'obligent à remettre

les premières en question. Je crois que la part de l'artiste à une continuelle intervention: va-et-vient de son impulsion créatrice à l'interrogation de la forme qu'elle lui apporte. À vrai dire, il ne s'agit pas de formes isolées qui s'additionnent les unes aux autres, mais d'éléments prenant peu à peu le caractère indissociable d'une synthèse : le tableau achevé.

Dans cette manière de peindre, la liberté de l'artiste étant à chaque instant en jeu, le tableau lui-même est un engagement total, témoignage poétique du monde dont on abandonne la validité au spectateur. On ne lui demande pas de retrouver une histoire, un paysage, une nature morte, des personnages, des animaux ou de fragments de ceux-ci, ni même un état d'âme éprouvé devant eux, bref une anedocte romantique, expressionniste ou d'un autre ordre. (5) On ne demande rien au spectateur: on lui propose une peinture qu'il voit à la fois en toute liberté et nécessité. Mais dans cette peinture le spectateur lui aussi se trouve naturellement engagé en entier. La position qu'il adopte devant un tableau de ce genre dépend et répond de son attitude générale dans le monde, et ceci avec d'autant plus de force que la peinture ne le renvoie pas à quelque chose d'extérieur à elle-même.

N.B. : La peinture telle que je l'envisage plus haut n'est pas un « art pur » opposé à l'« art réaliste ». Ce n'est pas un art gratuit, surtout pas un pur jeu de formes.

C'est une démarche qui engage à la fois l'homme et le monde. L'homme, autant le spectateur que l'artiste » (Soulages, 2009, pp. 12–13).

8. The numeration in the excerpt was inserted by the author of this text.

9. The original text is French is:

« Je suis spectateur de ce que je fais. Je me rends bien compte que je suis un spectateur très particulier, très compromis dans ce que je fais. Mais je peins d'abord pour moi; je ne crains pas de le dire, c'est pour que ma vie sa possible. Je peins pas que j'ai besoin de peindre. Mais je considère que ma peinture ne doit de l'art qu'à partir du moment où elle est vue, où elle est regardée par d'autres et où elle est comme une oeuvre d'art c'est-à-dire comme une chose que d'autres regardent et vivent à leur manière » (Soulages, 1973/ 2009, pp. 41–42).

## Dialogical Theory of Selfhood

Tiago Bento, Carla C. Cunha, and João Salgado

**Abstract**

Dialogism is presented as a relational paradigm in which intersubjective and communicational relationship is considered the most appropriate to further explore and understand selfhood. In abandoning the paradigm of self-awareness for the comprehension of selfhood, dialogism attempts to elaborate on the importance of the intersubjective relationship to the constitution of the psychological domain. For that, the relationship is grounded in the postulate of radical otherness. This means that the irreducible asymmetry and difference between Self and Other is considered to open an ontological relational space with logical and pragmatic qualities within which processes of subjective and intersubjective meaning construction take place. The characteristics and processes inherent to this external communicational and intersubjective space are considered to mold the internal domain of selfhood that is seen as being structurally and functionally continuous and dependent on such external relational space and processes. Selfhood is then conceived as a product of the continuous dynamic processes that are established between the I (as center of experience), the other-in-me (as the background from which the I experiences the world), and internal audiences that shape the specific positioning of content and processes of subjectivity in the experiential and communicative moment. On this basis, the future challenges faced by dialogical theory of selfhood are addressed.

**Keywords:** dialogism, dialogical self, alterity, selfhood, subjectivity, intersubjectivity

In the recent decades, we have been witnessing an important discussion, across humanities and social sciences, about the limits of modern epistemology for the conception and comprehension of human processes. In psychology this has led to the development and consolidation of new meta-theoretical configurations, such as social constructivism (Valsiner, 2007), *social constructionism* (Gergen, 1985a, 1985b, 1994), or *dialogism* (Marková, 2003; Linell, 2009; Salgado 2006; Salgado & Gonçalves, 2007; Salgado & Valsiner, 2010), and to the exploration of the contrasts that emerge between them and other traditional frameworks (Ferreira, Salgado, & Cunha, 2006; Hibberd, 2001a, 2001b; Marková, 2003). Although these recent movements do not share all assumptions, they are generally united

through an intellectual framework and orientation that emphasizes a social/relational and discursive/semiotic construction of reality and human phenomena and also reinstates the need to (re)situate and contextualize psychological knowledge. These pluralistic movements have elicited prolific epistemological, theoretical, and methodological reflections and discussions that defy the scientific assumptions, goals, and perspectives of traditional psychological science. From these movements emerged a common growing interest in the importance of social, communicational (e.g., Marcos, 2001; Mendes, 2001), hermeneutic (e.g., Bamberg, 2006), and intersubjective processes (e.g., Bråten, 1998; Stolorow, Atwood, & Braudchaft, 1994; Zlatev, 2008) to the constitution of the *psyche* in a multicultural world,

with expression in several areas of psychology like developmental psychology, psychology of self and identity, developmental psychopathology, psychotherapy, feminist psychology, or social and cultural psychology.

In this context, central to the dialogical approach to subjectivity and selfhood is the critique of the traditional approaches that tend to assume that subjectivity *is* manipulation of symbols and that think of human relations as something based on aprioristic and isolated selves. On the one hand, we consider that any perspective stressing that subjectivity (and intersubjectivity) is based on a prioristic and asocial mind endorses an unnecessary and misleading separation between mind and the process of relating with the world, a typical mistake of some traditional theoretical frameworks of psychological tradition (e.g., cognitive models of information processing); on the other hand, to assume the linguistic domain of signs and symbols by themselves as the foundational basis of human mind cuts the very possibility of discussion of a subjective mind, avoiding the discussion of problems such as experiencing an individual agency or freedom of choice, while human relationships become a matter of sign-exchange devoid of any subjective element. Dialogism appears precisely from the discussion on the limits that arise in these kind of approaches (Ferreira, Salgado, & Cunha, 2006; Salgado & Hermans, 2005).

### Arguing for a Relational Metatheory

In the field of psychological science, the proposal of dialogism is for the development of an approach to human psychological domain based on a relational ontology. In this context, the relationship within the communicational space becomes an invaluable notion because it is assumed to be the only relationship able to prevent a return to representational thought and to the figures of representation (subject, concept, being; Deleuze, 1994, Deleuze & Guattari, 2004) as the main or foundational matters of subjectivity and selfhood. Without disregarding the notion of representation, it is assumed that “referring to the world through representations” is part of the human mind, but it is not its fundamental or unique ontological element. Even if we would consider the human mind as constituted only by representations (perceptions, memories, symbolic symbols, etc.)—and this is the most common way of thinking about psyche—an acceptance to explain the mind based on its elements would mean to take the mind as a self-explanatory concept or an

explanatory principle. In our view, it is the purpose of psychology to explain the human mind and not only to take it for granted and to use it as an explanation for itself. To explain the mind, we need to take into account not only its constituents and their relations, but the transaction between the mind and the surrounding environment. In line with this, we follow Marcos (2001) in stating that “the figure of the ‘relationship,’ in its logical complexity and in its openness to novelty, is today the more appropriate to think of rationality [and selfhood]. It is the only way to prevent the affirmation of any absolute (ontological or ethical)” (p. 23).

Within this context, the developments for the dialogical theory of selfhood suggested here are based on an *interval ontology*—on the communicational processes that take place on the space (interval) between individuals. To be a self is a matter of relating and contrasting with the social and material world. Therefore, this ontology is rooted in the notion of irreducible difference between the Self and the Other, which is taken as *the* instituting and epigenetic operation of the psychological domain. The delivery and birth of a human mind is metaphorically and literally something involving and contrasting at least two different people in relation within a social and material world that is even larger than them.

### Beyond Sameness

Deleuze (1994) has argued that representational thought necessarily brings us to frameworks in which sameness tends to acquire an ontological sense. The existence of something would be granted by its intrinsic or essential features, following the Aristotelian logic of identity. In that sense, what can be said to exist is what remains unchanged. This highlights the fundamental problem of selfhood theories that, despite emphasizing relational and intersubjective processes, consider the symbolic or representational activity as the ontological basis of human beings. In other words, the representational (or linguistic) ability would be *the* intrinsic and defining feature of the human mind—implying consideration of the mind as defined by a specific and self-contained property. Relations with the world exist, but they are not defining features of the main substance (the mind and its symbolic activity). Dialogism is one of trends that refuses that ontological reasoning. Dialogical approaches attribute otherness an ontological sense. Along with other trends of thought in the twentieth century,

the human mind is, first of all, a matter of relating with others. As George Herbert Mead put it in his symbolic interactionist stance:

“[W]e do not assume there is a self to begin with. Self is not presupposed as a stuff out of which the world arises. Rather the self arises in the world.”  
(Mead, 1992, p. 107)

Thus, the mind and its symbolic activities, important as they are, will remain contingent on intersubjective processes that shape them. In this type of account, the relation with the world and, most of all, with other human beings becomes the origin of the self. Difference becomes a cornerstone notion for dialogical approaches to selfhood precisely because it suggests the need of something other than individual subjectivity for the understanding of its constitutive processes.

In recent decades, arguments have been put forward regarding the need to move beyond a linguistic or symbolic criterion for an intersubjective view of human beings (e.g., Habermas, 1992; Jacques, 1985, 1991). In psychology, it is in the field of psychological development of newborns that this approach seems to express itself more clearly, moving from a linguistic emphasis to a relational emphasis. Trevarthen (1998) describes the theory of intersubjectivity proposed in this area as follows: “It is a theory about how human minds, in human bodies can intuitively recognize impulses from each other, *with or without cognitive or symbolic elaborations*” (p. 17, emphasis added). It is this project that, we believe, should be pursued in other areas of psychology, and we will elaborate on that throughout this chapter.

### ***Relation, Experience, and Meaning***

The relational and communicational constructivism that characterizes dialogism (see Linell, 2009) as a consequence of its focus on the interplay between Self and Other does not imply that we abandon meaning-making as a central feature of a psychological understanding of subjectivity and selfhood. Nevertheless, dialogism also stresses that “to put communication in the domain of sign (linguistic, philosophical, theological or otherwise), is to set it up as an intellectual object, independent of the act that confirms it as relationship, as alliance, and as commitment; it is to isolate it and fix it as a mere representation, as a saying that does nothing” (Martins, 2001, p. 98). The question is not “What is language (or signs, or representations)?”

but “What do we do with signs?” The answer is: We relate, we communicate, and this relation is something that transcends language itself (even if it is partially enabled by language). The task is to obtain strong substantive theoretical and practical consequences from the postulate that human beings are relational beings.

What is suggested here, then, is that meaning-making processes must be conceived in continuity with the elementary structure of experience that is considered intrinsically relational in its constituent terms and processes. It is in line with this that, throughout this chapter, communication and meaning are elaborated as two asymmetric but interconnected axes, invaluable and fundamental to any discussion on subjectivity and selfhood.

### ***Alterity and Tension***

The Self–Other relationship has a tensional nature. Alterity or otherness processes involve the simultaneous presence of different interpretations in confrontation. The underlying assertion is that the “tensional nature of communication is its condition of possibility” (Marcos, 2001, p. 22).

It should be emphasized here, on the one hand, that to communicate is to share, co-reference, co-invest, and make sense with relational space. To coordinate with others, we need to achieve some mutual understanding. However, this coordination is something that people struggle to find, and even when it is achieved, mutual understanding is never “perfect.” It should be emphasized that this understanding does not take the form of two minds merging into one—to dialogism, this dream (or nightmare) is never accomplished: the difference between agents is the very possibility of their contact.

Thus, on the other hand, this relational space is always indeterminate. We must keep in mind that the intersubjective relationship follows a principle of *exotopy*, in the words of Bakhtin (1984). As de Man (1989) has noted, Bakhtin expresses with this notion the principle of radical otherness, taking it as the principle of reality. Creating an analogy with Freudian notion, de Man has argued that it is within the relation with others that a person confronts the world—a socially articulated and regulated world (including its material dimension)—to which the human subject is “subjected.” The intersubjective relation and the real that is built and negotiated within it depend on the irreducibility of its participants. It is the indeterminate condition of the relational space that makes it possible the emergence

of dialogical products of coordinated activities (cf. Shotter, 1997). The disorderly and unfinished background of communicational and meaning-making processes opens the possibility for unique variations and novel associations to emerge and be elaborated in the relational processes. Also, its unfinished condition feeds forward this constant movement of novelty emergence because the determined, finalized remains static and stable.

Furthermore, dialogism—although emphasizing the role of the Other—does not mean to suggest nor elaborate on an imagined, represented, or generalized Other with general expected qualities (the Other as role or trait). As Marcos (2001) has noted, this second position consists in “representing difference as a function of sameness. It consists, basically, in assigning not a difference but an indifference” (p. 77) to the role of the Other. Similarly, the words of Jacques (1991) are equally clear: “As long as the fact of difference invites us to take a monadic Self as our point of departure, the other will be constituted with a meaning that refers back to the Self” (p. xxii). As we will see later in this chapter, our proposal is the recognition of a real Other unavoidably different from the Self and, despite that, present and active in the psychological space of the Self (see Salgado & Ferreira, 2005; Ferreira, Salgado, & Cunha, 2006).

### ***Dialogism***

As we have noted, our proposal for the establishment of a post-rationalistic framework to the description of psychological domain is based on the instituting nature of the intersubjective relationship and on the correlative notions of difference and tension between two persons as their conditions of possibility. These are the organizing themes of a meta-theoretical framework that we must now systematize and lay out in its general terms.

*Dialogism* as a meta-theoretical framework is far from a robust systematization, and only recently have some approaches to this issue emerged (Linell, 2009; Marková, 2003; Salgado & Gonçalves, 2007). Nevertheless, the principles established by Salgado and Gonçalves (2007) allow us to lay out the key themes of this perspective (see Linell, 2009, for an expanded discussion on the axiomatic assumptions of dialogism).

### **RELATIONALITY AND BOUNDARIES**

The first of these principles is the *relational principle*. Here, the ontological position of the

relationship is stressed by stating that all human processes (cognitive processes of knowledge construction, emotional and identity processes, etc.) are essentially relational in their origin. As a relationship involves at least two elements in interaction, this issue is directly linked with the need to define contrasts (1) between subjects; (2) between each subject and a context or environment; and (3) between the constituent elements of this context, and so on. In this proposal, all human processes involve the presence of a figure-ground kind of relationship (see Holquist, 1990) that implies a contrast that simultaneously unites and separates the elements in relationship.

Following the implications of this notion of contrast, we claim that a dialogical relation implies (1) different elements and (2) a zone of contact between them. Thus, this contrast demands a membrane (Salgado & Valsiner, 2010): a space of contact between the elements in relation that not only contrasts but also establishes a functional contact. Like a cell, there is not only a mutual constitution of the person (the interior element) and the environment (the exterior element) but a zone of exchange between them. These boundaries delimit those elements, and these limits are specific of the relational moment of those elements. As the relationship unfolds through time, boundaries may change, and as they change, they also define the elements differently within the relationship. In this sense, dialogism makes use of this notion of boundaries to underline that dialogical relationships are constituted through a process that, in putting elements in relationship, both unites and distinguishes them.

### **DIALOGICALITY AND MONOGICALITY**

The second principle is *dialogicality* (see also Salgado & Valsiner, 2010). Human beings not only relate with the surrounding material environment—more important, they also coordinate their actions with social others. It is through the development of joint activities that we become capable of establishing a minimal mutual understanding with others, enabling the development of actions that are social in their origin. Even instrumental actions are developed through social guidance and, therefore, involve this coordination. It is our claim that such a scenario illustrates precisely the principle of dialogicality—that every human action, in its material and semiotic dimension, has always a communicative basis, placing

it as a form of social relation with others. Therefore, everything we do is dialogical:

But if people are not simply putting their ideas into words, what can they be said to be doing in their talk? Primarily, I suggest, they are materially responding to each other's utterances in an attempt to link their practical activities with those of the others around them; and in these attempts at coordinating their activities, people are constructing one or another kind of living social relationship.

(Shotter, 1997, p. 11)

With utterances and/or with practical activities, we are constantly producing something with potential social meaning, and therefore, through those words, we are constantly addressing others. Signs play an important role here, as it is through signs that we reach others—signs are placed at the membrane of contact between Self and Other. These signs, by their turn, stand for something else (they refer to other objects) and stand for someone else (they are addressed to social others and have a meaning potential to others). Therefore, it is through sign-mediated activities that we reach others and the world. However, this does not mean to reduce the dialogical relationship to the sign properties; it is the dynamic of sign-mediated activities that are relevant here, the constant process of relating and mutual positioning of Self and Other (Hermans, 2001a; Leiman, 2002, 2004).

Dialogicality must be taken as a constant process. However, in the tradition of Bakhtinian dialogism (Bakhtin, 1984, 1986), a distinction between dialogical and monological relations is often emphasized (e.g., Linell, 2009; Marková, 2003; Hermans, Rijks, & Kempen, 1993). However, this adds some confusion to the field that needs to be clarified. As we will argue, this distinction does not depend on the nature of the components involved (which will be always relational). It refers mainly, as the authors point out, to the nature of the relationship established between the elements—that is, to the communicative responsiveness and intersubjective engagement of elements. Usually, this notion is used to distinguish types of communication: dialogical and monological forms of communication. In dialogical communication, the agents remain open to the otherness brought to the situation by the interlocutors, and the dialogue evolves by a joint and common effort, whose final result is created by all parties. Thus, a dialogical relationship,

first, demands knowledge and active presence of other elements external to the object and to the relationship of knowledge (subject–object) so that it may arise and be described; second, it involves indeterminacy and originates what Bakhtin (1984) termed “surplus of vision,” the emergence of novelty and of a more general framework involving Self and Other's *visions*. In monological communication, one party tries to dictate his or her particular worldview, without considering the other in his human full capacities. However, even when this happens, there is a mutual relation, and therefore, a monological orientation still entails the principle of dialogicality (it is addressed and it calls for an answer, even if faked). Linell (2009) has a similar point:

All kinds of communication and thinking are arguably dialogical in terms of responsivity, addressivity, and genre-belongingness. At the same time, there are many monologizing (“undialogizing”) practices in the world, in which a speaker, author or sender tries to formulate a mono-perspectival message which is aimed at imposing one specific type of response from the addressee, in terms of his or her interpretation and responsive action. One might summarize the point by claiming that there are monological practices in our dialogically conceived world.

(p. 408)

This apparent paradox is, then, solved with this distinction between two basic ways of approaching communication: as a two-way, bidirectional activity between parties or as a single-way process of transmission. Thus, it is possible to treat the other in a monological way, just as it is possible to think about communication in a monological way. However, communication, even when monologically oriented, is always communication and, therefore, dialogical. As previously stated (Salgado & Valsiner, 2010), we should not mix “orientations to the dialogue” (that can be monological or dialogical) with the general principle of dialogicality (that is pervasive and extends itself even to monological forms of communication).

#### **OTHERNESS AND COMMUNICATIVE CONSTRUCTIVISM**

Involving the relationship in the ontological debate, dialogism is constituted by a third principle—that of *otherness*. Any human action (behavioral, intellectual, emotional) is always addressed to an Other.

The Self and the Other are, therefore, two essential poles for the emergence of any human process. It should be made explicit that the claim here is that there is no Self without an Other nor an Other without a Self, and it is in their figure-ground relationship that the possibility of emergence of a subjective psychological space is opened. Nevertheless, this emphasis on otherness and *relationality* does not intend to maintain the figures of relation and intersubjectivity at a purely conceptual level. On the contrary, dialogism establishes that these notions and the processes they circumscribe are on the basis of every particular action or cognition and should be directly applied to their understanding.

In line with this, dialogism tends to endorse a *communicative constructivism*: “[W]hen we construct the world, it is a question of intersubjective co-construction with the help of others and artifacts” (Linell, 2009, p. 19). Basically, dialogism assumes the world is not even there to be constructed for an isolated mind in any substantial psychological sense, nor would it be possible for such a mind to relate with it. Therefore, the Other assumes a vital role.

At the same time, it should be highlighted that under the notion of constructivism, we are endorsing the tradition of thought that integrates action upon the world with the representation of that world, without giving primacy to any of them. The long philosophical debate around action and reflection as the basis of our living in the world is dissolved here: We act upon the world, and through that action we create an “image” of that world that guides our future actions. Our constructions are ways of acting upon the world that seek our adaptation to the future circumstances. Communicative constructivism adds something to the cognitive constructivism (e.g., Piaget, 1955), affirming the role of the Other in this process of construction.

#### CONTEXTUALITY AND MEDIATION

The fourth principle of dialogism developed by Salgado and Gonçalves (2007) is the *contextuality* of dialogical processes. Human actions, being addressed, are also involved in a specific cultural matrix and depend on the semiotic tools available in this matrix. These semiotic tools are considered to be the means by which it becomes possible to contact with and know others and the world. Linell (2009) stresses that “our understanding of the world come to us in a necessarily mediated form, never immediately” (p. 19). Our relations with others and the world are never direct, immediate but indirect

and *mediated* by signs. This also explains why we place the relation between Self and Other at the center of our reasoning—it does not imply that the material is irrelevant, it simply means that the experiencing of the world is regulated by the social coordination of the human subject with social others. The world is “revealed” or “touched” through signs (see Leiman, 2002, on the “epiphanic” quality of signs), and these symbolic tools are not passive or “neutral vehicles” (Linell, 2009) but, rather, active elements in those relationships. At the same time, they are also involved in forms of interaction, in which they gain their value and are not limited to the linguistic or semiotic realms. In fact, as we have seen, any dialogical relationship refers both to itself in its constituent terms and to the exterior of itself. It is this reference to the outside that brings out a contextual environment to which it becomes dependent in terms of its processes and meanings.

#### *Moderate Holism and Dynamism*

Dialogism therefore commits itself with a contextual, interactional, and interdependent approach to psychological processes. Generally, as Linell (2009) has noticed, this moves dialogism toward a *moderate holism* in the sense of it assuming a “commitment to preserve the integrity and complexity of phenomena, such as the context matrices, situations and activities, in which constituent acts or the use of semiotic resources are embedded” (p. 18). This creates a constant tension between the particular, local, and momentary and the global, contextual, and developmental levels. Both levels are considered to be essential for an appropriate approach to phenomena that preserves their integrity as such. This also highlights dialogism movement toward complexity as it resists homogeneity, rigidity, and closure of phenomena.

Simultaneously, this focus on otherness and relationality separates dialogism from a conception of phenomena as static, stable, or constant. Open to what is external to them and dependent on it for their constitution, psychological phenomena are not defined on the basis of their identity, internal properties, or characteristics but, rather, on the basis of the dynamic processes of constant change and transformation that they undergo. It is the process of transformation and the dynamics inherent to it that is considered to be indicative or revealing of the nature and characteristics of phenomena rather than predetermined properties they may be assumed to have.

By the same token, this openness and constant interaction with external elements also makes phenomena permeable to those external elements or other phenomena. The dynamics inherent to the interactional processes determines how permeable the frontiers between them are. These changes in the border of a phenomenon are what define the phenomenon itself. This explains why dialogism resists and tries to transcend oppositions and dualisms (see Marková, 2003) such as *individual versus social* or *culture X versus culture Y*. The point is that culture X will appear in one way in relation to culture Y and in another way in relation to culture Z. Therefore, culture X will be attributed different qualities depending on which other culture with which it is compared. It is the specificity of the global pattern of its different qualities in different relations that defines culture X as culture X.

### The Dialogical Self Theory

Originally, the Dialogical Self Theory (DST) subscribes this relational framing by turning to the notion of *dialogue* to rethink the Self. We will now characterize this theory by elaborating, first, on the pioneer work of Hermans and collaborators (cf. Hermans, Kempen, & Van Loon, 1992; Hermans & Kempen, 1993; Hermans, 1996). These contributions have been extensively debated in several special issues in psychological publications (Hermans, 2001b, 2002, 2003, 2004b, 2008; Hermans & Lyddon, 2006; Hermans & Hermans-Konopka, 2008; Stam, 2010).

### Sources for the Dialogical Self Theory

The first formulations of the DST (Hermans, Kempen, & Van Loon, 1992; Hermans & Kempen, 1993) had four main sources of inspiration:

1. The work of William James (particularly his distinction between I and Me).
2. The metaphoric and narrative nature of cognition (highlighted by authors such as G. Lakoff and M. Johnson) and human life (particularly by T. Sarbin and J. Bruner).
3. The approaches that underlie the multiple and multifaceted nature of the Self.
4. The dialogical thinking of Mikael Bakhtin.

Combined together, these influences originate a notion of identity as something that is constructed from the dialogical engagement between different “voices” or positions of the Self. In this sense, although the multifaceted and narrative nature of

identity is recognized, something more radical is reinforced: not only do we construct multiple self-images or a diversity of stories where several roles and actors play their part, we are also multiple authors, involved in internal and external dialogical processes.

To reach this conception so distanced from the monadic version of identity, so long disseminated in psychology (cf. M. Gonçalves, 1995), Hermans, Kempen, and Van Loon (1992) depart from the classic distinction of William James (1890/2007) between I and Me. To James (1890/2007), the Self has a dual nature. On the one hand, there is the I (or *Self as knowing*) that refers to the agent responsible to a sense of experiential continuity, distinct from others and the world, with the consequent sense of volition and autonomy (Hermans, 1996). In other words, according to James, the I is associated to the construction of a subjective continuity through time, from which emerges a sense of personal identity as a unique individual (Bertau, 2004; Hermans, 2001a). On the other hand, the Me (or *Self as object*) is related to the construction of a self-image and the inclusion of objects/others in the world that become part of the Self in a physical and symbolic extension of what we are, what completes us, and what we call our own (such as objects in the world, significant others, and personal history; Hermans, 1996; Hermans & Kempen, 1993). Through these two dimensions—I and Me—the Self conjugates two fundamental properties: a differentiation between Self and world and the construction of identity in time.

In this sense, for James (1890/2007), identity is constituted simultaneously from pairs of mutually inclusive opposites: We are producers of images and narratives of ourselves (as products of our semiotic activity), but these self-images and self-narratives end up feeding our own subjective process. The image of myself in the world (Me) is the base that allows the I (as subject) to be guided in action and semiotic activity in the world. Furthermore, what one thinks about oneself (as products or part of Me) reveals one’s own reflexivity and subjectivity—that is, the I as agent.

This original distinction between I and Me was later retrieved by Sarbin (1986) under the narrative framework. In this view, identity is seen not only as a form of reflexivity but also the achievement acquired in the act of interpreting ourselves as social, historic, and contextual beings. As we exist in a given socio-historic-cultural context, identity appears as a

narrative project (O. Gonçalves, 2000) that we share and co-construct with others. According to this, the I of James is seen as an author that organizes experience through a socially articulated narrative structure, from several biographic episodes where the Me is both actor and protagonist (Sarbin, 1986).

Given these influences, Hermans and collaborators (1992) have conceived the Self as a specific organization of socially articulated meanings deriving from experiences lived in a temporal sequencing of episodes, events, and actions. These narratives are both subjective and social products, because they put symbolic, discursive, and material resources into play. Similarly, we can say that the initial movement of sense-making is both metaphoric (because metaphors use something to [re]present another), imaginative (because imagination allows us to construct what is not yet present and project something into the future), and relational (because sharedness allows the co-construction of meaning).

These original works from the beginning of the 1990s have traces of the zeitgeist of the moment. The emphasis on the complexity and multifacetedness of the Self, from a cognitive view, was also a marked influence on the earlier versions of the DST, because they were current efforts to surpass the traditional monadic, coherent, and stable view on the Self (cf. Linville, 1987; Markus & Nurius, 1986; Khilstrom & Cantor, 1984). Similarly, the movements within “the linguistic turn” sought to deal with the phenomenon of the multiplicity of the Self (especially the social constructionist movement).

Despite the reference on these cognitive and narrative influences in the early works upon the DST, they became less present in subsequent works (cf. Hermans, 2001a, 2004a). The main reason is that narrative appears as an insufficient concept in this theory, as we have argued. Thus, according to Hermans (1996), self-narratives, as products of discourse that usually privilege the temporal sequencing and coherence of episodes, do not fully consider the dialogue and the voices that become alive, therefore diluting the narrator in detriment to the story that is told. In other words, more important than the narrated content is the relationship between the author and the audience, established through the narrative. Moreover, according to Hermans, Kempen, and Van Loon (1992), the more adequate way to acknowledge the question of the multiplicity of the Self is through the use of the polyphonic metaphor and the notion of co-construction—that is, narrative cannot be more prevalent than the act

of narrating, which puts the Self (as interlocutor) facing an Other as an audience (either present or absent, real or imaginary). In these suggestions, the influence of the Bakhtinian thought becomes clear and demarks its difference.

### *The Emergence of an Alternative View on Selfhood*

We consider that four central notions in the DST constitute it as an independent, unique alternative, distinguishing it from other perspectives on selfhood:

1. The centrality of dialogue and polyphonic metaphor applied to the Self, both of Bakhtinian heritage.

2. The dynamic notions of *positioning* and *repositioning* of the Self in time and space and in relation to something/someone (in internal/external dialogues that place the interlocutor in a specific relationship).

3. The role of difference and tension in dialogical processes (both in the differential power acquired by parts of the Self and in the relationship between the Self and the world) for the construction of stability and sameness and the creation of innovation and novelty.

4. The polyphonic metaphor that Bakhtin applied essentially to distinguish the literary works of Dostoevsky, where the author is no longer presented as an omniscient entity narrating the story. On the contrary, it is presented as multivoiced and internally controversial, by being habited with multiple voices that defend different perspectives and worldviews in contrast with each other (Hermans, 2001a).

Inspired by this, Hermans and collaborators (1992) have claimed that the Self—more than an internal multiplicity that results from different roles and contexts—is a dialogic polyphony, where several voices are contrasted translating multiple experiential positions that co-exist in simultaneity. In this sense, the Jamesian view is radicalized: not only the stories are multiple, but the agent that constructs these stories is also diversified. Thus, even if self-narratives appear as a form to construct coherence and cohesion in identity, they no longer guarantee the personal unity and continuity given that we live with multiple authors that constitute our Self.

How to explain, then, identity and sameness? The answer proposed arrives from the notion of dialogue: through the dialogical articulation achieved

between different “voices” of the Self and from our interpersonal engagement with others in a cultural world (Hermans, 1996). Furthermore, a voice translates a specific point of view that emerges from a given existential position from where the world is experienced and perceived, forming a unique gestalt of experience (Holquist, 1990). In this line of reasoning, the dialogical Self is conceived as a tensional and dynamic multiplicity of self-positions that are occupied in an internal dialogical space that feed distinct and independent voices, within the same person:

... we conceptualize the Self in terms of a dynamic multiplicity of relatively autonomous I positions in an imaginal landscape. [...] The *I* has the possibility to move, as in space, from one position to the other, in accordance with changes in situation an time. The *I* fluctuates among different and even opposed positions. The *I* has the capacity to imaginatively endow each position with a voice so that dialogical relations between positions can be established. The voices function like interacting characters in a story. Once a character is set in motion in a story, the character takes on a life of its own and thus assumes a certain narrative necessity. Each character has a story to tell about experiences from its own stance. As different voices these characters exchange information about their respective *Mes* and their worlds, resulting in a complex, narratively structured *Self*.

(Hermans, Kempen, & van Loon, 1992, p. 28)

According to the Bakhtinian “law of placement,” the Self is always involved in these dynamics of positioning and repositioning, expressing voices that are related to spatial and temporally specific positions, from which emanate idiosyncratic views of the world (Holquist, 1990). Voices express meaning-making processes on experience, which are emotionally grounded (Josephs, 2000) and embodied (Fogel, Koeyer, Bellagamba, & Bell, 2002; Hermans, Kempen, & Van Loon, 1992). This dynamic movement of the Self between voices and positions emphasizes the role of internal alterity given the contrast between other (former and potential) voices or positions different from the voice of the experiential position that is occupied by the Self in the here and now (Valsiner, 2002).

In sum, the dialogical Self does not have a clear frontier with its external surroundings. Its borders are highly permeable. In fact, the outside world is also inside the Self in the form of external positions

(parts of the world that are identified with the Self; e.g., we can carry voices of significant others within ourselves or even internalize specific generalized cultural voices upon a given subject) that contrast with internal voices (relating to different roles or parts of the Self).

Although the DST attempts to surpass old dichotomies in psychology (e.g., Self–Other, Individual–Social), given the acknowledgement of the constant trades and interconnections happening through the flexible and permeable frontier of the Self, according to some authors (Bertau, 2004; Salgado, & Hermans, 2005), it is precisely in this social and cultural landscape of selfhood that we find the constraints in the movements and multiplicity of the Self. Salgado and Hermans (2005) are not as optimistic toward the versatility of the Self as the original definitions might convey: The potentialities of movement in the dialogical Self are generally linked to the possibilities allowed in a given society, which are always limited within certain confinements (e.g., constrained either toward the compliance and conformism or toward opposition and rebellion directed to the socio-cultural milieu).

### ***Moving Forward: Critical Elements to the Dialogical Self Theory***

Despite the developments that have been occurring within the DST, it is also necessary to recognize that some issues require a special analysis and further development. In our view, there are several aspects that should be clarified and problematized if we want to keep dialogism as the epistemological and ontological reference frame to the DST.

#### **EXPLORING THE IMAGINAL LANDSCAPE AND THE MULTIPLICITY OF THE SELF**

If we resume Hermans’ initial proposal of the DST, we may now state that in DST, the dimension of experience is usually conceived as an *imaginal landscape* in which different positions of the Self, or I-positions, move and relate to each other by means of dialogue. The imaginal landscape and the positions of the Self are therefore the structural elements of the experiential domain. As dialogism emphasizes *addressivity* as a fundamental characteristic of selfhood processes, the location and movement of I-positions in the imaginal landscape of the Self are considered to be a function of the correlative position of each one of them to the other I-positions in the system of Self.

It is considered that as two I-positions address each other, they become juxtaposed, one in relation to the other. This process of juxtaposition has been metaphorized as a dialogue (in opposition to a monologue). For an I-position to communicate with another I-position and the world, it is endowed with a voice that later becomes inter-related with other voices immanent from other I-positions, as in a dialogue. These narrative voices constitute the other dimension of meaning-making that is conceived to be dependent on constant positioning and repositioning of I-positions.

In another way, we could say that the dynamics inherent to positioning and addressing constantly sets up an experiential and narrative configuration that defines the relevance and salience of certain experiential and narrative contents in detriment of others that are elaborated and exchanged in dialogue with others (see Fig. 19.1).

As can be seen in Figure 19.1, the most frequent configuration of the dialogical Self assumes that the audience of each I-position is another I-position (e.g., Georgaca, 2001; Hermans, Kempen, & Van Loon, 1992; Raggatt, 2000). This leads to a conception of selfhood that is centered on the dialogical relations between I-positions, usually as dyads. However, the possibility has been explored that “instead of a dialogue between an I-position (a voice) and another, each I-position has dialogical relationships to its addressee(s)” (Leiman, 2002, p. 232; see also Leiman, 1992). This opens dialogism to other, more complex, and dynamic perspectives on selfhood (see Ferreira, Salgado, Cunha, Meira, & Konopka, 2005, for a comparison of several dialogical approaches).

**Figure 19.1** Dialogical relations between positions of the Self as dyads.

## THE PROCESS OF DIFFERENCE AND THE OTHER AS AN IRREDUCIBLE ONTOLOGICAL ELEMENT

The *process of difference* needs further exploration. We need to develop implications from the argument that the human psyche is ontologically based on the difference between Self and Other. As mentioned earlier:

The dialogical perspective is based on the fundamental assumption that human life is permanently an addressed existence. It therefore attributes a fundamental role to the Other in the constitution of the I - human existence is co-existence or is not human. Therefore, difference - the radical asymmetry between any two persons - simultaneity - the necessary co-presence of I and Other without which neither of them may exist - and tension - emergent from the simultaneity of insoluble differences - become invaluable concepts for the dialogical project. [...] Relationship, elaborated upon those concepts, is conceived to be previous to (id)entity: there is no previous I and no previous Other to the relationship that makes them an I to an Other and an Other to an I.

(Salgado, Ferreira, & Fraccascia, 2005, p. 13)

In fact, the process of difference is revealed as the basis of the genetic code of human psychological processes, with simultaneity and tension as the parameters that guide them on their trajectories. It is the conception of the relationship as consisting of these components that distinguishes the dialogical approach from others that stress the importance of relational processes. The figure of the relationship emerges as a gestalt, a configuration of the interactive processes of the elements that constitute it, and not as an object of study, a property, or a trait. However, we believe that this process of difference has not yet been fully developed.

Difference, we would say, is also related with continuous tensional process between Self and Other. However, we need to ask: *What are we talking about when we talk about an Other?* Traditionally dialogical proposals in psychology have assumed that the Other could be conceived as a represented other (Hermans, 2004a); a person, a group, or a community (Marková, 2003); a socially indexed fictional narrative (Wortham, 2001); or a part of the Self (e.g., Hermans, 2001a). The status of the Other seems rather unclear, and this vagueness may reach a point that sometimes seems confusing, if

not misleading. Moreover, this also represents a difficulty in taking into account otherness as a constitutive element of otherness.

On this basis, the remainder of this chapter further elaborates a dialogical proposal to attempts to contribute to a more full development of a dialogical approach to selfhood processes.

### ***Redescribing Selfhood from a Dialogical Perspective***

In previous sections, our elaboration on the ontological value of the difference between Self and Other led to the proposal that dialogical relations are constituted by: the Self, the Other, and the relationship between them (Holquist, 1990).

Dialogism defends the relation between Self and Other as the realm in which those two poles of communication emerge as two distinct, yet bounded, agencies (Marková, 2003). Therefore, this implies defending an “*exteriority*” of the Self, because the subjective experience of oneself is correlative with the Other with whom the person relates. However, this does not lead dialogism to claim, as some social constructionists have been doing, that we should avoid descriptions and explanations of the inner experience. Our claim, here, is that a dialogical account preserves this distinction between inner and outer realms and that subjectivity is brought to being in the borderline of contact of these two domains. Take an emotion, for example. On the one hand, an emotion is an inner and private experience. On the other hand, it also brings an outer expression that if the person does not make an effort of dissimulation, it will be apprehended by the surrounding people given its communication value. It is inner and it is outer. The production of an emotion, in itself, is based on some interpretation of the present situation based on the previous personal history of socialization that took place within contextual and historical specific backgrounds. Thus, if we ask, “What is the self-experience of this person at this moment?” and the answer is, “This person is feeling a strong feeling of rage against his boss,” we are connecting the interior and the exterior, the personal and the social, self and other. An emotion, then, is a bodily-sign—referring to something else, involving a joint interpretation of its meaning, while giving an embodied felt sense of the agent’s needs or wishes. To describe it only as the activation of a self-schemata of inferiority, for example, would be to cut the relation between self and other and to describe the

human mind in a self-encapsulated way. To describe it as an emergent social performance without inner qualities would be oblivious to the compelling attributes of inner experience of emotions. We propose to recycle these notions, articulating them simultaneously. Therefore, dialogism argues that the only way to look inside the Self and at the same time preserve its dialogical integrity is precisely by taking into account dialogical processes that occur inside and outside the Self.

Under this perspective, a communicational act implies: “(1) a speaker who is simultaneously addressing, (2) an object and (3) the subjective world of the listener” (Salgado & Ferreira, 2005, p. 145). This means that the act of addressing is not a simple movement from the Self to the Other (or from one position of the Self to another) but actually a twofold movement from the *world of the Self* to the “*specific world of the listener*” (Bakhtin, 1981, p. 282) and, simultaneously, to the “*world out there*.” This Bakhtinian heritage has been brought up by dialogical approaches to selfhood both within clinical psychology (Leiman, 2002, 2004; Leiman & Stiles, 2001) and social-cultural psychology (Marková, 2003; Valsiner, 2007; see Ragatt, 2010, for a general analysis of this issue).

In this context, we will develop in the next sections our previous attempts of giving a dialogical account of selfhood. We will defend the description of a triad of communicational agencies within the inner realm of selfhood: *I* (as a center of experience), the *other-in-me* (as the constructed and addressed Other), and *internal audiences* that shape the specific positioning of the moment. Moreover, this Self inner dynamics is always connected with the external dialogical activity in the world, in which we encounter real others and real objects.

#### **THE FELT I**

As Jacques (1991) writes, “[T]o the person, being is a process of self-production by a gradual self-identification. It is a process that acts directly on the Self, an activity which refers to itself in order to prevent us from making a substance of this self-activity” (p. 22). As we observe the approach of Jacques, it is close to that proposed by Damásio (1999), for example, in the sense that both have as primordial and elemental matter of identity the feeling that “whatever is happening is happening to me” (other authors would call this the experiencing self; Greenberg & Safran, 1987). Thus, the Self, the

feeling of being an I, does not emerge from the use of the personal pronoun as suggested by the discursive approaches. This feeling that “what happens, happens to me” sets up an experiential center that positions itself correlatively to the other elements of the structure of experience. The spatial metaphor here is not insignificant.

### THE OTHER

Returning to the previous question about the Other—What are we talking about when talking about the Other? First, as previously discussed, it is necessary to remember that the Other is *not only* a representation—it is another human agency that transcends the Self. We are talking to you, and our words come in touch with your inner realm, and in that way, we are an Other to you. We may be somehow represented by you, but our words have an element of strangeness that does not fit completely your representation. And this leads us to the second point: The Other remains separated from the Self. We feel the Other, we address the Other, but the real Other always remain partially alien. However, it is in the dance between Self and Other that they become mutually defined: If the operative principle is radical otherness, then we are led to the need of considering a real other to know and describe a particular Self and assume its positioning in the internal space of subjectivity.

Nevertheless, it is also true that Self and Other communicate by exchanges of signs or chains of signs. Therefore, the voice of these two bounded and separated elements comes in material forms that transports each stance regarding some specific objects—words, gestures, and signs that carry the perspective and purposes of the agents. Look to these words: You do not need to be here and now to hear what we are saying—we will read this in someplace else and in an unknown future to us. Therefore, signs are the media through which Self and Other relate with each other, and this enables the possibility of relating with unknown others.

Who or what is this Other? We come close to Marková's (2003) definition: a person, a group, a community—a communicational agency. However, familial values, cultural norms, fictional characters, social discourses, and so on, often assume the function of an Other and are not directly linked to a particular person. We could name them “collective voices” (Hermans, 2001a). Additionally, the representation of the Other created by the Self never exhausts the real Other, introducing

constant novelties and tensions within the space of the Self.

### THE OTHER-IN-ME

Another issue that needs further clarification has to do with how the Other gets in touch with the Self. We have just claimed their continual separation but in a way that maintains their mutual bond and definition. Then, the question is: From the perspective of the Self, how is possible to reach that Other?

A usual solution is to postulate representations of significant others. However, this has the problem of suggesting a self-enclosed mind. This happens in different theoretical postulates, like the notion of internal objects in psychoanalysis (e.g., Klein, 2002) or the possible selves in cognitivism (e.g., Markus & Nurius, 1987). Therefore, we think that this does not completely answer the question of how the Other is elaborated by the Self. Without denying that we do represent other people, in accordance with the framework, we have been advocating here representations are only means to relationships. More important, to have a representation of something does not entail, by itself, the possibility of having a communicational joint activity with that something.

In our view, this demands a semiotic stance, defending that it is through signs or chains of signs that people get a mutual minimal coordination that enables meaning-making. The possibility of joint activity between two people implies the elaboration of signs that they may trade. Consequently, communicative action becomes possible, and Self and Other relate to each other. Signs or chains of signs are vital tools for the dialogical involvement.

Therefore, in every communicative action—and every action is communicative, as it is always leaves a trace or a sign waiting to be interpreted—there is an agent semiotically addressing the Other. Initially, and whenever we engage in some activity with other people, there is a real Other. However, when these sign-mediated actions become internalized, we no longer need a real Other. We use signs “as-if” there was a real other waiting on the other end of our actions, utterances, or gestures. Many times, there is no one there.

We will say that from the perspective of the Self, the Other is always that *potential addressee* of his or her semiotic activities. At the same time, it is also an Other *constructed* by the Self—it is an Other-in-me. As a potential addressee, this Other-in-me

can take varied forms: It can be the interlocutor of a sign exchange taking place (“Tell me, where have you been this morning?”); it can be the same person, talking to herself or himself (“How stupid I am!”); it can be nobody—in that case, we would say that it is a virtual Other, an addressed agency lying in the other end of the message (e.g., leaving a book you like in a public space to let someone else read it); and we also admit that this Other-in-me can be a material object, constructed in an anthropomorphic way.

The way this Other-in-me is based on matching together what is happening in the moment (e.g., utterances from another person) with the personal previous experiences of similar circumstances that create a specific pattern of expectations around particular objects or themes. Returning to a Piagetian reasoning, we may call this patterned activity a “relational scheme,” in which this social circumstances activates specific purposes (needs, wishes) and expectations, guiding our social action (e.g., Safran, & Muran, 2000). This scheme is associated with specific implicit or explicit images of the Other, but it is not a static element—its value lies in its potential dynamics (creating needs, wishes, strategic moves, etc.). However, there is something more: This scheme is always matched with the “incoming” response from reality—the sign-mediated account about what is happening in the moment. Thus, there is always a possible mismatch between the “expected” Other and the “incoming” signs, generating a dialogical activity of positioning and repositioning.

Therefore, we postulate the existence of an Other-in-me: a process of continuous re-elaboration of the potentially addressed Other, which is put in motion by the articulation of a relational scheme (forming the “expected Other”) with the sign-mediated account of the reactions coming from the world (forming the “incoming Other”). In situations in which the Other-in-me is no real human agency, we may have no real answer, but we still have effects, and these effects are interpreted as socialized signs. They are understood given previous relations with real others. In simple terms, the Other-in-me is the addressee of the communicative actions of the agent.

In sum, we are assuming that within the Self inner space, there is a place to otherness. This opens a developmental route to accomplish a process of self-relating based on this other: If the Other-in-me is a half-constructed and half-alien addressee,

then there is no absolute limit to what forms this addressee may take—it may be virtual, fictional, or even the own person. Therefore, this Other-in-me is the opposite end of the road that leads the process of inner dialogicality.

#### INTERNAL AUDIENCES

The Other-in-me is the constructed and addressed Other. However, the person may have other audiences interfering with the addressed one. For example, our addressee may be a dear friend in whom we trust but who also has a very intimate relationship with someone we deeply distrust—Will we tell him our personal secret? This third party will be highly influential in the course of events, but it is not the addressee of my actions. Thus, we need to take into account third parties in every situation, beyond those that might be involved in the situation. We have been calling these third parties *internal audiences* that constrain internal dialogicality and the actual intersubjective and communicational process. As we stated elsewhere, these internal audiences are conceptualized

as the global context of the subjective realm. In our view, its development is probably rooted in personal and cultural history of each human life. It has to do with the accumulating experiences of being in contact with the world, especially, the intersubjective experiences. In some sense, it has to do with culture, with all the semiotic devices that we come in contact with. However, it is deeply idiosyncratic, since every utterance, sign, or exchange with someone or something else immediately creates a specific positioning of the experiencing I.

(Salgado & Ferreira, 2005, p. 149).

These internal audiences are compounded by all Others’ responses, beyond the ones coming from the addressee. Therefore, their presence within the inner realm of the Self creates a complex dialogical space, in which the person is polipositioned at every moment—not only socially but also internally.

#### *Progressive Differentiation of the Selfhood Domain*

As we have been referring, the real other has this function of generating the difference between the Self and the Other. In this, the Other simultaneously constitutes herself or himself as an I for himself and an Other to another I. This person also occupies a place in the system of Self, becomes an *Other-in-me*, generating the internal difference and

dialogicality of selfhood. The process of interpersonal relationship, or external dialogicality, is continuous with the elementary structure of selfhood and its intrinsic dialogical processes.

It is in this difference between Self and Other, and therefore in the interplay between internal and external dialogicality, that the possibility of self-consciousness and meaning (both personal and shared) is opened—as has been proposed, for example, by researchers in newborn development (e.g., Hobson, 1998). Progressively, real others generate increasing internal differentiation of selfhood as new relationships are established, bringing with them new meanings, new ways of relating to others and objects in the world, as well as new subjective states. This increasing internal differentiation of subjectivity simultaneously makes possible the intrinsic dynamism of its processes and also the participation in and intentional use of cultural semiotic systems.

Moreover, from an ontogenetic point of view, we argue that it is within interpersonal relationships that more complex forms of inner relations are developed, such as thinking through symbolic manipulation. Assuming a Vygotskian perspective, the tools that will enable self-reflection—the ability of using signs and afterward the use of self-referential signs, enabling self-identification and self-differentiation—are established through the social guidance and constraints introduced by caretakers. The developing child climbs the ladder of the successive zones of proximal development introduced by Others and then becomes capable of internalizing these tools (Vygotsky, 1978; Valsiner, 2007). When internalized, it becomes possible to use those tools to guide self-observation or any other form of self-consciousness.

### ***Dialogical Relations: Interobjectivity and Intersubjectivity***

Bakhtin (1981) has emphasized *double directionality* of any utterance. He has also emphasized that the words used in an utterance are half authored by the speaking subject and half given, as they carry with them the history of previous usages carried out by other persons. This idea of double directionality, emphasizing that utterances carry traces of the Other, not only suggests that the Other is brought inside the Self but also that the Self is constantly addressing, referring, to something outside of it. This delimitates a central process of selfhood: the constant interplay between centripetal (away from the Self or internalizing) and centrifugal (toward

the Self or externalizing; see Valsiner, 2007) movements, occurring simultaneously. The movement of addressing is, of course, a centrifugal movement, but as the Self addresses the Other and the world, she or he brings back traces of them that are incorporated in one's own experiences and narratives (as meaning contents) and serve as basis in future references to the Other and the world.

The Self is therefore moving and positioning simultaneously in two different domains: one is its relation with the objects in the world, and the other is its relation with the Other. On this basis, perhaps we could name the dimensions of the relation with the world as *interobjectivity* (Moghadham, 2003) and the dimension of the relation with an Other as *intersubjectivity*.

The double directionality of the Self generates those two simultaneous and necessarily connected life dimensions. Objects are always constructed by the person as semiotic objects, and because they can only become semiotic objects in the context of dialogical relations with others. Thus, interobjectivity is a realm achieved through the development of joint activities. The domain of intersubjectivity is mutually and reciprocally generated. Self and Other, in their process of positioning toward a specific object, are also positioning themselves toward each other. It does not imply an explicit commentary on the other party, but at least implicitly each human agent reveals himself or herself in the positions assumed toward something else. Thus, the Self obtains a “surplus of seeing” through the Other—specifically, through the positions he or she assumes toward the object of the joint activity, something is revealed about the Self.

Thus, objects are placed at the core of the dialogical relation. Each rejoinder in a social activity assumes a position toward that object that positions all the others involved in a certain way. These others will respond to this position with another position around that object, introducing a new perspective about it or introducing some new object that refracts the previous one. And the dialogue keeps on and on.

### ***Spatiality of the Self***

In the Bakhtinian tradition (Bakhtin, 1984), a spatial metaphor is used as well as the notion of position. If we assume that Self, Other, and the objects of their attention are disposed in a space, we may say that they have a co-relative position toward each other. This metaphor thus defines the impossibility

of two identical perspectives regarding the Other or the world and the impossibility of a subject simultaneously occupying two positions toward the world. However, it may happen that multiple social others are involved, and in that case the same position of the Self toward an object will create multiple co-relative positions I–Other. For example, if someone defends a friend against some threatening stranger, this person is assuming one single position but implying two antagonistic I–Other configurations (protecting the friend, and attacking the stranger). In other words, the specific position of the Self is determined by the combination of the several co-relative positions I–Other involved.

Thus, it seems that the DST gives the wrong impression when insisting in the polyphonic self. On the one hand, it is true that throughout time we may assume different positions regarding the same objects; on the other hand, the Self only occupies a position in any single moment.

## Conclusion

As we emphasized throughout this chapter, dialogism attributes to difference-in-itself an ontological status (very much in the same sense philosophers of difference like Deleuze do) and takes it to have a function of bridging opposing and asymmetric elements. Therefore, dialogism frequently considers antinomies to have an explanatory value by themselves instead of trying to favor one of their poles in detriment of the other (*see* Marková, 2003, for an elaboration on this topic).

The debate pertaining to the openness and closure of Self is, in DST, a function of two proposals: that the Self is bounded by a membrane that separates Self from non-Self, interiority from exteriority, and that the elements that internally and externally constitute the Self are mutually dependent and connected through referential semiotic processes. In this sense, DST endorses neither an individual constructivism nor a contextual or social constructivism. Both Self and the context in which it is immersed are co-constructed, and DST is focused on the processes by which it occurs and on what it involves.

The *experiencing-here-and-now-I*, as Valsiner (2002) phrased it, is always configured as “I, Other-in-me, and internal audiences” and draws always a separation between itself and its environment. The basis through which the Self draws this separation and addresses the Other and the objects is a specific configuration of those elements. This configuration

supports and expresses a given position of the Self toward its environment. Thus, we do not mean to suggest that the Self is permanently multipositioned, revealing different simultaneous positions toward the world. The Self does not *possess* multiple positions, even if throughout time it *becomes* a multiplicity of states and tendencies that are enacted in different relational contexts along time. Therefore, these positions (or configurations) of the Self are global self-states constituted by affects and thoughts, desires, signs, cultural values, and practices that are aggregated in a semi-stable global organization.

Temporality and spatiality appear in DST related to the functional and structural characteristics it attributes to selfhood. Although we are well-aware of the perils of such distinction (structure and function) and we recognize that it is not a clear-cut distinction, it serves a descriptive purpose. However, despite this, it has led to an overemphasis on the description of the components of selfhood in detriment of the development of its dynamic and temporal dimension. So, the relation between temporality and spatiality of Self is still underdeveloped. Moreover, it is not an easy question. DST does not favor a perspective on temporality that considers it as being continuous and a unified process. Both because DST is focused on the relations between elements of Self and considers relations with different natures at different levels, there will probably be several temporal trends involved in selfhood. However, generally, DST emphasizes Self to be oriented toward the future. The present does not exist as an extended and stable time; it exists only in its relation to the future and to its history and, therefore, its past. The present of the Self is an unstable moment in its process of becoming; it can only be apprehended by conceptually discontinuing a group of processes that are constantly on the verge of change and becoming different.

The debate around the unity or multiplicity of the Self is the last point we would like to stress. To summarize what we just argued throughout this chapter, we could say that in DST the Self is neither one nor several, neither single nor multiple. It is considered to be a decentralized and heterogeneous multiplicity. This means that there is not a central organizing element or a hierarchical chain of elements of different orders; no predetermined process is thought to decide which positions will emerge across time or how they will organize in relation to one another. This way, Self is like a *rhizome* in the sense that Deleuze and Guattari (2004)

have described rhizomatic entities: The several positions that come to constitute the Self throughout its history constitute centers of significance and subjectification. These functions of significance and subjectification are distributed across positions and are not dependent on any process besides the ones inherent to internal and external dialogicality of the Self; they are not subject to any pre-determined paths nor hierarchy.

These antinomies to which we just alluded to also help us to position dialogical perspective on selfhood in the global context of selfhood theories. Traditionally, theoretical models of Self tend to emphasize one the poles of each one of these antinomies while criticizing their competitor models for positioning on the other pole. Sometimes, they may accept some minor characteristics of the other pole but still emphasize that Self is essentially open or closed, for example. Dialogism, in stating that selfhood is constitutively relational in its processes and elements (even when we are referring to the phenomena of individual thinking), sustains that Self is essentially open and closed, temporal and spatial, constructed through narratives and dependent on non-narrative processes. In this sense, dialogical theory of selfhood is a positive and heuristic project in that it accepts and integrates constitutive characteristics and processes of selfhood that usually remain in opposite sides of the academic and scientific debate.

### **Future Directions**

Major changes in DST have taken place since the initial proposal of Hermans and colleagues. Some recent versions of it have made a long way from the scheme of I-positions involved in mutual relations within the landscape of the mind and contain some promises of reshaping the way selfhood is conceived within a dialogical framework. This has happened as dialogism has evolved and been articulated further as a global system of thought and as researchers have applied it to conceive specific phenomena. Although these two forces have been promoting further developments in dialogism and DST, their potential to generate novelty in the way psychology approaches and conceives human phenomena is also potentially hindered by the use of concepts like voices or positions in ways that may have lost their relation to dialogism. A major global challenge to DST, therefore, is to maintain itself as dialogical. As further developments and applications of DST are presented, it is important for it to maintain the

integrity between the worldview in which it is based (dialogism) and its conceptual and methodological dimensions.

In this context, several general questions are yet to be addressed. Two of them appear to be fundamental at this point. First of all, we argue that current descriptions of the dialogical self are still static descriptions in the sense that they are focused on structural and dimensional parameters describing the system of selfhood. But how does this structure behave in motion? It is the question of changes in its configuration over the course of experiential and communicational time facing us. Specifically, it is also, for example, the question of the self-and heteroregulation in the Self. Although these are still overly conceptual questions, they stimulate researchers to expand DST into a more comprehensive model of human psychological domain and to reach clear applications of DST throughout subdisciplines of psychology. In time, these developments will show the limits of dialogism, as a meta-theoretical framework, and will orient researchers to new theoretical developments and, most of all, to new synergies between dialogism and other general frameworks.

Second, the present descriptions are constructions derived theoretically. This gives rise to several methodological issues that relate essentially to the need to specify the properties of the constituent elements of the Self and the processes involved in their relations and the problem of access to the domain of experience. Specifically, this final issue will result in questions like: Is it possible to identify internal audiences, for example, in all activities (whether behavioral, cognitive, or emotional)? Hopefully, these questions will press researchers to develop dialogically sound strategies and methods of analysis of dialogicality inherent to selfhood without returning to traditional ways of conceiving phenomena and doing research that are hardly compatible with a strong dialogical framework. Because within dialogism, theoretical and methodological developments have evolved at different rates, this discrepancy between theory and method runs the risk of becoming a conservative force to dialogism innovative potential. Specifically, because the discussion around what would be dialogically informed research practices is still incipient.

# Narrative Scenarios: Toward a Culturally Thick Notion of Narrative

Jens Brockmeier

## Abstract

This chapter investigates the role of narrative in the relationship between individuals and their cultural worlds. Drawing on assumptions of interpretive cultural psychology and a Wittgensteinian concept of narrative as a cultural form of life, it proposes a culturally thick notion of narrative. At the heart of this notion is the idea of narrative as a cultural practice, a practice of meaning construction. This argument is developed in discussions of five traditions of research that have explored the nature of narrative (1) in contexts of cultural traditions and (2) socialization, (3) as a “form of life,” (4) with respect to fictional and nonfictional genres, and (5) as an instrument and practice of folk psychology. The resulting outline of a culturally thick notion of narrative is further elaborated by arguments from narratology, discussions on narrative in the light of evolutionary anthropology, and interpretive approaches to narrative in philosophy and the social sciences.

**Keywords:** narrative, narrative psychology, narrative practice, meaning, intentionality, socialization, folk psychology, narrative as a form of life

## Introduction

An inquiry into the nature of narrative that aims to situate its subject in the context of culture and psychology reasonably draws on two different families of theories. One is a family of cultural approaches to human psychology, the other a family of psychological approaches to culture. Essential to both is the effort to understand the relationship between individuals and the cultural worlds in which they live. In this chapter I make the case that language—particularly narrative—plays a crucial role in this relationship. I therefore also consider a third family of theories, namely, theories of narrative that emphasize its cultural nature and allow us to conceive of the great variety of narrative practices to be found in all human societies as a variety of cultural practices.

There is a twofold reason why narrative practices play a central role in humans’ cultural existence: they

are pivotal in binding the individual into a cultural world and in binding the meaning of this world into the individual’s mind. To explore this dialectic is the main purpose of my inquiry.

To do so, I first need to qualify the meaning of culture and narrative. As both are subjects of high complexity, it is not surprising that they come with an array of different conceptual definitions reflecting diverse points of view from which they can be considered. The point of view underlying my discussion is that of a cultural psychology. Cultural psychology investigates the relationship between individuals and their cultural worlds from a perspective that, in some respects, differs from, say, cultural or social and psychological anthropology. It also is different from sociology or social psychology, cultural studies, narrative studies, and hermeneutic philosophy. At the same time, however, cultural psychology draws on all of these traditions and uses

their resources—and they all are, in fact, part of the theoretical landscape that I want to survey. What is more, the understanding of cultural psychology that I bring to bear on this relationship is not that of a clear-cut disciplinary economy but rather that of a point of view, a perspective that cuts through several disciplines and that will become sharper as my discussion proceeds.

The qualification of culture and narrative, outlined in the second section of this chapter, leads to what I call a culturally thick notion of narrative—a notion of narrative as cultural practice and performance.<sup>1</sup> The notion of narrative as a cultural practice takes up Geertz's (1973) suggestion that an interpretive study of humans' cultural reality is to be based on experience-near concepts. Such concepts, sometimes called *emic*, are as close as possible to the experiential discourse of the individuals whose, in this case, narrative practices are at stake. Of course, "closeness" to experience is relative. All human experiences are generalized, but some are more and some are less so; some echo common sense and conventional everyday psychology, others give way to more reflected, individual, and deviant ways of meaning-making. The important point here is that emic concepts are concepts of a cultural world seen from within. They reflect the subject's point of view, the perspective from which people themselves consider their experiences to be meaningful. On the other hand, we have experience-distant "or *etic*" concepts. Etic concepts are used in the description and analysis of emic experiences—for example, by psychologists, philosophers, anthropologists, and narratologists.

When, in everyday life, people tell stories about themselves, they are typically concerned with issues that matter to them, with things they did, or with events affecting their actions, thoughts, feelings, and relationships with others. In telling their stories, they are arguably not concerned with the distinction of "story" and "discourse," as important as it may be in narrative studies, or the way their "storylines" and "plot structures" unfold and (together with other narrative, discursive, grammatical, and semantic registers) are shaped by and give shape to their sense of "narrative identity." Giving center stage to experience-near concepts not only enables us to become aware that people engage in very different stories about themselves (which is to say that there is no single "narrative identity" narrative)—irrespective of the fact that these narratives can be subject to the same categorical distinctions of "story," "discourse," "plot," and so forth. It also makes us more attentive

to the "local" specifics of the cultural models and vocabularies of self and identity on which these narratives draw. Further, we may recognize that their narrators do not necessarily have "a sense of having a narrative identity," perhaps not even a sense of having a personal identity at all. To be sure, even most people in traditions as obsessed with self-talk as European and North American ones would use a different language than that of "narrative identity" to talk about themselves.

Yet the proposition of a culturally thick notion of narrative does not only rely on the multidisciplinary resources just mentioned. There are more traditions of knowledge and thought that have contributed, in one way or another, to a notion of narrative as a cultural practice, which will be reviewed in the third section of this chapter. But before that—in the second part, after this Introduction—I outline three assumptions about culture and narrative that orient my ensuing discussion of the scholarly and scientific traditions relevant here.

The fourth section then takes a closer look at what is the quintessence of the notion of narrative put forward in this chapter: the idea of narrative as a cultural form of life. This idea centers on an emic notion of narrative that, rather than postulating universal components or ontological characteristics of storytelling, is based on a culturally situated mode of meaning-making. This notion also comprises how people give meaning to what they consider to be a "story." The fifth and final section offers an anticipatory look at important developments in the field: prospects of a culturally thick notion of narrative that permits us a fuller understanding of the intricate relations between the actions and minds of individuals and the cultural worlds that they create, populate, and change.

## Culture and Narrative: The Basics

### *Culture As Perspective*

In recent years, our concepts and theories of culture have undergone radical changes that also affect our understanding of the cultural charge of narrative. People have always been viewed as cultural beings, yet today many theorists have come to emphasize that people do not just live in *a* culture, but in a *variety* of cultural worlds. They are simultaneously embedded and entangled in distinct cultural realities, and these realities are often divergent and conflicting among each other.

Take people in a so-called "individualist culture" who, irrespective of this label, can live in a

very social and relational way—they may have a supportive family, a close network of friends, and be good team players at work. Whereas people in a so-called “collectivist culture” may not only work on their own and are without a family, but they may also behave and think in a self-centered and egoistic way. In addition, social realities can be experienced differently by different people within the same cultural world and even by the same people in different situations. Obviously, “individualist cultures” and “collectivist cultures,” terms widespread in cultural and cross-cultural psychology (for example, see Kitayama & Cohen, 2007), are prototypical experience-distant, or etic, concepts.

Moreover, although in the history of anthropology the existence of cultural traditions was long viewed as constitutive of a culture, there can be circumstances that exclude the formation of traditions. A good example, elucidated by Mintz (1974; Mintz & Price, 1992), is the socio-cultural world of the Caribbean in the extended period of conflict between colonial and postcolonial regiments. In this period many previous traditions came to an end without comparable new cultural continuities establishing themselves. Mintz’s findings have also confirmed a general observation: cultural experiences are typically contested. Interlaced with divergent powers and interests, they are subject to controversies and conflicts of interpretation that are often at the very heart of societal life.

All of these conflicts and complications, as well as their underlying political forcefields of power and economic interests, tend to be neglected when culture is meant to refer to a monolithic and bounded context—a meaning that has been, in fact, pervasive (not least, in quarters of cultural and cross-cultural psychology). One reason for this is that psychologists and social scientists in general, when describing and investigating culture in terms of a homogenized social unit, typically approach their subjects with concepts and models that reflect their own cultural worlds or, more precisely, the hegemonic theoretical assumptions of these worlds. This argument has been much discussed in the wake of two influential books by George Marcus, one written with Michael Fischer (1986), the other with James Clifford (1986). Marcus has argued that anthropologists have organized their observations of and thoughts about the people they study according to categories of their own cultural traditions. Many anthropologists and cultural theorists, discarding the idea that all people in any one society

experience “their culture,” have thus come to prefer a view more sensitive to the polyphonic, fractured, contingent, and often disharmonic ways of life and experience, a view that is more able to bring to the fore what Valsiner (2007) calls “the heterogeneous multitude of human dramas of everyday lives” (p. 87). Repudiating the imposition of a marked-off unitary culture concept on a group of people, a society, or civilization (typically alien and different from the investigator), many theorists now tend to conceive of social order as an unstable accomplishment that may be enforced, explained, legitimized, and exploited by some members of a society and, at the same time, questioned, rejected, and resisted by others.

On this view, today’s cultural worlds are increasingly open, inter-related, and fleeting. Sociologists speak of “liquid realities” (Bauman, 2000). Cultural worlds are permanently under construction. They extend on trajectories that link the local to the global. They are dynamic both in terms of internal differentiations and contradictions, and in terms of external (inter- and multicultural) relations. They are made up of processes whose dynamics go far beyond the idea of general laws, structures, or rules. Instead, to use the language of cultural theorist Appadurai (1996), they consist of emergent, fractal, and fragmentary configurations that follow nonlinear ways on which they temporarily overlap, interpenetrate, and again diverge.

Drawing on these discussions, the understanding of culture that underlies my approach to the inter-relation between individuals and their cultural worlds is neither substantialist, nor does it depend on generic terms or collective categories of culture. At stake, then, is not what is defined as culture by traditional anthropology (and *mutatis mutandis* by psychology in the wake of Wundt) as “that complex whole which includes knowledge, belief, arts, morals, law, custom, and any other capabilities and habits acquired by man as a member of society” (Tylor, 1871, p. 1). Rather than based on the assumption of such a “complex whole,” my understanding of culture (and, as I will explain in a moment, my ensuing understanding of narrative) is epistemologically and hermeneutically motivated. I propose comprehending the role narrative plays for our cultural being in the world by using the “cultural point of view” as a perspective. This perspective allows me to view human action (and, in the wake of Wittgenstein and Vygotsky, I also count language as a form of action) and other material and symbolic practices

in a context without which they would remain unintelligible.

It is important to see that the idea of the cultural as a point of view on the world does not imply culture as an institution, a force, or a power—that is, as “something to which social events, behaviors, institutions, or processes can be causally attributed,” to put the matter in Geertz’s terms (1973, p. 14). At stake is a context in the sense of a frame, a perspective within which certain phenomena can be intelligibly (or “thickly”) described. On this view, culture loses all folkloristic color. It turns into an epistemological, hermeneutic, and semiotic perspective: a way of interpretation that allows certain phenomena to gain meaning that otherwise would remain enigmatic. Geertz (1995) speaks of a ground against which a figure becomes visible, meaningful, understandable.

### CULTURAL WEBS OF SIGNIFICANCE

What is called the “cultural context” of a phenomena thus refers to a symbolic fabric, to a meaning context—that is, it is not ontological. It does not have, for example, a materially manifest existence like a castle, church, or parliament building. To say it is of semiotic nature means it is mediated by signs—that is, it is neither of ecological, socio-economic, ethical, or political nature, although all these contexts (and many more) are relevant here. Geertz (and, before him, Weber and Cassirer) has used a compelling metaphor for this cultural meaning context: that of humans as animals suspended in webs of significance they themselves have spun. My point now is that if we view the cultural context of human action and mind in this sense as a semiotic construction, as “the fabric of meaning in terms of which human beings interpret their experience and guide their actions” (Geertz, 1973, p. 145), then the most complex and comprehensive sign system, language—and especially the most complex and comprehensive form of language use, narrative—plays a pivotal role in spinning these webs of significance.

I should mention that the concept of language (and, by inclusion, of narrative) that underlies this argument is a Wittgensteinian notion of language as an open and fleeting form of life. This notion suggests a discursive and performative understanding of language as mingled with a broad spectrum of other practices of life, which is in contrast with an understanding of language lodged within an exclusively linguistic arena. The idea of language as a

form of life (Wittgenstein, 1953) defies a number of exclusionary oppositions, such as those between the verbal and the nonverbal, between linguistic and communicative practices, between speaking and acting (including bodily acting), and between linguistic and material action. With this in mind, let me qualify my point. On the one hand, I argue that without narrative, these cultural webs of meaning cannot be spun, which is to say that without the use of narrative, human beings cannot communicate, interpret their experience, and guide their actions, except in a restricted way.<sup>2</sup> At the same time, I propose that without narrative, we cannot investigate these webs and the way they are spun—that is, without the use and the analysis of narrative, we cannot scientifically and scholarly interpret people’s cultural self- and world-interpretations.

The hermeneutic circle inherent to this approach has often been explicated as unavoidable part and parcel of every effort to understand human action and mind (e.g., Gadamer, 1989; McDowell, 1994; Ricoeur, 1981), and cultural life at large (Rorty, 1979). Against the backdrop of this philosophical tradition of reasoning, the study of cultural worlds cannot proceed like a nomological and experimental science in search of laws but must be “an interpretive one in search of meaning” (Geertz, 1973, p. 5). This idea of human beings as “reaching for meaning,” which I have discussed in more detail elsewhere (Brockmeier, 2009), has long been established in the human sciences. It also became the springboard for Bruner’s (1986, 1990) vision of narrative psychology as a core area of cultural psychology. Bruner, one of the pioneers of cultural narrative psychology, saw this endeavor from the very beginning as closely connected to cultural anthropology.<sup>3</sup>

### *Functions of Narrative*

What then, more exactly, is the general role of language in the unfolding and understanding of cultural meaning contexts? And what is the particular role of narrative, especially, when we bear in mind that an essential assumption of the just mentioned project of a narrative psychology is to understand narrative practices as cultural practices? To explore this question, I take a socio-evolutionary and anthropogenetic vantage point. What characterizes human activities on a socio-cultural level as specifically human is that they are mediated through increasingly sophisticated forms of social sharing, collaborative action, and cultural learning. For Tomasello (2008), human beings have evolved

to coordinate complex activities. These activities comprise culturally essential forms of shared intentionality such as “reading” the intentions of others, emotional interaction, pretending, playacting, and gossiping. It is because they are adapted for such cultural activities—and not because of the cleverness of their individual minds—that humans are able to do so many exceptionally complex and sophisticated things. There is a hub to all these complex and sophisticated things that make human beings unique: this is joint sign-mediated meaning construction and interpretation, with language being the evolutionary and socio-historically most developed constructive and interpretive mode (Lock & Symes, 1999; Nelson, 1996; Tomasello, 2003, 2008). It is in this sense that Jakobson (1960a) pointed out that language “serves as a foundation of culture. We may go even further and state that language is the necessary and substantial foundation of human culture” (p. 107).

#### NARRATIVE COMPLEXITY

Yet this is not just about language or linguistic practices. The more humans’ social and cultural activities have become complex, both on an evolutionary and socio-historical plane—that is, the more they are socially inter-related, are based on shared intentionality, involve extended action sequences, and demand planning and anticipating—the more they involve complex linguistic practices. Why do we call these linguistic practices complex? Because they afford humans the possibility to navigate spatial and temporal scenarios that go beyond the here and now and encompass multiple events in several forms of past and present. Moreover, they allow us to look forward to and imagine future scenarios and hypothetical—subjunctive—events (Carrithers, 1992; Grodal, 2005; Nelson, 2007a). The overarching form of discourse in which such complex linguistic practices are organized is narrative. A great ape may communicate, “I want that banana.” However, a language at the complexity level of narrative is needed for the following sequence (taken from an ongoing conversation between a young couple): “I want that banana, but only if it is not from the fruit shop where you got those disgusting bananas yesterday—probably because you thought, ‘Wow, this is an eco shop, the first one in our neighborhood, terrific, terrific, and we must support it, and so on and so forth.’ We really should throw those mushy bananas in the trash before they start to rot.” Narrative, to make a long story short (and to foresee

some of what follows), combines and condenses all options of language and, in doing so, creates novel syntheses of meaning. No other sign system could handle and communicate the complexity of these syntheses in such a comprehensive, economic, and effective manner.

There is little doubt about the evolutionary advantages of narrative, even in its most elemental form as preverbal language of enactment, as Abbott (2000) has stated (on the evolutionary origins of narrative, see also Abbott, 2001, and Boyd, 2009). Performed storyworlds (i.e., enacted narrative scenarios) might have dominated an early evolutionary stage of narrative, which then, at the same time, would also have been one of the early stages of human cultural and intellectual history. Narrative, for Abbott (2000), “is not a product of grammatical language, but a preexisting condition for it that was later absorbed and enriched by language” (p. 255). Once fully developed, narrative becomes one of those capabilities whose evolutionary and cultural advantages so easily escape our attention because we are, from early childhood on, used to taking them for granted. We are immersed in it: we breathe it. It has become our element. Borrowing an analogy from evolutionary niche theory suggested by Hutto (2009), we can say “that narratives are a distinctive and characteristic feature of human cultural niches, just as dams are for beavers” (p. 27).

#### FOUR BASIC FUNCTIONS

To get a clearer sense of this unique capacity, we can distinguish several basic functions of narrative; all of which are at work in the example just quoted. All of them are functions of action—that is, they are in the service of human activities, which explains why they are as variegated as the forms of life which they realize. Building on Wittgenstein, we can view narrating as a way to do things with words. However (and here this view diverges from that of Austin’s [1962] famous founding question of speech act theory *How to do things with words?*), narrating is not only a way to do things with words; it also involves an array of other linguistic and nonlinguistic means, of media or semiotic environments, and of social and institutional constellations. It thus may be more appropriate to approach it as a means, or action, to carry out certain functions under certain circumstances, rather than by universally defining some structural properties or basic elements. I will come back to this idea of narrative as action in a moment, but first let me spell out narrative’s four basic functions.

First and most importantly, narrative, as already indicated, is crucial in enabling developed forms of social sharing, coordinating joint actions, and intersubjective understanding. This is narrative's communicative function. Second, narrative is a force to express and push forward particular views in the service of particular interests. Narrating is humans' most powerful means to make one's case—to explain, persuade, and defend something—against the case of others. This is the rhetorical function of narrative. Third, narrative not only allows people to share their emotional and intentional states with others, but also to make sense of the emotional and intentional states of others as well as of themselves. That is, it affords them to become aware of, reflect on, and regulate their feelings and other mental (and bodily) states. This is its empathetic or emotional function. And fourth, narrative has a cognitive function, a term I use as a shorthand for its manifold intellectual (or reflexive) and imaginative potentials.

The cognitive function is manifest in narrative's capacity to make sense of experience, to operate as a way of problem solving, and to give shape to the most intricate thoughts, visions, and imaginings—in fact, to have many of them come into existence in the first place. The cognitive function comprises special forms and capacities, such as ability (quite prominent in the quoted example) to construe multilayered temporal scenarios and gestalts of time, be they real or fictive, realistic or fantastic. These temporalizations go far beyond the sequential ordering of events and individual actions; they extend to the lifetime of individuals and the historical visions of communities. Narrative thinking enables us to follow a flow of events both in the here and now of our social and societal life, and within the broader temporal horizon of history and evolution. Perhaps the most powerful way, Bruner (2002) remarks, to distance ourselves from the immediacy of events and experiences is to convert what we've encountered into story form. And not least, the cognitive function allows us to give shape to and reflect on the cultural dynamics mentioned above, the dynamics ensuing from the fact that people live in more than one cultural world, which is especially manifest under conditions of modern globalization.

#### THE CASE OF CULTURAL IDENTITY

An illuminating illustration of this aspect comes with the thorny question of how we understand, under modern and global conditions, an individual's

cultural identity. An essential element of one's sense of cultural belonging is the inter-relation between social inclusion and exclusion. Although the desire for belonging seems to have developed one of the oldest, not to say archaic and most deeply rooted form of bonding, there have always been diverse, even contradictory forms of belonging: practices of simultaneously localizing oneself in several cultural narratives and symbolic spaces of identity (Brockmeier, 2001). For most people, the wish of belonging to a society leads to what Valsiner (2007) has called "a real effort at an impossible task," simply because a modern society has become too decentralized and too heterogeneous a field to allow for unambiguous identification. What further complicates matters is that most modern social and personal identifications refer to fictional units. A prime example is the nation state which, according to Anderson (2006), only exists as an "imagined community" because the members of this community cannot possibly know each other.

That cultural identity fans out in a network of often conflicting relations to other identities (and to other social networks) becomes particularly patent in the case of individuals' sense of national identity. In much of today's world, a sense of national belonging means balancing a difficult to entangle array of plural identities that reflect a multitude of inclusions and exclusions. One and the same Belgian can be a Flame and a Huguenot, a native speaker of French and Portuguese, an employee of an U.S.-based multinational company who lives in the Netherlands and is married to an immigrant from India. We are all familiar with such or similar identity constellations that can be lived out in many different ways and described in terms of many different but inter-related personal and collective identities (Straub, 2002). But, and this is my point, if they are to be articulated from a first-person point of view (perhaps in view of life as a whole, as subjectively meaningful gestalt, or as the search for such a gestalt, in a word, as a relation of figure and ground), then it unavoidably takes the form of narrative. In such a story, the four basic functions of narrative merge. We still may call it a personal (or first-person) narrative and also a narrative of an "impossible task," or a story that is supposed to impose order and coherence on the inherent instability of a post-modern "messy self" (Rosner, 2007), yet we should bear in mind that "the personal" here is a highly cultural arrangement—and so are the models and conventions of storytelling and autobiographical

narrative that bring about this arrangement. These models range from literary, philosophical, psychological, and political genres to popular and everyday genres of narrating; they encompass the entire range of what has been called “narrative folk psychology” (Bruner, 1990; Hutto, 2009).

### *Narrative As Action*

In line with most social scientists, psychologists have been interested in narrative first of all as a method or methodology, as a way to find out, as a means to an end. The stories people tell in research settings such as interviews are conceived of as providing access to either a given social or psychological reality or to the experience of such a reality. Specifically operationalized narrative methods allow researchers to “collect data” and objectify them through coding systems and other elaborative techniques. This sort of research proceeds on the assumption that narrative represents social or psychological reality, that it offers a window on such reality. What makes this assumption so persuasive is that it is well-articulated not only in the social sciences, but also in narrative studies and criticism. Many influential investigations of literary narrative have privileged nineteenth-century realist novels, generalizing their role of mimesis (i.e., of simulation, imitation, or representation), whereas they neglect the non-mimetic nature of much narrative discourse, as critics like Richardson (2006) have argued. In more general terms, this view piggybacks on an understanding of language as representation of reality or as the representation of the experience of this reality. Irrespective of a long tradition of critique, this paradigm of language as a mirror of the world (Rorty, 1979) has proved to be most resilient and continues to flourish not only in common sense, but also in many quarters of the social sciences and humanities, from psychology to narratology.

One problem resulting from the focus on narrative as representation is that it misses out much of what else narrative discourse is about. Let me give prominence to just one further use to which narrative can be put. As with all language, narrative not only represents (or re-presents, or reflects, or expresses) reality, but also creates reality. It is a way not only of organizing experiences but also of making new experiences. Rather than simply mirroring the world, it also invents the world; in fact, it evokes many worlds, storyworlds—be they fictional or factual, told by the liar, the poet, the visionary or by the accountant, the judge, the

documentarian. Using an expression by Goodman (1978), narrative has been conceived of as a “way of worldmaking” (Brockmeier, 2005a; Bruner, 2001; Herman, 2009a). What Whorf (1956) wrote about the “background linguistic system” of each language in general also holds true for the narrative registers of each language, namely, that it “is not merely a reproducing instrument for voicing ideas but rather is itself the shaper of ideas, the program and guide for the individual’s mental activity, for his analysis of impressions, for his synthesis of his mental stock in trade” (p. 212). Meanings are neither incorporated in the material world nor an inherent quality of words; they are, as Wittgenstein pointed out, negotiated in interactions within a cultural community. Wittgenstein put particular emphasis on the language games emerging in these interactions, with narrative as one particular language game (1953, § 23).

It is from within such a “cultural grammar,” an idea echoing both Wittgenstein’s and Whorf’s thinking, that we mentally organize our being in the world. “The categories and types,” Whorf (1956) wrote, “that we isolate from the world of phenomena we do not find there because they stare every observer in the face; on the contrary, the world is presented in a kaleidoscopic flux of impressions which has to be organized by our minds—and this means largely by the linguistic systems in our minds” (pp. 212–213). I take narrative to be one of these Whorfian linguistic systems, even if we might be more reluctant today in using the term “system” for such an open and fleeting form of life. Wittgenstein’s concept form of life also helps us to discern another essential quality of narrative discourse: its interwovenness with all kinds of actions, linguistic and not. As ecological and cultural linguist Harrison (2007, p. 205) has put the matter from the perspective of an empirical field researcher: languages exist and evolve to interact, convey information, and shape meaning “within a specific cultural matrix” that influences and permeates every level and aspect of them; they thus “must be studied holistically and in their natural – that is cultural – context.” When languages die off, Harrison maintains, entire reality-models (most prominently, those embedded in the lexical resources of a language) are lost forever (Harrison, 2011).

It is against this theoretical and empirical background that my cultural-psychological perspective gives center stage to narrative as action, as a cultural practice that is wider in scope, more differentiated

and powerful than what could be captured by a cognitive, linguistic, narratological, or critical focus alone. What could be seen as weakness turns out to be its strength: that the borders of a culturally thick notion of narrative are fuzzy because it is interlaced with many other cultural practices, linguistic and nonlinguistic.

Another way to understand narrative as action is to see the point of storytelling not as a mode of representing but of construing meaning. And this is an important difference. It is the difference between an idea of narrative as a reified entity (something Rom Harré and I have expounded as the “ontological fallacy”) and the idea of narrative as a discursive or cultural process, as a mode of meaning-making (Brockmeier & Harré, 2001). Taking Bruner’s point about narrative as meaning construction a step further, we have argued that a more appropriate way to study the discursive reality of this mode than classifying narrative structures or components is to examine the ways in which people engage in the very business of meaning-making and, in the process, use stories. There are no forms of narrative that exist as universal templates to be made concrete; instead, they are constrained to take the forms they do by the exigencies of the particular cultural situations in which they occur. Rather than conceiving of narrations as given ontological (or cognitive, or linguistic, or metalinguistic) entities, we have described them as *modus operandi* of some of our discursive practices or performances (Brockmeier & Harré, 2001, p. 53). The question, thus viewed, is not how people use narrative as a means to a representational end, but what are the concrete cultural conditions under which they tell stories and in so doing implicitly define what they take to be narrative. This may also comprise a view of narrative as representation.<sup>4</sup> It is in this fashion that the cultural study of narrative practices becomes *emic*, in the sense outlined at the beginning: it is based on experience-near stories of what people, at a certain point in time, consider to be meaningful in their lives.

### Exploring the Cultural Matrix of Narrative: Traditions

In the last section I have sketched a culturally thick notion of narrative, localizing it on three different maps: as a mode of interpretation through which people try to understand their being in the world, as a cultural practice realizing several (communicative, rhetorical, empathetic, and cognitive) functions, and as a form of action. In this third

section, I flesh out this sketch by reviewing five traditions of scholarship and research concerned with the relationship between culture and narrative. All of them have made, in one way or another, a significant contribution to the study of the cultural nature of narrative and the role of narrative within humans’ cultural worlds at large. Although some of these traditions have a remarkable history, which would be a valuable subject in its own right, my interest is not primarily a historical one. Rather, I view these approaches as shedding light on important aspects of the cultural matrix of narrative I have set out to explore.

### *Narrative and Cultural Tradition*

One of these aspects is the role of narrative in creating, preserving, and transforming cultural traditions—that is, its importance as a bond of intergenerational and historical continuity. Within the context of anthropological approaches, the study of this role goes back to Edward Sapir’s (1949/1933) idea of narrative as a “culture-preserving instrument.” Sometimes, the origins of this line of thought are even traced back one more century to the linguistic and philosophical work of von Humboldt (e.g., Jahoda 1992). To view publicly circulating stories of a community—myths, fables, fairytales, religious and historical legends, and other folk stories—as part of what Wundt (and Lazarus and Steinthal before him) described as *Völkerpsychologie*, was not unusual among literary and cultural-history scholars in the first half of the last century, the time of Sapir and Whorf. In the 1920s and 1930s, classicists examined the transmission of ancient Greek narratives in a world of orality (e.g., Parry, 1971) and early ethnographers of narrative and folklore such as the Russian Formalists (e.g., Propp, 1968) investigated what they saw as culturally canonical patterns of folk tales. Many works of the period were inspired by similar interest in the cultural nexus among social life, language, narrative, and other semiotic environments. Much discussed examples are Benjamin’s *Archades Project* (1999), never completed because of his death in 1940, about the cultural world of Paris he called “the capital of the nineteenth century,” and Mikhail Bakhtin’s (1993) studies from the 1930s and 1940s about the Renaissance and “Rabelais’ world.”

Over the last decades, linguistic anthropologists and ethnographers of narrative in the wake of Sapir and Whorf have extended the view of narrative as a “culture-preserving instrument.” The new,

extended view is meant to encompass not only the function of narrative for a cultural tradition but also the function of a cultural tradition for narrative or, more precisely, for the specific organization of narrative “speech events,” storytelling performances, and other linguistic practices and discourses (e.g., Bauman, 1986; Hymes, 1964; 1974; Duranti, 2006; 2009a). The idea of narrative practices as cultural practices has led to the analysis of language-specific and culture-specific narrative forms, such as genres, semantic and grammatical resources, indexical systems, situated contexts of communication, and language socialization.

### ***Narrative and Socialization***

As we have seen, the interplay between narrative and the cultural world can be approached from two different angles: whereas narrative practices appear to be shaped and guided by cultural traditions, they simultaneously play an important role in establishing and transforming these very traditions. To participate in social life it thus is essential for each individual to become a culturally competent storyteller, which is encouraged by members of a cultural world who are deeply concerned with children’s able participation in social life and command of cultural knowledge. Central to both is language and the skillful use of its registers, from grammar to narrative, conversational turn-taking (Ochs & Taylor, 2001; Ochs & Schieffelin, 2006) and other forms of “streetwise” language use (Zentella, 1997). How an individual learns to actively participate in the narrative language games of his or her cultural world is the central issue in a second field of research that I review in this subsection. This field has emerged from the study of language socialization and the developmental psychology of language. Influenced by the work of Vygotsky (1978, 1987)—another contemporary of Sapir, Whorf, and Wittgenstein—it has drawn attention to narrative and narrative practices as an important way of integrating different strands of linguistic socialization. It is in fact a synthesis of a broad spectrum of linguistic and psychological aspects of language development that is realized in narrative discourse. More than that, the implications and consequences of narrative development affect the entire cultural socialization of the child (Daiute & Lightfoot, 2004; Miller, Fung, & Koven, 2007; Nelson, 2007b). Learning how to tell and understand stories in early childhood is a process that combines linguistic, social, and psychological (cognitive, emotional, and moral) development

processes and fine tunes them, in a variety of intersubjective practices, to culturally canonical requirements (Brockmeier, 2004). For Rogoff (2003, p. 282), the focus on this “guided participation in cultural endeavors” is at the heart of the Vygotskian vision of human development.

Why is entering the world of narrative discourse such a crucial cultural endeavor? It induces the child into discovering a new experiential space, a space that opens to a symbolic universe with unprecedented social options, as Nelson (2004; 2007b) has argued. In learning the rules of narrative language games, children not only find out that stories can fulfill several functions that all extend their horizon of agency, but also that the same event can be told in different ways from different perspectives. This narrative multi-perspectivalism comes in tandem with a multicentered “theory of mind,” if we want to use this term to refer to the social and pragmatic skills of what, in an alternative view, has been called humans’ “interpretive mind” (Brockmeier, 1996; Ricoeur, 1981). The multiple perspectives, and the need to interpret them, that emerge in narrative interactions help children to understand that different stories often reflect different people with different minds; they articulate different beliefs and points of view on the world, and this includes the worlds and minds of others. Ultimately, understanding—interpreting—different stories is to understand different minds. And this is not little. It requires, Nelson (2007b) writes, “understanding the sources of differences among people—their background, personalities, relationships, histories” (p. 219). There is abundant evidence from a variety of empirical fields suggesting that narrative is pivotal for the emergence of this folk psychology of social understanding (e.g., Herman, 2009c; Hutto, 2008, 2009; Nelson, 2009; Ornaghi, Brockmeier, & Grazzani, 2011).

Drawing on Vygotsky’s theory of human ontogeny as based on social-interaction, we can say that language and, by inclusion, narrative can be conceived of as the pivotal hinge between the child and the cultural world within which he or she develops. Not least in view of narrative development, Nelson (1989a) has noted that we owe to Vygotsky the most profound explanation of the role of language in the development of the child—especially as far as his or her culturally shaped sense of self is concerned. Language, for Vygotsky, is characterized in a twofold way. It is operative as a societal semiotic system and, in and through the process of its individual

acquisition, as a mode of social, linguistic, and cognitive development that allows novices to enter a linguistic and cultural community. In Vygotsky's psychological semiotic, language is essential for all forms of what he called "higher mental or psychological functioning," by which he referred to mental processes that are mediated by tools, especially "psychological tools" or signs, that is, cultural signs.

This process gains a new quality as soon as children begin to understand and use narrative discourse practices because it is these practices that offer them access to the manifold storyworlds of a cultural community. The child is entering what Nelson (2007b) calls a new experiential space: a community of minds. Acting as a member of this community means "we learn to tell the stories that our social world values, and our storied thoughts come to confirm to the models of our society" (Nelson, 1996, pp. 184–185). In Nelson's Vygotskian view, this community is the core of cultural life. It encompasses cultural environments in which the child begins to explore the intersecting complexes of communication, narrative, conceptual knowledge, and memory. In these experiences,

the child begins to encounter and engage with cultural knowledge systems beyond the personal range . . . Practices in cultural environments common to life in the preschool years may be particularly significant: symbolic play and games, and cultural narratives—stories, myths, folktales . . . and so on—all contribute to narrative consciousness and thus to becoming a member of the community of minds where these practices originate.  
(Nelson, 2007b, p. 212)

The implications of this view are far-reaching. To assume that during their first 10 years children are developing toward membership in a human community of minds challenges the traditional concept of theory of mind. It broadens the concept from something that children (in a developmental "milestone event") invent for themselves or that emerges from their cognitive development to a "cultural conception of what it is to be a person within a human community" (Nelson, 2007b, p. 219). The point at issue is no longer a single mind and its theory but children—persons—and their minds, their interactions, and interpretations according to the cultural conventions of a community.

Whereas research in the first tradition, outlined in the previous section, has concentrated on cultural narratives, the Vygotskian approach has been

mainly concerned with personal stories (as a particular variation of cultural stories) and the discursive and social contexts of interaction in which they are told, performed, and interpreted—as in the classic studies by Miller (1982), Nelson (1989b), and Ochs (1988).

### *Narrative as a Form of Life*

Traditionally, developmental psychology has revolved around the individual child, and from this perspective, it also has viewed the development of an individual's linguistic and narrative "competence." Yet Vygotskian perspectives, socialization theories, pragmatic approaches, and other culturally oriented investigations have shifted emphasis: from the autonomous individual and his or her mental or cognitive life, to the intersubjective, contextual, institutional, and socio-economical realities of human development. In this way, narrative too has been increasingly examined as a form of communication and co-construction of meaning. At the same time, it has served as a method of investigation. This trend has been undergirded by disciplines and theories from distinct backgrounds. Notably, parts of sociolinguistics, linguistic anthropology, ethnography, discourse studies, auto/biographical studies, life story research, and action and practice theory have all contributed to the formation of a field that, by now, can be marked as a third overarching research approach to the cultural nature of language and narrative.

Bolstered by one of the most influential paradigms of modern philosophy of language—the non-representational notion of language as communicative and intersubjective form of action, unfolded by Pragmatism, Wittgenstein, Austin, Davidson, Habermas, Rorty, and others—many sociolinguistic and social-scientific-oriented studies have begun to explore narrative as a mode of interaction and, in the process, cast light on its culturally situated nature. Yet it is not only the orientation toward the contextually and culturally situated nature of narrative practices and the understanding of these practices as ways of meaning-making, it also is the recognition of their ubiquity in many cultural worlds that is a common feature in this field. The notion of narrative emerging here might therefore be best dubbed in a Wittgensteinian manner as a cultural form of life—or, to use a different expression, as a language game "consisting of language and the actions into which it is woven" (Wittgenstein, 1953, §7).

There are several more currents of research that have developed conceptual and analytical tools for the investigation of narrative as a cultural form of life. Let us begin with discursive psychology that studies narrative as a form of intersubjective action or, to be more precisely, as discursive intervention in ongoing events (Edwards, 1997; Edwards & Potter, 1992; Harré & Gillett, 1994). A case in point is positioning theory. It foregrounds the ways narrators carry out various actions by attributing certain positions to characters in their stories, to the audience of their storytelling, to themselves, and in respect to the cultural world at large (Bamberg, 1997; Harré & van Langenhove, 1999; Harré et al., 2009). In a similar vein, other authors have emphasized the inherently intersubjective dynamic of storytelling—of “narrative in interaction”—especially in everyday encounters and conversational events (Bamberg & Georgakopoulou, 2008; Georgakopoulou, 2007; Ochs & Capps, 2001). Similarly, in the wake of Sacks (1992), sociolinguistic and conversation-analytical approaches (e.g., Aronsson, 2001; Norrick, 2000, 2007; Quasthoff & Becker, 2005) have developed what could be called a *narrative pragmatics*—a term originally coined by Chatman (1981).

It is amazing in what a short period of time the use of narrative and discursive approaches in the social sciences has become business as usual. From an exotic outsider and underdog, narrative inquiry has transformed into a respected member of the academic club—a taken-for-granted part of the standard spectrum of ethnographic and other qualitative methodologies (e.g., Atkinson, Delamont, & Housley, 2008; Chase, 2005; Clandinin, 2007; Elliott, 2005; Holstein & Gubrium, 2008, 2009; Horsdale, 2011; Quinn, 2005). For some time now, it has been safe to say that narrative inquiry in the social sciences has entered a “post-polemical phase,” as Freeman (2001) put it. The time Freeman made this comment, the very beginning of the twenty-first century, can indeed be seen as a watershed. Since then, “[r]ather than *proposing* to do the desired work or proclaiming the need for such work, it is simply being done, constructively and vigorously” (p. 284).

In the process, social-scientific narrative research has become more differentiated, shifting from text and story-oriented paradigms to action and performance-oriented paradigms and models of pictorial narrative (Brockmeier, 2005b; Hydén & Brockmeier, 2008a; Kohler Riessman, 2007; Mattingly, 2007; Peterson & Langellier, 2006). It also has become wider in scope. Narratives are studied in institutional

and conversational or face-to-face settings (including those constituted by ethnographic and psychological research interviews) that involve cultural contexts such as development and socialization (as just reviewed), home and family life (Heath, 2009; Ochs & Taylor, 2001), the workplace (Fasulo & Zuccheromaglio, 2008), health and illness (Hydén & Brockmeier, 2008b), psychotherapy (Fasulo, 2007), politics (Andrews, 2007; Duranti, 2009b), cultural memory (Brockmeier, 2002), law (Amsterdam & Bruner, 2000), science (Harré, Brockmeier, & Mühlhäusler, 1999), and sport (Smith & Sparkes, 2009), to mention a few.

On a conceptual and epistemological plane, however, this differentiation and diversification has come at a price. The more social-scientific narrative research has established itself as a major player, the more it has become elusive—at least it seems so if viewed through the lenses of traditional methodologies that typically are appealed to in order to warrant the scientificity of inquiry. “Unlike many qualitative frameworks, narrative research offers no automatic starting or finishing points . . . ; there are no self-evident categories on which to focus, as there are with content-based thematic approaches, or with analyses of specific elements of language,” as Squire, Andrews, and Tamboukou (2008) explain the dilemma of many social and cultural scientists.

In addition, unlike other qualitative research perspectives, narrative research offers no overall rules about suitable materials or modes of investigation, or the best level at which to study stories. It does not tell us whether to look for stories in recorded everyday speech, interviews, diaries, TV programs or newspaper articles; whether to aim for objectivity or researcher and participant involvement.

(Squire, Andrews, & Tamboukou, 2008, p. 2)

That being said, the same picture has also been linked to an increasing fine-tuning of narrative research to a changing understanding of humans’ social and cultural reality, a reality that is intimately mingled with narrative discourses which, however, in order to be grasped, demand a new, more open and flexible view of narrative—that is, a second narrative turn.

## TWO NARRATIVE TURNS

Approaching the field from a historical point of view, Gubrium and Holstein (2008, 2009) have distinguished two narrative turns in social research. They discern the first narrative turn early in the last

century, launched by Propp (1968) and other social researchers of narratives and folklore. The tradition of narrative ethnography initiated here also led to efforts to study ordinary peoples' "own stories," as manifested in interviews and personal "documents of life" (letters, diaries, files)—material viewed as a window on distinctive social and cultural worlds. In the "Chicago tradition," dominated theoretically by George Herbert Mead (1934), early classics such as W. I. Thomas and Florian Znaniecki's (1958) *The Polish Peasant in Europe and America* on the immigration experience in Chicago after the end of World War I were followed by a stream of ethnographic case studies of particular social and cultural communities. Although such analyses concentrated on the content of participants' narrative accounts and on the social and cultural life they depicted, this interest widened in what Gubrium and Holstein (2008) called the second narrative turn. This turn, within which Gubrium and Holstein associated their own work, shifted the attention to the very practices of storytelling and the social and cultural circumstances in which they occurred; we might add that this second narrative turn already started in the 1960s and 1970s with ethnolinguistics, conversation analysis, and sociolinguistics entering the scene of language analysis. It reaches beyond the first narrative turn in that it brings to the fore the interplay between the content and internal organization of narratives, and the concrete social and cultural conditions, the "narrative environments," that regulate the production, distribution, and circulation of narratives.

Although there is no strict line of demarcation between . . . stories and storytelling, we need to know the details and working conditions of narrative occasions if we are to understand narrative practices. These details, in turn, can only be discerned from direct consideration of narrative environments. Stories are assembled and told to someone, somewhere, at some time, with a variety of consequences for those concerned. All of this has a discernable impact on what is communicated and how that unfolds. A life story might be told to a spouse, to a lover . . . , to a therapist, to a son or daughter, or to a fellow team member, among the huge variety of audiences to which narratives are conveyed. The occasion might be a job interview, part of a pickup line, a confession, or a recovery tale. The consequences might be amusing or life threatening.

(Gubrium & Holstein, 2008, p. 247)

It is, as we can conclude with Gubrium and Holstein, the social, institutional, and cultural environment of storytelling that impacts on the content and internal structure of narrative, just as the strategies of positioning influence the social profile of storytellers and the narrative scenarios within which they carry out actions. Thus, many narrative researchers have come to understand the performance and social organization of the storytelling process as meaning-making activity in its own right. "Meaning-making," write Gubrium and Holstein (2009), "is a practical activity that transpires in particular circumstances and puts into play the available resources for constructing stories" (p. 57).

### ***Fictional and Nonfictional Narrative***

The study of the relationship between narrative and culture in the three traditions mentioned so far has paid much heed to oral narrative practices. This is not to say that writing does not play a role in the sphere of oral narrative; in fact, it does. Under conditions of cultural literacy, structure, usage, and understanding of language is profoundly influenced by the existence of writing and its various semiotic media, including those that have come into being in the digital age (Brockmeier & Olson, 2002). Still, psychological, social-scientific, and sociolinguistic research on narrative has been concerned primarily with oral storytelling and their discursive or narrative environments. In contrast (as if in an odd division of labor), written narrative has been the subject of a distinct tradition of scholarship. The terrain of this tradition is the storyworlds of fictional and nonfictional literary narrative, complemented by the storyworlds of play and opera, film and television, photography, graphic novels, and digital or virtual environments. Roughly, the distinction between dominantly written and dominantly oral storyworlds corresponds to what Hyvärinen (2006, 2010) has described as the two families of narrative studies: one, rooted in the humanities, represents narratological and critical scholarship, the other has emerged with the narrative turn (or turns) in the social sciences. Hyvärinen notes that despite the common interest in narrative, there are only very few encounters between these two families.

I use the terms *storyworlds* and *literature* to mark this fourth tradition of narrative research because I think they are more appropriate for a discussion of the cultural nature of narrative than the more common term *fiction*. From a cultural point of view,

the distinction between fictional and nonfictional genres of narrative (and the derivative distinction of genres such as creative or narrative nonfiction and docufiction) appears to be problematic for several reasons. One is that there are many forms and genres of narrative that simply ignore the borderline between fictional and nonfictional narrative and cannot be understood by these categories. Consider “subjective” genres such as autobiographical narratives or first-person life stories, as we encounter them, for example, when people review their lives in hindsight (Freemann, 2010). If the criterion for nonfictional narrative is taken to be its truth value (Lejeune, 1989), or its reference to the real world (Cohn, 1999), or that it is falsifiable (Abbott, 2008), what are we to make of, say, an autobiographical narrator who offers possible interpretations of events in his or her life, events that so often happened coincidentally? The narrator may be fully aware of that but still might try to make sense of these events, perhaps by the help of Christian or Buddhist or Marxist or Existentialist assumptions. Who then would be able to judge, and by which standards, the truth value of these interpretations? And whether they refer to the real world? And are falsifiable?

But the questions that ensue from a cultural perspective for the fiction–nonfiction distinction are also evident in “objective” genres such as travel narratives. Pratt (1988) has noted that European landscape narratives evoke a cultural system of representation that works across the fiction–nonfiction line, which, in the traditional view, is supposed to separate genres such as the novel from a nonliterary genre like travel writing (what today would be called creative nonfiction). However, as Pratt has shown, from at least the sixteenth century on (i.e., during the epoch of colonialism), the two genres have completely interpenetrated and mutually determined each other. Drawing on a narrative analysis, “which decenters the question of truth versus falsehood, fiction versus nonfiction, literary genre versus nonliterary genre, and focuses instead on generalized strategies of representation,” Pratt (1988, p. 22) has found that what at first sight presents itself in both genres as a neutral and realist narrative—in fact, as a landscape description—functions as discourse of domination. The landscapes described within both literary and nonliterary narrative scenarios are part of a widespread cultural system of values in which nature is viewed first and foremost as a commodity, as something to be conquered and dominated. Fictional and nonfictional authors alike employ the

same linguistic repertoire in arriving at a cultural code of aesthetic, moral, and political values.

A second reason why a clear-cut borderline between fictional and nonfictional narrative is problematic is that the very idea of such a distinction itself is a cultural one. It emerged as a convention whose rationale and scope has depended on specific discursive and narrative environments. Even within Western traditions, it has undergone considerable change. For years, indeed centuries, these traditions did not specify any distinction between history and fiction. Even well into the eighteenth century, history was a literary art and historians were considered good historians because of their imaginative and inventive abilities, their qualities as writers of narrative prose (Burrow, 2007). That empirical evidence had to play a critical role became an academic conviction and culturally established rule only in the nineteenth century.

The storyworlds of all three areas of literary fiction, nonfiction, and those narratives that defy and go beyond this opposition are surrounded by discourses that meander in many public spheres. They also comprise a vast literature that is critical, philosophical, and sometimes even narrative itself. This literature interprets and reflects on exactly the interfaces between life and language, tradition and the individual, and action and interaction where we have situated narrative practices as cultural practices. This makes it even more difficult to understand why social-scientific research has almost entirely ignored the resources of critical knowledge that have been accumulated in a long tradition of narrative scholarship. My argument is that the storyworlds of fictional and nonfictional literature and the surrounding discourses of interpretation and critical reflection constitute the thickest narrative layer of our attempts to cultural self-interpretation. In these attempts, we can explore in much detail what it means that narrative binds the individual into a cultural world while it binds the meaning of this world into the individual’s mind.

#### THE CULTURAL FABRIC OF LIFE AND LITERATURE

Narrative prose realizes functions of all three fields outlined above: the historical and intergenerational, the individual and developmental, and the discursive and intersubjective. It furnishes the discourses in these fields with genres, plots, storylines, and models of reality, mind, and imagination, whereas it, in turn, continuously soaks up the

linguistic and experiential resources of these discourses, as well as those of everyday life in general. What makes this mutual enrichment of life and literature possible is that literary prose serves a variety of cultural purposes.

Taking a closer look at these cultural purposes we find, not surprisingly, that there is first an aesthetic intention. This intention and the way it is realized is studied in poetics, stylistics, and criticism. One could go as far as to argue that the explicit or implicit aesthetic intention, the artistic vision of literary narrative, is the distinctive feature that sets it apart from the rest of narrative. But then, its aesthetic component is only one among several; which is to say, there is more to literary prose than its poetic dimension. On the other hand, there also is a poetic component to everyday language, in fact, as Jakobson (1960b) said, to all language, even if this component is rarely dominating. But it is enough to assume a continuum of poetic qualities that reaches from ordinary to literary narrative. Whether it is poetry or an everyday exchange on the bus, language inherently has an aesthetic dimension, and so have all cultural practices of narrative.

Another cultural purpose of literary narrative becomes evident when we consider it as strategy of persuasion, as a way to convince others, and sometimes even the tellers of the tale themselves. I have already alluded to this as one of narrative's basic functions. In the humanities, this is the subject of rhetorical analysis. Like notions and standards of aesthetics, notions and standards of persuasiveness are strongly culturally defined.

Further, literature sets up processes of mutual interpretation between author and reader; this, too, piggybacks on an elemental function of narrative. In the realm of literary studies these processes are examined in reception-(or reader response)-theoretical, discursive, interactional, pragmatic, rhetorical, and cognitive narrative inquiries.

Next, narrative sets up processes of mutual interpretation among texts from various cultural worlds, present and past, real or imagined, conjuring up what cultural semiotician IUri Lotman (1990) has described as the textual "semiosphere," the interconnected signs systems that as a whole constitute the cultural sphere. Within a semiosphere, distinct narratives unfold networks of meaning relations among each other: through semantic and stylistic similarities, explicit cross-references, ironic comments, sarcastic allusions, friendly dialogues, and furious clashes. This kind of intertextual interaction among

narratives is also investigated in traditional philological and critical studies and in newer deconstructionist approaches.

Finally, there is a special focus on the interpenetration of narrative literature and the general cultural dynamic beyond literary discourse. For many literary and cultural theorists, the only way to fully appreciate a literary work is to examine the cultural world that it reflects and is embedded in, and this comprises the ethical value system, the "narrative judgements" (Phelan, 2007), which the literary work (in fact, every narrative) implicitly asks its audience to adopt while reading or listening to it. Greenblatt (1998) thus views what he calls "culture as a complex whole" as both continuously articulated and transformed by literary texts. According to Greenblatt, an important task of cultural literary criticism is to investigate the rules of the cultural power games upon which literary works are predicated. This understanding, he believes, must begin with the acknowledgement that each cultural order organizes what appears to be opposite things: constraint and control versus mobility and openness. Both are pervasive cultural forces that have become internal operators of literary dynamics.

#### BAKHTIN'S NOVEL

A case in point of the cultural charge of narrative prose is the genre of the novel, especially as understood by Mikhail Bakhtin. In Bakhtin view, the novel is a polyphone creation that comprises, on the one hand, all potentials of literature and, on the other, all spheres of social and psychological life in a given epoch. Like a human being always changes and is never fully realized or fully known, neither to himself or herself or to others, so are language and cultural life never fully realized and remain boundless and interminable in their potentials. This makes the novel the prime venue to grapple with what Bakhtin calls the unfinalizability of human life, for the novel is fundamentally concerned with all three: the individual and his or her experiential world, language, and humans' cultural existence.

Bakhtin saw literature as the semiotic dimension where an epoch comes to the most comprehensive and sophisticated notion of itself. This capacity is due, not least, to the heterogeneous and open character of novelistic discourse. The interplay in which the novel realizes the totality of language as a social system and, in this way, captures the totality of a particular historical world was the stage of the cultural dramas Bakhtin examined.

The novel can be defined as a diversity of social speech types . . . and a diversity of individual voices, artistically organized. The internal stratification of any single national language into social dialects, characteristic group behavior, professional jargons, generic languages, languages of generations and age groups, tendentious language, language of the authorities, of various circles and of passing fashions, languages that serve the specific sociopolitical purposes of the day, even of the hour (each day has its own slogan, its own vocabulary, its own emphasis) – this internal stratification present in every language at any given moment of its historical existence is the indispensable prerequisite for the novel as a genre. The novel orchestrates all its themes, the totality of the world of objects and ideas depicted and expressed in it, by means of the social diversity of speech types . . . and by the differing individual voices that flourish under such conditions . . .

(*Bakhtin*, 1981, p. 263)

In studying the modern novel as the narrative amalgamation of a manifold of languages and stylistics that “orchestrate” a multivoiced cultural universe, Bakhtin developed a theory of narrative as a hinge between the individual and his or her cultural world. Each voice in this cultural universe is taken as a particular point of view on the world, a point that, at the same time, also reflects (and contributes to) the consciousness of a particular individual. Both consciousness and cultural world are interlaced in a text of sorts, a peculiar cultural “text of the mind” whose workings are at the core of Bakhtin’s investigation (Brockmeier, 2005a).

Such a comprehensive philological and cultural-historical approach to narrative prose can be viewed as part of the project of a cultural narratology (or cultural narrative theory).<sup>5</sup> Currie (1998) has put forward two arguments in favor of a cultural narratology. One is narrative’s ubiquitousness in the contemporary world, a point already emphasized above. Currie remarks that narratives are so commonplace that it would be difficult to consider any cultural form or practice without encountering a narrative context. Similarly, Jakobson (1960a) has stated that “the principal way of diffusion for cultural goods is through the word, through the medium of language” (p. 103). We may add that the more these cultural goods are complex and semiotically mediated practices and artifacts, the more their diffusion involves the language of narrative. This leads to Currie’s (1998) second point, according to which

our cultural worlds not only contain narratives but are contained by narrative “in the sense that the idea of culture, either in general or in particular, is a narrative” (p. 96).

I take the arguments outlined in this section as supporting the claim that the storyworlds of fictional and nonfictional literature and the surrounding sphere of critical discussion and reflection constitute an unrivalled enterprise of cultural self-interpretation. Again, we may conclude that almost always the efforts of coming to terms with the cultural conditions of our existence transform into narrative efforts. And again, it is these narrative efforts that permit us to scrutinize the multifold interactions through which we are bound in a cultural world and in which we create what makes up the meaning of our life.

### *Narrative and Folk Psychology*

In envisioning the meaning-constituent dimension of narrative, a further, final current of research comes to the fore. Emerged only recently, it has highlighted that narrative practices (and all the more the traditions to which they belong) involve not only linguistic and other symbolic and physical activities, but also an accordant mental disposition, an intentional orientation. Often this is called *folk psychology*. Bruner (1990) described folk psychology as a cognitive system in the service of cultural functions, a system that regulates how human agents do things on the basis of their beliefs and desires, strive for goals, cope with trouble, and get a sense of themselves. Folk psychology is about people organizing their experience of, and knowledge about, the cultural worlds in which they act.

All cultures have as one of their most powerful constitutive instruments a folk psychology, a set of more or less . . . normative descriptions about how human beings “tick,” what our own and other minds are like, what one can expect situated action to be like, what are possible modes of life, how one commits oneself to them, and so on.

(*Bruner*, 1990, p. 35)

For the most part, Bruner’s cultural-psychological explanation of folk psychology dovetails with Geertz’s (1983) notion of common sense as a cultural system. But the intellectual history of this tradition is longer. Bruner (1990) himself aligns the cultural-psychological concept of folk psychology with early twentieth century anthropology, the ethnomethodology of Garfinkel (1967) and Heider (1958), and

the phenomenological sociology of Schutz (1967). Still, Bruner's own work is especially relevant here because it gives center stage to one specific feature of folk psychology: that it is organized in a narrative rather than conceptual or logical way. Narrative, in Bruner's picture, is particularly important in mitigating between the exceptional and the culturally ordinary. It links the normal with its break, the rule with its violation. Folk psychology is about the culturally canonical. It states not simply how things are but how they should be. "When things 'are as they should be,'" Bruner (1990, p. 40) writes, "the narratives of folk psychology are unnecessary." That is to say, not only is most of folk psychology laid out in narrative, stories also are the central instrument for folk psychology's normative and regulative authority. Although a cultural world must contain a set of norms, "it must also contain a set of interpretive procedures for rendering departures from those norms meaningful"; these procedures of "explicitating deviations from the ordinary in a comprehensible form" are narrative (p. 47).

The assumption of an intrinsic link between narrative and the cultural templates of folk psychology has been taken up by researchers in several fields. It has been elaborated, for example, in terms of a socio-cultural developmental psychology of children's acquisition of folk psychological narrative by Nelson (2007b; 2009), reformulated in the context of philosophy of mind debates as the "narrative practice hypothesis" that helps us to understand the socio-cultural basis of how people make sense of intentional actions by Hutto (2008, 2009), and integrated into a narrative-theoretical alternative to mentalist explanations of "theory of mind" by Herman (2008; 2009c).

To conceive of people's ideas about what makes human beings tick and what their own and other minds are like—that is, their theory of mind—as integral to an overall cultural system of folk psychology supports the claim, delineated in the last section, that the distinction between fictional and nonfictional genres of narrative dissolves when approached from a cultural point of view. Some recent developments in "post-classical" narrative theory have further elucidated the common ground of both types of narrative, lending more narratologically refinement to a culturally situated notion of narrative. Because my argument here is that this common ground is essentially the cultural fabric of folk psychology—with stories, at the same time, serving as the principal instrument of folk

psychology—these developments are particularly interesting.

#### THE CULTURAL SCOPE OF POST-CLASSICAL NARRATIVE THEORY

In contrast with classical narratology that was dominated by structuralist linguistics and its concern with the code structures of written and literary text, post-classical narrative theory has freed itself from both structuralist and philologist constraints, extending its space of inquiry to the study of cultural phenomena beyond the boundaries of literature. In this way, a more comprehensive view of the inter-relations between narrative and the mind has emerged, elaborated especially in the work of narrative theorists who have explored how understanding literary prose requires making sense of how human minds work—both the minds of fictional and actual characters (e.g., Herman, 2009c, 2011a; Fludernik, 1996; Palmer, 2004, 2010; Alber & Fludernik, 2011). This view complements the reverse assumption (underlying, among others, my line of argument) that everyday narrative practices continuously absorb resources from literary, dramatic, and filmic discourses and from the popular arts. This exchange works so smoothly and indeed typically escapes our attention because it involves on both sides the same basic psychological abilities and practices.

If we thus assume that a large portion of our experience is mediated through narrative, then Fludernik's (1996) suggestion to consider narrative as a particular mode of experience or, as she calls it, of human "experientiality" appears as an obvious next step. Narrative, on this view, is not so much a plot or the representation of a sequence of events as a human form of experiencing the world that has more to do with how our consciousness works than with linear, causal, and closed story structures. And how does our narrative consciousness (or narrative mind) work? My answer to this question is that it works by entangling us with the cultural world in which we live; that it entraps us in a human—that is, intersubjective and interpersonal fabric web of concerns—of meanings, thoughts, intentions, and emotions (Brockmeier, 2007). It is in this context that I understand Fludernik's view that narrative centers on a human experience and that it operates by means of a "projection of consciousness"—the consciousness of the character in a story, of the narrative voice, or of the narrator or listener/reader. Hence I find it plausible, within the cultural and cultural-psychological scope outlined in this chapter, when

Fludernik (1996) describes the crucial point of this narrative projection in terms of “human immundation” and “situational embodiment.” The important element in the context of this chapter is that the equalization of narrativity as experientiality spans across a continuum of narrative practices from the everyday oral, performative, and pictorial to the most sophisticated forms of written literary prose.

In building on an argument that Herman (2011b) has put forward in favor of a unified approach to either literary and everyday narrative, we might say that the vision of narrative as a psychologically fundamental practice of human meaning construction that cuts across the putative divide between fiction and nonfiction allows us to bring to bear on the study of this practice the full battery of investigative tools being developed in literary, narratological, art-theoretical, psychological, and anthropological research on the cultural nexus of mind and narrative. To be sure, much of post-classical narratological research on this nexus is not overly interested in situating its subject within a cultural framework; significantly enough, drawing on analytical philosophy of mind, cognitive science, and evolutionary psychology, it has become known as *cognitive narratology*. I believe, however, that the scope of issues being investigated here exceeds the somewhat narrow limits associated with the cognitive focus in psychology. There is no doubt that it can enable us to fuller comprehend a pivotal point: that at the base of both literary and everyday processes of meaning construction are the same narrative operations, realizing fundamental processes of human understanding and intersubjectivity, including affect and empathy (Keen, 2007). What is more, it permits us to extend the implications of this comprehension toward a culturally rich notion of narrative.

Consider Herman’s analysis of the inherent link between narrative and human intentionality. Storytelling operations, he says (2008, p. 240), are “irreducibly grounded in intentional systems,” which is to say that in understanding these operations we employ concepts of intentionality that are part and parcel of “culturally transmitted folk-psychological templates” (p. 256). Now, how are we to understand “intentional systems?” Herman takes great pains to explain that they are all but merely cognitive constructions, introspectively to be localized in individual heads like “mental models.” Rather, intentional systems are intersubjective contexts of operation: “intentionality in narrative contexts is built into

the doing, the activity structure, of storytelling and interpretation” (Herman, 2008, p. 256). More precisely, we face contexts of interaction that encompass the story (in a particular medium), its narrator(s), and reader(s) or listener(s) or observer(s) involved in efforts of mutual interpretation. We have to be aware, then, of what I would call an extended cultural framework of interpretative intersubjectivity, if we want to understand how narrative and intentionality are interlaced. While narrative is grounded in cultural patterns of intentionality, as Herman (2008, pp. 240–241) puts it, “intentional systems are grounded in storytelling practices.”<sup>6</sup>

Viewed in this light, the study of the narrative microstructures that interweave intentionality and folk psychology opens a direct route to a culturally sensitive notion of narrative. It has been from this perspective that I have discussed this approach to narrative and folk psychology, as I also have explored in this section four other traditions that have queried narrative practices—in contexts of cultural history, contexts of socialization, as a form of life, and with respect to the common ground of fictional and nonfictional genres. I have selected these five traditions because they have contributed, in different ways, to the study of both the cultural nature of narrative and the role of narrative for humans’ cultural life. Hence, my overview has foregrounded aspects of these traditions that provide investigative lenses for this project. Using these lenses, I turn now to a more specific qualification of what is at the center of this project: the very notion of narrative as cultural practice, its ways of application, and implications for further research.

## **Narrative As a Cultural Form of Life: Applications**

### ***The Principle of Narrative’s Singularity***

Considering the five traditions reviewed in the last section that have enriched the culturally motivated understanding of narrative that I want to carve out in this chapter, we face this situation: both in the humanities and in the social sciences, narrative practices are conceived of as important cultural practices. But as these practices are so multifarious, they are investigated by a perplexing multitude of different methods and techniques, developed in a great many distinct disciplinary contexts and from a wide range of theoretical approaches and perspectives. Is there a method to come to terms with this large variety of narrative methods?

I believe it would not only be difficult to draw generalizable conclusions about the nature of narrative and the methods that involve narrative, or examine it, or aim at both; it would be highly problematic to do so. There is an implicit presumption in many discussions in literary theory and narratology, and this might be of even greater significance for psychology and social research: the methods of each narrative investigation are to be sensitively fine-tuned to its subject, a subject that is always particular. Particularity has indeed been claimed to set narrative apart from general explanations (Bruner, 1990; Herman, 2009b). And it seems that it has been this sensitivity for the particular that has made narrative attractive not least for the social sciences, from the very beginning of their narrative turn.

But then cannot general explanations also be formulated in a narrative form? And does not narrative have many techniques and devices to present the particular as the general and the general in the particular? Hence I think, within a culturally reflected conceptual framework, we must go further and recognize narrative as something genuinely *singular*. One could call this the principle of narrative's singularity, and I take it to complement the principle of narrative's cultural ubiquity.

In a momentous analysis of a literary text, Barthes (1974) made the case that stories are singular, in fact, individual events. They are as individual as their narrators and the situations in which they are told. More than that, each narrative comes, in principle, with a multitude of individual interpretations; these interpretations are not added to a story, but are an essential part of it. The focus on singularity thus implies confronting the world as a field of differences—a vision in which Geertz (2000) recognized the essence of anthropology: “If anthropology is obsessed with anything, it is with how much difference makes” (p. 197). Translated into narrative methodology terms, this is to say that the question of what investigative procedure and analytical focus is appropriate can only be answered *vis-à-vis* of the concrete narrative and the cultural environment in which it occurs and within which certain interpretations take shape.

Of course, the principle of narrative's singularity raises another question—namely, what is (if there is anything at all) common to all those innumerable cultural practices that are referred to by the fickle term *narrative* and approached with such manifold methods and techniques? Obviously, the term narrative itself has a metaphorical side. But does it also

have categorical and analytical rigor? If all stories are singular events (in the language of methodology, single cases), and if the world is a field of differences, are there any general characteristics at all that justify the use of a common category of narrative that is more than a metaphorical label? This is the question I discuss in this section.

### ***Good Stories and Bad Stories***

It is fair to say that everyone working with and on narrative has a working definition of narrative, as intuitively and rudimentary as it may be. In view of the absence of a more than occasional dialogue between the humanities and psychology (and the social sciences in general), it is all the more surprising that there is widespread agreement in both literatures on what counts as narrative. I already mentioned the axiom of narrative as representation and some of the problems resulting from it. Further, most authors concur in assuming at least three structural or inner characteristics of narrative. These three elements constitute, to use a term coined by Leitch (1986), a minimal *narrative ontology* defining the essential components that make up a story. First, there is the idea of narrative as a sequence of action or events, which, second, is organized in time and which, third, constitutes some kind of inner structural coherence. The sequentiality of narrative means that the succession of action or events implies some kind of logical or intentional or psychological causality; the temporality of narrative means that the sequence is temporally organized; and the coherence of a narrative implies that it is told as a sound and plausible fashion story. Contributing to narrative coherence are not only the first and second features, sequentiality and temporality, but also the closure of its plot structure. At stake in this view, then, is the notion of a “good story,” with a marked beginning, middle, and end—as it is classically defined as *narratio* in the Aristotelian tradition of poetics.

This reference reminds us that we deal here with a tradition of literary poetics that has influenced not only classical (structuralist) narratology, but also most of sociolinguistic and social-scientific narrative research so far. Its criteria of a well-structured story—reflecting the composition of classic Greek tragedy, the ancient dramatic art form that underlay Aristotelian poetics—have been canonized in a long and venerable history of drama, poetry, and narrative. Now, this tradition faces a serious problem. Although the notion of narrative is modeled

on a “good story,” a well-structured *narratio*, not all narratives are good stories. That is, not all narrative practices produce Aristotelian plots.

The problem is a historical one. It emerged in modernity—particularly with modernism—even if it became manifest only later in the twentieth century. In Modernism, literary narrators began to employ new, non-Aristotelian forms and techniques of narrative, especially in discourses of consciousness. Later in the twentieth century, narrative research followed and also went beyond the borders of the traditional literary canon to examine narrative practices created not primarily with aesthetic intentions but as part of naturally occurring everyday discourse. More precisely, then, the problem is that neither the modern and postmodern narrative forms developed in literature, film, theater, and other artistic venues, nor the narrative practices embedded in the cultural contexts of ordinary life can be captured by the traditional model of a “good story.” Typically, our everyday narrative practices do not aim at closed and well-structured stories. Forms of action that serve many purposes, they have, as already noted, fuzzy borders. Often, “they are undecided, fragmented, broken, narrated by voices struggling to find words” (Hydén & Brockmeier, 2008a, p. 2). Ochs and Capps (2001, p. 3) call them the country cousins of well-wrought narratives. Not surprisingly, these country folks do not bother about a proper narrative ontology (and likewise unsurprisingly, most narratologists have excluded them from their terrain). So what do they bother about? Why do we tell stories, even if they are bad stories?

The reasons that we narrate are as variegated and as good and bad as the reasons why we act and live. We are entangled in countless narratives and narrative events, and only rarely do these produce the monologic, well-structured, and coherent stories that are the subject of standard definitions both in narratology and the social sciences. If we would rigorously apply these scholarly classifications and their implicit narrative ontologies, we would have to conclude that most of the time we tell bad stories, or weird stories, or failed stories, or do not narrate at all (Medved & Brockmeier, 2010).

This is all the more the case when we interact outside of institutionally regulated cultural and narrative environments such as schools, law courts, health facilities, and so forth. Take an incidental encounter. We may tell a story to get in touch with someone, trace some trouble that we can't get

a handle on, or pose a question to which we don't know the answer. Or we narrate because we try to hide embarrassment, insecurity, shame, or regulate other emotions and mental states. We tell a story, as Mark Twain once put it, because we don't have anything to say. We also may share a story to crack a joke, to make a point, or comment on last night's TV show; or because we want to ridicule a politician or superior, pass on gossip, or excuse ourselves for being late. All of these discourse genres, and many more, make use of narrative forms that we have to add to the traditional list of established narrative genres, the “good stories,” with which the “bad stories” are, of course, interlaced in manifold ways. Borrowing from them, challenging and cannibalizing them, sometimes the bad ones just want to be good ones. Still, whatever they are or are not, it is not because they comply or do not comply with any general “narrative ontology.”

In those narratives that I have described as a form of social action, another precarious aspect of the narrative ontology assumption comes to the fore. Often there is no clear line between the narrator and the listener or reader of a story, as it is known from genres of monologic storytelling. As a consequence, the notion of a story continues to blur, and its putative ontology becomes even more elusive. Not only that the audience (the listeners and readers of a story) always construct in their individual receptions their own versions of the original story; as we know, the story told by a narrator is rarely identical with the story that takes form in the listener's perception and imagination. To put it again from a Wittgensteinian perspective, there is no meaning of a narrative without the uptake of the addressee or, in Duranti's (1986) terms, without “the community's testing and approval” (p. 240). For his part, Duranti has argued that it is especially in storytelling where “the form and content of talk is continuously reshaped by co-participants” (1986, p. 242). Often the audience already influence what is told during its very articulation. In turn, envisioning the possible (desired or undesired) reception of the local addressee, the narrator can fit the narrative to the reaction of the listeners, be it manifestly demonstrated by their behavior and reactions (as in an oral narrative environment) or imaginatively anticipated (as the “implied reader” in the writing of a story). Finally, narrators and co-narrators can operate with different common sense notions of stories that they use as conversational (or rhetorical) acts: “This is not the story here . . .” (Stokoe & Edwards, 2006).

All this comes together in what Norrick (2007, p. 127) has called genuine conversational narrative:

Genuine conversational storytelling is always interactive, negotiated, and not simply designed for a particular audience by a single teller; indeed, it is often hard to determine who is the primary teller, especially when the events were jointly experienced or the basic story is already familiar. Conversational stories may be deeply contextualized, diffuse, and not easily detachable from the local conditions that occasion them.

This is most apparent in situations Bakhtin (1981) called polyphonic, where a non-hierarchical narrative community acts at the same time as an interpretive community that, claiming the same storytelling rights as the teller, is interrupting, evaluating, and co-narrating. Norrick elucidates this as “many-voiced narration” in cultural contexts where no single participant can control the course of the story, “and multiple voices vie for the right to formulate its point” (2007, p. 128). This brings us back once more to the question: What, then, is the story? And how can we tell it from the contributions of the other voices in this polyphonic discourse?

### ***Narrative and Meaning***

Numerous arguments have been put forward to challenge the idea that there are universal components of a discourse genre “narrative” that exist prior to and independently from a culturally situated narrative event. Rather than assuming the existence of an abstract entity called “story,” the attention now has shifted to the concrete contexts of action and interaction in which a linguistic or otherwise performed action sequence is perceived as a story. Thus, the question of what distinguishes a narrative from other discourse genres, as Leitch (1986) concluded his review of possible distinctive criteria, is not to be answered by reference to the inner structure of a story as such, but depends on how a discursive sequence is understood in a given situation. What counts as a narrative arises from “the audience’s perceptions, projections, and reintegrations” of the sequence (Leitch, 1986, p. 130).

In this view, narrative is not constituted by a set of given structural features such as sequentiality, temporality, and coherence; rather, it takes on its form in a context-dependent process of meaning attribution or, in Bruner’s (1990) terms, in an “act of meaning.” This links to the argument, made above, to see narrative not primarily as a

mode of representing but of construing meaning. What is taken to be a convincing story in one circumstance may be an incoherent, embarrassing, or failed attempt at storytelling under different conditions. The joke told by the boss is confirmed by his employees as a “funny story”; the illness narrative told by the patient is not registered by the doctor but immediately translated into “medical data”; whereas the one-word sentence of the toddler is commented on by her parents as a wonderful little story. Likewise, imagine how a school teacher would mark a narrative essay of a student written in the experimental style of James Joyce’s *Finnegans Wake* and—as we are in a thought experiment—also imagine how Joyce might have retold the teacher’s report. Many traditional narratives by North or South American aboriginal people were long classified by anthropologists as lists of names, descriptions of kinship relations, or ritual reports. Only recently, ethnographers have questioned the appropriateness of Western concepts of narrative to understand fundamentally different, non-Aristotelian ways of storytelling—a problem that is further complicated by the fact that many aboriginal narrative performances cannot be isolated from the presence of a specific local geography and from particular cultural occasions (Basso, 1996; Chamberlin, 2004; Cruikshank, 1998). Often these occasions are spiritual or even sacred in a markedly non-Western, indigenous sense (Benham, 2007).

What all these examples have in common is an implied notion of narrative that is only comprehensible if it is viewed in connection to a multitude of other stories. In the realm of written and literary stories, this phenomenon is known as intertextuality: each narrative text refers to other narrative texts, in this way widening its horizon of meaning and interpretation. In oral storytelling, a comparable intertextual framework is evoked by the cultural and historical traditions to which a story belongs. I already expounded the role of narrative for cultural traditions; at stake now are narrative traditions and, in tandem with them, the issue of the historical rootedness of all symbolic meaning constructions (Straub, 2005). In the case of the Joyce-inspired student, these traditions comprise literary modernism. In the case of the doctor’s version of the patient’s illness narrative, we face the institutional and linguistic constraints of the medical apparatus. And in the case of aboriginal storytelling traditions, we are confronted with non-Western forms of life, both narrative and non-narrative. Isolating

a story from its living context and reducing it to an autonomous narrative structure means losing a constituent dimension of its meaning. For Gee, it is exactly this being steeped in cultural meaning traditions that distinguishes narrative from other forms of discourse. A narrative, Gee (1991) wrote, becomes “meaningless apart from a surrounding narrative context, connections to social memory, and the resources of a system of themes that can create (what counts in a given group as) a coherent (satisfying) pattern” (p. 13).

#### BEYOND NARRATIVE ONTOLOGY

Viewed in this way, there is no need—indeed, no basis—for a normative model or a universal ontology of narrative. In resisting this idea, as powerfully as it has been elaborated in the narratological literature, the focus shifts from the noun “narrative” as a monument of stable categorical identity to the “adjectival ‘narrative’ as an element of ongoing processes,” as Hyvärinen (in press) puts it. What shapes the adjectival perception of a linguistic or otherwise symbolic action as a story depends on local cultural environments and traditions in which the rules and meanings of narrative practices have been formed, where “particular audiences have accepted particular discourses as stories” (Leitch, 1986, p. 25). Rudrum (2005) makes the same point on Wittgensteinian grounds when he argues that the “form a narrative ultimately takes—and, hence, the properties by which one would attempt to define it—is as mutable as the uses to which it is put, making the task of neat definition a practically hopeless one” (p. 200). To be sure, the hopelessness of defining narrative fiction is not a new experience. Rudrum himself builds on the work of Iser (1989) who pointed out, “the more fiction eludes an ontological definition, the more unmistakably it presents itself in terms of its use” (p. 267).

Narrative, then, is not an entity that can simply be found in the everyday reality of our lives, not even in a linguistic or textual reality. “As such,” state Ochs and Capps (2001), “narrative bows to no simple generic blueprint that sets it apart once and for all from other forms of discourse” (p. 8). In a similar vein, Herman (2009b) has observed that whatever counts as a “prototypical story” is perceived “in a gradient, more-or-less way, and emerges from the strategies on which people rely in their everyday narrative practices” (p. 6). Because narratives “are both structured by and lend structure to the communicative contexts in which they are

told,” their analysis cannot but give center stage to what Herman has described as their situatedness in specific “narrative occasions” (2009b, pp. 37–74). “Narrative occasions” is taken in a double sense as communicative (or narrative) environments “shaping how acts of narration are to be interpreted, and, reciprocally, as contexts shaped by storytelling practices themselves” (Herman, 2009b, p. 37).

As a consequence of all this, even the concept of a “prototypical story” appears more and more difficult to pin down—except as another narratological projection. Perhaps we should keep in mind an important Wittgensteinian point of which Herrnstein Smith (1981) already reminded us many years ago: concepts such as “story” and “narrative” represent distinctions that “are drawn, not discovered, by narratologists” (p. 228).

Interestingly enough, despite poor communication between literary and linguistic narratologists, and social scientific and psychological narrative researchers,<sup>7</sup> they sometimes come to similar conclusions, as when Gubrium and Holstein (2009) have suggested a “loose commonsensical” understanding of narrative “as a basis for unpacking and paying empirical attention to how story and storyteller are discerned, defined, and responded to in practice” (p. xviii). In other words, what stories amount to and what other discourse forms (description, account, list, etc.) they may absorb and transform cannot be defined axiomatically. It is a result and not a precondition of narrative analysis—that is, of cultural narrative analysis. Patently, in this argument, the principles of narrative ubiquity and of narrative’s singularity are joined.

#### *Narrative Dimensions*

If we view narrative as a quality attributed under particular circumstances to discursive practices (which also include enactive or performative practices), several aspects of storytelling are cast in a new light. This light makes narrativity appear as a relative quality that is displayed in numerous dimensions to different degrees and in different ways. Ochs and Capps (2001) have distinguished five such narrative dimensions that structure what I have described as culturally situated perception of narrative. Ochs and Capps’s approach is especially fruitful if read from a cultural perspective because it promises to do justice to both narrative principles, that of singularity and that of ubiquity. Moreover, it offers a non-reductive way to come to terms with narrative’s bewildering cultural flexibility and adaptability.

Ochs and Capps (2001) propose to examine a sequence of discourse that is conceived of as narrative—as genre and activity—in terms of a set of narrative dimensions that the sequence takes on along a spectrum of graduations. The first of these narrative dimensions is *tellership*. It refers to the extent and kind of involvement of different protagonists in the actual recounting of a story. The question here is: Who tells the story? The second dimension is *tellability*, which is related to the question of how tellable and convincing a story is. How much is it in accordance with the local cultural notion of narrative? In everyday interaction, personal narratives can take different qualities of tellability, from high to low. If a discourse goes below a certain level of tellability, then it is not perceived as a story any longer. A third narrative dimension is marked by the *embeddedness* of a story in surrounding discourse and social activity, its being rooted in an narrative environment. This environment can be shaped by institutional constraints. Yet it can also be shaped in a more narrow discursive sense. For example, the extent to which a personal narrative is told and perceived as a structured whole unto itself or as part of ongoing conversation is related to the organization of turn-taking (i.e., the sequence of the contributions) in a conversation, its subject or theme, and the way it is rhetorically structured. *Linearity* is the fourth dimension. In personal narratives, it concerns the extent to which events and actions are organized along a single, temporal, causal, and closed path (as it is characteristic for an Aristotelian storyline with a clear beginning, middle, and end) or, alternatively, in a nonlinear, intermittent, fragmentary, and open order.

Finally, the fifth dimension: the *moral stance* that a narrative conveys. Typically, personal narratives do not pretend to present objective accounts of events or experiences but rather perspectives on events and experiences. Central to these perspectives is the moral stance of the narrator. There is no story that does not offer a perspective, if not several perspectives, that explicitly or implicitly expresses judgments and evaluations. The moral stance, the sense of right or wrong and good or bad, gives personal narrative its punch, its urgency, and its commitment. Ochs and Capps refer to Taylor's (1989) philosophical conception of narrative as a moral framework for understanding human comportment: "Making sense of my present action, when we are dealing with . . . the issue of my place relative to the good, requires a narrative understanding of

my life, a sense of what I have become, which can only be given in a story" (p. 48).

It is not difficult to see that these five narrative dimensions enable us to categorize storytelling along a broad range of culturally situated discourse formats. These formats range from social activity to a textual reality, from oral to written discourse, from virtuoso verbal performance to mundane everyday exchange, from naturally occurring conversation to literarily composed prose. To view in this way narrative activities as a heterogenous gamut of cultural practices underscores once more the argument that there is no boundary between everyday and literary narrative discourse. Both are inter-related in a myriad of ways, displaying the same narrative dimensions of tellership, tellability, embeddedness, linearity, and moral stance. Steeped in the same cultural world, both take part in the same never-ending circulation of language; both have a say in the endless conversation of storytellers.

## Conclusions

I started this inquiry with the claim, ensuing from an interpretive cultural psychology, that narrative practices are pivotal for human existence because they bind the individual into a cultural world while binding the meaning of this world into the individual's mind. I have explored this interplay in developing a culturally thick notion of narrative—of narrative as a form of life—that builds on Geertz' cultural anthropology, Bruner's narrative psychology, and Wittgenstein's philosophy of language (which I zoomed in on narrative as a particular language game). To this end, I have traced this notion from three different angles: as a mode of interpretation through which people try to understand, and give meaning to, their cultural being in the world; as a cultural practice realizing several (communicative, rhetorical, empathetic, and cognitive) functions; and as a form of action.

My outline of a culturally charged notion of narrative did not start from scratch. It has emerged from the discussion of five research traditions that have examined the nature of narrative: as an instrument of cultural traditions and of individuals' socialization; as a form of life, with respect to fictional and nonfictional genres; and as a form and practice of folk psychology. One conclusion drawn from these discussions I called the principle of narrative's singularity, which complements the principle of narrative's cultural ubiquity. The principle of singularity means that the ways narrative scenarios are to be

investigated are to be sensitively adjusted to the particular cultural (i.e., local) circumstances of their occurrences. This also goes for the very understanding of what counts as narrative, an understanding that likewise depends on the contextual conditions under which the meaning of narrative is attributed to a discursive sequence. For this meaning—and this is the important point here—is not given. There is no such thing as a universal and pre-cultural definition of narrative.

But make no mistake, there is an imposing concept or category of narrative, and this is solid and stable enough. Well-established in countless discourses, it has foisted upon a vast variety of fluid forms of life an illusionary identity and an ontological weight that, as Rudrum (2005, p. 201) has remarked, narratives themselves, as dynamic acts of meaning, do not have. Hence, if we want to avoid falling in this ontological fallacy, we have to take a radical stance and understand each narrative as a singular phenomenon, as an individual act of meaning in its own right. This inference is all the more stringent because each narrative practice is carried out within an intersubjective context of interpretation. To be sure, this view challenges not only the idea of a narrative ontology but also research methodologies in psychology and other social sciences based on principles of generalizability and nomological validity. But then, as we have seen, even within today's social-scientific narrative inquiries, more and more attention is allotted to the concrete cultural contexts of action and interaction in which a discursive action sequence is perceived as a story.

After narrative ways of knowing and inquiring fell from favor early in the twentieth century's social sciences, they have begun to re-emerge over the last decades as a legitimate and highly successful way of investigating humans' cultural existence (Hyvärinen, 2006; Pinnegar & Daynes, 2007; Polkinghorne, 1988). Providing another strand to the post-positivist paradigm and a further refinement of interpretive methodology in the human sciences, they can be seen as propelling a shift that promises to overcome longstanding reductionism and open up a more comprehensive, differentiated, and humanistic view of our being in the world. All of this could also be framed in political terms; indeed, as already emphasized above, it would be an unjustified reduction to see the cultural sphere without the forcefields of power and political and economic struggle that underlie most cultural dynamics—dynamics of which narrative is not

only a seismograph but in which it also is a most momentous factor.

With this in mind, Rom Harré and I have argued that the culturally sensitive study of narrative unveils a particularly flexible and open structure of action and human agency; it allows us to explore precisely these fundamental aspects of human life, its openness, and its flexibility – which often also means its messiness – that are, for the most part, neglected by human sciences (Brockmeier & Harré, 2001). The practices of narrative are fleeting constellations of forms of life that can serve us as a guide to the variable and fluid nature of human reality because they are, in part, constitutive of it.

### **Toward a Culturally Thick Notion of Narrative: Future Perspectives**

Much of what I have outlined is work in progress—a research agenda that is, however, already well underway in the shaping of a culturally rich notion of narrative. I want to end with offering three questions, delineating desiderata but also offering prospective vistas on further research in this hard-to-contain field. The first prospect is of narrative as a cultural way of meaning-making. In repudiating a narrative ontology, the question of what makes up a narrative has not dissolved; rather, it has shifted to an *emic* question: what do people do when they understand, in a specific cultural situation, a discursive sequence as a story, regardless of the Aristotelian definitions of “good” and “bad” stories? What practices does it take to constitute—and to perceive—a narrative scenario? More exactly, how is a narrative act of meaning in which something takes on the meaning of a story carried out? To indicate the routes possible answers to these questions might take, let me sketch three minimal conditions for an act of narrative meaning constitution. With each of these three conditions, different, although interrelated, answers to the issue of what we do when we tell and understand stories come into sight. For one, we bring a perspective to our experience, knowledge, thought, imagination, and much of our emotional life, a perspective (the term is closely related to what narrative theorists call “point of view”) that organizes how we face the world in which we live and how we position ourselves and others in this world. Second, we connect (not least through this perspective) several distinct elements to each other as to constitute a whole—that is, we create a synthesis of meaning, a gestalt that is more than the sum of its isolated elements. And finally, narrative is a way

to do things. It is discourse in a strong sense, a mode of action and performance inextricably entangled with what Wittgenstein called the grammar of our cultural world. In a nutshell, a discursive sequence is configured as narrative in so far as it operates as a perspective, a synthesis, and a form of life. To investigate these elemental conditions of narrative meaning-making, as well as their interconnection, along a number of different “dimensions” (Ochs & Capps, 2001), will significantly deepen our knowledge of the narrative meaning construction of narrative.

From here, the second prospect follows. It hinges on the question of how the meaning-making options of narrative differ in various languages and linguistic communities. After all, languages are the background systems of our cultural worlds, and the world’s thousands of distinct languages open up thousands, at least in part, of distinct cultural worlds. There is a first generation of pioneering studies, some referred to above, tackling the implications of this variety for narrative discourse. Yet there can be little doubt that we will gain a fuller understanding of the cultural fabric of narrative, mind, and social life when a new generation of multilingual researchers, aware of the novel insights associated with the narrative turn, go about these issues—especially, in examining the make-up of narrative scenarios in non-European languages. In the introduction to this chapter, I mentioned Benjamin Lee Whorf, who persuasively argued that there is an intrinsic connection between “multilingual awareness” and the “culture consciousness” that he saw as necessary for the study of the relationships among language, thought, and reality (Darnell, 2006). This, I believe, holds particularly true for the cultural nature of narrative.

A third prospect has emerged only recently with the increasing interest in the nexus of narrative and the mind in psychology, philosophy, narrative theory/cognitive narratology, narrative medicine, and related areas. Now, imagine a close and persisting dialogue—if not a joint investigative effort—would unfold and a bridge would span between this promising new area of research and the culturally oriented narrative inquiry with which this chapter has mainly been concerned. Would narrative not be a uniquely appropriate subject to overcome some longstanding borderlines, questionable as they are anyway—such as those between the cultural and the mental, as well as between psychology, the social sciences, and the humanities?<sup>8</sup> It would not be hard to envision the outcome of this joint effort: an unrestricted and

unreduced access to the cultural nature of the narrative mind.

## Acknowledgment

I would like to thank Molly Andrews, Alessandra Fasulo, David Herman, Lars-Christer Hydén, Matti Hyvärinen, Maria I. Medved, and Jaan Valsiner for helpful comments on earlier versions.

## Notes

1. Throughout this chapter, I use the terms *practice* and *activity* more or less interchangeably; *performance* refers to a particular cultural practice or activity.

2. This is not to say that these constraints—as in individuals suffering from diseases (e.g., Alzheimer’s), injuries (e.g., neurotrauma), syndromes (e.g., autism), and (genetic) neurological disabilities—do not allow for specific forms of communication and meaning construction. Of course they do. Yet the discussion of these forms is beyond the scope of this chapter.

3. For Bruner (1996), “The historical separation of anthropology and psychology, whatever may have caused it, must surely be counted as one of the most stunting developments in the history of the human sciences . . . In spite of their staking out separate territories of inquiry, the two disciplines were never able to ignore each other” (p. xiii). Bruner goes on to argue that the “cultural study of man” requires a “consortium” of psychology and anthropology. On Bruner’s long and close relationship with (social, cultural, and psychological) anthropology, see Mattingly, Lutkehaus, and Throop (2008).

4. The claim that an action- and performance-theoretical concept of language resonates with the culturally thick notion of narrative put forward in this chapter does not reject the idea that narrative has a representational side or can be used as a representation (e.g., a particular “representation” is offered as part of a discursive or rhetorical move) and that, under certain circumstances, this side can be the dominant one. Understanding narrative as a mode of representation seems to have been particularly plausible in contexts of literary, media-theoretical, and traditional narratological reasoning, where most cases of storytelling fall within the “scope of narrative viewed as a kind or category of text,” as Herman writes (2009b, p. 6); although the understanding of narrative as representation is also widespread in the social-scientific literature. In fact, for narratologists from Genette (1980) to Herman (2009b), representation is the “most universally accepted feature of narrative” (Ryan, 2007, p. 25; for a critical discussion, see also Rudrum, 2005). Although in investigating narrative as a cultural form of life I privilege an action-theoretical view of storytelling, this does not exclude the idea of narrative stretching along a continuum from action to representation, from text to performance, and from the storyworlds of fiction to the life worlds of everyday interaction—an argument that will be discussed in more detail in what follows.

5. Whereas in the past, the term *narratology* was mainly used in the context of structuralist narrative theory, today narrative theory, narratology, and narrative studies have become synonyms in much of the theoretical and critical literature, as in my discussion.

6. Note that this view does not need the idea of narrative representation. Herman (2008) makes clear that the understanding of what a story is about (i.e., its representational or referential

aspect) depends on the interactional context of communication and interpretation in which the “intentional stance” of storytellers as well as the entire “intentional system” of their stories are grounded. It is this cultural context of communicative and interpretive practice—which I have pointed out in terms of an action-theoretical concept of narrative—that gives shape to the representational side (or use) of narrative. Hence it seems to me more appropriate to view the representational side as an aspect of narrative “worldmaking”—that is, of cultural meaning constructions grounded in intentions, communicative interaction, and acts of interpretation that always remain defeasible.

7. There are only a few theorists who, like Jerome Bruner and David Herman, have systematically drawn on both fields of research and scholarship.

8. Perhaps the current study of literary narrative could serve as a model. James Phelan (2006, p. 86) notes that narrative theory has so productively developed along various theoretical lines because the distinct approaches have remained in dialogue with broader trends in theorizing the human condition. Consequently, it is not dominated by a single view but, rather, is marked by a range of approaches: formalist, structuralist, phenomenological, cognitive, rhetorical, psychoanalytic, feminist, marxist, and others. “What is especially striking about this variety,” Phelan remarks, “is that it has produced relatively little conflict. Instead, practitioners of the different modes are generally happy to learn from each other, and to use the insights of one approach to enhance the quality of their own investigations and reach of their own conclusions” (2006, p. 86).

# Culture in Action: A Discursive Approach

Kyoko Murakami

## Abstract

The overall aim of this chapter is to discuss an approach to studying culture by drawing on the project of remembering and reconciliation from a discursive psychology perspective. I demonstrate discourse analysis from research using a case of the Anglo-Japanese reconciliation. I provide a brief overview of the development of discourse analysis and discursive psychology and highlight key philosophical foundations and theoretical assumptions on which discursive psychology and practice of discourse analysis are based. As the examples of discourse analysis, I will demonstrate how culture can be studied as a topic of members' concern. In this view, culture is not a matter of the researcher's concern to handle as a causal factor or independent variable. Discursive psychologists study culture as a resource for the participants. Finally, I will discuss the implication of the discursive approach and its far-reaching challenges for advancing the methodology of studying time-relevant phenomena of people's experience as a matter of duration and transformation.

**Keywords:** discourse, culture, discursive psychology, cultural psychology

## Introduction

Since the discursive turn in social sciences, discourse has become a common currency. For one thing, critical movement in psychology and other social disciplines promoted a rapid development of discourse theory and discourse-based studies. There are many versions of discourse-based studies and discourse analysis at present. Those include namely, but not exhaustively, Critical Discourse Analysis (Fairclough, 2001; Wodak & Meyer, 2009), Sociocultural Discourse Analysis (e.g., Gee, 1999; Gee & Green, 1998), Foucauldian Discourse Analysis (e.g., Burman, 1996; Hook, 2001; Hook, 2005; Parker, 1997; Parker, 1999; Parker, 2002), and other discourse theories (e.g., Bakhtin, 1981). Because of its large variety of discourse studies and analysis, I shall not attempt to chart comprehensively the variations in these discourse-related approaches.

The overall aim of this chapter is to introduce a concept of discourse and discuss an approach to studying culture by drawing on a project of remembering and reconciliation from a discursive psychology perspective. I shall demonstrate discourse analysis from the research using a case of the Anglo-Japanese reconciliation (Murakami, 2001a, 2001b, 2007; Murakami & Middleton, 2006) and discuss the relevance, implications, and challenges of discourse analysis for research in exploring the relationship between culture and psychological phenomena. In the following, I will provide a brief overview of the development of discourse analysis and discursive psychology to highlight key philosophical foundations and theoretical assumptions of social sciences disciplines on which discursive psychology and practice of discourse analysis are based. Using examples of discourse analysis, I shall demonstrate how culture can be studied as a topic

of members' concern using an analytic concept called "membership categorization device" (Sacks, 1989, 1992). Membership categorization device is a discursive resource for the participants in talk-in-interaction to do social action and perform social accountability. Therefore, culture is not a matter of the researcher's concern to handle as a causal factor or independent variable to bring about differences in behavior, perception, and attitude—discursive psychologists study culture as a resource for the participants. Finally, I shall discuss the implication of the discursive approach by referring to other approaches that forefront culture as a main research object and its far-reaching challenges for advancing the methodology of studying time-relevant phenomena of people's experience as a matter of duration and transformation.

### ***The Project of Remembering and Reconciliation***

Toward the end of World War II, 16 British prisoners of war (POWs) died in a labor camp located in the mountains of central Japan. The cause of death derived from illness induced by malnutrition, severe climate, and living conditions in the previous camps in Singapore and Thailand. Initially, British soldiers were captured by the Japanese army in Singapore in December 1941 and worked on the construction of the Thai-Burma Railway from 1942 to June 1943. Three hundred British POWs were then transferred to Japan to work in a copper mine until the end of the war in August 1945. During the captivity, a grave for the dead POWs was built by fellow British POWs. After the war, local Japanese villagers refurbished the grave and erected a memorial. In October 1992, 47 years after the war, 28 former POWs and their family members returned to Japan and visited this grave on a reconciliation trip.

In the spring of 1999, I set out to interview surviving POWs and family members who took part in this reconciliation trip. The key interview question was: Why had they decided to go on the reconciliation trip? This question was designed to elicit their accounts of wartime captivity and post-war experiences of living and coping with difficult times—war-related illnesses and disease, trauma, and presumably any other medical problems. Also, the interview invited them to share their views on reconciliation with the troubling past. The occasion of the interview created a participatory framework of revisiting the past. That is, the participants, being engaged in a conversation with a Japanese

interviewer, were doing the remembering of the past events and actions. Such remembering is a socially organized communicative action situated in an inter-/cross-cultural social setting. To study this inter-cultural phenomenon within the project of remembering and reconciliation, I use discourse analysis using the perspective taken from discursive psychology.

### **Discourse Analysis**

The term *discourse* has been used in a number of different ways within the community of discourse analysts and scholars of social sciences (Heath, 1997; Potter, 1998; Potter & Wetherell, 1987). The general consensus is that discourse analysis is a study of language in use and refers to a field of research encompassing a broad range of research drawing on the philosophical and methodological traditions in linguistics, psychology, sociology, and anthropology and cultural and literary studies. For discursive psychology, the term *discourse*, in a least limited sense, is used "to cover all forms of spoken interaction, formal and informal, and written texts of all kinds" (Potter & Wetherell, 1987, p. 7). Discourse analysis deals with naturally occurring talk and text, including interview transcripts and other forms of both spoken and written communication.

Discourse analysis, a method of analysis of *discourse*, was born out of a synthesis of contemporary critical movements in psychology—particularly social, cognitive, and experimental psychology as well as other social science disciplines. Discursive psychology might be construed as one of those separate strands as the application of discourse theory to the classic questions of psychology, but discursive psychology itself has grown to be a complex field, upheld by a multiplicity of different ideas and arguments (Edley, 2001). For the purpose of this chapter, rather than offering an account of the various latest developments within discursive psychology, I shall underline key features and assumptions for grounding the ensuing discourse analysis that I shall present as the illustration of how culture in psychological phenomena can be studied.

### ***Language as Social Action***

Among the principal features of interview as social practice of reconciliation, action orientation to talk, joint construction of meaning, social actions of blaming, justifying, forgiving, and apologizing are performed. Rather than treating reconciliation

as an interior psychological phenomenon of conflict being resolved, reconciliation is researched as the social relationship, as a practical interactional business that interview participants attend to and accomplish. Similarly, the central focus on studying reconciliation rests on the intercultural communication, how cultural differences are brought off as a problem or posed as an obstacle for achieving reconciliation, and these cultural issues were analyzed as a members' practical concern that was accomplished interactionally.

There are several principal features of discourse analysis that are relevant to the study of inter-/cross-cultural communication in an Anglo-Japanese reconciliation practice. First, discourse analysis is concerned with the content of talk, its subject matter, and with its social organization rather than linguistic system, structure, and grammatical rules (e.g., syntax, phonetics, semantics). Second, discourse analysis has a threefold concern with action, construction, and variability. Simply put, in talking (and written communication), people perform social action. Third, discourse analysis examines the rhetorical organization (argumentative) of everyday talk and thought, revealing the dilemmatic nature of discourse attending to potential versions of argument (Billig, 1997; Billig et al., 1988). Finally, discourse analysis is concerned with the cognitive issue of reality and mind—particularly with how cognitive issues such as knowledge, belief, fact, truth, and explanation are handled in talk and text. This reflects its origins in the sociology of scientific knowledge (e.g., Mulkay, 1979) and the reworking of psychological categories of memory, attitude, learning, and so on (e.g., Harré & Stearns, 1995; Middleton & Edwards, 1990; Potter & Wetherell, 1987).

The development of discourse analysis centers on language as a main focus of psychological investigation. It derives from philosophy, linguistics, and literary and cultural studies as to how we view and understand the function of language. The discursive approach is premised on an action orientation of language, especially on the language use in context and materialized in social relations, within which such a context allows. Therefore, language is not treated as merely a tool or medium to represent the inner states of the mind. Language takes up a larger and more central role in our everyday communication and social interactions, and it is in the social interaction where the remembering and

reconciliation is achieved and how language in use is observed.

To further explain the discursive approach to language as social action, let me now trace the contemporary development of linguistics and philosophy of language. Chomsky's theory on the nature of language development and acquisition features what is termed as *generative grammar*, a set of underlying linguistic rules that innately exist in the form of deep structure (Chomsky, 1965). Among the critique of Chomsky's theory and its approach to underlying cognitive psychology is that it tries to separate the issue of linguistic competence from linguistic performance. Linguistic performance and competence are not easily separable, being intricately related to one another. Chomsky's empirical work is taken from speech data that is idealized compared with ordinary speech (Potter & Wetherell, 1987). Such data are so far removed from the natural speech, with errors, hesitations, self-corrections, and so forth, that they do not capture the interactional features of natural speech (Potter & Wetherell, 1987). In contrast, discourse analysis attends to the performance of naturally occurring speech to determine how people use language in the course of different kinds of interactions.

The second feature of discourse analysis pertains to the way in which the relationship between the object (reality) and language is accomplished (Potter & Wetherell, 1987; Silverman, 1997, p. 115). This point refers to the notion of sign (the signifier and the signified) as to how such an arbitrary relationship between the object and the linguistic labeling is established. This notion of sign derives from a Saussurean approach to signification and semiology and heavily depends on the larger structure of society. Whereas discourse analysis is interested in the local production of meaning and knowledge, Saussurean linguistic approach links its analysis to an abstract level of social structures and other broader concerns of the society such as power, hierarchy, class, race, gender, and so forth. In semiology, theory of society is generated independently from what meanings are locally produced within a given linguistic and cultural community. In other words, semiology does not necessarily account for the local meaning making process as it "tends to produce . . . static idealized analysis" (Potter & Wetherell, 1987, p. 31). The emphasis is placed on "looking at structure ("la langue") rather than specific uses ("parole"), along with a focus on examining meaning at a

single instance rather than processes occurring over a period of time, ruling out a number of important and interesting questions” (Potter & Wetherell, p. 31). For the discourse analysis, this means that it should focus on how members in a particular cultural community establish the social relations and moral order of the group using language (Edwards, 1997; Potter & Wetherell, 1987). Discourse analysis aims to explicate the process of producing and changing meanings at the time of their occurrence.

Studies of the function of language from linguistic philosophy are also concerned with examining the processes of labeling and pointing as language functions, how the meaning (a set of relations between the object and the language) is produced over time. Speech Act Theory (Austin, 1975 [1962]) moves away from the idea that the primary function of language is to describe some state of affairs, some aspect of reality. The most useful distinction Speech Act Theory makes on language use is between doing and stating, specifically the ways in which people use language to perform social actions. To illustrate this point further, let me use some modified examples cited in the work of Potter and Wetherell (1987). For example, the sentence:

*I declare war on terrorism.*

is not a description of the world that can be seen as true or false. Rather it accomplishes some practical action and brings about specific consequences when uttered in appropriate circumstances. This example illustrates an action-orientation to language—that is, language is performing an action: request, declare, agree, disagree, and so forth. This view of language underlines the key foundation of discourse analysis.

One of the main difficulties with Speech Act Theory, however, is that it tends to deal with idealized linguistic phenomena or “made-up” sentences taken outside the context of use or highly ritualized speech forms. This problem is common to the Chomskian approach. Studying these idealized, made-up examples poses another challenge. Often we hear a single utterance that performs a number of acts at once, or acts may be spread out in more than one sentence including a question and response sequence. As Potter and Wetherell argue, “[i]n practice the decision about what act an utterance is performing is often made by referring to the response rather than to any features of the utterance itself” (1987, pp. 29–30). Speech Act Theory does not consider the sequential feature of interaction as

a way of validating their categorization of speech acts. This shortcoming is complemented by the perspective developed by ethnomethodology and its branch entitled conversation analysis, by which the ensuring discourse analysis is influenced.

Discursive psychology acknowledges and draws on contributions made by Vygotsky and Wittgenstein, as they both emphasized an importance of the role of language in the development of knowledge, thought, memory, and cognition. Vygotsky’s theory, or what is known as Socio-Cultural Theory (or other labels of cultural-historical theory), forefronts concepts such as mediation and cultural tools and artifacts and their relation to human activity (Harré, 2011, Chapter 9; van der Veer, 2011, Chapter 3). The theory influenced the early development of the discursive movement. Equally influential to the contribution to development discourse analysis is Wittgenstein in his famously known notion of “language-games” (Wittgenstein, 1968 [1958])—the role of language in shaping thoughts and other cognitive functions and the action-orientation of language. He states, “[T]he term ‘language-games’ is meant to bring into prominence the fact that the speaking of language is part of an activity, or of a form of life” (para. 23). Regarding the problem of categorization in social sciences, he comments:

When philosophers use a word—“knowledge,” “being,” “object” (etc.) . . . —and try to grasp the essence of the thing, one must first ask oneself: is the word ever actually used in this way in the language-game which is its original home?—What we do is to bring words back from their metaphysical to their everyday use?

(Wittgenstein, 1968, para. 116)

Wittgenstein’s critique, similarly applied to semiology, refers to a problem of our understanding of the relationship between language and context. It reveals the taken-for-granted nature of social scientists’ producing arbitrarily constructed operational definitions of phenomena without ever studying the “language-game” in which the phenomenon has its everyday home (Wittgenstein, 1968). Discourse analysis, in line with Wittgenstein’s critique, problematizes the analysts’ production and superimposition of their categories on the social phenomena. In its distinct epistemological position, discursive psychology’s practice of discourse analysis aims to explicate how members produce them and make them relevant in talk.

The aforementioned points suggest that analysis should be focused on the language in use, not on excavating formal rules embedded in language and the underlying cognitive processes. This means that the study of language does not confine itself to formal linguistic analysis as in the transformational grammatical approach and analysis of sentences that the analyst himself/herself generated to prove their point. Nor does it mean a diachronic approach of studying the history of the word meanings and explicating the process of change. Drawing on the arguments by Wittgenstein, Austin, and Vygotsky, discursive psychologists point out that language in use, including communication and interaction, is itself a form of practice. Language is used to do things in everyday communication—giving orders, making promises, and thinking and arguing. From this view of language, reconciliation comes to be understood as something that is done or accomplished in the course of social interaction, in which discourse is observed. In this view, language is a tool to be used for the accomplishment of social action (Middleton & Edwards, 1990, p. 36), steering away from the notion of the representational instrumentality of language seeing versions of events as pragmatically variable accomplishments.

### **Discursive Psychology: Principles for Discourse Analysis**

Discursive psychology is the culmination of a number of independent developments in psychology, sociology, linguistics, anthropology, and philosophy. More specifically, it was born out of the critiques of traditional psychological methods—behaviorism and positivism (Gergen, 1978; Harré, 1979) and also the critique of psychological theory, cognitivism, which favors explanation in terms of mental states or processes. Roots of discursive psychology go as far as a number of independent developments, including the work of Mead and Vygotsky (Harré & Gillet, 1994). In particular, it incorporates contemporary movements such as ethnomethodology (Garfinkel, 1967; Garfinkel, 1974; Heritage, 1984), social constructionism (e.g., Gergen, 1997; Shotter, 1990; Shotter, 1991), and ethnogenics. Edwards and Potter (1992) have profiled key features of discursive psychology in terms of action-orientation, construction of knowledge about reality, and variability of versions of reality. The focus of discursive psychology is the action-orientation of talk and writing. “For both participants and analysts, the primary issue is the social actions,

or interactional work being done in the discourse” (Edwards & Potter, 1992, p. 2). Moreover, its interest is the nature of knowledge, cognition, and reality as to how events are described and explained, in the forms of factual reports, or narratives, and how cognitive states are attributed. Instead of assuming the speaker’s (or writer’s) underlying cognitive states in such discursive constructions, they are “examined in the context of their occurrence as situated and occasioned constructions” (p. 2).

### **Action Orientation, Construction, Variability in Mundane Settings**

The view of language as social action is also commonly shared in the sociological tradition of ethnomethodology (Garfinkel, 1967). It refers to “the investigation of the rational properties of indexical expressions and other practical actions as contingent on-going accomplishments of organized artful practices of everyday life” (p. 11). As the term suggests, *ethnomethodology* is concerned with the study of (-ology) ordinary people’s (ethno-) methods. It is the study of the methods that ordinary people use to produce and make sense of everyday life. Ethnomethodological research seeks to learn about the activities of everyday life as phenomena in their own right. According to Sacks and Garfinkel (1967; Heritage, 1984), founders of ethnomethodology, talk is considered as an activity and “doing” talking provides ways of understanding as to how common sense views about the world and practical reasoning in a given situation get produced and shared.

The treatment of language as action is a common concern for discursive psychologists and ethnomethodologists. This implies that language is a constructive medium that people use resourcefully to accomplish things. The discourse analysis is aimed at explicating “the constructive and flexible ways in which language is used should themselves become a central topic of study” (Potter & Wetherell, 1987, p. 35). The present study of identity and accountability fully exploits this feature of language. It also follows that our position on the role of language allows us to see the variability of people’s views and opinions in talk (and texts). Ethnomethodology’s concerns with the way members’ knowledge and understanding get produced reflect discursive psychology’s interests in people’s pragmatic use of language in terms of talk as action as practical accomplishment. Thus, the focus on variability yields analytical resources for studying accountability.

In the next section, I shall show what makes discourse analysis a viable approach for the concerns of the research on remembering and reconciliation. In doing so, I shall elaborate on the features of action orientation, construction, and variability to identify a body of influence—namely, ethnomethodology and conversation analysis—which would lead to another important notion called accountability of social action.

### **Accountability**

The project from which the discourse analysis was conducted makes a major emphasis on the centrality of accountability for making sense of the participants' discourse. Mainstream psychologists also have paid close and systematic attention to one level of accountability, specifically where people attribute responsibility for events. Another level of accountability is that of the speaker who is producing the report, or the description of the world, from which the causal inferences are supposed to be drawn:

[T]he discursive approach where versions of events, things, people and so on, are studied and theorized primarily in terms of how those versions are constructed in an occasioned manner to accomplish social actions.

(Edwards & Potter, 1992, p. 8)

Conversation analysis (CA) helps translate this perspective to systematic analytical procedures in studying naturally occurring conversations. Conversational analysis is focused on the sequential organization of conversation—the ways in which people take turns in conversation, the management of repair, and the analysis of the topic organization. The meaning and interpretation of the first speaker's utterance is examined in the second speaker's utterance. Heritage (1984) terms it as *intersubjectivity* and explains as follows:

[S]ome analysis, understanding or appreciation of the prior turn will be displayed in the recipient's next turn at talk . . . Conversational interaction is structured by an organization of action which is implemented on a turn-by-turn basis. By means of the organization, a context of publicly displayed and continuously up-dated intersubjective understanding is systematically sustained . . . It is through the "turn-by-turn" character of talk that the participants display their understanding of "the state of the talk" for one another.

(Heritage, 1984, p. 259)

The contribution of CA to discursive psychology is that CA provides evidential basis, or a proof procedure of how speakers establish intersubjectivity, shared understanding of reality in interaction. The analysis of the interview talk is empowered by the conversation analytic principles, and relevant issues to illustrate the performative nature of identity and constitutive process of accountability as action were examined.

The aforementioned features of discourse analysis and discursive psychology—action orientation, construction, and variability—have important implications for studying culture in terms of cultural membership in the project of remembering and reconciliation. The discursive approach (i.e., the umbrella term for the methodological approach used in discourse analysis) attends to the particular analytic concerns—our identities and culturalness arising out of interactions with other people. Cultural identity or what it means to be a particular member of a culture is constituted in interaction, and it resources to perform social actions such as invitations, agreements and disagreements, blamings, displays of neutrality, and so forth. Thus cultural membership is achieved discursively by mobilizing the members' knowledge and understanding of social categories (e.g., class, ethnicity, gender, age, etc.)—what it means for the participant to be a member of a given community. The discursive approach does not take these categories as provided by the analysts without looking at what is actually produced in talk. People orient to these categories in talk and construct what they mean to them, rather than how those categories are shaping the way they think about their identities. The constitutive process of cultural membership is important to the studies of social remembering and reconciliation. People do not consistently produce the same version of the past when accounting for a problematic past, especially when the events relate to violence and other unpleasant acts committed during the war. People fashion talk (and texts) about the wartime past, orientating to identities of the speakers and the hearers and perform social actions in making his or her claim of the past. Hence, a multitude of discourses are constantly at work constructing and producing our identity. Variability of views, opinions, and identity descriptions, therefore, work to be the analytical resource for discourse analysts.

### **Discursive Approach to Studying Culture**

Language users engage in talks and texts not only as speakers, writers, and listeners or readers but also

as members of groups, professions, organizations, communities and societies, and cultures. As members of given groups, they interact in complex combinations of social roles and cultural identities. In participating in discourse, members (i.e., language users) display roles and identities, which become visible for discourse researchers as a dynamic, flexible category that the participants use. Thus social categories such as gender, age, class, and ethnicities and cultural background alike are relevant resources for members to use to accomplish social action. Power dynamics and asymmetries can be observed in a given interaction as part of the participant's concern and orientation to the talk at hand and work within the interactional order and hierarchy of power positions (Linell & Luckmann, 1991). Below I will present a few extracts and demonstrate the discursive approach to analyzing interview materials, especially how a cultural marker (whether one is British or Japanese) is treated as a member's topic of concern, rather than an independent variable assigned by the researcher. The analysis is guided by the analytical concept of membership categorization and ethnification processes, which I discussed earlier. The analysis will illustrate the ways in which the participants' claim of difficulty with a rice diet is addressed in the interview where participants' and the interviewer's orientation to culture becomes an issue. Let us now look at the examples of such talk.

### ***Culture and Membership Category***

What does it mean to say one is treating culture as a topic of its "members?" Discourse analysis examines the member's notion of culture and seeks to address how the concept of culture is put to use in talk in interaction and negotiate and forge meaning to it. With this approach, culture is considered as a dynamic concept, not a fixed, stable category that members in conversation/interlocutors use. Culture is always on the move and in action. I shall hereby present an example of discourse analysis from previous research that examines the ways in which people talk about others of different culture or ethnic origin (Murakami, 2001b).

I analyzed interview talk of the British World War II veterans about their experiences of captivity in the POW camp in Japan and their recent activities of reconciliation nearly 50 years after the war. Proposed is a discursive approach (a discourse analysis by discursive psychology) to the study of culture and cross-cultural communication. This approach is sharply contrasted with work drawing

on cultural models in cultural anthropology (e.g., Holland & Cole, 1995), cultural script in pragmatics (e.g., Nelson, 1981, 1986; Wierzbicka, 1994) and ethnographic conversation analysis (e.g., Moerman, 1973). The discussion is guided by two analytic concepts—membership categorization and ethnification processes. The analysis concludes that the ways in which cultural knowledge is socially constructed—negotiated and shared—are discursive accomplishments of the veterans' social action of accounting for the wartime past and their dealing with the problem attributed to cultural differences and misunderstanding.

### ***Ethnification As a Topic***

This particular example analysis explores the notion of ethnification: how people ethnify others in talk in a cross-cultural context (Moerman, 1973). Taking a discursive approach informed by discursive psychology (Edwards & Potter 1992), ethnomethodology (Garfinkel, 1967), and conversation analysis (Atkinson & Heritage, 1984), I will look at how cultural otherness is marked, constituted, and put to use in talk. Also, I will show ways in which a particular cultural aspect of others is made to be a topic of concern in interaction and establish its relevance to accomplishing social actions. Discourse examples are taken from interviews with British World War II veterans, who were taken as POWs by the Japanese. During the interviews, they gave accounts of the wartime past and shared their views and experiences of reconciliation. The analytical task is twofold: first, to illustrate how rice is rendered as a member's category relevant to the interview talk and how it becomes a discursive resource; second, to examine a process of ethnification, defined as "ethnic identity as a situated accomplishment of interlocutors" (Day, 1994, 1998; Moerman, 1974). Finally, I will discuss the methodological payoff of the discursive approach as a way of studying culture and cross-cultural issues.

### **ETHNIFICATION PROCESS**

I now introduce the analytic concept of "ethnification processes," with which the use of identity categories in ethnic (and linguistic) group categorizations have been explored (Day, 1994). Ethnification processes are defined as "processes through which people distinguish an individual or collection of individuals as a member or members respectively of an ethnic group" (Day, 1994, p. 154). Arguably Day's study takes a discursive

approach and views “ethnic identity as a situated accomplishment of interlocutors” (Day, 1998, p. 151). The important distinction is that the discursive perspective does not ask how someone’s ethnic background shapes or determines what they say, but, rather to ask how this ethnicity becomes a resource for them—and others to use (Day, 1998). Within this view ethnicity, identity is a topic in its own right, and its relevance for interlocutors becomes an empirical question (Day, 1998).

From a systematic observation of a large corpus of data gathered for the study, it became clear that certain topics and experiences were recurrently talked about by the veterans in the interviews. Such topics included food and eating practices in the camps, especially a rice diet in the Japanese camp. Their experiences related to rice were central to the life as POWs, and rice was emblematic of the culture of the camp. The topic of food and hunger during any war is a universally poignant theme. For example, the autobiography titled *The Railway Man* by Eric Lomax (1996) depicts the eating regime in the prison camp—not only rice but any eating incidents—at length and with fine details during his captivity in Singapore and other locations in Asia during World War II. The selected extracts used for this chapter concern conversational topics of rice and a rice diet. The discourse analysis reveals a nuanced way of talking about their problem of a rice diet. The ex-POWs’ accounts of rice and rice diet mark the Japanese as cultural other and display their understanding of the Japanese people and their cultural practices in the interview while they recall how the POWs viewed the rice diet at the time. The aim is to produce some empirically grounded analysis and discuss how the topic of rice and rice diet is constituted as a culturally emblematic category of membership and used to accomplish specific social actions—that is, to claim and account for their difficulty with a rice diet in the POW camp.

### ***Marking the Cultural Other: An Anthropological Approach***

I consider two studies in anthropology to see how culture is studied in various social science disciplines. Ohnuki-Tierney’s work on rice as self (1993) is the most relevant work on rice here. It typifies an anthropological approach to cultural knowledge and the symbolic representation of self through food. She takes a view that food is a way of marking cultural other and examines collective representations of self, change, continuity, structure

and transformations in relations to other peoples” (Ohnuki-Tierney, 1993). The work is based on the notion of “a presentation and representation of the self, using food as metaphor of self” (p. 4) and explores how the Japanese people use the metaphor of rice to think about themselves in relation to other peoples (e.g., ethnic groups or nationalities). It aims:

to show *how* the Japanese notion of the self has taken on a different contour as a different historical other has emerged and rice and rice paddies have served as the vehicle for deliberation, although not always conscious, in these process.

(Ohnuki-Tierney, 1993, p. 5)

She acknowledges a methodological challenge in studying collective representation of consciousness as follows:

In a broader framework it is a question of the development of a powerful representation of the self by the people themselves, on the one hand, and of how to reconcile a dominant representation with apparent multiplicity within a culture, on the other hand.

(1993, p. 6)

The discursive approach differs from her approach, focused on representation of self through the object such as rice. Instead of looking at a multiplicity of voices, selves, and variability of people’s views, opinions, and positions as something to be reduced to a model or fit to a conceptual category as a manifested form of collective representation, the discursive approach views them as a members’ topic, discursive resources for the purpose of achieving social actions such as arguing, justifying, agreeing and disagreeing, and claiming differences and similarities in representing culture of their own and others. Therefore, tensions between individual and collective representations and between heterogeneity and homogeneity are not treated as a problem and are to be resolved in terms of contested or negotiated meanings and symbolic interpretations in studying culture and self. In this vein, the task here is to show and demonstrate what people “do” with culture, the ways in which they make cultural difference an issue, and attend to the issue of self-representation vis-à-vis cultural others. This analysis proposes that the discursive approach provides a basis for showing people’s (members’) moment-by-moment and here-and-now sense-making of their culture, and others, in relation to the past, present, and future.

### Culture As Local Production of Meaning

Equally relevant to the present chapter is the ethnographic and conversation analytic study of Thai culture by Moerman (1973). Writing of his approach, he comments that “culturally contexted conversation analysis tries to limit the ingredients of interpretation, the components of meaning” (Moerman 1973, p. 7). This is a modified adaptation of the ethnomethodological stance, which “treats members’ inquiries as locally occasioned, managed and accomplished, within and with reference to the ‘here-and-now’ circumstances of their production” (Hester & Eglin, 1997, p. 2). Branching off the orthodoxy of conversation analysis (e.g., Schegloff, 1992), Moerman analyzes talk between villagers and an official and highlights some instances of locally triggered significance of cultural systems in which rice (and other food) as an identity marker or a member’s category do the business of labeling ethnicity. Also the interactional use of the category “rice” invokes social relations of power and authority of state, which constitute the dominant and dominated in a particular social setting (Moerman, 1973). Such conversation analysis permits us to see the active situated use of cultural ideas and local production of meanings accomplished in interaction. In what follows, I shall illustrate discourse analysis and its approach to studying culture as discursive accomplishment by using the research on remembering and reconciliation.

### Interviews With British Prisoners of War Veterans

Two extracts were selected from a transcript of a 5-hour recording of a group interview with those veterans who agreed to take part in the research. They were asked to share and discuss their views and post-war experiences of reconciliation with respect to their captivity in the POW camps in Thailand and Japan. The interview was conducted in a participant’s home in a northeastern city in England. The participants included four former POWs who took part in the reconciliation trip in 1992 and two of their spouses. Two spouses did not accompany their partners on the reconciliation trip. The interviewer was the researcher herself.

#### *Analysis: Rice in the Prisoners of War Camp*

#### TALK OF RICE AS DISCURSIVE RESOURCE FOR ACCOUNTABILITY OF ACTIONS

Extract 21.1 below exemplifies an analytic view that rice is a members’ category with which the

participants display their cultural understanding of rice and a rice diet and establish its relevance in talk. Prior to this interview segment, they trace their experience of being transported from Thailand to the camp in Japan. They speak of a drastic change of diet. What is demonstrated here is that the participants used rice as a category, which is emblematic of life at the Japanese POW camp. Rice, as being central to the life at the camp and to the very basic need for survival, is brought up as a conversational resource, whereas the participants account for what it was like to be in captivity and live and work in a Japanese POW camp. The ex-POWs' work of managing accountability entails the presentation of a rice diet as an unfamiliar cultural practice of the Japanese, as well as a claim for the POWs' difficulty with such a diet.

The analysis of this extract focuses on the ways in which cultural otherness is constituted through telling about items that the POWs used to use in the camp and later brought back to Britain as memorabilia and produced as souvenirs (line 1). The word "souvenirs" refers to the things they brought back and they form the object of remembering the camp days. Stories produced about these items give rise to

both personal and shared meanings of the past in the present interactional circumstances. A tangible object such as a lunch box, which represents a particular past at issue, becomes an aid for recalling past events that are relevant to a particular conversational setting and organization of social relations. In other words, the objects work as discursive resources for entering into a particular moment in the past and establish its relevance in interaction. In this extract, "rice" is treated as a common reference point, and the talk about rice establishes a mutual understanding of what it was like to live with a rice diet and other related cultural practices that were markedly different from and unfamiliar to their own.

In this extract, "rice" deserves a term that denotes something more than a simple reference point. I suggest that it is a membership category. The membership category refers to classifications or social types that may be used to describe persons in its original definition (Sacks, 1992), but it is later extended to collectivities and non-personal objects (Hester & Eglin, 1997). Descriptions of objects and events provide for the accountability of actions; they are used to generate excuses and generally deal with "attributional" issues of cause, intention, and responsibility (Edwards & Potter, 1992). A fine-grain analysis of the organization of turn-taking and uptakes unveils the ways in which various descriptions as to how rice was cooked and served in the camp are produced *in situ* interactionally. These descriptions ascribed to the category "rice" constitute a claim for the participant's difficulty with a rice diet, and they are subsequently formulated as a problem.

**THE CULTURAL PRACTICE OF A RICE DIET IN THE PRISONERS OF WAR CAMP**

In the opening sequence, a reference to souvenirs is specified in Ted's utterance, "a little box to put in a little brown ball (2.) pap rice and eat with" (ll. 4 & 5). He gives a detailed and animated description of what the box is and how it was used for eating rice (ll. 4–6 & 9). The term *souvenir*, as referred to things that the POWs brought back from the POW camp, seems to be ironic considering the context in which the interviewees reflect about their experiences of captivity and reconciliation. "Souvenirs" are, in a conventional sense, a reminder, a token, or memento of a place one visited in the past, but in this case the experiences may not necessarily be pleasant. Rather than speculating the intention of the speaker, Ted, let us look at how

this is received in the next turn. Does the interviewer treat this as irony? Here, the interviewer's receipt and the brief pause (l. 3), albeit not actively, solicit and encourage the speaker Ted to continue. The descriptions make reference to a mealtime and crockery with which to serve rice, including details as to how rice was prepared and how it was served and eaten in the camp. For example, the exact mealtime is debated among the participants, Ted and Charlie, marking some significance of the time of breakfast (ll. 12–15). This exchange makes a point (and even a complaint) of how little and infrequent the POWs ate at the camp. Issues dealing with food shortage, scarcity, and constant hunger are talked about later in the same interview (see the discussion in Extract 21.2).

### ***Ethnification and Shared Understanding of the Past***

Let us look at how the researcher–interviewer's identity as Japanese is marked and made relevant in talk. In line 18, Ted actively seeks the interviewer's response by checking his memory of a Japanese term for lunchbox that is at issue (ll. 16 & 18). First, after the debate over the breakfast time, Ted refers back to the topic "little box" in line 1. 16 ("then you got (.) your little box (.)") and a brief pause at the end for his pursuit of the interviewer's response. Then, in line 18 he specifically asks the interviewer to reply to his question ("your bento, was it?"). This formulation needs unpacking. Along with the pronoun "your" predicated to the lunchbox, the way to which this is responded by the interviewer indicates that Ted's question, using the Japanese word "*bento*" has a direct relevance to the interviewer and therefore interactionally nominates the interviewer to take the next turn. The Japanese word *bento*, the English equivalent of lunchbox, ethnifies the interviewer as Japanese, someone who is assumed as culturally informed and linguistically competent on the topic in progress. Joint construction of what *bento* means is interactionally accomplished: The interviewer displays her knowledge by offering a gloss in English (l. 19, "hum, lunch [box]"), which is completed by Ted with his embodied action (l. 21). This joint construction of what *bento* means not only ethnifies the interviewer but also constitutes a mutual understanding of the particular past at issue (ll. 16–23).

#### **CLAIMING DIFFICULTY WITH A RICE DIET**

The talk in this extract illustrates how Ray's problem with a rice diet is worked up, which warrants

another example of discursive accomplishment with a resource of the membership category "rice." The difficulty of eating rice is discursively formulated by the description of the box, a container used to serve and transport rice at the Japanese camp. In addition to the descriptions given by the participants with reference to how the box was used, the speaker's embodied action—for example, the clapping sound of simulating a packing of rice in the box (ll. 6 & 21)—demonstrates a cultural practice of what to do with rice in the Japanese camp.

Now I would like to focus on the latter part of the conversation (ll. 24 onward) and discuss how talk of the box mediates further telling of difficulty with a rice diet and affords the speaker Ray's claim of difficulty with rice (l. 36, "You couldn't eat the rice"). How is this claim formulated as being sensible and legitimate without making an explicit blame? Clearly, the generic pronoun "you" is used to distance the speaker from the claim of difficulty with a rice diet. The problem is attributed to two features of rice and its cultural practice. First, the tastelessness of rice is invoked in Ted's description in line 24 ("and maybe if you're lucky a little bit of uh Soya source or something in it"). This formulation seems to be ironic, for "maybe if you're lucky" orients to the opposite of being lucky, and it is offered as a mitigated claim of the extremity of hard conditions in the camp. This claim is endorsed and warranted in the way in which Ted's utterance is duly picked up—that is, the affiliational uptakes of the other speakers such as Sidney's recitation of the utterance (l. 26), followed by Mary's laughter (l. 27), and the interviewer's recitation and interpolated laughter (l. 28). The interviewer's summation in line 31 ("just plain rice") displays her understanding of the nature of the problem and aligns herself with the other speakers.

The second feature of the difficulty is the unusual appearance of the box. This is registered in Ray's description of the box in line 32 ("The first time we got those boxes they had been varnished or something hadn't they"). The emphatic reference to the rice holder as being "varnished," as well as the rice being served in a little box, exoticises the cultural practice of how rice was eaten. All these allusions as to how food was prepared in the Japanese camp have bearings on the speakers' normative expectations of how to prepare food in their own culture. Ray's claim of difficulty with the rice diet as something legitimate and warrantable is achieved by how he describes the preparation of the rice. In the ensuing

section, I further examine the ways in which this claim of difficulty with rice is handled interactionally and discuss the interactional consequences of it. To this end, I will use an analytical concept of membership categorization device (Sacks, 1992). I will argue that culture is treated as a topic of talk and a members' concern, rather than it being presumed an *a priori* concept. I will then consider the usefulness of such a concept in analyzing discourse.

### *Rice As a Membership Category*

In the next extract, the participants are discussing their experiences of and displaying their knowledge of rice. Various descriptions regarding the category "rice" have emerged and are attributed to a particular ethnicity or culture of other. In Sacks' terminology, describing can be considered a "category-bound activity" (1972). Sacks notes many activities are common-sensically associated with certain membership categories (1972). Considering that the interview pertains to the war-time events such as captivity in a POW camp, what has been brought off as part of a members' category can be highly consequential to the future trajectory of interaction and become a source of potential conflict among the interlocutors. We now look at how those categories and descriptions are introduced and worked up and identify what are interactional upshots as part of managing a delicate nature of the interaction.

This extract is rich with a collection of descriptions (or subcategories) regarding the category

(Italicized words are of Japanese origin; names used are pseudonyms.)

rice—the Japanese rice, flaky rice, the inferior rice, the best rice, rice for sowing, lime rice, planting rice, seed rice, brown rice, and unrefined rice. How do the varying descriptions of the category rice work in relation to Ray's earlier claim of the difficulty with a rice diet in the camp? The focus of the analysis of this extract is to ask how Ray's claim is handled in the interaction. Let us focus on the ways in which the speakers (Ray, Charlie, and Ted) bring up the category rice and see what they accomplish interactionally. The problem of a rice diet is formulated as a legitimate problem for the POWs. Here the ex-POW speakers do not make an explicit criticism of the Japanese rice diet, nor do they implicate the interviewer into the problem of this cultural practice.

In the opening sequence, Ray goes on to elaborate on his problem with a rice diet. By formulating in this way, Ray implies that a rice diet is not just his problem but that it is also problematic for the other prisoners, including experts such as cooks (ll. 40–41, “all our cooks didn't know to cook rice did they?”). Here, as the speaker is normalizing the problem, he offers further descriptions of rice (l. 45, “some of the rice was er:”). This is followed by a brief silence (l. 46), indicating his pursuit for comments from others. Charlie takes over from Ray, providing a description of rice that elaborates on Ray's point. Here, two descriptions of rice become available (ll. 47–48): one is the rice that was eaten by the POWs (“not as good as Japanese rice (.) the rice (.) Japanese is flaky (a bit) innit”), and the other is Japanese rice that, by implication, is of better quality and is presumably eaten by the Japanese. This contrasting set of descriptions of rice made by the speakers suggests that the problem of a rice diet is linked to their being British POWs. What is more, the problem of a rice diet, originally attributed to the food having no substance and taste (from Extract 21.1) is now being reformulated as implicitly having to do with a differential, possibly discriminatory, treatment at the POW camp.

Let us examine line 49 onward to see how the participants and the interviewer handle this statement. In doing so, we can examine how multiple categories of rice, brought off interactionally, contribute to accounting for the troubling past. In Charles' statement (l. 49, “but we got inferior rice as the prisoners of war”), the use of “we” as a collective voicing of the problem of discrimination is now attributed to the discriminatory practice of being fed the inferior rice. Charlie implicitly blames

the Japanese at the camp for their differential treatment of the POWs. In addition, he suggests that it may have been done deliberately on the part of those Japanese who treated the POWs. The ascription of the rice with the adjective “inferior” appeals to the morality (or lack of by the Japanese) in such treatment and thus makes the criticism legitimate. With all the possible ways of talking about differential treatment, this could be said, for example, to be “different” rice rather than “inferior.” The point here is that the analyst is making a judgment about how it should be said, or in this case, what adjective should have been used. It is the way in which the category rice was used to perform a social action of blaming the Japanese at the camp and how such a recollection was shared and established as to what happened at the camp.

The interviewer responds to this problematic attribution as a dispreferred answer, seeking further explanation (l. 51, “oh yeah?”). Ted's emphatic response in line 52 overlapping with the interviewer also seems to attend to Charlie's problematic statement. Charlie's reformulation (l. 53, “we didn't get the best rice”) is elaborated by Ray, who offers more category-related terms: “treated with lime” and “rice for sowing” (ll. 55–56). Additional categories mitigate Charlie's charge (and suspicion) that the POWs were served with the inferior rice on purpose. Following from Charlie's agreement (l. 57), Ted endorses this category (l. 58) and offers another category “[rice] used for plantin' the rice.” The descriptions of both speakers, Ted and Ray, in lines 62 through 65 seem to be ensuring that they stay on the topic of the lime [rice] with preservatives and seed rice. The upshot of these categories hearably works as a repair of Charlie's earlier problematic formulation, by emphasizing the technical properties of rice, rather than judgmental or moral attribution.

Not only the ex-POW participants but also the interviewer participate in talk about rice. How does the interviewer handle the series of formulation and reformulation of the problem? When Ted speaks of lime rice in lines 55 through 56, the interviewer actively seeks an explanation (l. 57, “what's that?”) and acknowledges Ted's explication (l. 59) as a news receipt (l. 61, “Oh”). The category that the interviewer offered, “brown rice” (l. 67), matches up with a collection of categories for rice—rice for planting and sowing, or seed rice. The interviewer makes claim to her understanding of rice served in the camp by producing the category brown rice as

part of the collection of category rice. Brown rice is accepted by Ray in line 70 and Charlie with his reformulation as “[rice] with rusk on you mean” (l. 71). The interviewer has another go at producing “not not refined rice” for reassurance, and this is ratified by Charlie (l. 73). As shown here, the interviewer produces a few categories, displaying her cultural knowledge that is relevant to the topic of rice. She is not a passive hearer of the talk about rice but takes part in the ongoing talk, signaling her participation. The turn-taking and production of categories of rice illustrate the ex-POWs’ work of accountability to addressing the difficulty of the rice diet in the camp—what it was like to live in extreme circumstances, in which food and eating become a crucial, daily concern for survival. The interviewer’s role is noteworthy here; her participation in the talk about rice collaboratively accounts for the problem of the rice diet. The ex-POW participants manage to talk about the problem vis-à-vis the Japanese interviewer without becoming hostile and making an overt criticism of the cultural practice of eating rice.

### ***Summary of the Analysis***

The extracts analyzed in this chapter illustrate the way in which cultural issues were addressed in the research interview between the British veterans and the Japanese researcher concerning the rice diet at the Japanese POW camp during WWII. The Japanese rice diet emerged as a key conversational topic in the interview with the ex-POWs, and in the unfolding interaction the veterans expressed their views and experiences of reconciliation. As demonstrated in the analysis, a close examination of talk allows us to see what people do with a seemingly mundane conversational topic such as a rice diet and how the unfolding talk brought about a cross-cultural tension in this interactional setting, where the groups of two different nationalities talked face-to-face. The rice diet was discussed as seemingly mundane but then was elevated to different kinds of rice, which led to an implied criticism against the Japanese for discriminatory practice at the camp. The problem with the rice diet was constructed as such that it linked with the way in which the POWs were treated in the camp. This discursive process of construction was guided by the analytical concepts of ethnification and membership category. The analysis illustrated the ways in which a culturally emblematic category of rice was made use of by the ex-POW participants as an interactional

resource. Certain descriptions and properties of rice and the rice diet were predicated and established as legitimate interactionally. This was done as performing accountable actions, accountability—claiming the participants’ difficulty with the rice diet in the Japanese camp. Notably, rice itself is not bound to an intrinsically fixed symbolic meaning, as shown in the participants’ talk about their experiences of rice and the rice diet. Cultural anthropologists would treat rice in terms of a symbolic representation of self and society at large. The researchers subscribing to the cultural model/script might look for an underlying cultural model implied in the rice and rice diet. Here, however, rice is treated as a member’s concern and is used as a discursive resource in performing social action with which interlocutors orient to what it is to live in a culture of others. Cultural otherness is constructed through such talk.

Rice and its related activities are central to the life of the POWs and therefore are emblematic of the culture of the camp. The talk offers a reference point and context, in which the participants discursively manage the sensitive issues of talking about difficult experiences without having to be hostile or aggressive to the interviewer, who represents the nationality of the perpetrator. This point is evidenced by the ways in which ex-POW participants and the interviewer display their understanding and affiliation to an argumentative position *in situ* as discursive accomplishment. The analysis takes place at a microlevel, focusing on turn-taking and how sequential organization unravels the ethnification process by which the participant ethnifies the interviewer and seeks her alignment to undertake work on a potentially problematic statement and claim. In turn, the interviewer’s accommodation to the ethnification is registered as part of the interactional upshot, collaborating to the interviewees’ accountability work.

Production of cultural knowledge and its development and dissemination is often a principal academic concern for some anthropologists, sociologists, philosophers, and psychologists. Their academic endeavors are invested to explicate forms of cultural knowledge in terms of folk theories, folk psychology, and cultural models. Discursive psychologist Derek Edwards states that “approaches to categories and categorization are closely linked to notions of cultural knowledge” (1997, p. 250). Cultural knowledge is considered in “the ways in which ordinary people categorize and understand

things and events, including human actions and mental experiences” (ibid.). Edwards argues that much of the analyst’s discussions on these forms of cultural knowledge are based on analytical categories in which analysts themselves conceptualize the culture they are set to investigate (ibid.). Consequently, “important features of common-sense understanding are systematically obscured, such that we are left with nothing but abstracted cognitive sense-making to explain the data” (ibid., p. 251).

Drawing on this discursive approach to studying culture, I argue that the ways in which cultural knowledge is constructed, established, and shared is a discursive accomplishment. Discursive psychologists and discourse analysts are concerned with explicating how cultural knowledge becomes available to people—the ways in which the participants in conversation topicalize culture and work with categories and categorization in interaction. A discursive approach provides an analytical tool to investigate what it is to be (or not to be) a cultural member of a community in a given moment and setting. It does not impose the analyst to generate conceptual categories beforehand and apply a standardized coding technique to analyze the data. This approach provides an empirical basis for studying the constitutive nature of emerging forms of cultural knowledge. This epistemic stance is one of the most distinctive features of the discourse analysis that sets it apart from other forms of qualitative analysis. In the following, I take this point further by discussing two bodies of work pertaining to studying culture within psychological phenomena.

### **Whose Culture?**

As demonstrated in the above analysis, the rice diet and eating regime in the Japanese POW camp is one of the topics that were most commonly to be recalled and reminisced by those ex-POW veterans. I showed that within the interview talk on Anglo-Japanese reconciliation, the members’ (former POW British veterans’) main concern over the hardship and other difficult experiences of the prison camp in Japan was addressed as an issue of intercultural communication difficulty and lack of knowledge about rice as a normal Japanese diet. The above discourse analysis demonstrated that the issue of intercultural communication was discussed in the specific cultural practice of a rice diet in Japan. In appraising the significance of this analysis, I refer to two other popular approaches to studying culture and intercultural communication.

### ***Cultural Scripts and Cultural Models***

The body of work pertaining to studying inter- or cross-cultural communication (including miscommunication) has well-established traditions and perspectives that are commonly taken by sociolinguists and linguistic anthropologists. Nelson (1981) and Wierzbicka (1994) are well-known for their work on the concept called “cultural script.” The objective of their research is to extract the cultural script in cross-cultural communication—and it can involve miscommunication. According to Wierzbicka (2004), “[c]ultural scripts are formulae written in very simple words that attempt to articulate, on the basis of linguistic evidence, tacit cultural rules” (p. 576). Also, cultural scripts are formulated in words that have the exact semantic equivalents in all languages.

Similarly to cultural script, cross-cultural psychologists and cognitive/psychological anthropologists have devoted themselves to producing a cultural model in a context of the practice. For example, the cultural model of success (Kim, 1993) is focused on the adaptation pattern from a migrant/immigrant of Korean background to a successful person integrated into a mainstream American culture. This cultural explanation is a strategy of attributing the success or failure of people to cultural compatibility and discontinuity. Then they break the model down to constituent categories such as cultural values and communication styles as part of operationalization. Rooted to cross-cultural psychology, the cultural explanation relies on Confucian tradition, and so forth, as a background to this psychological phenomenon of adaptation and integration. To what extent do we move inward and outward from a person/individual? How does the social matter in working up to a cultural model and cultural explanation of successful integration? In the following, I will discuss a socio-cultural perspective, a perspective similar to the cultural model to understand the major body of work in studying cultural issues within psychological phenomena.

By tracing the changes of the word meaning over time, the socio-cultural discourse analysts insist that cultural models are not fixed but are open to modification, expansion, and revision by members as they interaction across time and events. This perspective also suggests that “cultural models (whether local or broader framing models) constitute a set of principles for actions in particular cultural domains and for particular cultural processes” (Gee & Green, 1998, p. 124). And “the dynamic process involved

in constructing a cultural model can be seen if we consider how notions of ‘coffee’ have changed in the last decade” (Gee & Green, p. 124). The idea that the cultural model is constantly changing strikes a chord with the key assumption of the discursive approach, but the socio-cultural perspective indicates that the socio-culturally informed “cultural model” perspective needs to design research that incorporates an empirical task of examining changes over time.

Both approaches to studying culture by focusing on cultural model and script—a socio-cultural perspective or cognitive anthropological—tend to emphasize the importance of cultural models/scripts as the researcher’s pre-established object for investigation. The discursive approach differs on this ground. Evaluating my analysis presented in this chapter, I am not suggesting that those participants did not learn the norms and routines of the camp because of the lack of a cultural model (or script) relevant to the context of the camp. Neither would I suggest that the interaction in the interview is devoid of the cultural model. I question how the cultural model is generated and by whom. The difference in approach between discourse analysis and the other research traditions I referred to is epistemic. This epistemic stance leads to another aspect of discourse analysis regarding how to treat the context of the research.

Within the discursive psychological community, to what extent does the analysis presume and take in and foreground the context and any other available information beyond what is represented in the transcripts? Some are more vigilant about the importation of the context and other ethnographic information and argue that the analysis should refrain from considering a larger context and the circumstances. However, I would say that the context of the interview as well as the history in which those British men in captivity endured a deprived and extreme condition and were subjected to forced labor is important. Within the discourse analytic community, including that of ethnomethodological and conversation analytic orientations, there is an ongoing debate about what constitutes the context and to what extent the analysis takes it into consideration (Billig, 1999a, 1999b; Schegloff, 1997, 1999; Wetherell, 1998). The debate allows me to nestle my analysis in a spectrum of positions, whether the analysis should look at only the utterances or at the immediate context of the interviews as a background. In addition, the other end of the spectrum

might have a view/position that the context and history of the events involving this case of Anglo-Japanese reconciliation over World War II should be foregrounded. If those men had been made familiar with a rice diet as the norm of the Japanese diet and that the diet they were exposed to was inevitable under the time of war, would their life in the prison camp be remembered differently? Although discursive psychologists would not pose such a question, as it is beyond their remit of studying culture as being a topic of concern of the participants, some linguists and cognitive/psychological anthropologists would find this issue of intercultural communication quite important. In the following, I review the alternative approach to studying culture-related phenomena for a cultural script or cultural model.

### **Future Directions: Implications for Discourse in Culture and Psychology**

Studies of culture and cross-cultural communication have traditionally concentrated on classifying and interpreting features of data taken from a particular culture. The researcher then puts forward a universal model, script, or set of explanations of the culture through his or her theorizing cultural phenomena and the application of researcher’s criteria and categories in abstracted cultural models or cultural scripts. In contrast, the discursive approach commits to explicating locally produced and situated meaning in the making—illustrating the ways in which members handle cultural issues and establish their significance interactionally. The discursive approach employed in this analysis provides a viable tool, as it makes visible the very moment-by-moment process in talk where people’s cultural understanding and knowledge are displayed, shared, and established as relevant. Membership categories such as rice are discursive resources used to achieve social actions of accountability of the past in social practices of reconciliation and other socially organized sense-making activities.

I suggest that the discourse analysis produces a theoretical critique to a notion of culture and its methodological orientation regarding how to study culture. Also pertinent is culture and its role in psychological research. Culture demonstrated in the discourse analysis in this chapter is treated as a topic for the participants (i.e., the veterans and the research interviewer); cultural difference and intercultural understanding is central to discursive reconciliation—the argument I put forward is that reconciliation is not a static concept in which

opposing, multiple views are unified and harmonized, and differences between persons are to be extinguished. In talking about rice, the British veteran participants' views on rice as a cultural issue at the time of their captivity in a Japanese prison camp as a POW is brought off as a relevant topic of concern, rather than as a cultural script, so as to iron out and erase differences between two national groups.

In the remaining section, as I draw this chapter to a close, I wish to address far-reaching implications and unresolved challenges and issues for studying culture in psychology and offer a call for a special and, if possible, concerted effort to advance the discourse-based methodology. It is becoming clear that culture has “the constructive openness in using it as an intellectual catalyst in psychology continues” (Valsiner, 2009, p. 7). Despite many breakthroughs in recent years in psychology and other social sciences, understanding culture in psychological phenomena continues to pose challenges to psychologists and researchers alike. The discursive approach acknowledges culture as a dynamic, unstable category for the interlocutors as it is in the social interaction where the meaning of being in a given culture gets nominated, accepted/disagreed, and negotiated to reach a consensus (albeit it is not permanently settled). This implies that the research on culture in psychology is fundamentally designed to be impossible because of “[t]he Bearable Vagueness of Culture” (Valsiner, 2009, p. 7). The research and the researcher's position and his/her value system affect the way the research questions are phrased around the issues of culture. Culture then seems to be inflected in the inception of the research as “the projection of social values into the term—*culture is not a neutral term*” (Valsiner, 2007, p. 7). Research on culture in psychology therefore is a value-laden, moral project of the academics (*see* a similar argument in Brinkmann, 2006, 2009).

Following the above, it may be fair to say that our quest for methodology, whether via discourse or otherwise, continues. One far-researching challenge I see at present is how to approach discourse beyond the research object. The metaphor river might better describe our relationship to discourse, which moves and has some properties, patterns, and rules so that we can make them visible and therefore be able to describe them. Yet, the minute we capture the phenomena, it becomes already obsolete, as the experience we capture is in irreversible time (Sato & Valsiner, 2010). How can we come to understand a

phenomenon in duration while the same phenomenon is constantly in motion and defies the notion of stability and permanence?

To understand any experience such as the POW's experience of captivity and post-war experience of struggle and reconciliation over decades in this chapter, it is imperative for the researcher to sensitize himself/herself to different conceptions of time and to consider a methodology that uses an account of transformation of the British veterans. The idea that the cultural model is constantly changing (like a river) resonates with the key assumption of the discursive psychological approach to discourse analysis. Furthermore, the socio-culturally informed “cultural model/script” perspective seems to require a research design that incorporates an examination of changes over time. But what interval of time is appropriate to be able to observe changes as discernable and significant to the researcher? The decision over a research time has been somewhat underexplored by the socio-cultural and cross-cultural psychologists as much as the discursive psychologist tends to see instances of turn-taking and overlooks a longer time frame. Culture might be considered as the ecology in which psychological phenomena such as people's transformative experiences can be studied in terms of a dynamic flow of meanings.

## Appendix

[	Overlap begins
↑↓	Vertical arrows precede marked pitch movement, over and above normal rhythm of speech.
Underlining	Signals vocal emphasis
°I know it°	“degree” signs enclose obviously quieter speech
( )	Inaudible, indecipherable utterance, uncertain hearing
(0.4)	Pause (in seconds and/or tenths of a second)
(.)	A micropause, hearable but too short to measure.
((text))	Additional comments from the transcriber, e.g., gesture, context or intonation, comments by the transcriber

(Continued)

she wa::nted	Prolonged syllable or sound stretch
hhh	audible aspiration or laughter
.hhh	audible inhalation
bu-u-	hyphens mark a cut-off of the preceding sound
>he said<	“greater than” and “lesser than” signs enclose speeded-up talk.
<he said>	the other way round of the sings enclose slower talk.
solid.= We said	latched utterance (no interval between them)
Sto(h)p i(h)t.	Laughter within speech is signaled by h’s in parentheses, audible aspiration within a word

## Note

The transcription convention used in this paper has been developed by Gail JEFFERSON for the purposes of conversation analysis (see ATKINSON & HERITAGE 1984). The exact transcription notation employed in the extracts is listed in the appendix.

## Social Representations As Anthropology of Culture

Ivana Marková

### Abstract

The Theory of Social Representations studies formation and transformation of meanings, knowledge, beliefs, and actions of complex social phenomena like democracy, human rights, or mental illness, in and through communication and culture. This chapter examines the nature of interdependence between social representing, communication, and culture. It first explains differences between mental, collective, and social representations with respect to culture and language. It then focuses on two meanings of social representing: first, on representations as a theory of social knowledge and second, representations as social and cultural phenomena and as interventions in social practices. Rationality of social representations is based on diverse modalities of knowing and believing shared by groups and communities; it is derived from historically and culturally established common sense. This perspective justifies the claim that social representations should be treated as anthropology of contemporary culture. Finally, the chapter discusses main concepts linking social representations, language, and culture.

**Keywords:** two meanings of social representations; rationality of social representations; polyphasia in knowing, believing and communicating; figures, metaphors and myths; communicative and cultural themata.

In this chapter we explore interdependencies between social representing, language, communication, and culture. In contrast to individual representations, social representations are dynamic phenomena that are embedded in culture and formed and transformed in and through language and communication. The researchers of social representing aim to understand how citizens think, feel about, and act on phenomena that are in the center of societal, group, and individual interests and discourses, be they political, health-related, environmental, or otherwise. Such phenomena pose significant challenges for social psychology generally and social representing specifically. Their understanding cannot be fitted within narrow and static frameworks, which still dominate large parts of social sciences. Instead, the study of social

phenomena requires researchers' and practitioners' creativity in broadening and deepening the scope of their disciplines. This involves a scholarly interest in the ways in which traditions and novel ideas enrich each other, in the ability to understand how the relatively stable and new phenomena struggle for dominance and transform one another and how these tensions and conflicts are reflected in thought and language. The Theory of Social Representations, we shall argue here, provides researchers and practitioners with the means of coping with such challenges and so ensures the credibility of social psychology as a scientific discipline.

Because the concepts of "representation" and "representing" are used in different fields of social sciences and psychology, the study of social representing must dispel confusions between social and

individual representations, the problem of rationality and irrationality, and misunderstandings of meanings of concepts linking social representing with cultural anthropology. Such issues also pose challenges for social psychology as a social scientific discipline: Can we make it theoretically convincing and useful in practical interventions?

## **Representation and Culture**

During its long history in European scholarship, the meaning of representation has undergone considerable changes and diversification. Today, there are three main meanings of representation in human and social sciences and in philosophy. They stem from diverse epistemological traditions, address different levels of analysis, and imply contrasting relations with respect to culture and language.

### ***Mental Representation, Culture, and Language***

The first meaning refers to mental representations. It has been associated, at least since the seventeenth century with philosophers René Descartes and John Locke, with glorification of the cognition of the individual and with mirroring of the objective reality. According to this tradition, the self's cognition is the only source of certain knowledge or representation of reality.

The concept of mental representation as a mirror of objective reality has nothing to do with culture. The proponents of this perspective attribute any mistaken representations to the influence of other people and, indeed, of culture. As Descartes (1637/1985) put it, true knowledge cannot be pursued by an "example and custom." Whereas Descartes did not say much about language, the philosopher John Locke (1690/1975) argued that the perfection of knowledge could be hindered or facilitated by incorrect or correct use of words. Although views of these philosophers were highly original in the context of philosophy and science of the seventeenth century, they have become a hindrance in social sciences of the twenty-first century. Their variations with respect to representations, culture, and language still play a significant role in contemporary cognitive sciences and in philosophical traditions based on foundational epistemology (for criticism of foundational epistemology, see Rorty, 1980; Taylor, 1995). Reflecting on views of foundational philosophy, the anthropologist Gellner (1998, p. 3) characterizes them by saying: "We discover truth alone, we err in groups." In his

influential book *Reason and Culture*, Gellner (1992) claims that human reason is innate and universal and that it exists independently of culture. On the one hand, it can be argued that this idea expresses an essential presupposition that all humans have the same potential for rationality and for the development of intelligence and so that it mitigates racism. Gellner insists that culture and common sense knowledge hinders this universal human potential: "reason is latent in us all," but "most cultures fail to promote it" (Gellner, 1992, p. 53). On the other hand, we shall see later, to ignore culture in the growth of human intelligence leads to a paradox: any human individual always belongs to one culture or other, and it remains questionable what it could possibly mean to claim that reason can be explored independently of culture or that culture fails to promote reason.

### ***Collective Representation, Culture, and Language***

A different meaning of representation was held by the sociologist Emile Durkheim who, despite remaining philosophically within the framework of Descartes and Kant, dramatically altered the concept of representation. First, Durkheim (1898) sharply distinguished between individual and collective representations. Individual representations are of physiological and neurological nature and do not have much to do with knowledge. In contrast, collective representations do not originate in single minds but arise directly from social structures. They are generated in social life and in social groups, institutions, and cultures. For Durkheim, representing referred to various forms of thinking—whether scientific, religious, social, or ideological—rather than to specifically defined objects. Such meaning was fully in agreement with the French use of the word representation in arts, literature, and daily discourse as well as in social sciences.

Collective representations are social facts, and as such, they form the basis of all understanding, knowledge, and logic. Durkheim's ambition was to develop the idea of collective representations as a theory of sociological knowledge. Being social facts, collective representations impose an irresistible pressure on individuals who yield to their coercion, internalize them, and so perpetuate specific forms of thinking, feeling and acting. For something to be knowledge, it must be stable. Durkheim held the position that representations change very slowly during the historical journey of mankind from

religion to science and from less to more adequate representations.

In Durkheim's time, social and cultural phenomena were understood as intertwined and Durkheim's concept of collective representations formed an interface between culture and society; he used the term social both for social and cultural systems. Representations included religion, normative constraints of society, moral orders, social solidarity, as well as systems of beliefs and knowledge. Being social facts, collective representations are external to individuals who acquire them through internalization. Language, too, is a social fact. It circulates in society, forms the individual's social environment, and imposes itself on the individual. When the individual acquires language, he/she adopts the whole system of social thoughts, their classifications, and evaluations. Words fix ideas and transmit them from generation to generation. Therefore, language is a social thing (Durkheim, 1912/2001; Marková, 2003/2005).

### ***Social Representations, Culture, and Language***

Having considered relations between mental and collective representations with respect to culture and language, in the rest of this chapter we turn to social representations.

Building on the ideas of Durkheim and Piaget, Serge Moscovici has proposed an original Theory of Social Representations and developed it, both conceptually and empirically, in *La Psychanalyse: Son Image et Son Public* (Moscovici, 1961/76). This book was published in English as *Psychoanalysis: Its Image and Its Public* (2008). This classic explores transformations of professional and scientific knowledge of psychoanalysis into everyday thinking and discourse of various social groups, and the mass media reporting, in a specific socio-political culture in the late 1950s in France. But we need to make a general point: it would be a mistake to understand the transformation of professional and scientific knowledge into everyday thinking as a naïve form of thinking and developing simplified lay theories. Instead, these transformations into common sense thinking and knowledge are accomplished and enriched through different means of communication and images; they involve arguments based on trust and distrust of others, collective memories, conscious and unconscious beliefs, myths and metaphors, fears and hopes. Following the publication of *La Psychanalyse*, social representing has been studied

in various social, political, health-related, and other kinds of phenomena preoccupying the minds and discourses of general public (for a comprehensive review, see Wagner & Hayes, 2005).

### **THE DYNAMIC NATURE OF SOCIAL REPRESENTING**

Moscovici's social representations, in contrast to Durkheim's collective representations, are dynamic: they arise and are maintained and transformed through interaction and different forms of communication between the established social structures—for example, traditions, on the one hand, and the individuals' and groups' mental and social activities and social practices on the other. From the inception of the theory, language and communication have been vital features of representing, and this is already expressed in *La Psychanalyse*. As Moscovici explains, a representation is always directed at others: it speaks through pointing something to someone; it communicates through mediating meanings and symbols to someone. Representing and communicating is jointly generated by human subjects and groups that have different histories and experience. Their interaction does not follow the Durkheimian path of the progress from less adequate (e.g., religious representations) to more adequate (e.g., scientific representations). Arising in traditions, social experience, and communication, social representations are discontinuous; emotions, contents of beliefs, and images are sensitive to socio-cultural changes and to tensions and preferences of the *Zeitgeist*.

In contrast to collective representations that refer to various ideas and forms of thinking, social representations refer to specific objects or specific social phenomena. For example, the way citizens think, feel, and act (or represent) democracy depends on their historical and cultural experience as well as on their knowledge of, beliefs, and images about contemporary socio-political circumstances as well as of their expectations of the future. What is important to emphasize, however, is that it is not the object that is social. On the contrary, social representations arise from the fact that objects or phenomena are socially shared (Moscovici, 1988; Wagner, 1998; Wagner et al., 1999).

Unlike Durkheim's time, contemporary meanings of the notions "social" and "cultural" are not synonyms, although the boundaries between them are not always clear. The notion social ranges from usages in social sciences and their subdisciplines (e.g.,

economics, sociology, social psychology, politics, etc.) to professional fields like social security, health services, social work and social practices, among many others. Numerous attempts and failures to define culture as an entity point to inherent difficulties of this notion, and these difficulties also transpose themselves with respect to their relations to social representations (Duveen, 2007). These problems are raised by Jodelet (2002) in her article, "Social Representations in the Field of Culture." The author draws attention to the changing relations between psychology, anthropology, and culture in the course of the last two centuries, arising both from diversifications within human and social sciences and from the more recent cognitive revolution, among other factors (*see also* Valsiner, 2003).

During the five decades after the publication of *La Psychanalyse*, the explorations of social representations have become widely differentiated. A large volume of research has been carried out in different social and cultural conditions. Individual researchers have subscribed to divergent underlying epistemologies, and numerous studies have been performed on different topics, contents, and structures. As a result, some researchers (e.g., Wagner et al., 1999; Wagner & Hayes, 2005; Palmonari & Emiliani, 2009) speak about social representational approaches—or schools of social representations—rather than about a single theory. For example, these authors refer to the Aix-en-Provence school based on structuralistic approach that emphasizes central nucleus and periphery of representations (e.g., Abric, 1994a, 2001; Flament, 1994a, 1994b; Guimelli, 1994), whereas the Genevean school of Doise specifies organizing principles of social representations (Doise, 1985, 1986). Jodelet's approach is anthropological and cultural (e.g., Jodelet, 1989/1991, 2002, 2006a, 2008); Wagner, Duveen, and their collaborators (Wagner et al., 1999, 2000; Duveen, 2007) bring to attention the role of social construction and discourse; and Valsiner draws on the role of semiotic mediation and social experience (e.g., Valsiner, 2003). In addition, one can hardly discuss social representations and culture without foregrounding language, communication, and, more specifically, dialogicality as a major feature of the relation between social representations and culture (Marková, 2003/2005; Valsiner, 2003).

Within these diversities in focus, we can nevertheless distinguish between two fundamental meanings of the concept of social representations that underlie all approaches (Jodelet, 1989/1991;

Duveen, 2002; Marková, 2003/2003). First, the Theory of Social Representations is a theory of social knowledge. As such, it establishes networks of concepts and figurative schemes that are generated in and through tradition, common sense, daily knowledge, and communication and that are shared by particular groups and communities. The theory of social knowledge enables the researcher to define research problems. Second, social representations or social representing refers to concrete social phenomena and to forms of apprehending and creating social realities in and through communication, experience, social practices, and interventions (Jodelet, 2006a; in press) and semiotic mediation (Valsiner, 2003). This also enables the researcher to understand problems posed by the theory and to attempt their answers. Let us consider these two meanings in some detail.

#### **SOCIAL REPRESENTATIONS AS A THEORY OF SOCIAL KNOWLEDGE**

There is a fundamental difference between what is considered by knowledge in cognitive sciences and in the Theory of Social Representations. In the former, building blocks of epistemologies are knowledge and justified beliefs arising from the cognition of the individual. In parallel with this, in social sciences, epistemologies are often considered as paths from beliefs to knowledge, implying a gradual progress in intellectual development (for a historical account of these ideas since ancient times, *see* Lovejoy, 1936). Such was the position, for example, of Jean Piaget whose epistemology focused on transformations of less adequate patterns of thought to more adequate ones. In his studies of moral development, Piaget (1932) conceptualized this path as a gradual transformation of beliefs into knowledge or as a transformation of the morality of constraint to the morality of cooperation. Asymmetric relations—say, between a child and an adult—imply constraint and, therefore, only the possibility of belief or compliance resulting from the authority of the source. In contrast, symmetric relations in terms of social status and influence between individuals allow for co-operation and, therefore, for the mutual construction of knowledge (Duveen, 2002). As we have already seen, Durkheim's ideas concerning the transformation of less adequate to more adequate collective representations throughout human history take a similar path. The Piagetian and Durkheimian way of progress in the intellectual development relies on classical—that is, the Kantian form of—rationality.

This means that the action of reason and of intellect excludes partly or totally those actions based on motives, desires, or emotions—that is, on irrational activities (Kant, 1788/1873). The Piagetian rationality (1970), like the Kantian rationality, is universal. All children pass through the stages of operational development, and through these stages they acquire, step by step, higher forms of intelligence.

Although informed and inspired by Durkheim and Piaget, Moscovici takes a different route:

The proper domain of our discipline is the study of cultural processes which are responsible for the organization of knowledge in a society . . . In parallel more attention should be paid to language which has not until now been thought of as an area of study closely related to social psychology.

(Moscovici, 1972/2000, pp. 55–56)

But how can one link, epistemologically, culture, language, and knowledge, in and through social representations?

#### *From Taxonomic Psychology of the Ego-Object to Representing Through the Ego–Alter–Object*

Moscovici's (1970, 1972/2000) analysis and criticism of what he called a "taxonomic" social psychology is instructive. It will lead us to overcoming problems of taxonomic psychology and to understanding the fundamentally important link between culture, language and knowledge. The study of the relation between the Ego and the Object in social psychology refers to no more than classification—or taxonomies—of stimuli or variables. For example, in taxonomic social psychology that is undertaken in numerous laboratory experiments, the Ego is treated (or classified) as undifferentiated and undefined; it is a subject without culture. The aim of such experiments is to discover how social stimuli affect classes of variables like perception, attitudes, judgment, and so on. But humans live in societies and are differentiated from one another in many ways; they live in cultures and they communicate. Therefore, "others" are not "other subjects" with whom humans compare themselves—for example, as in Festinger's (1954) social comparison theory—in order to reduce uncertainty with respect to what is right and wrong, or good or bad; neither are they subjects whose presence facilitates the Ego's activities, as in Zajonc's (1965) social facilitation theory. Instead, the Ego and the Alter communicate and jointly generate knowledge and social representations. Therefore, we must substitute the dyad

Ego–Object, in which the Ego is taxonomically undifferentiated, by the triad Ego–Alter–Object. Once we introduce the Ego–Alter, we are immediately in the realm of language, communication, and culture. The Ego–Alter are not undifferentiated and undetermined subjects; they interact, communicate, and speak. As it is already clear in *La Psychanalyse*, representing takes place in communication. If knowledge is generated neither by the Ego nor by the Alter alone, but jointly by the Ego–Alter, then the minimum unit in the formation of knowledge cannot be expressed as a relation between the Ego–Object but as a triadic relation, the Ego–Alter–Object (Moscovici, 1970, 1972/2000, 1984; Bauer & Gaskell, 1999; Marková, 2003/2005; Jesuino, 2009). But who is it that stands behind these abstract notions, the "Ego" and the "Alter?" Although in this generalized model the "Ego–Alter" could mean an interaction between any kind of the self and other(s), in concrete and contextualized dialogical situations, there is always the specific Ego and the specific Alter (or the self–other[s])—for example, "I–you," "minority–majority," "I–group," "group–another group," "I–culture," and so on. Indeed, these specific Ego and Alter are embedded in other dyadic Ego–Alter interactions. For example, a mother–child interaction (Ego–Alter) takes place in a specific culture; this means that we can conceptualize this mother–child dyad as the Ego within a particular culture (Alter), or that this same dyad can be conceived as the Ego within a specific social group (Alter), and so on. Or a conversation between two individuals is not just an exchange of words between I and you that takes place in a specific here-and-now, but it has its past, present, and future. Moreover, parents, leaders of political groups, friends, the "generalized other," and so forth, speak through the mouth of each conversational partner. All these social and language-based interdependencies make the dyadic relations between the Ego–Alter dynamic, with implicit and explicit meanings affecting their discourses and contributing to transformation of representations in all dialogical participants. They all contribute to different dialogical perspectives and create tensions among them.

Language and communication as a point of departure in epistemology of social representations has yet another implication: to communicate means to take diverse routes, leading once to intersubjective understanding between individuals or between groups or cultures, once to conflict; to negotiation, to compromise, or to a firm self-positioning.

Therefore, communication does not necessarily lead to a better understanding and “true knowledge.” In contrast to the ascent theory of knowledge toward science and true knowledge that was adopted by Durkheim and Piaget, the Theory of Social Representations does not presuppose progress toward higher forms of knowledge or toward more adequate representations. Instead, it presupposes transformation of one kind of knowledge into another one; transformation of different kinds of knowledge is pertinent to specific socio-historical and cultural conditions. This is why the triangularity of the Ego–Alter–Object forms the basis of linking language and communication, culture, and social representation.

#### THE DIALOGICALITY OF THE EGO–ALTER IN MIKHAIL BAKHTIN

We can arrive at the triangularity of the Ego–Alter–Object from a different theoretical perspective, like the dialogicality of the Ego–Alter in Voloshinov’s (1929/1973) and Bakhtin’s (1981) approaches to language and communication. For these scholars of the early part of the twentieth century, alike, social knowledge and social reality is jointly created by the Ego–Alter. In Voloshinov’s and Bakhtin’s work, too, the Ego and Alter dialogically co-constitute one another in a dynamic figure-ground set-up. I am using the term *dialogicality* to characterize the fundamental capacity of the Ego to conceive, create, and communicate about social realities in terms of the Alter. What the human individual has become through the work of the past, and what his/her prospects are for the future, results from dialogicality (Marková, 2003/2005).

To my mind, these two epistemological approaches, the one stemming from Moscovici and the other arising from Bakhtin (1981, 1979/1986), enrich one another and provide potential, in the Theory of Social Representations, for a more focused study of relations between knowing, believing, language, and speech. In both epistemologies, the Ego and the Alter transform one another’s representations in and through dialogical and symbolic interactions. The concept of transformation in both approaches is characterized by tension and by multifaceted and heterogeneous relationships between the Ego and Alter. There can be no single mind without other minds: they dialogically co-constitute one another. Neither for Bakhtin nor for Moscovici can dialogue be neutral. Neutrality can be only artificially imposed but daily speech is

always judgmental, evaluative, and orientated to creating new meanings.

Bakhtin expressed this idea pertinently in his analysis of Dostoyevsky’s novels. Consciousness must be in interaction with another consciousness to achieve its proper existence: “justification cannot be *self*-justification, recognition cannot be *self*-recognition. I receive my name from others, and it exists for others (self-nomination is imposture)” (Bakhtin, 1984, pp. 287–288).

#### *Social Representations As Phenomena and As Interventions*

The second meaning of social representations refers to the ways in which humans apprehend, interact with, and create their social reality. As they attempt to orientate themselves and create meanings of events in their lives, humans form representations of complex social phenomena that are in the center of social life and social disputes, whether they are political, ecological, or health- or community-related. Resources for generating social representations are phenomena that disrupt routines, turn them upside down, and call for action. Specifically, firm or irresistible beliefs (*see below*) concerning, say, democracy, management of banks, social responsibility, mental illness, distrust, freedom of speech, and so forth, are sources of action, and they instigate social change. Complex phenomena obtain their specific and multileveled meanings in interdependence with culture and in relation to other representations within that culture and community. For example, the representation of freedom of speech would be related to other social representations and actions within that particular culture, like political protests against terrorism, expressions of abuse of the dominant political Party, censorship of any dissent, of the media, and the like. Thus, freedom of speech would have different meanings in relation to different semiotic networks and social phenomena. Two points should be mentioned as fundamental with respect to culture: social representations are phenomena in the making and representing can take part of action and intervention.

#### SOCIAL REPRESENTATIONS ARE PHENOMENA IN THE MAKING

In emphasizing relationships between social representations and communication, Moscovici (Moscovici & Marková, 1998, pp. 393–394) draws attention to viewing them “in the making, not as

already made.” This characteristic is essential both historically and developmentally. Social representations are not quiet things (Howarth, 2006); being phenomena in the making, social representations are formed and transformed in and through asymmetries, conflict, discontinuities, and tension. Representing, like communication, requires commitment. For example, one cannot study influence and innovation processes between majorities and minorities by removing tension and engagement: “Whether in conversation or in influence processes, one deals with change, with negotiation between two opposing partners—one cannot exist without the other” (Moscovici & Marková, 1998, p. 394).

Interdependencies between communication and different social groups can be illustrated by Duveen’s analysis of communication systems in Moscovici’s (1961/1976) *La Psychanalyse: Son Image et Son Public*. Specifically, Duveen (2008) analyzes Moscovici’s thoughts about social groups in relation to different communicative systems through content analysis of the French press. Focusing on different types of social groups in relation to the three genres of communication—that is, diffusion, propagation, and propaganda—Duveen identifies specific forms of affiliation corresponding to each communicative genre and consequently also to different representations of the members of the in-group and the out-group in each instance. He characterizes diffusion as the voluntary association of the members of in-group who possess a skeptical intelligence, whereas the out-group embraces forms of dogmatism. Duveen describes this kind of group in terms of sympathy. Propagation, on the other hand, refers to groups in which a central authority sets limits to creativity or intellectual curiosity. The out-group does not share the belief in the legitimacy of such authority or the relevant ideology. Duveen calls this kind of group a communion. Finally, propaganda is used by groups whose political commitment and organization defines the way of conduct of in-group. In contrast, the out-group is either committed to a different kind of ideology or simply does not share the ideology of the in-group. Duveen characterizes such group in terms of solidarity. His analysis shows that commitment to a particular kind of ideology elicits a particular kind of communicative genre. It illustrates that communicative genres of groups are part of their particular cultures and that, therefore, representing, like communication, is never a neutral exchange of information. Moreover, if we attempted to remove tension from communication, “it would

become a kind of dead psychology” (Moscovici & Marková, 1998, p. 394).

Thus we arrive at an important feature of representations as phenomena in the making: Social representations are structured semiotic mediators that are constantly in the process of innovation, created in and through conflict and tension (Valsiner, 2003). In experiencing tension, humans attempt to construct a predictable world out of great diversity and regulate their conduct. Referring to Moscovici’s back-and-forth movement between experiencing and representing Valsiner (2003, p. 73) concludes: “representing is needed for experiencing, while experiencing leads to new forms of representing.”

#### REPRESENTING AS ACTION AND INTERVENTION

Another feature of representing, Valsiner (2003) maintains, is its implication for action and social change, or its function as intervention. Jodelet (in press) characterizes intervention as a practice involved in an “explicit and intentional project of a deliberate act of change.” Intervention encourages transformation of knowledge and behavior of individuals and groups toward better standards of living. Jodelet specifies three forms of activities interconnecting social representations and intervention: first, social representations can modify thinking of individuals or groups about a practical issue; second, they can transform practices, and these, in turn, can lead to transformation of representations; and finally, intervention of social representations is intentionally directed at producing changes in activities of individuals and groups concerned.

The relation between intervention practices and social representations is itself an object of research practice (Abric, 1994b), in particular in health research (Jodelet, 2006a; Jovchelovitch & Gervais, 1999; Morin, 2004) or in education (Garnier & Rouquette, 2000). For example, intervention should allow for exchanges between traditional and new forms of knowledge (Quintanilla, Herrera, & Veloz, 2005), the preservation of culture, and its negotiation with emerging alternatives in society (Jodelet, 2006b). Doise (2002) regards social representations of human rights as interventions into social relations, whether these concern relations between individuals and groups, or individuals and institutions. Human rights must be clearly defined precisely because they are interventions of one kind or other.

## CULTURE AND SOCIAL REPRESENTATIONS ARE RELATIONAL PHENOMENA

Referring to two ways of studying social representations (which basically correspond to the two main meanings as discussed in this section), Jodelet (1989/91) emphasizes that when we focus on positions held by individuals and groups with respect to objects, representations are treated as structured fields. By “structured fields,” she means relations between contents contributed by subjects (or the Ego and Alter) and principles that organize contents, like cultural schemata, norms, and so forth. This perspective draws attention, again, to the relation between social representations and culture. I suggest that this does not mean to consider a social representation on the one hand, and culture as its context on the other hand, and to ask how they are related. Equally, it would be wrong to consider culture as a container within which one can identify a set of specific social representations.

Jodelet’s concept of a structured field, I suggest, can be viewed as something like the concept of an electromagnetic field in physics of relativity. Electromagnetic field is a totality of forces that exists “between the two charges and not the charges themselves, which is essential for an understanding of their action” (Einstein & Infeld, 1938/1961, p. 151). Thus “force between particles,” rather than “behavior of single entities” defines the field. Equally, we cannot understand the specificity of the Theory of Social Representations without taking on the concept of the force of interaction that binds elements to one another as complements, rather than as behavior of single entities (individuals, groups) that come to interact with one another. Taking Jodelet’s concept of the structured field, individuals and groups are not undifferentiated subjects as in the taxonomic psychology (*see above*), but their meanings are defined in and through concrete society or culture. Their internal interaction (in contrast to external interaction; e.g., in the analysis of variance) constitutes a new reality: the interacting components define one another as complements, whether this involves institutions vis-à-vis environment, institutions vis-à-vis groups, one group vis-à-vis another group, or social representation vis-à-vis culture (*see above*, the Ego–Alter). Like an electromagnetic field, the structured field of social representations is dynamic. It is open to participants’ new experiences and to social change.

There is yet another implication of the concept of structured field. Just like when speakers communicate, they select different ways of expression with respect to one another depending on their relations, status, experience, and otherwise, so when they represent a phenomenon they are in an intimate complementary relation with culture. In other words, it is not the case that the same culture would be in relation with a set of different social representations. Such a position would be something like Piaget’s mountain seen from different perspectives. In this case, the mountain remains the same, but the child’s position is different and through the growth of intellectual development, the child learns to understand this. In contrast, the relation between social representation and culture is unique. Each social with culture in a specific manner; it selects different aspects of that culture because not all aspects are relevant in the same way for each social representation. Consequently, the forces of interaction between them imply that for each representation we have a slightly different meaning of culture. If we return to communication between groups and their communicative genres, propaganda and propagation view different aspects of culture. The former places emphasis on authoritarian aspects of the culture, whereas the latter focuses on more democratic features.

We need to view forces as both constraining and stimulating. In Moscovici’s words, “society is an institution which inhibits what it stimulates. It both tempers and excites . . . increases or reduces the chances . . . and invents prohibitions together with the means of transgressing them” (Moscovici 1976, p. 149).

### **Social Representations As Anthropology of Contemporary Culture: The Case of Rationality**

Throughout his career, Serge Moscovici (e.g., 1987, 1993a, 1988/93; Moscovici & Marková, 1998, 2006) has persistently insisted that the Theory of Social Representations is—or should be treated—as anthropology of contemporary culture. Cultural anthropologists are concerned with the totality of life of social groups under study—that is, with beliefs and knowledge, myths, images, as well as with social practices in daily living. To understand these phenomena, anthropologists study them in relation to one another, like meaningful wholes, rather than as independent elements that, if need be, could either be joined together or disjoined. In the previous

section, I touched several times on the problem of rationality, culture, and social representations. This issue is significant in contemporary social sciences, and it raises specific questions in relation to social representing; therefore, in this section, I turn attention to this issue in some detail.

### ***Rationality and Irrationality in Social Sciences***

Whatever we can say about rationality and irrationality of, and within, social sciences, it is necessary to place this issue in the context of natural sciences. Since the end of the seventeenth century, natural sciences have been based on “knowledge which eliminates mystery. In contrast to Greek science it does not end in wonder but in expansion of wonder,” as says Michael Foster (1957, p. 53) in his treatise of “Myth and Philosophy.” Since the seventeenth century, natural sciences have prided themselves on being rational disciplines.

In contrast, social sciences started their scientific career as irrational disciplines. As Moscovici (1988/1993) reminds, they originated in the study of phenomena like nationalism, religion, myth, and beliefs. For example, Weber and Durkheim commenced from religion, Simmel from the relativity of values, and Marx from a kind of the Hegelian concept of historical forces. Vico, Herder, Hamann, and Humboldt were developing ideas of relativism and cultures. Other social scientists, like Le Bon, Ortega y Gasset, or McDougall, preoccupied themselves with the study of collectives and crowds in which rational individuals turned themselves into irrational beings.

Since the nineteenth century, the ideas of relativity, variability, and the evolution of species have been drawing attention to the importance of perspective-taking in the growth of knowledge. Yet perspective-taking has influenced natural sciences and social sciences differently. Natural sciences, despite the influence of theories of evolution and relativity, defined these scientific discoveries in rationalistic manner and so remained rational disciplines; in social sciences, however, we can observe a split between rationalistic and less rationalistic (or non-rationalistic) approaches.

In social sciences—specifically in anthropology and social psychology—the meaning of rationality has become a subject of keen interest. This has led to the search for universals that apply to all humans and to all cultures. Consequently, this has raised questions about the sources of relativism and

irrational beliefs. Rationality as opposed to relativism even forms titles of classic volumes like those by Wilson (1970; *Rationality*) and by Hollis and Lukes (1982; *Rationality and Relativism*). The contributors to the latter volume suggest that the problem of understanding relativism and irrational beliefs arises from the fact that different cultures, languages, and the minds of others can be understood only within their own idiosyncratic socio-historical situations, rather than universally. Can we, therefore, identify anything transcultural among humans? Does culture challenge “the very idea of a single world” (*ibid*, p. 1)? The dichotomy between the presupposition of universal rationality and questions concerning the sources of irrational beliefs as well as their rich and extensive presence in different cultures have led to the search for different forms of relativism. For example, researchers have been concerned with weak and strong forms of relativism, types of representational beliefs (convictions, persuasion, opinions), and different kinds of translation, interpretation, and explanation of beliefs.

Yet such questions can hardly be settled by academic discourses about rationality and relativism. Cultures are no longer isolated in their geographical ghettos. Therefore, Harris (2009) argues that it would be less misleading to abandon the notion of a singular rationality and speak, instead, about rationalities in the pluralistic sense. The contemporary world of societies is opened to other cultures and it set the stage for permanent situations of uncertainty moving cultures in different directions. In this situation, reason is not a private domain of the individual but it must be negotiated (Rosa & Valsiner, 2007, p. 697). A narrow rationality of the individual defined in formal terms cannot meet the world of ambiguities of the contemporary world, and it transcends not only individual reason but also a particular cultural reason. In these circumstances, judgments of what is right and wrong and what is and is not ethical guide any kinds of preferences, control the individual and social choices, and confront different reasons for choosing something rather than something else. In these confrontations, “Reason then turns into *Rationality*” (*ibid*, p. 697), giving rise to *Ethics* and to *Objectivity* that emerges in and through transformations of rules and new norms. As Rosa and Valsiner (*ibid*, p. 698) argue, “Rationality, Ethics and Objectivity” (all with capital letters) cannot be disentangled from one another. It is in this sense that we shall view rationality and social representations.

## *Reason and Cultures*

The interdependence between culture, rationality, and social representations is perhaps most clearly expressed in Moscovici's (1993a) lecture on *Razón y Culturas* (Reason and Cultures). One could say that the red thread through this lecture is an ethical concern of culture and social representations. Moscovici notes that the Cartesian approach discarding example and custom has also led to discarding culture, whether religious or profane, and substituted it by a narrow concept of rationality. However, to rationalize in this narrow way, Moscovici argues, means to ignore moral and ethical values of traditions in human histories and cultures as well as their symbolic values. He raises the question as to whether this narrow approach means that social psychology has nothing to say about arts or literature or whether this means that humans are satisfied with perceiving others, making judgments about objects, or looking for motivations of their conduct. Moscovici notes that humans have deep experiences in and through living in their cultures; they read novels, appreciate arts, listen to music, and experiment with ethical and moral values. These issues that have been neglected by social psychology are brought back to life by the Theory of Social Representations. Moscovici draws on three fundamental concepts: social representations, anthropology, and culture.

The lecture on *Razón y culturas* was written at a time when it became clear that the cognitive revolution failed to cope with complex human and social phenomena. In the late years of the twentieth century, cultural psychology gained importance because it was thought that it would solve questions of economic, educational, and political psychology as well as of child development and transformations of mental faculties in adulthood, migration, and nationalism, among others. Cultural psychology was seen as a plausible alternative to individualistic and mechanistic approaches (e.g., Bruner, 1985; Jodelet, 2002; Valsiner, 1987; 1989, 1998; Valsiner & Lawrence, 1996) in focusing on intentionality, indigenous psychologies, language and communication, and on semiotic and symbolic practices. But, Moscovici points out that even if cognitive revolution were to succeed, these phenomena could be understood only with reference to culture. But instead, as we have seen in the previous section, contemporary social psychology and anthropology are still disputing problems of rationality and the relation between universality and cultural relativism. These problems are not new.

## THREE PARADOXES OF THE INDIVIDUAL AND COLLECTIVE MENTALITY

Moscovici (1993a) identifies three historically established paradoxes with respect to individual and collective mentality; both Durkheim and Lévy-Bruhl struggled against them in their particular ways. Therefore, Theory of Social Representations, to fulfill its role as anthropology of contemporary culture, needs to address these paradoxes.

The first paradox concerns individual rationality and collective irrationality. As we saw at the beginning of this chapter, for Descartes and Locke, only the individual was rational whereas culture and language were sources of error. Yet no individual starts thinking and talking from nothing like the biblical Adam; each individual lives in a culture and in language. Durkheim acknowledged this paradox, and therefore, for him, all representations were rational beliefs; however, as mankind progressed from religion to science, some became closer to true knowledge than others. Collective representations are socially true, as Durkheim (1912/2001) states in "The Elementary Forms of Religious Life." They are founded in the nature of things and they hold to and express reality. Religions, too, express reality, and therefore, all are true in their own fashion: there are no religions that are false. All religions respond, although in different ways, to the given conditions of human existence, and this is why for Durkheim a collective representation is a rational belief. In contrast, and as Moscovici (1998a, p. 134) analyzes this question, Lévy-Bruhl showed that members of different cultures did not view rationality of social representations in the same way. He has studied throughout his life the ways of thinking of primitive cultures and tried to understand why it was not possible to explain one form of thought by another one.

The second paradox to which Moscovici refers concerns the presupposition of "the mental unity of mankind" that contradicts with the observation that local cultures are very diverse. This paradox leads to the question as to whether it is possible to find any commonalities within these diversities. It is this question that is being vehemently discussed by social scientists and particularly by social psychologists and anthropologists, as we indicated above.

The difficulty of resolving this paradox might be magnified by ancient beliefs that were clearly expressed in Darwin's assumption that all species could be placed on an upward continuum and that humans differed from animals in degree but not in kind (Lovejoy, 1936; Ingold, 2004). As Ingold

explains, for Darwin, “the evolution of species *in* nature was also an evolution *out of it*” (Ingold, 2004, p. 210, his emphasis) as the mind progressively liberated itself “from promptings of innate disposition.” This means that ancestors of humans became humans gradually, in stages, rising from primitive savages to humans, developing (in degrees) reason and language. But at what point does an animal become a human?

If no organic being excepting man had possessed any mental power, or if his powers had been of a wholly different nature from those of the lower animals, then we should never have been able to convince ourselves that our high faculties had been gradually developed. But it can be shown that there is no fundamental difference of this kind . . . yet this interval is filled up by numberless gradations . . . Differences of this kind between the highest men of the highest races and the lowest savages, are connected by the finest gradations. (Darwin, 1859/1874, p. 157)

Darwin stated that in *The Origin of Species* he aimed to show this continuous development of species toward perfection (compare this with Durkheim’s and Piaget’s ideas toward progress). Thus the idea of gradual perfection might have led to an implicit assumption that cultures could be at different stages of their development, and it seems that this assumption is implicit in the ideas of rationalists and relativists that we discussed above.

The third paradox concerns the difficulty of intergroup or intercultural communication. Moscovici notes that groups or cultures in general believe that others understand their point of view but, in fact, others are not always capable of understanding others. Groups are often closed to the perspective of other groups, and communication between groups is absent even if groups occupy the same public space. This incommunicability affirms mutual incompatibility between different social representations and diverse forms of communication, and it characterizes our present society, which consists of numerous groups with noticeable antagonistic representations. For example, Europeans can hardly understand exotic beliefs of primitive assumptions. Moscovici maintains that a question like, “What objects constitute the world around us?” cannot be answered otherwise than by specifying the framework of a particular representation to which it is pertinent. Loyalty to certain values makes groups insensitive to values of others (Geertz, 2000, p. 70). The third paradox results in incompatible implicit

or explicit ethnocentric beliefs. These beliefs, on the one hand, are based on assumptions of superiority of the own group, and at the same time, groups propagate multiculturalism.

How does the Theory of Social Representations respond to these three paradoxes? The first paradox, arising from treating the individual and group as independent entities is being resolved by treating the Ego–Alter as interdependent. The second paradox, arising from the narrow treatment of rationality, is substituted by fiduciary rationality (see below). The third paradox can be surmounted by the reflection of the group on the existing incommunicability and attempting to improve communication. Yet overcoming this paradox remains one of the challenges for social representing. In conclusion, all paradoxes arise from the difficulty to overcome the traditional epistemology based on reasoning capacities of the individual, the narrow concept of rationality, and the treatment of groups as independent categories.

### ***Fiduciary Rationality***

Interdependence between the social representation and culture of a group also makes the communication within a group preeminent above the communication with outsiders. I suggest that to understand the nature of this preeminence, we need to return to the epistemic question of rationality in the triad Ego–Alter–Object. The Ego–Alter dialogical relation within a group comes from the ethics of common sense pertaining to social representations of that group. Social representations captured by common sense within a group, Moscovici argues,

are analogous to paradigms, which, contrary to scientific paradigms, are made partly of beliefs based on trust and partly of elements of knowledge based on truth. In as much as they contain beliefs, validating them appears a long, uncertain process, since they can be neither confirmed nor disconfirmed.

(Moscovici & Marková, 2000, p. 253)

Within the epistemological triad of Ego–Alter–Object, relations between these components can take on different forms and strengths. For example, if the Ego searches for knowledge of this or that, he/she might pursue the route of own discovery and autonomous thought, focusing, within this triangularity, more strongly on the Object than on the Alter. In this case, the Ego would examine, in a step-by-step strategy, dispassionately and systematically, the object of knowledge. Dispassionate knowledge

can be expanded by new learning, or it can be suspended, resisted, or ignored. Moscovici (1993b) calls such kinds of knowledge (or beliefs) resistible.

For example, if the knower does not care about certain facts like “The Earth is not flat,” or “AIDS is caused by a virus,” then he or she might ignore, not think about, or suspend such facts and substitute them by others that appear more convincing. In a way, in such cases we can say that we possess beliefs just like other kinds of possession; if we do not need them any longer, then we can dispose of them.

Another kind of relation within the triangularity of the Ego–Alter–Object could be based on a strong relation between the Ego and Alter, whereas the relation between the Ego and Object would be treated as secondary. In this case, knowledge/beliefs can range from those that Moscovici calls irresistible to those that would function as constraints—be it compliance, conformity, or obeisance. Let us consider the latter, irresistible beliefs. Such beliefs can hardly be changed through evidence to their contrary, by facts, or by persuasion. Irresistible beliefs can lead to self-sacrifice and other-sacrifice of individuals and groups, rather than to their change. Such strong beliefs within a group are often based on trust and trustworthiness of the other. Irresistible beliefs “are like perceptual illusions: we are not a liberty to dismiss them, to have them or correct them if need be. Like many ideas, memories, or rituals, they take possession of us and are . . . independent of our reasoning” (Moscovici, 1993b, p. 50).

The rationality of these forms of relations in the epistemological triad is based not only on knowledge and justified beliefs but on the totality of human experience embedded in, and accumulated through, history and culture. It includes the struggle for social recognition, desires and their symbolic transformations, ethics and morality, myths and metaphors, judgments and evaluations of the self/other relations, and objects of knowledge. It is the epistemology of living experience and of daily thinking rooted in common sense, which is being transformed into new social representations when conditions for them are obtained.

In his analysis of *Razón y culturas*, Moscovici (1993a) argues that what makes one group distinguishable from another one is “the act of privileging a type of representation and as a result, a form of communication” with other members of that group. He calls this kind of group loyalty the *fiduciary rationality*. As I understand it, fiduciary rationality is a form of dependency among group members

that arise from within, from trust and loyalty, rather than from an outside pressure. Fiduciary rationality functions like irresistible beliefs. It is rooted within the group and it binds groups together. Rationality of the common sense, too, is based on fiduciary rationality.

We need to view social representations of various dependencies within a group—for example, rules and norms of acting and constraints of group members and solidarity and sympathy as established in and through tradition, history, and culture. They are present already in informal organizations that develop from within the group, before any more formal organization is formed. Similarly, communication is based on an inner contract among the in-group members. A contract is an ethical requirement for communication (Rommetveit, 1974), and we can say with Mikhail Bakhtin that there is no *alibi* for communication.

### **Concepts Relating Social Representations, Language, and Culture in Empirical Research**

The term culture permeates a great deal of empirical research on social representations—particularly the research that aims to separate itself from narrow rationalistic and cognitive perspectives. This research examines diverse topics ranging from political, ideological, and historical issues to mental health, illness, social services, and child development, among others. As one would expect, in many studies the terms social representations and culture are rather nonspecific and could be easily replaced by other terms like opinions, attitudes, stereotypes, or prejudice in the case of the former, and context, situation, or community in the case of the latter. In view of this, in this section I focus only on those studies that theoretically enrich this growing field addressing relations among culture, language and communication, and social representations. To do this, I focus on three fundamental concepts of the Theory of Social Representations that make such contributions—specifically on cognitive polyphasia; figures and metaphors; and communicative and cultural themata. These concepts, we shall see, are not mutually exclusive or exhaustive, and I can do no more than to draw attention to them.

### ***Cognitive Polyphasia and Heterogeneity in Thinking and Dialogue***

One of the basic features of the Theory of Social Representations from the beginning has been the

focus on dynamic co-existence of distinct modalities of thinking and communication in common sense knowledge (Moscovici, 2008). These distinct and rich modalities of thinking and communicating co-exist in communicative actions, contribute to viewing the issue in question from different perspectives, and so enable formulation of diverse arguments. They originate from knowledge and beliefs shared by social groups, and they have been established through their cultural and historical experiences. Such communication-centered thinking is directional and controversial, although it checks and validates its normative coherence (Moscovici, 2008, p. 168). It forces humans to take up their own positions in social situations and defend them; it is the thinking that judges, evaluates, criticizes, and makes proposals for action. Moscovici coined these diverse modalities of thinking and communicating as *cognitive polyphasia*.

It is not that humans change their ways of thinking according to their mood, temporary preferences, or personality characteristics. The concept of cognitive polyphasia is inherently dialogical. The divergent modalities of thinking are articulated as specific Ego–Alter communications. This point is important: We relate to others dialogically, which means that we express our thoughts as it is specifically pertinent with respect to this or that Alter. Whereas a Cartesian scholar would expect that the thought of the individual should be rigorous and should follow an identical logical route from one moment to the next, in the Ego–Alter dialogical communication, different cognitive and emotional goals employ heterogeneous modes of thinking. To think means to pursue diverse mental routes. These may range from scientific to religious, from literal meanings to metaphoric interpretations, from jokes to formal expressions, and so on. They are suited to and articulated in different contexts of which they are parts. Speakers create links to others' communications, anticipating their responses, reactions, and feelings. Moreover, the speakers' dialogues are also filled with ideas of absent others; in communication, speakers express commitment and loyalties to views of those who are not physically present in dialogue or they object to, reject, or contest opinions of absent "others."

Probably no other work has provided a deeper insight into cognitive polyphasia than Jodelet's (1989/1991) research on social representations of madness. We can see here that cognitive polyphasia dominates different kinds of communication

among villagers, and Jodelet examines in these contexts the production of social representations from communication, different modes of thinking, and knowledge. She shows that cognitive polyphasia emerges from the villagers' necessity of coping with fear of mental illness and enabling villagers to live together with patients. At one level, most villagers do not believe in medical dangers coming from mental patients. They know that mental illness is not contagious and that the lodger with mental illness does not transmit germs or microbes as in the case of tuberculosis. At another level they believe in contamination, but these beliefs remain unspecified because they are difficult to articulate. Beliefs take form of folk-fantasies, superstition, and convictions of a magic power. Jodelet emphasizes the persistence and forms of dual appeal in speech and actions of villagers, ranging from "biological and social, to ancestral, indeed archaic, representations of insanity with their magic contents borrowed from the realms of animism and sorcery" (Jodelet, *ibid*, p. 300). At the same time, villagers pride themselves on living in modern ways, on using advanced technology like fast trains or television, and on being aware of new means of medical treatment. Jodelet raises the question as to how can archaic beliefs retain their power in the face of modern medical treatment. She comments:

The embedding of these beliefs in the language codes which are transmitted by communication and the everyday acts which are transmitted by tradition, both conditions of collective memory, suffice to explain their permanence, not their intensity of character or the veil of secrecy with which they are covered.

(Jodelet, *ibid*, p. 300)

Such diverse meanings and beliefs are usually implicit and hidden in linguistic codes and in meanings of words. One may guess that they have been unconsciously transmitted for generations and that the contradictory forms of knowledge and belief have their specific expressions in particular social situations.

Other researchers have presented many examples of cognitive polyphasia in common sense thinking, and we can find excellent reviews of these studies (for example, *see* Duveen, 2007; Jovchelovitch, 2007; Wagner & Hayes, 2005) showing diverse forms of thinking in different social and cultural settings and among different groups. Numerous studies show that different cultural communities—for example,

in India (Wagner et al., 1999), in Chinese immigrants in the United Kingdom (Jovchelovitch & Gervais, 1999), or citizens in Turkey (Narter, 2006)—think about health issues both in terms of traditional ways of thinking and modern medicine. Cognitive polyphasia also dominates new and old ways of thinking about environment and science (Castro & Lima, 2001). Psaltis (2011) is concerned with diverse forms of thinking between Greek and Turkish Cypriots, relating them to varying meanings, emotions, distrust, and threat. These forms of thinking about the Cyprus issue express cognitive polyphasia when groups consider solutions to the problem from the point of view of the past, the present, and the future.

Research on cognitive polyphasia directs attention to shifts and changes in societies that experience movement from traditional forms of thinking toward modern forms. Yet it shows that traditional elements of representing, for example, mental illness, are deeply embedded within the communal life and are drawn “into a more *active* form of reflection and change through this process of cultural contact, communication, and exchange” (Duveen, 2007, p. 557, his emphasis).

Wagner and Hayes (2005, p. 235) have argued that the concept of cognitive polyphasia highlights two research areas. Instead of treating language and thought as independent, “representations are social because of their articulation within the context of their genesis and enactment.” The other research area places attention on the processes of change and transformation in representational systems. Just as a contemporary society’s culture is constantly in flux and transformation and rarely in the state of equilibrium, so are the modes of thought and representations within it. Wagner and Hayes observe that cognitive polyphasia emerges primarily when members of groups are coping with new conditions during their lifetime and that transformations in forms of thinking and communicating continuously run between different generations.

### **Figure, Myth, and Metaphor**

From the outset, the Theory of Social Representations included the figurative dimension—or images and metaphors—as features of representing. The term *figure* is preferable to *image* because imaging could be confused with mirroring or with a passive reflection (Moscovici, 2008, p. 20). I wish to emphasize once more that the transformation of one kind of knowledge into another one, including

that from science into common sense, involves creating metaphors, figures, and myths. Scientific discoveries diffuse themselves into common sense not as simplified versions of science; transformation of scientific knowledge into common sense knowledge is accompanied by creating figurative schemes and metaphors. It is well-documented that the science of the nineteenth and twentieth centuries has had a profound effect on literature, art, and public imagination (e.g., Beer, 1993). For example, the discovery of X-rays at the end of the nineteenth century has led to artists’ and public’s images of the invisible world and to fantasies and occult ideas. More recently, metaphors of illnesses like cancer, tuberculosis, and HIV/AIDS in language and thought and their transformations in public representations were captured by Sontag (1978, 1989). Political, economic, and educational changes, too, are accompanied by new images and metaphors. The collapse of the Soviet bloc was marked by creating new symbols in re-emerging states. For example, Baltic States, in designing their new banknotes, chose symbols that represented preferred values of the newly created free nations (Mathias, 2008). Images, Moscovici (2007, p. 9) maintains, speak to the public and accelerate communication. In her chapter on “Crossing Latin America: Two French perspectives on Brasil and Mexico,” Jodelet (2007) shows that since ancient Greece, alterity or others have always played crucial roles in imagination. The discovery of the New World has created, from the beginning, rich forms of imagination of indigenous peoples in Latin America by European intellectuals, arts and literature, as well as social scientists and has contributed significantly to generating social representations filled with imaginary others.

If we turn to the research on figurative schemes, metaphors, and images in social representations, we find that it has considerable methodological implication. To access processes of thinking and communication, questionnaires and scales are substituted by other means such as drawings, analyses of the media images, posters, and by studies of semiotic contents of these.

### **REPRESENTING IN DRAWINGS OF MAPS**

One of the first studies of figurative schemes was the exploration by Milgram and Jodelet (1976) of drawings representing mental maps of Paris. The study showed that subjects were not drawing maps based just on their personal experiences but that they were transmitting images of certain subcultures and

ethnic groups to which they belonged. For example, certain places were drawn only by those belonging to special professions—for example, slaughter houses were drawn by butchers but scarcely by anybody else. Other places, such as the icons of the town like Notre Dame, Place de la Concord, or the Eiffel Tower, were drawn by nearly everybody. We can say that drawings express historical-cultural networks of meanings that are part of subjects' and subgroups' experiences, knowledge, and feelings about the place where they live (Guerrero, 2007). Institutions that societies create are nourished by collective memories, myths, national identities, and imagination (Banchs et al., 2007).

Imagining based on drawings of maps inspired extensive studies in Latin America (Arruda & de Alba, 2007). In her study of maps of the city of Mexico, De Alba (2007) shows that the symbolic construction of the city is an imaginary sphere in which mythical references, mystical beliefs, reveries, and urban legends have no correspondents in the real world. An interesting theoretical issue discussed in Arruda and Ulup's (2007) research of mental maps of Brazil is the presence of blank spaces in the center or center-west region. The authors maintain that void spaces coincide with the colonial occupation of these territories and that drawings sometimes reproduce the ancient images of isolated and dangerous places. The authors observe that although one might consider empty spaces on maps as signs of lack of knowledge, it is more likely that these distant places in the center of Brazil express strangeness from which subjects wish to dissociate. These empty places may also serve as reminders of the past and collective memories of occupation. Thus, emptiness does not always mean nonexistence but a choice or a defense (Arruda, Gonçalves, & Mululo, 2008). In contrast, seaside spaces were filled with images. They were inhabited by Europeans and civilized local people. In addition, the authors found that the participants from northern Brazil represented south as a very different region because of its temperate climate and its population of the European origin.

#### FIGURATIVE SCHEMES IN COMPARATIVE RESEARCH

A considerable amount of research has been carried out to compare figurative schemes and images in different fields like health and illness (e.g., Herzlich, 1973; Joffe, 2003, 2008; Joffe & Haarhof, 2002), biotechnology (e.g., Wagner et al., 2002), the body (Jodelet, 1984), the body and hygiene as culturally

determined (Jodelet, 2005; Wagner & Hayes, 2005), historical and cultural events (e.g., Sen & Wagner, 2005; Wertsch & Batiashvili, 2011). Kalampalikis (2007) analyzes symbolic conflicts embedded in social representations of two interpretations of history that are embedded in the name of Macedonia.

Equally, images and metaphors in social representations have been explored across cultures or in specific groups. In the 1980s, De Rosa (1987) carried out a multimethod research on the social representation of mental illness. In this research, children and adults were asked to draw images in connection with madness; their drawings suggested the presence of ancient images of madness (*see also* Schurmans & de Rosa, 1990).

Visual images in the press, advertisements, and campaigns are used to influence or change social representations of political or health issues (De Rosa, 2001; Joffe, 2008). Intentions of the producers of posters, on the one hand, and images of the public, on the other hand, could be quite divergent. For example, some posters produced on behalf of people with mental disabilities sometimes confirmed, rather than changed, the existing representations (Marková & Farr, 1990). Visual images in the press have been particularly influential in staged photographs capturing public images about genetic engineering as injecting tomatoes with genes that make them grow bigger (Wagner et al., 2002). Wagner and Hayes (2005, p. 181) comment that images of tomatoes injected with genes remind inoculation and injecting foreign materials into bodies known from medicine and chemistry. There is also an associated belief of infection that passes from one organism to another:

Finally, the monstrosity of genetically engineered organisms is related as well. The topic of '*Frankenstein foods*' is not far from these ideas and in fact frequently came up in interviews. Just as tomatoes are good to eat, they are also good to think with. These images and metaphorical projections capture the 'What is it' and the 'How does it work' part of popular imagination about 'genetic engineering.'  
(Wagner & Hayes, 2005, p. 181)

These examples show how the two opposite yet complementary explanations of phenomena in the world of reason and myth, or logos and mythos, mix to generate social representations. Nevertheless, it would not be correct to say that sciences are guided by logos (*see* Moscovici, 1992, on "scientific myths") and common sense by mythical thinking.

A recent volume on *Mythical Thinking and Social Representations* forms a true dialogue between anthropology and the Theory of Social Representations (Paredes & Jodelet, 2009). The contributions to this volume show that mythical thinking does not disappear with scientific progress, technology, and mass education but that it continues to be present in everyday reasoning and that it permeates daily practices. Jodelet (2009, p. 31) observes that there are at least three central aspects that relate social representations and mythical thinking. There is an instrumental aspect of common sense that utilizes certain mythical thinking in the construction of social life. Furthermore, production of common sense re-activates ancient myths with requirements of contemporary cultural identities. Finally, through functional aspect of common sense, the formation of myths facilitates interpretations of events or objects in social life and in social relations.

### ***Communicative and Cultural Themata***

In contrast to cognitive polyphasia, figurative schemes, metaphors, and myths, the concept of themata has entered into the Theory of Social Representations more recently (Moscovici, 1993c; Moscovici & Vignaux, 1994/2000). It has since become one of the most important theoretical concepts in social representations with respect to culture and communication. Let us explain.

One of the fundamental features of human thinking is making distinctions and understanding phenomena as antinomies. For example, we understand freedom in contrast to what we consider to be a lack of freedom; justice is understood through what is considered to be an absence of justice; logos as contrasted with mythos, and so on. Antinomies are features of thinking, language, and communication in all cultures, but different cultures and societies employ their capacity of making distinctions and thinking in antinomies in specific ways. We find them throughout eons of human history both in scientific and in common sense thinking, although very often they are present implicitly without becoming an explicit topic of discourse. Socio-cultural changes, however, may bring implicit antinomies to the public awareness and into discourses, reflecting societal tensions and conflicts. This means that from that moment on, they turn into *themata*, whether in scientific thinking where they generate scientific theories (Holton, 1975, 1978) or in common sense thinking where they generate social

representations (Moscovici, 1993c; Moscovici & Vignaux, 1994/2000).

Many antinomies are implicitly present in our common sense thinking for centuries, and they may never be brought to explicit awareness. This is so, because there may never be any reason—or at least there may not be any reason for many generations—for them to become problematized and thematized. For example, logos and mythos could be viewed throughout history as complementary antinomies until, for one reason or other, logos become a superior and rational way of explanation of phenomena, whereas mythos is degraded as irrational thought (Moscovici, 2009). In principle, all antinomies can become themata—that is, issues for public debates and disputes—but many of them do not rise to that status.

Themata that generate most social representations are those pertaining to the Ego–Alter, like private/public, morality/immorality, justice/injustice, and freedom/oppression, among others. Such themata are in the heart of social sciences, and they generate social representations of phenomena like democracy, citizenship, quality of life, and health and illness, to name but a few. How and in what ways themata become problematized and which meanings become foregrounded is specific to the structured field in which a social representation is engaged. A social representation is rarely generated from a single thema. If we consider, as an example, a social representation of HIV/AIDS and its vicissitudes over the last three decades in different parts of the world, we find that re-thematization of morality/immorality has been associated with re-thematization of social values related to sexuality, promiscuity in the general public, discrimination of minorities, and social recognition, among other issues (Marková et al., 1995). Although the antinomy morality/immorality itself has not been questioned, the content and context of morality/immorality has been differently thematized in different structured fields in which the social representation of HIV/AIDS has been engaged. For example, the question of personal and social responsibility, medical confidentiality, and human rights all became part of discourse in such specific structured fields. Communicative processes, through which these changes in meanings are usually achieved, carry symbols and images, which not only circulate in public discourses but also organize and generate discourses; they shape common thinking, language,

and behavior; and provide grounds for the formation of new social representations.

Liu (2004) describes themata as “deep structures” of social representations. In his research on rapid changes of social representations of the quality of life in China, he identified two themata that, in contemporary society, compete with one another: “to be” and “to have.” *Being* prioritizes traditional Chinese values like the authentic relation between subject and object, a union between self and others, and their rootedness, connectedness, and mutual commitment. *Having*, on the other hand, gives priority to how subject instrumentalizes object as a resource to be possessed and consumed. Possession has become a new value in the rapidly changing China, whether it is the possession of money and material objects or of symbolic objects like social status and power. Neither having nor being exist in pure forms, but they are both dynamically interrelated into the meaning of the quality of life in contemporary China.

In their research on social representations of Roms, Pérez et al. (2007) identified two underlying themata. One of them highlights nature versus culture. This polarity emphasizes the superiority of cultured European majorities over natural minorities of Roms. The second theme, human versus animal, represents Roms as having deficits in human qualities. Drawing on his socio-anthropological research, Moscovici (2011) shows that in the case of Roms themata are also articulated along the extensive historical narratives artistic/criminal.

Research on social representations of genetically modified food as presented in the press shows that these are underlain by themata of health versus disease and risk versus safety (Castro & Gomes, 2005). The already noted research by Wagner et al. (2002) implies that social representations of genetically modified tomatoes, both in the press and in interviews with citizens, are triggered by themata like natural versus unnatural.

### ***Morality of Human Rights As a Thema***

Although Doise (2002) does not use the concept of thema, we can subsume his work on human rights as social representations under this concept. Moral universality of human rights codified itself in societies as a basic thema, although naturally, it has been thematized differently in specific cultures and societies. Doise’s own empirical research shows that participants in different countries express consistent attitudes on general principles or articles of the

Declaration of Human Rights. This strong coherence disappears, however, when subjects respond to specific contexts in which human rights are presented. Having examined theories and practices in relation to human rights, Doise concludes that the basis of legal thinking on human rights is not to be sought in their institutional expression, but it is profoundly anchored in normative social representations. Doise traces the origin of normative social representations of human rights in communication and human interactions. Communicative contracts carry implicitly ethical norms (Rommetveit, 1974; Bakhtin, 1979/1986) that regulate our mutual interactions, mutual commitment, and social recognition of one human by another. These contracts are then built into social norms and social representations.

In a similar manner, Mead (1915) drew attention to the error in the assumption of theorists who were convinced that individuals had originally possessed their natural rights before any formal societal organizations existed. He was critical of those who thought that formal organizations had to be established to protect those natural rights. Mead argued that, on the contrary, already in informal organizations that developed within groups, the rights, rules, norms of acting, and constraints had already existed. Mead specifically referred to philosophers like Hobbes, Spinoza, and Locke who were not aware of this fact. Thus, he said that if Locke had the knowledge of the contemporary anthropologists, then he would have recognized that people had been organized in informal groups from which governmental institutions later developed. Governmental institutions arose out of communities that already had formulated their customs. In other words, rights were already in existence, and they were recognized by group members, although in a different form than in governmental institutions. No special introduction or special instruments were required to establish them in formal institutions.

Doise has maintained that although norms do not translate themselves automatically into institutional expressions, they remain to be the shared references to which victims can appeal (Doise, 2002, p. 25). Concerning the issue of how to assess whether human rights are upheld by different countries, normative social representations are used as a tool of evaluation. Countries use their own norms and ethnocentric social representations of human rights to evaluate different countries with respect to discrimination and prejudice in others, and they commonly overvalue their own morality. Doise has

analyzed contemporary trends and habits of speaking about different kinds of human rights—for example, individual rights, socio-economic rights, the self-determination rights of ethnic groups, and rights for natives to maintain special ties with the land of their forefathers. Variability in dealing with human rights is great and anchored in different kinds of beliefs that are rooted in histories, politics, and in common sense.

### **Conclusion: Toward Theoretical and Empirical Diversity in Social Representing**

After World War II, the social sciences exerted a strong effort to establish their places in reconstructing the world and to coordinate themselves internationally. Among these efforts was the UNESCO research of the roles of social sciences in higher education. Social psychology was grouped together with cultural anthropology and sociology because it was assumed that this was its proper place (Moscovici & Marková, 2006). But the UNESCO research showed that the position of social psychology was split between psychology and sociology. In the years to come, social psychology leaned toward experimental psychology and its methods, and the relation to culture considerably diminished or totally disappeared. Equally, language and communication played only a minimal role in social psychology, the situation that Moscovici (1972) and Rommetveit (1974) deeply regretted.

In contrast, we have seen in this chapter that from its beginning, the Theory of Social Representations has been conceptualized within culture, language, and communication. In this chapter I have discussed three concepts: cognitive polyphasia; figurative schemes, myths and metaphors; and themata. These three concepts have made most significant contributions to the Theory of Social Representations. However, there is also substantial empirical research in social representations that covers diverse topics in education, politics, environmental problems, health, mental health, and aging. There is growing research on social representations of otherness or alterity, everyday life (Haas, 2006), identity (Moloney & Walker, 2007), and historical events. Jodelet (1992) has initiated the study of collective memories as an important aspect of social representations. Examining historical perspectives of collective memory in the work of social scientists like Halbwachs and Douglas, she has analyzed the process with the Nazi Klaus Barbie that took place in 1987 in France. Numerous studies of social representations of historical events

that have followed Jodelet's research have provided accounts of groups' representations in which history and collective memory have mixed and organized and have transformed these representations. Such accounts are never neutral cognitive narratives but dialogical evaluations and justifications of history; they are forging many ethnic, social, and national identities and pose questions about how histories could be re-interpreted and rewritten on the basis of politics and ideology (e.g., Liu et al., 2009; Lastrego & Licata, 2010; Paez, 2010). Raudsepp, Heidmets, and Kruusvall (2008) have explored social representations of collective memory in their study of the socio-cultural context of Estonia during the transition from a post-Soviet republic to a liberal State in the European Union. They have analyzed explicit and implicit socio-cultural regulative principles, and they have explored how these principles have transformed in the course of the transition period, focusing on the changed roles of Russian minorities and Estonian majorities during that time. Social representations of collective memories of daily life during communism in Rumania have been captured by Neculau (2008) and those of the Cyprus conflict by Psaltis (2011). Findings of these substantial empirical studies feed back to the theory.

### **Future Directions**

The growing interest in theoretical and empirical research in social representations also highlights challenges and problems for the future. Among these I mention the following.

First, despite the fact that strong emphasis on language and communication was already part of *La Psychanalyse*, this remains a neglected area of studies of social representations. Language and communication are usually taken for granted as essential features of human interactions but rarely studied as phenomena that require a specific exploration. We only see beginnings of such research in dialogical studies of different kinds of discourse (e.g., conversation and dialogue, polylogue, inner speech, focus groups studies) that have been recently emerging. They include analyses of various grammatical structures like modalizations, positioning, deontic claims, and other means by which speakers take distance from or express closeness to objects of social representations (e.g., Harré, this volume; Salazar Orvig, 2007; Marková et al., 2007; Salazar Orvig & Grossen, 2008; Linell, 2009). In addition, what participants communicate to one another is not produced solely by them; they necessarily draw on their

cultural resources, on perspectives of the parties that are not present in discourse (third parties), and on groups to which they belong or which they reject. For example, absent others could become, directly or indirectly, participants in talks among villagers in Jodelet's (1989/1991) research on madness, because absent others could become invisible or semi-visible judges of relations between villagers and patients. Groups do not live in a vacuum but are part of a broader community. Outsiders coming to the village are not neutral onlookers but they communicate with in-groups: they can make flattering as well as damaging comments about relations between villagers and patients. A close association with mentally ill patients could downgrade, in the eyes of others, the villagers' social identity. These different circumstances involving numerous communicating parties reflect themselves in diverse modalities of thinking.

Participants in interactions may jointly construct utterances that may suggest that they share—or assume sharing—a social representation. Alternatively, in and through a joint construction of utterances, they may question limits of their shared knowledge (Marková, 2007). They may refer to beliefs, to a super-addressee (god, generalized other, consciousness), the law and its different kinds, rules and norms, morality and ethics, traditions, habits, and stereotypes. There are countless examples of the interdependence among language, communication, and social representations that have not been explored or have only just become subjects of research interest.

Another challenging issue was implied earlier in this chapter. It concerns the fact that cultures live no longer in isolated ghettos, and rather, the contemporary world of societies is open to other cultures and they “set the stage for permanent situations of uncertainty,” moving cultures in different directions (Rosa & Valsiner, 2007). This is also the issue that Moscovici expressed in his third paradox concerning incommunicability among different groups (see above, p. 497). The challenge for the Theory of Social Representations concerns the issue of studying ethical problems arising from the growing uncertainty in the world of increasing complexity; and with problems how to establish reflective communication in intergroup and intercultural relations. Such issues concern the future developments of relations between the Theory of Social Representations and culture (Permanadeli et al., 2012). Moreover, the Theory of Social Representations is only one psychological approach that focuses on culture. Cultural

diversity is studied, for example, by structuralist, discourse, anthropological, phenomenological, narrative, and other approaches (Jodelet, 2012). Among all of these, what specific contributions can the Theory of Social Representations make that will differentiate it from other approaches? This is a challenge in the world of rapid changes that is characterized by a series of “trans-”processes (Jodelet, *ibid*) What different forms will transformation of knowledge take in these changes where the local competes with the global and crossbreeding thinking produces new kinds of cognitive polyphasia?

Finally, there are theoretical challenges concerning the epistemological status of social representations. Both knowing and believing co-constitute social representations, although some social representations are based primarily on knowledge or factual beliefs and others mainly on passionate beliefs and convictions. Knowledge and beliefs are transmitted in and through culture, language, and communication, as well as through learning (tacit or explicit) by repeating and changing others' activities. But what status can be attributed to knowledge generated from trust in authority of other individuals or institutions and of collective norms? Can these serve as preconditions of rationality and coherence of reasoning?

No doubt there are other theoretical and empirical challenges. The theory is now 50 years old, and over these long years it has undergone transformations and has become gradually enriched by different cultures all over the world as it has spread from Europe to other continents—particularly to Latin America and most recently to Asia.

## Acknowledgements

I am very grateful to Denise Jodelet for her generous help in providing ideas and references to research on social representations and culture and to Angela Arruda for references to the research in Latin America. This chapter was written during the period of my Emeritus Fellowship awarded by the Leverhulme Trust, and I wish to acknowledge the Trust's generous support for this project.

# Life-Course: A Socio-Cultural Perspective

Tania Zittoun

## Abstract

This chapter characterizes a socio-cultural psychology of the life-course, and shows how it differs from other approaches of the life-course. General principles for such a psychology are highlighted, and a particular attention to ruptures, transitions, and the processes these involve, is proposed. Such a basic “grammar” enables us to highlight a few dynamics of development; empirical situations chosen along typical life-courses exemplify them. Issues to be further examined can thus be highlighted.

**Keywords:** development, socio-cultural perspectives, life-course, transitions, ruptures

The possibility shadows every single person and changes the nature of his life; for (and this is another well-known axiom of existential mathematics) any new possibility that existence acquires, even the least likely, transforms everything about existence.

(Kundera, 1996, p. 36)

The study of the life-course, an important issue in the social sciences and psychology since the 1970s, can also be considered as the effort to understand the mutual constitution of a developing person and her changing cultural environments. It is easy to admit that there is no human life outside of a culture—one can thus speak of the “cultural nature” of human development (López, Najafi, Rogoff, & Arauz, 2011; Rogoff, 2003) or of the “cultivation” of humans (Josephs & Valsiner, 2007)—yet *how* culture mediates development demands explanation. The current *Oxford Handbook* offers various ways of advancing such understanding; here, I propose to focus on the person’s changes through his/her life-course.

## The Study of the Life–Course

Why does a person become who he/she is? Is it true that our fates have been sealed before we even

speak (in a secret roll, in our genes, or in our social class)? Or on the contrary, can we “make ourselves” as we wish? What is our margin of freedom, how much can persons become who or what they want to be? The reflection on the nature of life-course finds multiple roots in old philosophical questions and has found beautiful forms in arts and literature. Life trajectories became the object of systematic scientific investigation relatively recently. In psychology and social sciences, reviews usually consider as first life-span studies these of Charlotte Bühler and Erik Erikson’s analyses of biographies. In the 1950s, a certain number of longitudinal studies were published in the United States, and these gave a new grounding for the research on how people develop over a life (*see* Giele & Elder, 1998, for a review).

Currently, two disciplinary traditions have emerged and have been given contrasting appellations. On the one hand, the orientation in psychology that considers the development from infancy to old age and death calls itself *life-span psychology* (Baltes, Staudinger, & Lindenberger, 1999; Overton, 2002). On the other hand, the sociological orientation that examines life trajectories considers itself as developing a *life-course* theoretical

perspective (Elders, 2004). Because these two fields of investigation develop in different disciplines, they have deepened different questions:

Life-span psychologists typically begin with psychological functions and ask questions about change and stability, individual differences, and intraindividual plasticity. Life course sociologists typically begin with social change and ask how it influences communities and families, and, in turn, trajectories of development. For all their significant theoretical commonalities, the two perspectives often begin the research process by asking distinct types of questions.

(Shanaban & Porfelli, 2002, p. 399)

### **Life-Span Psychology**

Since the 1990s, the life-span approach to development has made itself known thanks to its elegant propositions. First, it has proposed meta-theoretical principles according to which the role of natural growth and culture vary through life. From this perspective, the person's natural capacities and cultural mastery initially grow, until at some point of one's development, his/her biological capacities start to decline. At this point, culture plays a growing role in one's life. For example, when sight diminishes, one starts to use glasses; when one gets to the limits of his/her memory, online reference completes the amount of available information, and so forth. However, at some point, the biological state of person declines so much that culture cannot compensate it anymore. Second, life-span psychology proposes that development is regulated through *selection*, *optimization*, and *compensation* (SOC): people first select a certain number of skills, competencies, or relationships on which they will invest efforts; they then optimize these selected fields of activity; they finally compensate, in the limits given by the meta-theoretical model, their weaknesses by other means (Baltes, 1986; Baltes, Staudinger, & Lindenberger, 1999). Studies in life-span psychology have particularly explored aging and old age, yet many other researchers over other periods of the life-course have been inspired by the model. However, the generality of these principles does not allow for a more fine-grained analysis of the processes of development nor the specific role of culture in these dynamics (Gillespie & Zittoun, 2010). How can we describe the process enabled by culture, in what sense does cultural production participate to development, and in what respect is

cultural mediation different in a 5-month-old than in a 90-year-old person?

### **Life-Course Sociology**

On their side, sociological approaches to the life-course have been struggling for accounting both for social and historical effects on personal trajectories and individual agency (see Mayer, 2009, for a review). Elder, Kirkpatrick Johnson, and Crosnoe (2004, pp. 11–14) have highlighted five paradigmatic principles in life-course theory:

1. The principle of life-span development: human development and aging are lifelong processes;
2. The principle of agency: individuals construct their own life-courses and the choices and actions they take within the opportunities and constraints of history and social circumstance;
3. The principle of time and space: the life-courses of individuals are embedded and shaped by historical times and places they experience over their lifetimes;
4. The principle of timing: the developmental antecedents and consequences of life transitions, events, and behavioral patterns vary according to their timing in a person's life; and
5. The principle of linked lives: lives are lived interdependently and socio-historical influences are expressed through this network of shared relationships.

Mainly based on large samples over long periods, life-course studies have developed complex methodological strategies enabling combination of quantitative and qualitative data so as to show the interacting effects of context and biography, structure, and agency. They have tried to capture the commonalities of people born and developing under comparable socio-historical circumstances—for example, with the help of the notions of *cohort effect* “when historical change differentiates the lives of successive birth cohorts” and *period effect*, “when the impact of social change is relatively uniform across successive birth cohorts” (Elder, Kirkpatrick Johnson, & Crosnoe, 2004, p. 9). However, it is not certain that people from a given cohort, in the same period, develop along the same line. Researchers have used the notions of *social pathways*, *trajectories*, *careers*, and *navigation* to describe the individual life-courses people trace within a given social and historical structure (Furlong, 2009). Scholars also

seem to agree on the importance of studying *transitions* within trajectories; they have acknowledged their role as *turning points*—events that “involve a substantial change in the direction of one’s life, whether subjective or objective” (Elder, Kirkpatrick Johnson & Crosnoe, 2004 p. 8)—and have tried to capture their long-term consequences.

If we accept the five principles above and retain the importance of transitions in a life-course, how can we account for the processes whereby a person might decide the course of his/her life within a given sets of constraints and relations? How can we account for what is unexpected? And how is this connected to the cultural means at his/her disposal?

### ***Using Traditions—Studying Transitions***

Research from the two traditions of life-course and lifespan studies have been published in separate journals, and researchers have presented their studies in different conferences and have developed their own research traditions. Only on rare occasions do they attempt to see their contributions as complementing each other (Levy, Ghisletta, Le Goff, Spini, & Widmer, 2005), then facing complex methodological as well as theoretical issues. These two traditions have also kept their distances toward the current developing field of cultural or socio-cultural psychology (and reciprocally)—even if their object is ultimately the same. Indeed, from a socio-cultural perspective, it is clear that it would be absurd to consider human development out of its cultural, social, and historical constraining and enabling conditions; yet for various reasons, socio-cultural psychology neither developed models enabling us to fully understand the nature of “cohort effects” over individual trajectories (but see Sato, Yasuda, Kido, Arakawa, Mizogushi, & Valsiner, 2007) nor gave much attention to the evolution of the biological constraints of development. In that respect, both lifespan and life-course studies might contribute to our enquiry. However, the core issue of socio-cultural psychology is to account for the life of humans as meaning-makers. Here, we first need to define the specificities of a socio-cultural approach to the study of the life-course, which is open both to the multilinearity of development and to the centrality of human meaning-making in their worlds of culture. We will thus propose a theoretical model for exploring the life-course, drawing on various studies of different traditions, using the notion of transition as transdisciplinary “analyzer” as proposed by

Levy, Ghisletta, Le Goff, Spini, and Widmer (2005, p. 365).

### **General Principles for a Socio-Cultural Perspective on the Life-Course**

As much as there is life, there is change: things move, evolve, are constructed, become organized, decompose, and perish. Galaxies dilate and suns die; it rains, water evaporates; our bodies grow and become weaker; we inhale and exhale; the seasons pass. As humans, we perceive discourses and information, we think and dream, we communicate with others, and as William James (1892) wrote, our consciousness *flows*—it flows, as one might say it rains, or it snows. Human perception of these passing events, realized thanks to various social and cultural markers, produce *time*—as a personal sense, or as a collective history.

Cultural psychology tries to account for the experience of humans *in time* and *in social and cultural environments*. A person’s birth takes place in a certain moment of history (of the group within he is born), and from that moment on, his/her life will unfold as times goes on. It also takes place in a family, with its beliefs, located in an area of the town, in a country that has current policies—that is, in a social, material, and symbolic environment. As the person develops, she will explore that sphere of experience, its boundaries, and explore other spheres. Finally, each of the others met by the person are changing him or her, the mutual relationships of persons, environments, societies, with their own rhythm and periodicities, produce the complex environment in which a person’s life occurs. Hence, cultural psychology examines the ongoing *transactions* (Dewey & Bentley, 1946) or mutual adjustments between developing persons and their changing environments.

One of the specificities of human life, over other forms of organisms, is to be found in the central role of *meaning making* (Bruner, 1990). Young humans not only perceive their environment, they also feel it, develop memories and expectations. Their environments not only provide them with food and warmth but also with lullabies, rhymes, and fairytales. Children learn to read other people’s intentions, and they make themselves understood; as they grow older, they learn to use and produce words, toys, colors, and ideas, to understand what occurs around them, to represent their ideas of the world, and to create alternative realities. On

the other hand, the experience of human groups is deposited and registered in concrete objects—a car is the result of many generations' experience of how to facilitate human locomotion—and in cultural elements primarily meant to carry meaning, such as chronicles, novels, psychological textbooks, and cartoons that convey, under a semiotic form, people's experience of life.

A core idea of cultural psychology is that each person, as one particular instantiation in time and space of the infinities of shape that can take humans, is absolutely unique. That person, exposed to the discourses, shapes, and rites of his/her environment, is likely to understand them in a sufficiently shared manner so as to remain in interactions with others; but these discourses, rites, or lullabies will also find a form of unique understanding, and translation, in her mind—where it will be integrated with other traces of experiences, bring to psychological reorganizations, and so forth. Such process of *internalization* thus brings the person to develop his/her own “personal culture” (Valsiner, 1997). On this basis, he/she will also be able to communicate, make his-/herself understood, move, take specific postures, by which he/she *externalizes* (translates unto a semiotic form) what occurs in him/her, or within specific interactive dynamics (Lawrence & Valsiner, 2003; Valsiner, 2000). Internalization and externalization can thus be seen as the core processes by which meaning can be produced, individually and collectively. Cultural psychology examines human development with a specific attention to the *dynamics of meaning-making* in which groups and individual are engaged.

With the help of other sciences, cultural psychology has developed a theoretical basis, notions, and models to account for human development, its transactions with environments, and dynamics of meaning-making (especially Boesch, 1991; Cole, 1996; Josephs & Valsiner, 2007; Valsiner 1997, 1998, 2007; Valsiner & Rosa, 2007; Wertsch, 1991).

### ***Life-Course As Lifelong Development***

Stating that everything constantly changes is of course just a starting point. It is clear that change occurs only within a constant tension between continuity and change. Our bodies remain “the same” even if each of the cells of our organism is replaced every year. Paul can cut his hair, change jobs, and divorce, but he remains Paul—for himself and for his mother, and even for his ex-wife, even if she has fallen out of love. How can we account for the fact that we are both the same and not the same?

In psychology, there has been for many years a tendency to identify structures of personality, and types of character, as if these were acquired once for all—one believed that if Paul was an introvert he would remain so, or that if he had a low IQ he just had to live with it. Other parts of psychology have in contrast tried to account for how these structures have developed through time—what is the genesis of cognitive structure (Piaget, 1967), how a person's identity matures over years (Erikson, 1959). Finally, recent approaches have proposed models that emphasize the mutability of humans—Paul is not a father and a plumber, he is *doing* the father or positioning himself as a father in a specific sequence of dialogue with his son's teacher, which vanishes as he is doing the soccer fan with his friends 2 hours later (Harré & Davies, 1990). Similar debates have been legion in life-course studies: Is it true that a child's fate is defined by the first 3 years of his/her life (e.g., by the attachment style developed, or by the mode of resolution of his oedipal conflict?), or by the profession, income, and numbers of books read—that is, social class—of his/her parents?

Whether we change or remain the same through time, whether we are constrained by the hazards of our birth or whether we can develop in any direction, is a recurring question in human history. It has been treated as a philosophical question (about freedom and determinacy) and as a political issue (whether we are produced by our class, can emancipate, or can determine our own fate). As cultural psychologists, we can take a nuanced position.

### **TRANSITIVE AND INTRANSITIVE CHANGE**

Drawing on dynamic system theory, cultural psychology can distinguish between *sorts of change*. In an open system, some changes are quasi-circular: people eat cakes, digest them, eliminate them, and eat again. Students read books, write notes, raise questions, check references, and borrow more books in the library. There is a “virtuous circle”; even if each book is different from the other, it remains a book that will be borrowed, read, and serve as a source of questions. Such changes are called *transitive*, in the sense that the circle is “symmetrical”—it can be considered from any point, and the other points will be found (this is what van Geert [2003] has called a “level 1 change”). Of course, transitive changes can also involve slight displacement and evolution—if Paul and Mary have the habits of swapping novels they have read and liked, then they are in an transitive movement; yet one day Paul can

propose to Mary not a book, but a DVD, which will also bring Mary to propose a Paul a DVD she liked (it can be distinguished from the former form of transitivity by being called a level 2 change: here, the structure remains the same even if some components vary). Other changes lead to total new forms of conduct or situation, from which there is no coming back: if Paul has an accident and loses a leg, then he will not recover it, and he will have to reorganize his life accordingly; if Paul goes to evening classes and gets a degree in law, then he will not “unlearn” what he has acquired, and this can also open new life possibilities. Such no-return changes can be called *intransitive* (or a level 3 change); these require real re-elaboration of one’s understanding, means of actions, or relationship to the environment. From such a perspective, it is clear that these different sorts of change also have various degrees of freedom—transitive changes do not enable radical innovation, whereas intransitive require them. And, in turn, intransitive changes are sometimes imposed but can also be deliberately provoked.

Change occurs in continuous forms, as slow accumulation of reconfigurations of person–world–others dynamics, or through events that appear as caused by or causing discontinuities. Continuous change has been described as processes of maturation, growth, increase of expertise, and so on and so forth, which have been privileged in the studies of child learning and development. Events bringing discontinuities specifically call for change. Studies on youth and adult life have mainly focused on these.

#### **RUPTURES AND TRANSITIONS**

Not every change has durable consequences—this appears very clearly once we replace types of changes within a person’s life trajectory. From that perspective, transitive changes are part of the daily transactions between the person and his/her environment, whereas intransitive changes are linked to more clear-cut changes that we can call *ruptures*. Ruptures are moments in which existing modes of progressive adjustment are interrupted. A rupture can result from internal factors or causes (as when Paul decided to leave his wife after a long period of doubt, or when he decided to take evening classes) or by external ones (as when he lost his leg); they can be expected by the person, as when a nursery child is anticipating and imagining his first day at primary school, or not (Winther-Lindqvist, 2009).

Ruptures are what life-course researchers call “turning points” or “critical moments” (see above). They usually constitute *bifurcation points* in a trajectory—some pathways are opened, others are closed, and generally their outcomes are not yet decided (unless the rupture is one’s own death). Hence, Paul’s new degree opens the possibility of working as a lawyer, but also of starting full-time studies again; his accident forbids him to play soccer but instead, after re-education, brings him to kayaking, which he always wanted to do.

The interesting thing is that ruptures experienced by a person demand substantial, intransitive changes—processes of adjustment, or adaptation, between him/her and his/her environment. It is these processes that we will call *transitions*. From a life-course perspective, then, ruptures followed by transitions are moments of accelerated or catalyzed changes. For researchers, they offer the opportunity to study substantial, observable development, and this probably explains the current popularity of studies on transitions.

In life-course research, the notion of transition has been used to designate moments of change either from the perspective of a person’s life trajectory or from an observer’s perspective. Adopting such second perspective, the studies on the “school-to-work transition,” for example, examine the fact that groups of students end school and enter the labor market. Such a perspective has enabled researchers to distinguish “normative transitions,” which are expected to be experienced by certain group of persons of a certain age in a given society, from non-normative transitions (Elder et al., 2004), which affects the way in which individuals perceive changes as ruptures or not. It is usually easier to engage in a transition in a normative way than non-normative, because one is more likely to find appropriate social support and acceptance: for example, when a young graduate applies for his first job, his lack of experience is likely to be tolerated as part of a “normal” school-to-work transition, whereas if Paul applies for a first job after his studies in middle life, he might be considered as too old for too little experience. Hence, the normative nature of a transition might facilitate the processes of change in which a person is engaged, whereas non-normative transitions might be experienced as stronger subjective ruptures. More generally, such studies highlight certain of the structure of constraints within which change takes place.

In contrast, when we focus on ruptures actually perceived as such by people, as we do when we focus on meaning-making, we observe that socially observable ruptures are not always felt as such (Zittoun, 2006a); also, people experience as ruptures and engage in transitions for events that are not visible for an observer (e.g., a grandmother died, a close friendship ended, or the person developed some new self-awareness).

#### LIMITED PLASTICITY

From a socio-cultural perspective, we need to propose a model accounting for the ways in which psychological change is enabled and constrained by biological and social situations.

On the one hand, it is clear that one cannot speak of meaning-making without considering the person's embodied existence. Any meaning-making is just one part of the ongoing processes of perceiving, moving in, understanding, acting in an environment that we constantly *experience*. In that sense, experience seems enabled and limited by our senses, the capacities of our bodies and minds—which are plastic to some extent only. However, these capacities are themselves mediated by our own meaning-making (we overhear advices that we do not like, or hormonal processes are modified by moods or achievements) and by our understanding of our social and cultural environment (that valorizes certain capacities rather than others, encourage us to develop other, and cure and replace further ones). For example, we can imagine that Paul developed a good memory as a consequence of his interest in soccer and his intention to be acknowledged as expert; this memory then helped him as he started his late studies, even if his bad hearing could have limited his participation to seminar discussion. Also, we can imagine that Paul is a rather handsome slim man and that his usual facility to charm people enabled him to develop a sense of self-confidence; hence, received for a job interview, he might have made a good impression in an environment that valorizes self-confidence and slimness. Hence, our bodies are important in sense-making as it is as embodied person that we experience ourselves, the world, and others, and through these bodies that we make sense of our experiences; also, it is as embodied beings that we are recognized by others and addressed and treated by our societies. Indeed, it is also clear that our societies, with the quality of the environment it creates, the modes of life it encourages, its industries and medical systems, shape the changes of our bodies, as other perceive us,

and how we experience the world. It is thus important to emphasize that if it is clear that biology sets important constraints in human development and change (Baltes, 1987), then its action always already is in great part mediated, if not guided, by individual and collective semiotic dynamics.

On the other hand, human development is also canalized by social or cultural conditions. But what do we mean by that? The social is so much “everywhere” that talking about the “influence” of the social is as absurd as talking about the influence of “matter” on cells—cells are made out of matter, matter circulates through their inner and outer membranes, it is around them... More interesting, and more difficult, is to define ways of describing the multiples modalities through which the social and cultural becomes psychological and back.

Many authors have proposed such descriptions (see Valsiner & Van der Veer, 2000, for a review; Valsiner 1998, 2007; Zittoun, Valsiner, Vedeler, Salgado, Goncalves, & Ferring, in press).

Here, building on the socio-cultural tradition, I will distinguish five modalities on a continuum through which the social and the person interact. First, the social and the cultural is already “in the mind” of each person. Since birth, each instant through interactions with the world, the person internalizes portions of discourses and signs that will participate to the development of his/her thinking and acting possibilities. This constitutes the mind—as always already social (see below). Second, every time a person interacts with another person, there is the construction of the social—as coordinated perspective, which is eventually designated by symbolic meaning exchanged (Gillespie, 2010). Third, every time a person interacts with or creates an artifact, the person is actually interacting with a symbolic object—an object that designates a world of shared meaning in a social group on the one side, and his own life on the other (Zittoun, 2005, 2010). Fourth, each sphere of experience in which people are located are socially structured and organized according to rules, which allocate them rights and mutual positions; it is supported and usually reinforced by material arrangements (it is often called a “social frame”). Hence, a school in a closed environment, such as a boarding school, creates a total institution that gives quite clear indications to people about what can be done, or not (Goffman, 1958). Fifth, the social and cultural is pervasive; present in the daily organization of the public and mediatic space; it

imposes, on the fringe of our consciousness, certain messages, values, and beliefs that constitute our belonging to a social world. For example, the smoking bans in most north European towns have created zones for smokers separated by a yellow line on the floor and glass boxes in airports, and they impose smokers to freeze in front of restaurants while their beer warms up inside, repeatedly making smokers feel unwanted, and non-smokers learn to see them as deviant (*see* Zittoun, Valsiner et al., in press).

Meanings move from one modality to the other. The meaning of the smoker–non-smoker segregation is that “smoking is bad,” which eventually becomes internalized and guides the action of the not-yet-smokers who hesitate to buy a first pack of cigarettes. The issue of the smoking ban can also become an object of discussion between peers. The famous Marlboro poster is an artifact that now crystallizes these many meanings for a middle-aged viewer: the imaginary freedom associated with smoking, now overwritten by the fact that “Mr. Marlboro” had cancer, by the scandals of tobacco companies manipulating public opinion, and the present smoking ban. Interacting with the social and cultural around us, more or less reflectively, we constantly internalize and revise our earlier understanding and our systems of orientation. In turn, we can also externalize our opinions, make our friends change their views, produce discourse or art pieces that will be seen by others, and use various means to reshape our environment; we can smoke out of the smoker zone, move country, or, like in certain parts of Switzerland, use our democratic rights to show that the smoking ban is unconstitutional and suppress it.

#### **MULTILINEARITY, UNPREDICTABILITY**

Life is not a quiet river. It is a tortuous torrent, full of surprises. It can be characterized in two ways.

First, the development of a child or a person is not linear and therefore cannot be predicted. Our contemporary societies encourage people to travel, work or study abroad, or meet foreigners in their office or in their street; we are exposed to a wide variety of information about alternative life choices, other countries, and innovative professions; we live in a world that has lost its economical and ecological stability; we know that every other marriage will end up in a divorce; we are offered ways to alter our bodily appearance and physical strength; we hear

stories of colleagues “turning green” or scientists abandoning their universities to live on sailing boats. At every step of our lives, social discourses, fictions, narratives, and gossips present us with alternative lives. Nourished by these semiotic means, but also by our own past, affective lives, and our imagination, we constantly explore the possible outcomes of situations, alternative choices, new versions of the past, or possible futures. Each moment, we engage in an action by closing down an alternative.

In addition, the world in which we live is not predictable, neither at an individual level nor at a collective one. Cohort-studies retrospectively show how a given generation went through comparable events—for example, very old people in Switzerland all experienced two World Wars, years of crises, and years of economical optimism (Lalivé d’Epinay & Spini, 2008), yet how these events have affected each life is not predictable. Hence, if sociologists thought that in the 1960s (an until the mid-1980s) work trajectories were quite linear (e.g., a middle-class young worker would enter in a company, make his way through the hierarchy, and have a good retirement), then retrospective analysis have shown that unexpected events (such as an evolution of the market’s needs), disturbed predictions, and personal crises brought people to have very personal trajectories, not so much depending on their social or economical background or initial training as on a synthesis of unexpected opportunities, luck in meeting others, accidents, random injustice, personal imagination, re-examination of one’s situation, and moments of personal decisions (Goodwin & O’Connor, 2009). Hence, if life trajectories were never fully predictable (i.e., people always had accidents the day before graduation, fell in love with a person from a different social class, or experienced a war), then our contemporary society brings us to deal with a much more generalized uncertainty.

The second characteristic of life trajectory is their multilinearity: there is always more than one way to get to comparable points in the life-course. Studies classically have shown that children can start walking after crawling or might just stand up and walk (Bottos et al. 2008; Valsiner, 2000); one can become a lawyer studying straight after college or as a mature learner; one can have children early in life and then establish oneself as a professional, or one can acquire a professional stability and then have children; and one can learn the violin as an adult. This has two implications. First, not everyone develops skill A in the same spatio-temporal place

(e.g., in the classroom, third grade); very often, skill A is developed in other circumstances. Second, the so-called “learning disabilities” often more result from the fact that a person might be engaged in a pathway that does not enable him/her to change or develop that particular understanding or skill—an alternative way might enable the person to develop in such way that the disability is suppressed or avoided (Vygotsky, 1929).

Unpredictability and multilinearity always characterized human lives; only our current society constantly reminds us of multiple choices we have, the ambivalence in which we live (Sato, Fukuda, Hidaka, Kido, Nishida, & Akasaka, 2011), and the uncertainty that we have to tolerate in daily lives. Do we have more freedom, or are we more slave of our own fears?

### ***Freedom in the Life-Course***

Life-courses depend on many personal choices, social forces, and random events; they are not predictable in a strict sense. Studies that have used mainly “objective” data (i.e., income, health assessment, and standardized tests of well-being) have tended to show, initially, the structuring effect of the social or the irresistible effect of biological constraints on human lives; this has then been debated by others who have wanted to confer some agency to actors (Furlong, 2009; Goodwin & O’Connor, 2009; Levy et al., 2005). However, if one considers that human lives are as much made by what is invisible (i.e., what people believe in, who matters to them, how they find the world meaningful or absurd, how they enjoy the sunset or an illegal copy of an alternative music band) than by what is visible (i.e., their income or their ability to run 100 meters) then the discussion takes another dimension.

Indeed, within and beyond the modalities of social constraints as defined above, people have various means to expand their life worlds. People engage not only in reasonable or practical activities, they are also constantly imagining—beyond considering *what is*, they engage in thinking *what if* (the distinction comes from Vaihinger, 1924; Josephs, Valsiner, & Surgan, 1999). Imagination—that is, thinking beyond the here and now—takes various directions: remembering, which is an imagination of the past, thinking alternatives in the present (I am sitting here at my desk, but *what if* I were now at the movies or walking the dog or visiting Tunisia), and anticipation, which is imagining the future. These imaginations can be minimal loops,

as when I consider *what if* I would have another cup of coffee, or can imply major construction, as when *what if* I gathered the best scientists in the world and we would build a spaceship that could bring a country to the next liveable planet. Considering imagination, one can understand why very old people, with limited mobility and reduced social networks, still consider themselves as happy as years earlier (Lalivé d’Epinay & Spini 2008) or how people in very hard detentions conditions could actually survive thanks to the powers of their mind—living in faith, exploring their past, or living alternative lives (Bouska & Pinerova, 2009). Such hypothesis is also needed to understand why, in all times of visible or invisible oppression, some people are taking the risk to object to absurd rules or engage in changing the society. Imagination is usually accompanied by a good dose of forgetting—forget that we are on Earth just for a minute and that our action will not change much (something that depressive people usually cannot forget anymore). Of course, some people might object that surviving in a situation of oppression thanks to a world of one’s own or to minute degrees of freedom is still a form of alienation; but actually, who can say whose alienation is bigger, that of the bank director who plays golf, flies first class, and eats sushi (as it is expected) or the street cleaner who writes absurd novels after work?

The freedom of imagining is made possible through the mediation of signs, and so it intervenes at each of the modalities of our encounter with the social; we can imagine on our own, we imagine as we discuss with others, we enter in imaginary worlds when we read novels, and we can continue being surprised at our environment and remember how it was and how it could be. We are infinitely constrained by our social and cultural environment and yet very free from it. However, sometimes, it becomes harder to imagine, and this we have to account for. In what follows, I propose concentrating on two of the five modalities of the social and cultural as part of our lives: how we encounter it in our immediate environment, and how it is already in our mind, as part of our personal cultures, constituting a system of orientation.

### **A Sketch of a Theory of Transitions in the Life-Course**

#### ***The Plurality of Spheres of Experiences in Contemporary World***

In our complex worlds, we participate in various social and material settings, which are structured by

certain rules and organized through specific webs of meaning, that participate to the allocation of mutual social positions and define ranges of possible, encouraged, or forbidden actions. Typically, a child participates in family life, classroom interactions, playground during school time, family life, and perhaps going to football rehearsals, visiting his cousins, or gaming on the Playstation®. Each of these settings creates, for the person, a specific *sphere of experience*. These spheres of experiences, partly defined by the environment (as affording certain actions and thoughts rather than others) and by the person, have been described in different traditions (as social frames, microsystems, community of practices, symbolic contexts, etc.) that metaphorically consider that each sphere is “bounded” (socially and/or personally perceived as different from another one).

Ruptures, as what generate transitions processes, sometimes are caused by the passage of one person from one sphere of experience to another one; sometimes ruptures occur within a given sphere of experience; and sometimes what causes them is more general (e.g., a war) and therefore might be experienced in parallel in different spheres of experiences.

There has been abundant research on various forms of transitions *between spheres of experiences* (these are often perceived as problematic and are socially more visible). Authors sometimes distinguish vertical transitions, which suppose a development through time (such as the passage from primary school to secondary school for children, which is actually an intransitive change), from horizontal transitions, the daily passage from home to school, and back (which is a transitive change). Given our observations above, we will not call the daily passage from home to school and back a transition, although the question of how a person manages these passages (sometimes thematized as boundary crossing) is a relevant question from a life-course perspective. In effect, it raises the question of transfer of knowledge or, rather, moments in which a skill typical for one sphere of experience, a way to present oneself, can be used in another sphere of experience—what we have called *boundary crossing events* (Grossen, Zittoun, & Ros, 2012).

### ***The Mind As a Meaning System***

What is it of the self that remains self while changing? In the dynamic perspective outlined above, we need a working model in which even what

is perceived as having some stability is dynamic. If the person is essentially a meaning-maker and grows and develops through culture, then the mind has to be described as a semiotic system, producing sense about real and possible worlds. In psychology, various models are based on similar premises. The model of the psyche promoted by Freud precisely describes how streams of thought transit through layers of consciousness and undergo various semiotic transformations, under the constraining forces of internalized cultural rules on the one side and biological needs and strives on the other (see Salvatore & Zittoun, 2011). The “dialogical self model” represents dynamics taking place between various I-positions, resulting from internalized positions developed in specific social situations, within the “imaginal landscape of the self” (Hermans & Kempens, 1993). Here, we follow the idea that as humans develop in cultural world and internalize signs under some form of translation, these become progressively organized, differentiated, and hierarchized (Valsiner, 1998, 2007; Werner & Kaplan, 1963). We learn to identify some experiences as “sweet” and “likeable”; we organize them in classes of experiences, which we then prefer or avoid; our general beliefs (i.e., that people are good) guide each of our actions—for example, trusting unknown persons, and so on.

Some of our experiences get organized and classified into formal categories, which are usually called “concepts” and are the basis of scientific reasoning—hence, from that perspective, we say that what a dog, a cat, and a mouse have in common is that they are mammals. However, we also have other, more experience-based modes of organizing experiences: one might also say that a mouse, a cat, and a dog have in common the fact that they live at my grandmother’s or that they run after each other in some cartoons. Developmental psychology has usually considered such grouping of experience as preconceptual (Nelson, 2007; Vygotsky, 1934), as a step to acquire the mode of organization of experience required by our society (and schooling system). It is also typically the mode of organizing experience observed by psychologists studying the modes of memory of various indigenous groups that had no formal education (Cole, 1997). However, such more intuitive, affective-based organization of experience remains active and can easily be convoked in daily lives (Zittoun, 2010); their logic is not conceptual, but affective, based on personal relevance.

Preferred associations between components of experience can be said to be grouped in *semiotic sets*, often in prereflective ways; hence, a person can think herself to be a “decent woman,” because she does not go out with foreigners, she has good cooking skills, and she expects a decent man to marry her (Zittoun, Avelling, Cornish, & Gillespie, 2011). Such semiotic sets are partly organized according to one’s experience and partly caused by the internalization of shared values or social representations. They constrain one’s actions and feeling about one’s actions; they can be reshaped through experience (self-reflection, or psychotherapy, *see* Zittoun, Valsiner et al., in preparation) and they slowly evolve. They also can be the object of progressive distantiations and reorganizations.

Progressively, certain zones of one’s personal culture acquire some stability because they are recurrent, efficient, and enable a good enough understanding of one’s environment. People hence define their version of a “system of orientation”—a sort of meaning-producing system that renders the world intelligible and actionable, made out of semiotic sets and concepts (Zittoun, 2006a). A system or orientation is produced through progressive distantiation from experience, its differentiation in more or less formal classes (semiotic sets, categories, scientific concepts) and progressive distantiation. Distantiation enables us, on a first dimension, to transform more concrete, specific, embodied experience into abstract and more general values and to have the latter to guide and channel concrete experiences. Of course, these can be more or less mutually adjusted: it is quite often the case that young people have certain values of being “good students,” which is contradicted by poor school results, for example, or that they decide to become “non-violent vegetarians” yet find difficult to refuse a nice steak. On what can be seen as second dimension, distantiation enables us to organize experiences along what people feel to be a time perspective—some experiences are connected to earlier ones, others are felt as oriented toward future—although it is clear that any new experiences bring a reorganization of past experiences. However, in parallel to these processes of differentiation, hierarchization, and time orientation, other links organize traces of experiences according to logics of affective or subjective similarity. Such affective logic enters in dynamics of free association, can connote different zones of experience, and superimpose a different

temporality to one’s time perspective (Green, 2000; Salvatore & Zittoun, 2011). Hence, the same experience of meeting a deer in the fields can on the one side feed my experience of wild animals, my knowledge about deer inhabiting this countryside, and complete my personal narrative; in parallel, it might enter in more floating and much less conscious fantasies about wildlife, entrapment, or cannibalism.<sup>1</sup>

Examining daily reasoning as a socially situated practice, the facility with which some signs are made socially available, internalized, and acquired a power to reorganize a person’s life is at times striking. For example, it is very easy for a teachers’ committee to jointly consider that a series of disconnected actions of a little girl actually belong to the same semiotic set conventionally designated as attention-deficit hyperactivity disorder (ADHD) (Hjörne & Säljö, 2004). In turn, offering a girl to be treated as ADHD might be extremely convenient for her, as it brings adults to be more tolerant of her actions; this might bring her to more or less deliberately act as-if she were an ADHD child (Abbey & Valsiner, 2003). Such processes might durably shape the life-course of a person. Such analyses also suggest that it does not take much to attribute different values to one’s experience and to reshape a life-course!<sup>2</sup>

In summary, a person’s view on the world is a randomly stabilized system of orientation, and bases for sense-making processes, resulting from the internalization of various socially situated and shared experiences, as well as from the responses her externalizations find in the world. Systems of orientation are the basis through which a person confers sense to his/her experience, which includes the affective valuation of experience, its semiotization, turning it into possible narratives, and the basis of development of more generalized beliefs and values guiding one’s life.

The study of the life-course can thus be seen as the study of the slow evaluation and variation of people’s systems of orientation, which are likely to require reorganization of semiotic sets or transformation along the two dimensions of distantiation and time. Of course, what the metaphorical notion of system of orientation designates cannot be studied directly; it can be only inferred on the basis of people’s externalization. In what follows, I propose to examine of transitions in people’s lives, as these offer occasions of changing and to elaborate new meanings.

## *Ruptures and Transitions*

Psychology, as well as many other developmental sciences, has been looking for moments of progressive evolution as well as of sudden change, called alternatively “irritations,” “disequilibrium,” “turning points,” “conflicts,” and so forth (see Zittoun, 2009). Although there is something structurally comparable in all these developmental studies, it is important to see that what is considered as changing or being re-equilibrated or re-elaborated after a disrupting event depends on the theoretical perspective envisaged, the object of study, and the models used to represent its usual functioning.

In a psychology focused on the development of persons through the life-course, the object of study is the person. Because we consider persons as meaning-makers, we have to consider ruptures perceived as such (and not, for example, the reorganization of schemes involved as a child realized that a quantity of liquid remains the same even if it changes glass; Piaget, 1941). Hence, the notion of *transition* designates here the processes triggered by a rupture experienced by a person and that lead to a progressive, new adaptation between the person and his/her environment. (It is, of course, clear that the new “adjusted” situation still involves changes but only the smooth transactions of transitive changes.) But what is re-elaborated during transition dynamics? How can this adjustment be made?

At one level, it is the system of orientation of the person that has to be reconfigured. But this construct is extremely abstract, phenomenologically inaccurate, and difficult to operationalize. Actually, our system of orientation and semiotic sets appear to us in some forms of stabilized configuration, which people and social scientists identify under different labels in different contexts. Hence, identity (what a person thinks she is, or how others recognize her) is a stabilized or recurrent sets of beliefs and meaning about oneself. We can thus define a model that is closer to data and phenomenological experience—a midrange model (Zittoun, 2008). Research in development and the learning sciences have developed, through numerous studies, notions that enable us to capture some aspects of the person’s changing activity after ruptures. Hence, at another level, grouping these analyses, we have proposed to consider that ruptures in the life-course lead to three mutually dependent lines of change: processes of *identity definition*, perception or positioning; processes of *learning* or definition of modes of understanding or acting; and processes of *sense-making*, linked to the

valuation of the situation, working through affects, or the linking of a situation to one’s own experience and in one’s time perspective (Perret-Clermont & Zittoun, 2002; Zittoun, Duveen, Gillespie, Psaltis, & Ivinson, 2003; Zittoun, 2005, 2006a).

*Learning processes* have been widely studied by researchers focusing on transitions between institutions, or from school to work (see below). Learning designates the acquisition of knowledge and skills, which are often identified through the fact that a person can actually solve a problem or handle a situation. *Identity processes*, including the elaboration of social identities, issues of positioning and recognition, or self-definition, have been the focus of studies of life changes, but also have more recently been included in studies in adult learning and learning in sensitive populations. Identity processes are engaged when a person is required to define who he/she is (in a job interview, in a questionnaire) or when he/she has to stand for what he/she believes he/she is (often because he/she is treated in a different manner). *Sense-making dynamics* have been approached through studies on narratives, biographical elaboration in the life-course, or representation of the future (Bruner, 1990; Dominicé, 2007; Mc Adams & Logan, 2006; Masdonati, 2007), but within transition and life-course research, rarely as an overarching process. In some studies, sense-making processes and learning, or identity and learning, are seen as mutually dependent. However, our proposition is that sense making, a direct production of what we have called a system of organization, plays a central role both in identity changes and in learning.

## *Uses of Resources in Transitions*

People experiencing ruptures in their life-course might use any available information or help to facilitate processes of transitions. Beyond the umbrella notion of “copying”, it is possible to study what resources people find in themselves or in the environment and how they use them to facilitate these processes. Many of these resources play an important role in facilitating the process of imagination, enabling the consideration of alternative options, reconsidering personal narratives, or opening possible futures.

One important class of resources is *institutional*; many social settings are actually meant to facilitate transition processes in the life-course. Vocational trainings, birth preparation courses and groups of parents, alcoholic anonymous, and religious congregations are such settings, which might more or

less tolerate exploration and offer a safe space for try-and-fails, and support identity changes, sense-making or the question of skills. Then, people often activate *interpersonal relationships*, which might play an important role in offering a protected space to experience sharing, dialogue, mutual perspective-taking, and distantiating from experience, whether it is friendships or family or professional “transition-helpers” such as counsellors, priests, and psychologists. People also might look for, and more or less deliberately use *semiotic resources*—social knowledge, information, scientific knowledge, (including what can be more specifically called symbolic resources)—cultural elements that primarily demand an imaginary experience, such as films, novels, arts, and poems (Gillespie & Zittoun, 2010; Zittoun, 2006a). Symbolic resources might play important roles of mediation of transition and processes, first because they support and guide affective imaginary experiences (isolated from daily constraints), and second, because their semiotic form provides people with means to contain, take distance from, and transform personal experiences. Finally, people might simply use their own reflective ability, and in a less mediated way draw on their past experiences to establish links between situations, take distance, and redefine problems—what we might call *personal resources*.

As a contribution to a life-course socio-cultural psychology, it is very fruitful to describe the processes whereby uses of various resources support transition processes (for such analysis, see Zittoun, 2006a, Zittoun, Cornish, Gillespie, & Aveling, 2008). As we will see in the examples below, it is possible to show how each resource used by a person facilitates (or not) playful exploration, and consequently, identity changes, the acquisition of knowledge, or sense-making processes and thus, the transformation of one’s system of orientation.

### ***Dynamics and Variations in the Life-Course***

The study of the life-course has to account for the complex interplay of social changes, the constraining role of culture, psychological development, and the margin of freedom of each person in given circumstances. Identifying spheres of experiences, ruptures, processes of transitions, resources used by persons, and the work of imagination, one might attempt to capture some of the dynamics of the life-course. Rendering visible such dynamics might be useful for the identification of further comparable

processes, and it might also offer entry points for practitioners (teachers, parents, counsellors) who accompany people in different moments of transitions in the life-course.

The three types of changes—learning, identity and sense-making—are deeply related and mutually dependent. In most cases, changing one of these aspects will imply changes in one of the other aspects, in the shorter or longer term (see Fig. 23.1). For example, an adult that takes language classes (learning) might progressively feel more competent and, consequently, take more initiative in his/her workplace, where he/she might then be given new responsibilities, which changes his/her social and personal definition (identity); in turn, the person might then imagine new options for his/her life—for example, further studies or a professional change (sense).

From this follows that when a person who has experienced a rupture seems to resist one of these changes required by a new situation, the problem is often that one of the two other changes is impeded. For example, if after arrival in a new school, a formerly good student does not learn anymore (NO learning), it might be that he/she cannot tolerate the position of a newcomer he/she has in this new school (NO identity change); or perhaps the family of the young person plans to soon return to a foreign country where he/she would anyway take on the family company for which this knowledge is not required (NO sense).

Then, as noted above, each person participates to a plurality of spheres of experiences. It is very often the case that transition processes start in one of the spheres of experience only; yet these can extend beyond these boundaries, to others’ spheres of experiences, which might then evolve at various speeds. The plurality of spheres of experiences has interacting effects, which can be stabilizing or destabilizing, facilitating transition processes or impeding them. A teenager finishing compulsory

**Figure 23.1** Mutual dependency of dynamics of transition.

school might experience a rupture in his educational trajectory; yet he might, in parallel, still regularly attend his piano classes, his theatre activities, and his informal gathering with his friends. There is thus a transition in one sphere of experience but not in the others. However, the older person who enters in a pension might at once experience a rupture in the sphere of daily life but also put an end to her weekly meetings with neighbors, her attendance to church, and the monthly visit of her grandchildren; here, rupture diffuse in many spheres of experience and demand numerous transitions at once. In addition, this multiplicity is co-evolving. Often, key events in one's sphere of activity result from events in others—a professional transition might be caused, or facilitated, by a coincidental meeting with an uncle at a family dinner, or a person's ability to deal with the demands of a new job might be facilitated by his weekly discussions with childhood friends in a local pub.

In addition, each sphere of experience is socially structured and sets precise demands on people; consequently, for different reasons, the system of orientation of a person and, following from them, the sense a person is prone to confer to a situation, her ways of defining skills and identity, can at times be consonant, yet also extremely dissonant within a given sphere of experience. The experience of dissonant demands might thus be the cause of a felt rupture within a given sphere of experience. For example, religious young men who have developed a meaning system in a religious environment, which is extremely functional within that sphere of experience, might precisely feel that they do not have the means to deal with daily events once they are in a secular context, because their values and semiotic resources are dissonant there (Zittoun, 2006b).

It then seems that people can more easily engage these processes of change when they can work through one of these aspects at the time, leaning on at least another, more stable one. Hence, when a person changes country and sees her whole life questioned, having with her personal objects or pictures can offer a sense of personal continuity beyond the rupture, on the bases of which she can initiate other changes (e.g., learn the new language) (Habermas, 1996; Zittoun, 2006a). Similarly, in some cases, a person who is living through a rupture in one sphere of activity can, under some conditions, use resources coming from other past or present spheres of experiences to facilitate these transitions<sup>3</sup>.

Finally, to generate change in any of these aspects, a person has to engage to some degree in exploration, try-and-fail, and approximations; it is by acting “as-if” one is qualified that one can have the experience of being treated as qualified; it is by accepting to be treated “as-if” one were ignorant that one can learn; and, most of all, it is by exploring possible explanation, narrative, moods, possible outcomes, and preferred lives that one can develop and confer sense to a situation. Hence, each of these processes demand the work of imagination, through which a zone is created for potential actions and thoughts not-yet possible. Very often, these explorations are rendered possible by the immediate social environment, which accepts a student's wrong answer, an adult's divorce, or a period of confusion in a young woman's life (Hviid & Zittoun, 2008).<sup>4</sup>

Many of the surprising curves and bends in a life-course simply result from the multiplicity of a person's spheres of experiences, their mutual dynamics, and the dynamics of transitions, and so these have to be studied if one wants to address life-course development.

### **Current Issues in Life-Course Transitions**

In this section, and based on the framework defined above, I use a series of empirical to highlight four inter-related issues that could be further analyzed in the study of the life-course.

First, the processes suggested here are meant to account for any transition, at any age, in the life-course, including very young children. Paying attention to such experiences of transition is a first step to develop a life-course analysis. Second, the principle of plurality of sphere of experience might help us to understand dynamics traditionally studied in isolation, such as the school-to-work transition. Third, the question of *what changes* as persons get older and accumulate experience through life has to be raised; and fourth, transitions of one person are likely to influence others, especially in inter-generational relationships. If the first two issues are currently being at the heart of a growing number of studies, the latter two are still to be explored.

### ***Transitions to New Spheres of Experiences: Childhood***

Although the interest for the study of transitions in the life-course has mainly focused on youth and aging population, transitions as defined here obviously start very early, and birth is probably one of

the first substantial transitions a human person has to go through.<sup>v</sup> Without going that far, we will examine early childhood experiences. The passage from home to kindergarten, or from kindergarten to primary school—even if usually prepared by adults through different techniques—is lived by every child as a particular transition (Lam & Pollard, 2009) depending on his past experience, his preferences, his social insertion, and his ability to play with reality. Even if very young children do not have the capacities to develop long-term time perspectives, research documenting children's externalization have shown their ability to reflect on what happened to them and what might soon happen (even as young as 2 years old; Nelson, 2006). For example, Ditte Winther-Lindqvist (2009) followed two groups of children for 8 months, before the end of nursery school and after the entrance at primary school, and before and after their move from primary school to secondary school. Here, I report some of the observations of children age 5 years and analyze them with the notions proposed above.

James is a popular child in the nursery school. In that social frame, children are free to organize their time as they please, and the most valued activity by the boys is soccer. As James is very good at it, he is recognized as very competent by his peers and himself feels quite content. In contrast, Benjamin is friends with girls and is bad at soccer; the other children consider him incompetent, and he says he doesn't like them; he often withdraws, and seems bored when adults do not organize time for him; his main commitment is in adult-conducted activities. Before changing schools, both children construct anticipations of what might happen:

James is sitting in the couch reading when Ollie asks him if he is coming outside to play soccer. "Yes, when I have finished reading this book," he says. I sit down next to him. It is a spelling-pointing book. He pronounces every word carefully as he points at it. Sometimes he asks me to read a word aloud if he is not certain. He sits a long time concentrating with the book. "I know my dad's telephone number," he says and recites it for me. "I am attending school next Friday," James says. "Only after the holidays," I correct him. "No we are to visit them next Friday and they will show us around and everything," he says with excitement. "That is why I rehearse reading," he says, as he puts the book away and joins his friends in the playground.

(Winther-Lindqvist, 2009, pp. 134–135)

Benjamin and Mark are drawing at the table with the adult Mia. All children are supposed to make a drawing for Liva as it is her birthday. Benjamin concentrates and works with commitment on the task.

Mark: I am done (stands up).

Mia: But Mark you only just arrived! When you start school you can't just quit when you feel like it... Draw some more....

Mark: (grabs the pen and draws for 10 more seconds without sitting down) Now it is done!

Mia: Mark, you know in school there is no such thing as not being bothered! (Sighs) Alright, this will have to do then.

(Winther-Lindqvist, 2009, p. 134)

James seems to be positively anticipating school, and playing as-if he would be already at school. He is actively creating a zone of proximal development, with the help of a book, and his experience developed in another sphere of experience—knowing his father's phone number. Benjamin is not reported in such active explorations, even if he is part of interactions that signal him what is expected in the primary school.

After having changed school, things appear quite differently. James is put in a different class than his good friends. Soccer is not the main activity anymore and is even difficult to practice: it can be played only during breaks, yet the sport ground is far and always very busy. Eight weeks after the beginning of the school year, the researcher writes the following:

(protocol notes from the school interview). James draws an unhappy face to the general question: How do you like school? And the class teacher asks him what it is about school he does not like. He shrugs and cannot tell her. "Is there something you miss from day care?" she asks him. "I miss my friends," he says. "But you have nice friends, also in school, don't you?" He shrugs. Regarding the questions about scholastic activities, James also says that lessons are boring, and learning rhymes and singing is dull.

(Winther-Lindqvist, 2009, p. 138)

In contrast, Benjamin seems to do fine: "in school he is not supposed to decide for himself what to do with his time, and he is engaged in the project of learning and being a good student, recognized by all teachers and peers for his hard work with drawing, counting, writing letters, remembering rhymes and lyrics, putting his hand up when wanting to speak, etc." (Winther-Lindqvist, 2009, p. 138). He

still does not have many friends, but this fact seems to worry his teacher and his parents more than him, as he seems to enjoy schoolwork.

The examples enable Winther-Lindvist (2009) to highlight how, in different spheres of experience, children's "orientation" and social identity are welcome or not and lead to integration versus disintegration. In our terms, it seems that in the new school, James was relying on his good identity as a good soccer player, reinforced by his friends' acknowledgement and supported by the related skills; in the new sphere of experience, there is no occasion to practice these skills and to reactivate his friends' admiration so as to support his own identity. The expectations he had for school, through which things could have acquired a personal sense (e.g., reading and knowing telephone numbers), on the other hand, have not been met by reality: so far, children do "boring" things like rhymes and singing, which are much less grown up activities than writing phone numbers! Hence, the whole activity seems devoid of sense, which is suggested by the general emotional tone of James' externalizations (his unhappy face, his comments on missing friends and finding things boring). James has thus experienced the school change as rupture, and it seems that he could rely on none of the dimension identified above: identity is questioned, skills become redundant, and the sense degrades. In contrast, Benjamin was described as having had difficulties establishing a strong positive identity, and his skills enabled him to execute what was asked from him. The entrance in the primary school enables him to actualize such skills in an environment where it is valued, and where he becomes acknowledged as a good pupil; in turn, one might think that through this, and perhaps, through a genuine epistemic pleasure hence generated, Benjamin seems to confer some sense to school as a place to learn—manifested by his enthusiasm. Here, some pre-existing skills are reinforced and support an identity in the making. Hence, in the new sphere of experience, the processes of transition in which James engages seems to take an involutive shape, whereas it is more generative in the case of Benjamin.

In this example, we see the intricateness of learning, identity processes, and sense-making, ranging from affective connotation to anticipation of the future and evaluation of the adequacy of the situation, as these might take place at any moment of the life-course. We also see that such mutually dependent dynamics take place in specific spheres

of experience, where relevant social others play an important role. Others acknowledge or not, validate or ignore, a child's externalization; this might facilitate or hinder the exploration or the change in which the child is engaged—his attempt to understand something he did not, his work of conferring sense to a situation, or of redefining himself.<sup>vi</sup> In addition, the role of these others might be guided by institutional rules: a kindergarten teacher can let children play, why a primary teacher has to bring them to read according to a certain agenda. Hence, to actually observe dynamics of transition, one has to consider not only the person's actions and externalizations but also how these enter in interpersonal dynamics, in a given socially defined setting.

### *Youth Transitions—Relationships Between Spheres of Experiences*

Typically, youth (including adolescence and what is at times called "emerging adulthood") is a period of many transitions; several changes of spheres of experience might occur in a short period, each of them creating experience of ruptures and subsequent readjustments. This partly results from the fact that young people often involve more time in the social world and in imaginary worlds than children do, through their leisure and because of training and economical reasons. For example, a study on secondary school students' uses of symbolic resources (SYRES) has shown that many young people spend, besides school and schoolwork, up to 20 hours a week in playing music, working out and combat sports, pocket bikes, art school, and in addition, during weekend, mixing to earn some money, or investing online. Each of the spheres of experience to which a person participates can involve processes of transitions. These spheres of experiences might be felt as more or less connected or disjointed, and young people might seem to experience a plurality of identities, might create boundary-crossing events between these spheres of experiences (Grossen, Zittoun, & Ros, 2012), or might reflect these in a rather unitary way. In the frame of this study, interviews were made with 20 young persons regarding their leisure time and their relationship to school knowledge (Zittoun, Padiglia, & Matthey, 2010). The data that follow comes from an interview with Marc, a young man engaged in vocational training. His interview enables us to show relationships between spheres of experiences.

In the sphere of school experience, Marc presents what is initially an involutive circle, because of

what he considers a lack of skills: “[School] is very demanding for me, I need to work a lot, I am dyslexic and things are very difficult for me. I never liked school . . . That is also why I trained as a carpenter”. Dyslexia, a learning difficulty, is for Marc an identity, and it seems to limit his engagement in further learning. On this basis of such negative identity, Marc seems to have engaged in a negative choice, choosing to study the less demanding trade:

I did a CFC [diploma] of carpenter [a few years ago] and (...) I worked 6 months in a company, and I didn't correspond to me at all, the work . . . It was not the act of working, it was the relation to the trade, the stress, and also the workshop chief was a bit lunatic, and as I was all the time with him it was too heavy. (...) Then I worked with another boss (...) someone I knew personally, a friend of the family. And there the atmosphere was nice, much nicer. But I wanted something else, to work alone in the workshop didn't correspond to me.

Marc seems unable to define a positive sense in a trade chosen as a consequence of negative self-definition. This experience led him to change his orientation. In the first company, Marc disliked the work and the other persons, which prevented him from developing a vocational identity—he felt as not “corresponding.” Marc then changes place—that is, sets a relationship to examine “what if” would then happen, exploring ways to generate more sense. However, even in the new, supportive environment, the work still does not make sense, and Marc decides to go back to school to re-orient his professional pathway. Marc engages in a vocational bachelor after difficult entrance tests. Suddenly his relationship to learning changes, which surprises Marc himself:

It is funny at the beginning of the school year, because French has always been the discipline that I don't link, because of dyslexia, spelling mistakes. It never worked for me. But coming here, surprisingly, my grades became very quickly quite good. And I don't have the same relationship with the discipline than in compulsory school.

The interviewer asks him about this sudden change, and Marc answers that he believes that the teacher played a role. First, the teacher often talks about things that are external to the course, and students feel that it increases their general knowledge. Second, French is taught in a different way: it is for the first time that the construction of a text is analyzed and discussed, and Marc discovers a new way

to read and question a text. Marc realizes that he can read despite his dyslexia and that complex texts can make sense. He explains how, through his activities in the worker's union, he came to think again about the novel *Germinal*, by Zola, that had been read and analyzed at school. In other words, in the new school, Marc can engage in French learning, confer sense to it, and, possibly, change his identity into that of a competent student.

Contrasting with his school experiences, Marc is very assertive about his skills and identity in the sphere of musical activities:

I started to play in a brass band [13 years ago], I started to play drums; after [3] years of training I could have the costume and of on parade, and soon this was not enough for me anymore, I went to the conservatory, I played a lot of drum, I made few years of xylophone which I had to stop because of the vocational training, and then I concentrated on percussion (..) and suddenly the director of the brass band left and I took it on. Now I play less, I direct, and I am still at the conservatory. (...) I compose pieces for concerts, I have a team of 114 young people, I have to teach them, manage the team, last week we were second at the [regional] competition with the percussion.

Music is a strong component of Marc's life; the members of his family play music and most of his friends were known through the band. Now, with the prize obtained, Marc feels also the public acknowledgment of his work. As musician, Marc's legitimacy is self-evident. Marc listens to a lot of music; he developed over the year his personal taste, he is actively exploring the musical field, attends concerts, and shares his interests with friends. Identity as musician and learning go hand-in-hand. In terms of personal sense, Marc is also aware of the way in which music is personally meaningful to him. On the one hand, music can be directly resonating with personal experiences. Hence, asked whether music he listened to could be related to his mood, Marc answers about his experience as adolescent using music to regulate his emotional state:

Very much so. There was a period in my adolescence, during which I was . . . a bit in love with a girl and it didn't go, and it is true that I turned to music which were revolting or a bit hard. (..) it makes the energy go out. In general it easily calms me down. (...) There was also a song, where the text corresponded really to what I was living, and I listened a lot to it . . .

Playing has various other benefits:

Playing enables me to cut from everything that is going on (...) when I play I don't think about what is going on anymore, it also enables to let the steam off, especially drums, sometime it hits hard, and now what I like is to be able to transmit to younger ones in the band. And this concourse... is also a bit (...) an acknowledgement.

Marc gives a narrative account of his changing relationship to music through time, and of the evolution of its use as symbolic resource. In the past, he used music for emotional regulation and to reflect about a love affair. In the present, music can be used to create intergenerational relationships in teaching; and played in public, it can produce social acknowledgement. Other people's recognition (students, the public, juries) comfort Marc in his competent musician identity. Sense follows: through these activities, one can also share his pleasure and expertise and enjoy the satisfaction of doing so. The transmitting activity becomes very important in Marc's present life. He enjoys it, and his comments show how seriously he reflects about the didactics of music in his ensemble:

It is really interesting, the youngest is 10 years old. So, to teach them, is quite interesting. (...) I compose most pieces, it is easier for me because I can write according to their level, I can make voices which are progressive and not too difficult.

Hence, for Marc, in the musical field, an identity of musician, the learning it engages, and the sense that one can extract from it are mutually supportive and generative. That music makes personal sense supports engagement in learning, which supports social recognition, which supports identity and enables transformation of the sense one finds in it, until it changes the activity of learning, now oriented toward the development of teaching skills.

If we now consider Marc as a whole, we see that he developed in one sphere of experience an identity of incompetent learner, bringing inadequate learning and meaningless activity, whereas in another sphere of experience, learning, identity, and sense are united positively in music. The key point is that Marc, after his second work experience in the workplace, realized what was missing:

I wanted to be able to transmit what I had learned, and there I thought that teacher of handcraft, this would be a good thing, yes, to be able to transmit, and to be in contact with other persons.

(Interviewer: as you were doing in the brass band?)

Yes, that is what was missing on the professional plane.

Hence, it seems that Marc could connect his experiences in the sphere of school and in the sphere of music playing: having the identity, the skills, and the reasons to "transmit what one knows to younger ones" is something that can occur in both spheres of activity. It can be read as a specific semiotic set, crystallized enough to cross boundaries. Thanks to it, the identity of self-as-teacher comes to enrich the identity of self-as-learning-a-manual-trade; and the experience of being skilled in teaching, what is socially acknowledged, and the sense it has for self can now support the vocational sphere of experience.

Note that not all young people have to develop convergent understanding of different spheres of activity. Some young people develop parallel, but disjointed, skills in their spheres of music-mixing or Asian film watching and at school; others might in contrast have a clear unifying definition of their activity through different spheres, as Mara, who is interested in visual arts and uses every information provided by the school to develop her own exploration of arts, art books, and her practice of painting in an art school or in her daily life (Zittoun, Padiglia & Matthey, 2010). There is still a tendency in psychology to claim what sort of life configuration is "better"—predictive of better social integration, or more well-being, and thus emphasizing the importance for people to elaborate more "integrated personalities" (Erikson, 1968), or on the contrary, more diversified, multifaceted self-definitions (Proulx & Chandler, 2009; Moshman, 2009). Given the open-ended nature of these processes, it is not possible to say whether some of these modes of joining or maintaining disjointed various spheres of experience is "good" or "not good" for facilitating development over time. One might even say that for some people, under some circumstances, some modalities might be better than others. Hence, for a young woman enrolled in the war effort, working in the fields with no possibilities to change activities, it might be good to have leisure experiences felt as very disconnected, such as Walt Disney film-watching, whereas at other moments, reading botanic books and literature about life in nature can serve as a symbolic resource that enriches daily practice (Zittoun, Cornish, Gillespie, & Aveling, 2008). In the state of our society, it might simply be good to find, when necessary, the psychological and social conditions permitting playfulness,

imagination and explorations of alternatives; these conditions are extremely variable.

### ***Moving Through Life: Experience in Transitions***

As people advance through life, they also are likely to accumulate experience from transitions. Hence, if transitions lived by older persons might still be similar in kind with those experienced by young people, they might simply have known more of them and learned from them or about them. Personal experience is not the simple accumulation of distinct moments; it implies the constant re-elaboration of one's system of orientation. With it, not only do people have the ability to use more resources in new transitions, but also, the modalities of experiencing these transitions might be different.

In the following sequence taken from an essay called "November Hurricane," the Czech writer Bohumil Hrabal,<sup>vii</sup> age 75 years, describes how, seeing the crowds getting organized in Prague in November 1989, he reminisced about dramatic past experiences that occurred in November 1939 (on reminiscence in old age, *see* Coleman, 2005):

So there I stood in front of the pub in my Russian fur hat, while all the people who'd been in Wenceslas square streamed past me, shouting and carrying placards – I watched them, astonished as this May Day parade on Eastern Monday, still without its customary whipping and lashings... I'd never seen so many beautiful unblinking people, I'd never seen such solemnity in young people... I walked along with them, and I came to my old Law Faculty, where across the bridge the white helmets gleamed and shone, proclaiming no entry—and I stood where fifty years ago I saw the Army and the SS-Waffe hounding my fellow-students out of the Faculty – it was morning, my friends from the University were forced at rifle butt into army trucks with green tarpaulins, while I stood on the corner of Bilkova and saw what I saw... And as the side-flaps were slammed shut, and those lorries set off, making for Sachsenhausen, I heard my fellow-students singing... *Kde domov můj*... our national anthem... Today I stood there and saw young men in jeans bending their knees and squatting down on a patch of lawn to light candles by a little memorial I'd never spotted before... (...) [where was a marble tablet in the memory of a young man fallen for freedom in 1945]

(Hrabal, 1998, pp. 111–112)

In this passage, a present moment—linked to a dramatic transition in Czech's people's lives, the end of socialism in 1989, 75-year-old Hrabal as narrator sees the situation through the eyes of someone who has experienced similar events and their meanings —1939 and the transition of Czech people under the German occupation but also 1968 with the arrival of the Russian tanks leading to a totalitarian state. Hrabal's description of the past events, his fellow students' arrest, is already interpreted through the lenses of the present: in 1939, Hrabal did not know that they were sent to Sachsenhausen. The emotional intensity of that excerpt seems to be result from the fact that it is not a simple experience of a transition; it is vibrant of all the traces of comparable, past transitions, with their various meanings and longstanding consequences on the narrator's life and on that of a nation. In that sequence, then, these past events and the lessons learned by the narrator are also questioned and reread, for, if past November events lead to dramatic events, the present one, full of dignity, will actually see the "victory of the people," demanding a radical rereading of the past: hence past deaths, which seemed meaningless in the past, seem now to find a meaning in the new freedom acquired.

This active work of understanding, linking, and working through experience, takes place all through life, yet gets depth with experience (of course, in the case of a writer, the effect of experience goes hand-in-hand with the development of creative skills).

### ***Intergenerational Relationships and Transitions***

Finally, it might be worth returning to the principle of inter-related lives; in effect, very often, how a person lives and experiences (or has experienced) transitions affects other persons living their own transitions. Intergenerational relationships affect, among others, nuclear families, teacher–students interactions, as well as grandparent–grandchild exchanges.

The fact that people's lives are inter-related has been largely shown by systemic psychotherapists. Trying to understand how interactions taking place with one or members of a family could have an effect on other members of a family beyond the therapeutic encounter, Dreier (2008) has proposed a complex ideographic study of a family, where not only a session with one or more members of the family are registered but also where the family members

are interviewed at home. Hence, the study enables us to see how, for a person, transitions in one sphere of life (e.g., therapy) are linked to changes in other spheres (e.g., family encounters); it also examines how transitions in the life of one person affects the lives of others and conversely, how the resistance to engage in developmental transitions hinders daily transactions in the other family members' lives. Such study enables us to advance in the understanding of the mutual relationships between transitions that are synchronic, affecting various persons, in and through various spheres of experiences.

A second type of mutualities are those affecting transitions lived in the past by an adult and the ones experienced by younger persons with which the adult interacts—that is, interacting with a child, the adult is in the position of the adult who was played by another person as he was in the position of the child. Such position exchange (Gillespie, 2011) and reactivation of old transitions can bring the adult either to simply exchange position (become the adult that once dealt with him) or, having the possibility to reflect on that situation, transform the situation. In either case, young people or children are confronted to some respect, to a re-actualization of a drama that already happened. Hence, psychologists call the “Pygmalion effect” the tendency of teachers to treat students as small themselves or modeling them in that direction (Rosenthal & Jacobson, 1968); and conversely, it is part of the hard work of teachers or parents to realize that their children or students are not the sorts of students or children they once used to be and that the transitions experienced by younger persons are different (*see*, for example, Hatchuel, 2007). This tendency to align present transitions with old ones in which one had a different position can typically be identified in the adult's constant complaint that “youth is not anymore what is used to be”—less well-educated, less politicized... To advance our understanding of such dynamics, in the study on secondary school students mentioned above, we interviewed teachers about their past transitions, and their modalities of uses of symbolic resources then, and we examine how, in classroom interactions, teachers tend to promote, in their students, the same sorts of uses of resources, and through that, a similar transition experience; we then compare this with the students' discourses on their transitions. This type of study can thus participate to a better understanding of the mutualities between transitions in people whose lives are inter-related.

Finally, studies on grandparenthood have suggested that although dynamic of experiences of reactivation of past transitions in the present of interactions with grandchildren, the different positioning gives occasion of creative re-invention. First, grandparents are not stressed with their children's troubles as they used to be as parents (Attias-Donfut & Segalen, 2007; Cesari Lusso, 2004); but second, intergenerational exchange allows for an explicit transmission of experience, with grandchildren being more likely to accept to learn from elders—especially, but not limited to, their grandparents—than from the generation of their parents. Today, as longevity increases, the co-existence of three to four generations becomes common in some families; at the same time, the drop of birth rates produces many elder persons without offspring. Researchers and policymakers have called for a “new intergenerational pact” so as to allow the establishment of new relations between generations (Fragnière, 2010)—within or across family lines. As traditions, which usually provided semiotic resources to guide most of life transitions, tend to erode, one might wonder whether such trans-generational transmission might bring the emergence of new forms of crystallized experience—that is, the embryo of traditions. In the future, such studies should pay attention to the role of mutually dependent transitions in inter-generational dynamics.

### **Conclusion: Life-Course Dynamics**

The study of the life-course is an old project in the social sciences. Given the research methods that have been privileged so far, wide groups meant to be representative of some universal beings have been considered; this has led researchers to focus on what is general among trajectories—either the impact of social and historical events affecting many people at once, or the biological necessities of aging. From a socio-cultural psychology perspective, the core issue is elsewhere: it is located where people render their experience significant—be it in the here-and-now of the emerging moment, or when 2 weeks or a whole life is examined at once. It seems reasonable to ground such a socio-cultural study around the study of transition, as this notion might facilitate trans-disciplinary synthesis.

In this chapter, I have retraced the main theoretical assumptions of a socio-cultural perspective on the life-course, and I have in particular proposed to focus on two of four aspects through which human “cultivation” occurs (Josephs & Valsiner, 2007): in

the constant evolution of one's system of orientation, and in the interactions that take place in various spheres of experiences. Using a deliberately limited number of processes, I have tried to highlight basic dynamics taking place as people experience transitions through their life-course as many occasions for development. In the last part of this chapter, I have also suggested some issues for systematic studies, such as the evolution of people's modalities of experiencing transitions and using resources to facilitate them, as they gain more life experiences, and the inter-relations of people's experiences transitions.

From what precedes, it becomes clear that to move toward the construction of a more general socio-cultural psychology of the life-course, less wide-samples studies are needed than well-thought case studies (or ideographic approaches). Beyond the strategies evoked here (quasi-ethnographic work, interviews, use of personal writings), there is a current scientific effort to rediscover and emphasize methods that would be adequate and to which the reader might refer (Abbey & Surgen, 2012; Toomela & Valsiner, 2010; Valsiner, Molenaar, Lyra, & Chaudhary, 2009). More generally, we can invite the reader to be creative—as long as data collection respects the basic theoretical principles exposed here (and by others) and preserves the unexpected dynamics of the life-course.

### **Future Directions: Life-Course in the Twenty-First Century**

The study of the life-course presents new challenges in contemporary times. The acceleration of time perceived by more and more humans—both resulting from actual technical, political, ecological changes, and to the information about these—changes the perceived stability of human life. More and more people become migrants or feel nomadic, and experience frequent transitions. In this moving environment, the strong social or cultural canalization becomes less visible—we live with the illusion of being free, when we are not. With less explicit cultural guidance, people would have to rely more on their personal system of orientation and on the resources they are able to find in themselves, with the help of others, or around them. Learning from experience is vital, and for those who, in rich societies, do not have to focus on daily survival, learning from experience involves mainly being able to reflect on one's experience and to develop strong basis of usable knowledge mobilizable in unexpected situations. This also requires an enhanced

creativity—not only that which brings some of us to engage in a craft or an artistic creativity, but a daily ability to question the obvious, to explore the possible, and to see what is not yet the case.

A psychology of the life-course should give means to advance the understanding of humans in the contemporary world. I have attempted to highlight a few ideas toward that goal; yet this exploration also leaves us with open issues: How can the theoretical ambition to develop a psychology aware of the complexities of dynamics of the person in context really be translated in empirical work, and how can this empirical work be generalized? How can the notion of transition really become an “analyzer” by which advances in various sciences might contribute to such complex understanding? Then, how can a knowledge that emphasizes dynamic processes offer tools for teachers and practitioners? And more generally, how should we define human choice and responsibility in a changing world? How can our society, which educational institutions tend toward self-maintenance, facilitate the development of persons who are equipped to deal with unpredictability?

### **Notes**

1. Hence, three modes of organizing one's experience can be proposed: first, the organization of experience according to formal logic and that tends toward scientific knowledge; it involves causal reasoning and temporal succession, and it refuses contradiction. It is what we usually call “rational” thinking. A second mode, which we have here associated to the creation of semiotic sets, is experience-based and as such might engage reasonable, yet not rational, reasoning—what one might call “common sense” thinking (with all its positive and negative connotations!), which is highly sensitive to cultural variation and is typically displayed in narrative accounts of one's lives. The third mode is the logic of affective dynamics, which are much more embodied and ignore time and causality. We have very little control over it, yet it might infuse other modes of thinking, especially common sense. The first and third modes have been described by psychoanalysis, as resulting from conscious versus unconscious logics, secondary processes, and primary processes (Freud, 1898) or as “asymmetrical thinking” versus “symmetrical thinking” (Matte Blanco, 1998; Salvatore & Venuleo, 2010). The first mode is also privileged by learning and developmental psychology. The third mode has been explored by psychoanalysis but is still widely ignored by psychology, with the exception of some streams of social psychology (Moscovici, 2000). The second mode is the preferred object of study of social psychology and “folk psychology” (Bruner, 1990) yet has the less clear status of all. It is often seen as a combination of the two other modes of thinking (it is close to Freud's “preconscious” thinking, it demands a combination of symmetric and asymmetric thinking) but has still received very little attention in itself. However, it is quite likely that this mode of thinking groups a large number of identity dynamics, cultural experiences, and daily thinking, which participate in

what we call sense-making—and that is the object of study of cultural psychology.

2. It is to this sort of goal that some forms of meditative practice tend to orient people and reveal the random nature of the world in which we believe and, therefore, its vanity (in a Pascalian sense).

3. This raises the complex issue known under the idea of “transfer of knowledge” or of “use of resources” from one sphere of experience to another (see Zittoun, Valsiner et al., in press, for a discussion).

4. Such explorations take place in what Vygotsky had called a zone of proximal development (as it is created in children’s play, or in adult–children interactions, see Van der veer & Valsiner, 1991) or as transitional phenomena in the sense given by Winnicott—between what is and what is yet to be (Helson, 2009; Winnicott, 1971).

5. It is not only a biological change but also and immediately a symbolic one: a child enters in the world of culture. All traditional cultures accompany birth with actions aiming at facilitating the cultural birth of the child, such as circumcision, baptism, or name-giving rituals. Humans, who are used to reasoning in terms of transitions, are pushed to question where these children were before being there. The question, “Where do children come from?” is a classical anthropological and religious question; raised by most children, it is quite likely to be present in many people’s minds, even if in a very unconscious form. Parental theories (ethnotheories) about how to accompany the child’s progressive mastery of biological functions (progressive sleeping hours, whining, sphincter control) can also be seen as actualization of implicit knowledge about transitions: people might act as if it were better to accompany self-generated transitive changes, eventually bringing more substantial changes (as when parents decide to follow the child’s sleeping rhythm); on the contrary, they might privilege clear transitions by imposing a rupture to the infant and having the child adjust to it (as when parents decide to have their child learn to “make their hours”). Whether one believes in the importance of early experience or not, it is probably the case that these first handling of experience of ruptures in children might constitute a basis for further handling of ruptures and transitions. However, as humans are extremely plastic—especially in early age—and because of the multiplicity of experience and the multilinearity of development, it is quite likely that some experiences of demanding transitions might be compensated by later experiences, and memories of the one and the other revised accordingly.

6. The model of the semiotic prism, proposed elsewhere, enables to capture these dynamics of recognition in sense-making (e.g., Zittoun, 2006a).

7. The text of Hrabal belongs to a series of “letters to Dubenka”—although they are very written, they have the specificity of having the form of a freeflow of consciousness—with Hrabal (2008) explaining that his work consists in absorbing during the whole day experiences and situations, and emptying himself on the paper afterward; his work has been qualified as “total realism” (Naughton, 1998).

## Being Poor: Cultural Tools for Survival

Ana Cecília S. Bastos and Elaine P. Rabinovich

### Abstract

Poverty has been a subject of interest in psychological theorization and research, inasmuch it is related to many problems and fields with which psychologists deal. Nevertheless, the narratives on poverty available in psychological research and theory are not enough: one might say there exists a “poverty of psychology” regarding this condition, which is a quotidian reality for the majority of the world’s population. In this chapter, we intend to approach the reality of being poor as a living experience in process, by addressing several considerations: What does it mean to be poor in the perspective of the poor? How can the relation poor versus non-poor be understood? Which cultural tools are employed in the struggle for survival? This chapter analyzes the historical emergence of the notion of poverty and its uses in research and social policies, identifying the different discourses related to it, the official, the activist, and the discourse of living experience. The approach on cultural tools highlights the concepts of collective memories and resilience, presenting relevant features concerned to them: folk and oral culture, group identification (belongingness and spirituality), hope, and destiny.

**Keywords:** cultural tools, poverty, otherness, collective memory, resilience

*I remember your words very well, Your Excellency: our misery is profiting well. In order to live in a country of beggars, one needs to show the wounds and the boys’ salient bones. (. . .). This is the current word: gather the debris to easy the view of the disaster. The outsider should be able to contemplate all that “poorness” without making too much effort.*

—Mia Couto, 200. (*Mozambique*)

*It has always been the main European argument to colonize other nations the right to compare cultures in a hierarchical way that gave them tranquility of spirit to proclaim they were bringing civilization to the non cultivated, barbarian and savage Indians. How to compare past and experiences?*

—Pepetela, 2009 (*Angola*)

The idea of a “poverty of psychology” is not new. In 1970, Arthur Pearl wrote a chapter with this title, remarking:

“psychologists as a group, along with other social scientists, have been guilty of refusing to accept the challenges that poverty presents to a society of unparalleled affluence”

(Pearl,<sup>1</sup> 1970, p. 348; Harper, 2003, p. 185)

Representations of poverty throughout history have been complex and multidimensional in their nature. Such representations need to be understood in their socio-historical contexts, rather than treated as homogenizing stereotypes. The approaches to the topic of poverty vary, of course, according to the culturally and historically situated place and time and their prevailing philosophical and theoretical assumptions. The condition of living in poverty implies that the poor, as a social category, do not usually have the opportunity to produce academic knowledge about their reality from their own perspective. Studying poverty is possibly one of the greatest epistemic and ethical challenges concerning the I–Other relationships in a multicultural world that increasingly needs to learn about the complex dynamics of otherness. When it comes to poverty, the very possibility of the social visibility of the other is the first problem: the poor as agentive people become invisible. The academic, political, and financial centers of decision-making, from the outside, study, evaluate, make diagnoses, and implement programs that still relate to the poor in a condescending or patronizing way, offering explanations and solutions that hardly fit the reality of poverty as an ongoing process of living experience—just like other human conditions. In doing so, those institutions, scholars, and technicians implicitly deny, to the people and communities living in poverty, the possibility of expressing their own voice.

Alternatively, we want to adopt in this chapter a different perspective on poverty, a perspective capable of revealing the cultural tools that the poor wield for survival, and the developmental poetics present under adverse and paradoxical circumstances. Such an approach aims to overcome the blindness—still present in psychological research—toward the broad variability of modes of living, and in doing so, allow us to dialogically consider diversity and otherness.

### The Dialogical Perspective

Bertau and Gonçalves (2007), accepting the Bakhtinian idea of dialogicality as a potency referred

to as the expectation of the other’s addressivity to oneself, have emphasized the dialogical form that characterizes the dynamics of selfhood: “the dialogicality of the self is defined in terms of a dynamic multiplicity of I-positions which can be endowed with a voice in the landscape of the mind” (p. 5). Thus, the *Other* can be an external voice inside the self, yet a voice personally signified:

This dynamic perspective on selfhood has proven itself to be one of the most promising ways to surpass the old static conceptions of self which viewed the self as a monadic structure capable of relating with other monadic structures (Sampson, 1993), but still each independent from the other. The reality of the individual self was, in this sense, different from the reality of relationships.

(Bertau & Gonçalves, 2007, p. 5)

Perhaps this claim can also be applied in broader spheres (as done by Hermans & Dimaggio [2008], when bridging dialogicality and globalization) inclusive of the relationships between social classes, inasmuch as, besides material constraints, complexes of meanings sustained by poor and non-poor build and maintain poverty as a social reality. No understanding of poverty is possible without taking into account this social-psychological dimension, and it is better if done from a dialogical standpoint, which implies:

Human expressions are in interrelationships with other’s expressions: any single expression, such as a spoken utterance, a written text, a thought (even if not yet exteriorized) is a reply to other’s utterances, texts or ideas. In this sense, dialogicality refers to a property that is essential in all human meaning-making processes. (...) Linell (in preparation) goes beyond the level of expression and addresses the human condition: “*The term dialogicality (...) refers to some essence of the human condition, notably that our being in the world is thoroughly interdependent with the existence of others.*”

(Bertau & Gonçalves, 2007, p. 6, emphasis added)

Therefore, if dialogically considered, alterity or otherness (Simão, 2008) is itself constitutive; the *I* depends on the view of the *Other*. For our purposes in this chapter, the *I* and the *Other* are historical and culturally context-situated. The poor is “the other” in our discussion—the other to whom the *I* is related. In this relationship, *I* and *Other* need to be mutually recognized in his/her otherness as being part, at the same time, of an equal human condition. If the

poor cannot be seen from this relational standpoint, then there is not complete consideration of his/her reality; then there is not an encounter between different objective and subjective realities from which a new understanding can emerge. Which kind of relationship does psychological research put in motion when studying, approaching, and intervening on poverty?

This chapter intends to approach the reality of being poor as a living experience in process by addressing several considerations: Which cultural tools are employed in the struggle for survival? How do meaning-making processes inform and direct life trajectories under poverty? What does it mean to be poor from the perspective of poor persons? How do we approach the relation poor *versus* non-poor as a social relationship? What can the non-poor world learn from the lives of the poor?

The literature in psychology, history, and social sciences has been screened to select studies where the perspective of the communities and persons under focus is effectively considered. Special attention has been given to studies that illuminate processes, mechanisms, and cultural tools involved in facing the reality of poverty.

### Meanings of Poverty: Historical Roots

*Seeing so much poverty everywhere makes me think that God is not rich. He gives the appearance of it, but I suspect some financial difficulties.*

—Victor Hugo, *Les Misérables*, 1862

As a reality, poverty is known in every society and time throughout history; yet noteworthy is Mollat's claim (1986) that the word "poverty" only became diversified and part of the vulgar languages in the 13 and 14 centuries. Etymologically, *poverty* comes from Old French *poverté*, Latin *paupertatem*.<sup>2</sup> The word "poor" comes from Latin "pauper," meaning "small" and "to give birth." Originally, it was used to refer to unproductive land or cattle. The main feature here is the idea of infertility: something that is small and cannot generate (give birth); gradually, the term began to be used as an attribute of people.

The study of poverty must be approached from each of the two poles that support it: the process of being poor and social conditions (objective and subjective). According to Mollat (1986), "poverty refers initially to the quality, and later the condition of a person from any social status struck by privation" (p. 2), and also:

Poverty was quite broadly defined. A pauper was a person who permanently or temporarily found himself in a situation of weakness, dependency and humiliation, characterized by privation of the means to power and social esteem (which means varied with period and place): these included money, relations, influence, power, knowledge, skill, nobility of birth, physical strength, intellectual capacity, and personal freedom and dignity.

(Mollat, 1986, p. 5)

The image constructed about the poor at different times is connected to social goals and varies throughout history, ethically and aesthetically, according to the values of the time (Geremek, 1995). This image can carry notions and experiential realities that are basically similar, but the relationships between the concept and the living situations are difficult to apprehend (Mollat, 1986). Mollat's assertion takes into account the Middle Ages but could perfectly fit contemporary times.

Examination of Mollat's classical study in social history, *The Poor in the Middle Ages*, not only verifies the polysemy of the concept of poverty, considering its several dimensions (biological, economical, and cultural) but identifies the historical roots of signs that are still associated with the poor—in addition to, of course, the array of conditions that enhance poverty: from material deprivation and social inequalities to war and violence. All these dimensions should be considered in any discussion about the poverty line,<sup>3</sup> which indicates the existence of degrees of poverty. They are also intertwined: poor hygiene and health appear linked to the lack of economic resources and are used to generate social exclusion:

In the Middle Ages, to suffer a loss of status meant literally to fall from one's estate, to be deprived of its instruments of labor and of the marks of its condition. For a peasant this meant the loss of farming implements and animals; for an artisan, loss of the tools of his trade; for a merchant, loss of his shop; for a cleric, loss of his books; for a noble, loss of his horse and arms. Without these things a man ceased to be anything, because he no longer possessed the means to carry on a social existence. Stripped of his social position and excluded from the community, he was forced into emigration and vagabondage. The poor man was uprooted and alone.

(Mollat, 1989, pp. 6–7)

However, starting from the sixteenth century, there were changes in the image of the poor. The term

*poor* has begun to refer to the person that cannot maintain him-/herself: the beggar, the sick person, the old, the widow, the landless farmer, the abandoned child, the soldier with no war to fight. The epidemics turn out the beggar as a factor of popular disorder. The *poor* have become a social danger. To control these “marginal” people, society has based itself on moral arguments. (*Petit journal de l'exposition*. 1997).

One could identify here some roots of the current discussion on the concept of poverty, but should it emphasize economic indicators or social exclusion? The social construction of the image of the poor entails process and steps. In this way, the term poor is historically employed, first as an adjective with several connotations (e.g., condescendence, disdain, contempt, repugnance, fear), then as a substantive and only later in its plural form, acquiring here an abstract dimension: the poor, charged by feelings of pity and/or social disquiet. In his description of this process, Mollat (1989) recognizes:

The word *poor* in an abstract sense [is used to] evoke not only an image of the afflicted individual and the state of his or her affliction but also an affective component of compassion or horror, which carries with it considerable potential to provoke rebellion or social fear.  
(p. 2)

From a cultural-semiotic perspective, the word “poor” can be seen as a hypergeneralized sign (Valsiner, 2007), a semiotic regulator that orients important psychological mechanisms that contribute, on a personal and social level, to maintain or modify the social *status quo*. Just as other conditions of being in the world, the image of the poor has the power of a hypergeneralized sign, presenting a dense, dynamic, social and personal quality, likely to interact with affective-semiotic fields set up by feelings of empathy-repulsion, inclusion-exclusion, compassion-indifference and from which emerge complex attitudes and responses to poverty—keeping in mind Mollat’s claim that “evidence concerning these attitudes and responses generally exhibit only one point of view, that of the non-poor casting their gaze upon the poor” (1998, p. 2). Considering that the *Other* carries what Souza (2009) refers to as “a way of perceiving the future as a possibility (p. 104),” the images of the poor constructed by non-poor are, on the other hand, just as other social realities, value-laden and may underestimate or excessively idealize poverty and poor people, as this author emphasizes.

The historic roots of charity offer another good example in explaining the ambiguities of poverty as a concept and as a reality. In the Christian tradition, as in other more ancient religions, being poor appears as a virtue. In the Middle Ages, Mollat (1998) reports the honorific use of poverty in the expression “pauper of Christ,” initially applied to monks who chose poverty for love of God, and later, with Saint Francis and Saint Benedict, with the connotation of a means of perfection or a virtue in itself (the poor hold an inherent dignity and it is a social duty to restore this dignity if broken). Starobinski (1994) highlighted that the role of “poor” as representing the salvation of souls through charity turned out to be indispensable to distinguish between “good” and “bad” connotations of the word: the one that worked and the one that did not. The first, the “poor for Christ,” needed to be helped administering charity (and not giving alms in the streets) so the new urban order could be maintained. Later, with Illuminism, poverty became an issue of politics and government, no longer of charity.

As Mollat’s perceptive analysis has noted, the central ambivalence lies in considering poverty as “a form of spiritual sublimation” or “a permanent disgrace” (p. 9):

The idea, derived from the Gospels, that the pauper was created in the image of Christ the Redeemer was frequently contradicted for brutal contempt for the peasant (...).

... the misery of the pauper is often described dispassionately and with the purpose of reminding society of its duties towards the poor. But what was proposed? Resignation in anticipation of consolation in the hereafter? A social upheaval that would humble the proud and exalt the humble without changing the structure of society? A balance between rights on the one hand and duties on the other, based on some notion of mutual charity?”  
(pp. 9–10)

As also stressed by Starobinski, here Mollat refers to a notion of the “true poor,” whose belongingness to a group implies living on scarce resources generated by humble work, in contrast with the false one, the vagabond, wanderer, the beggar. The latter could be seen as a rebel, likely to disseminate social disorder and epidemics. Using these polarities as a basis, Ezequiel (1998) has commented on the many nuances around the subject of poverty and the image of the poor, which need to be studied over the course of history. Only by the late Middle Ages was

the notion of the poor as a social group established, with important social and moral implications:

What had been an individual affliction became a social scourge. Poverty, once seen as a consequence of, and punishment for, individual sin, was later considered a form of social parasitism or even (as in the case of beggary) a crime. (...) Humanist praise for success, with its concomitant exaltation of wealth, eventually contaminated the poor themselves, who were rightly or wrongly accused of giving in to the natural tendency of the poor man to envy or desire the comforts of the rich.

(Mollat, 1998, p. 297)

And he continues:

A new word came into use as a rival to *charity* and *mercy*: *beneficence* (with its equivalent in other languages), a precursor of the more modern *benevolence*, which first came into use (in French) in the eighteenth century, along with *philanthropy*. (...) And meanwhile, governments guided by the principle of *raison d'état* invented the idea of policing the poor – an idea more rational than it is charitable. (p. 298)

The contemporary meanings of being poor refer to social conditions of social disqualification (Paugam, 2003), stigmatization, and criminalization (Wacquant, 1999). To deal with those conditions, the poor develop cultural tools for survival: it is not only the lack of food and not having somewhere to live and a job. According to Paugam (2003), understanding social disqualification demands for us

“to study the diversity of statuses which define [people living under this condition], their personal identities, i.e., the subjective feelings around the situation experienced by these individuals along their social experiences and, finally, the social relationships they hold with other people, inside the same social condition and in different situations.”

(p. 47)

As a social category, connected to the Marxist notion of class struggle, the contemporary concept of poverty comes from mercantilism, incorporating the French Revolution's claim of *liberté, égalité, fraternité*, and the fight for living with dignity—the latter, according to Mollat (1998), originating from one of the conceptions of poverty within Christendom, well-expressed by Saint Francis. Marx (1890/1968) himself did not approach the subject

of pauperization directly: he was interested in the mechanisms that generated this reality. The Marxist analysis is structured around three main axes: the mismatch between labor income and purchasing power; the industrial reserve army (mechanism of the capitalist system that has control over the establishment of a constant distinction between the mass of wages and productivity); and the structural unemployment (with the decrease in the elasticity of the industrial army reserve). The changes in these three areas lead to increased illegal economic activities, institutionalized drug trafficking, underemployment, piracy, and informal trade.

The much-discussed crisis of capitalism and the demands and realignment that it brings on a global level have revived the discussion on the issue of poverty, by scholars and international agencies. Governments create ministries and special offices for dealing with poverty (e.g., the Brazilian Department of Solidarity-Based Economy). This conjuncture allows the emergence of new concepts (or new emphasis) around poverty as an international reality, such as the ideas of Amartya Sen (1999) on “development with freedom”. He highlighted the idea that development is not possible in a socio-economic model that excludes human life as a value by itself.

Eventually, initiatives characterized by solidarity or community life introduce new perspectives that consider the voice of the poor man himself. From the standpoint of the poor, considering their living reality, the process of globalization entails displacements and realignments with deep and as yet poorly understood impacts on the self. These are some of the consequences of belonging to an industrial army reserve that, in the words of Serge Paugam (2003), is not more “reserve” but “obstacle.”

To understand how these concepts impact the research, be it through scholars' ideological and epistemological biases or through the measures the studies adopt, let's consider the three different kinds of narratives on poverty that can be currently identified: the official discourse, and the discourses of activism and of living experience. The critical point here is that the official discourse is structured upon the naturalization of social inequality: two different kinds of logic are accepted and taken for granted—one for the rich, another for the poor (Fonseca, 1987; Chaves, 2009).

### ***Poverty According to Official Policies***

The understanding of poverty that prevails contemporarily in academic and political spheres

is based on some central ideas, which come from the end of the nineteenth and the beginning of the twentieth centuries. The first concerns the criteria to identify a poverty line and classify families according to their position relative to this line.

The first of these criteria is *subsistence*. Families were defined as in poverty when their income was not “sufficient for maintaining mere physical efficiency” (Rowntree, 1901, p. 86). Food, rent, and clothing were taken into account as indicators. If the family income minus rent was not sufficient for the consumption of the items above, the family was classified as under the poverty line—Rowntree’s construct. After Rowntree’s studies in England (in 1901 and 1918) and the policies on Social Security in the 1940s (Beveridge, 1943), the poverty line concept greatly influenced the scientific research and such national and international policies and agencies as the World Bank. In the United States, the idea of subsistence predominated in governmental policies for poverty reduction until the late 1970s (Usdheh, 1976). This conception can be found updated in Gazeley and Newell (2000).

*Basic needs* constitute the second criterion. The concept of subsistence was criticized as long it was built exclusively on physical needs, without consideration of social ones (Rein, 1970; Townsend, 1979). In the 1970s, the International Labor Organization (ILO) argued that basic needs should include two components: (1) minimal consideration of consumption: adequate food, habitation and clothing, and minimum housing and furniture; (2) access to community services in general, such as water, sanitation, public transport and health services, education, and culture (ILO, 1976, 1977). This framework has a very important role in the international scenario, strongly influencing the public policies for fighting poverty for all nations that sign the multilateral programs of ILO (Brandt, 1980). Broadly understood, this concept also produces a frame of reference not only for survival but also for the prosperity of populations in all countries.

*Relative deprivation*, which has been a very popular concept in psychological research related to poverty in the 1960s and 1970s (Carr, 2003), resulting from the emphasis on prosperity over survival, guided social scientists to formulate the third contemporary conception of the meaning of poverty. In such a case, poverty applies not only to the victims of poor income distribution but, in a more precise way, to the people whose resources do not allow them to satisfy the demands and social norms

prevailing in the society to which they belonged. In this sense, people are suffering from relative deprivation when they cannot get nourishment, amenities, standards, and services that allow them to play social roles, participate in relationships, and have the normal behavior as members of a given society. People can suffer from relative deprivation in any country—even the more developed ones—and it may concern one or more spheres of life (Townsend, 1985, 1992; Desai & Shah, 1988; Sen, 1983, 1985; Lister, 1991).

Therefore, the policies to eradicate poverty have been highly influenced by these conceptions. More recently, a dialogue between the so-called “official” discourses and policies have begun to benefit from the discussion on poverty as social exclusion, elaborated mainly by French social scientists as Bourdieu and Paugam (Ezequiel, 1998).

As the recent report on the world social situation by the United Nations (2010) stresses, there is not a single criterion that separates the poor from the non-poor. The experience of poverty is multifaceted and multidimensional, encompassing dimensions of time and relativity. Therefore, multiple indicators are needed to capture its scale and dimensions (p. 3); there exists, recognizably, a “poverty of poverty measures” (p. 45) to be overcome. The study “Voices of the Poor”, conducted by World Bank, is also a good example of a new research direction (Carr, 2003b; Spink, 2003; Eyber & Ager, 2003).

#### THE DISCOURSE OF ACTIVISM

The Brazilian scholar Pedro Demo, synthesizing the discussion around poverty and inequality, poverty and social exclusion, avers that “the most obstinate center of poverty is its political nucleus of social exclusion, in addition to material deprivation” (p. 9): and here the “poverty politic” finds fertile ground to develop, having an impact also in the “poverty” of many studies of poverty, marked by the same “political naiveté”—not to mention the researchers that benefit and draw prestige from the poverty of the majority.

Activists criticize welfarist policies, as long as they consider that these policies delegitimize communities’ political and emancipatory initiatives. The argument has been clearly exposed by Demo:

[Public] assistance is a radical citizenship right concerning material survival, linked to democratic ethics and, thus, independent of the market. The right to survival cannot be determined by insertion

in the market, because this would destroy *ipso facto* the notion of subject implied in the law. This is the problem: how to do assistance in such a way that the beneficiary is not reduced to a recipient target of minimal and minimalist material aid, thwarting his/her emancipatory horizon? (2003, p. 10)

In the context of developing countries, welfarist policies represent part of the solution but also part of the problem, as much as the social projects so characterized can weaken civil society and promote the depoliticization of the social question:

In this context the poor are renamed by their fragilities, and not for their effective or potential strength. In technocratic discourse, they arise decontextualized and de-historicized, reconstructed by a new kind of surveillance, which disregards the social values that allow solidarity, spontaneous cooperation and fraternity in daily life (Ribeiro, 2005, pp. 20–21)

The issue of the political approach to poverty is complex; let's just emphasize its insufficiency, ambiguity, orientation for social control and the fact that the poor are rendered invisible as agentic persons.

The activist discourse is relevant as much it draws attention to this. However, it is possible that the real movement of the crowd—those anonymous people so important in history (de Certeau, 2001)—be kept out of reach.

Demo (2003), inspired by French literature on the matter, defines poverty as social exclusion, characterized thus by “non-belongingness, social irrelevance, weak identity, mental depressions and discriminatory nature” (p. 33). Here, instead of centering the discussion on income levels (material basis for poverty), the author stresses the increasing vulnerability of the vast majority (social exclusion), whose condition becomes more visible and globalized. According to Demo (2003), it is necessary to realize that social exclusion cannot be reduced to the lack of essential goods but is, mainly, the situation of someone unable to raise him/herself to the status of controlling his/her destiny. Here, what is denied is emancipatory autonomy.

Close to social exclusion stands social inequality, on the basis of the unfair distribution of the income.

Poverty arises when scarce goods become privileged goods, in a material and immaterial sense. At its heart is the removal of political content—an imposed, unfair condition, historically produced and maintained.

(...) The economist approach persists in reducing

human complexity to its material face, despite of important scholars as Sen, who overcame this barrier. (Demo, 2003, p. 37)

In psychological research, a counterpart of the activist discourse can be found in the intervention studies, particularly when it comes to action-research. In the United States, the work of Garbarino (1992, 1992b, 2008) and Kozol (1992, 2005) has illustrated this trend, as have Latin American studies in education and social inclusion (Lacerda & Guzzo, 2010; Ferreira-Santos, 2009; Iriart & Milani, 2009) and the so called “psychologies of liberation” (Watkins & Shulman, 2008). Thus, Villarreal and Díaz (2009) have stressed that, in place of the “real plans of death” that the Mapuches sustain to be imposed by the Occident on indigenous people, a “plan of life” should be proposed. And from Algiers, Mekideche (2009) asks: Does territory, as designed by the North, constitute a concept and a reality connected to the economic contexts of the South? Her answer is that this must be epistemologically questioned.

#### THE DISCOURSE OF LIVING EXPERIENCE

Saint Bernard would have said that “no man should commend poverty unless he is poor.”<sup>4</sup> The analysis of famine in Africa made by de Waal (2005) illustrates the gap between the poor and non-poor world, evident through the many contrasts between the concepts of famine held by European and American scholars and those held by the people who actually suffer famines. His exemplar analysis, considering Africa's situation, identifies how the difference between economic indicators and being poor as a living experience impacts the efficiency of programs meant to diminish famine in the world.

de Waal's claims that the notion of famine could be better understood “if we discard the English notion of ‘famine,’ and instead adopt the concepts used by the people who have experience suffering famines” (p. 24). An interesting example for illustrating this point comes from the different words used to refer to the experience of famine, as happens in Bangladesh: there are *akal* (scarcity, when times are bad), *durvicka* (famine, when alms are scarce), and *mananthor* (famine widespread in the whole nation, bad times). These ideas go far beyond the international definition commonly adopted:

... widespread food shortage leading to a significant regional rise in death rates.

(de Waal, 2005, p. 9)

Indeed, the words above indicate several layers of complexity involved in the experience of famine, its extension, and its diverse causality.

In the current world scenario, the case of famine, analyzed by de Waal, is a good example also to demonstrate the conflicting interests involved in initiatives to eradicate poverty, especially considering relations between rich and poor countries.

More than famine is at stake:

This work should be seen in the context of other work which centered on starvation and the command over food for the starving, for example that of Sen (1981). The implication in Sen's work is that command over food is the overwhelming, even the only concert of famine victims. The implications of the anthropological studies are that even when people are dying from starvation, the "conceptual centre" of famine, for both the victims and people studying it, may not necessarily be that same starvation. *The experience of a threat to a way of life may be more real than the experience of the threat of starvation.* (p. 29, emphasis added)

The imposed aid may be a burden, inasmuch as it overlooks the perspective of the starving. Many times it is based on inconsistent constructs and techniques, such as "child's thinness," "anthropometric surveillance:"

The development of techniques such as nutritional surveillance creates a "citadel of expertise" (often inappropriate expertise) which prevents dialogue with lay people, including the famine victims. It also reinforces the "otherness" of famine, and its isolation from ordinary life (Hewitt, 1983). *"Famine" has become a technical malfunction, not a human experience.* (p. 29)

Furthermore, the recipients of this imposed aid only rarely have the power to decide what this aid is and how it can be used. Thus,

*The concept of poverty is bound to what we (the non-poor) can do to alleviate it, rather than what they [the poor] can do to alleviate it.* The point of this is not to pronounce upon the ethics of the aid business, but to place famine relief in the context of power relations between rich and poor countries. (de Waal, 2005, pp. 31–32, emphasis added)

Although shy, new measures emerge in social research to approach the reality of living in poverty. Aside from the traditional measures of poverty

(income poverty, food poverty), the new construct of a *subjective poverty* has been proposed and valued inasmuch it gives the word to the poor so that they can express their own suffering and expectations (Ferroukhi & Bedrani, 2009). That concept is grounded on a non-utilitarian perspective from which these authors, based on Sen's work, accept the idea that maximizing personal reasons is not the only individual leit motiv: therefore, individual action can be motivated by compassion or social commitment. Improving other people's well-being can improve one's own well-being. This approach implies the valorization of abilities and the understanding that having resources is not enough unless the aptitude for using them well is also active.

The meaning of "being poor" varies widely according to the particular experiences individuals and societies go through. Hundeide (1999) has evinced how this meaning is cultural and historically situated, considering four different communities living in poverty: Begumpur (slum-dwellers of Patna, India); Simpruk (slum-dwellers of Jakarta); the homeless poor in the United States; and Jews of Eastern Europe. The author observes:

These four communities gave four different reconstructions of their similar situations. The Begumpur population believed that everything in life happens according to a predestined pattern leaving no room for individual effort. For the Simpruk slum dwellers fate determines the possibilities of life and the fulfillment of these depends upon personal effort. The Western slum dwellers, with their individualist and materialistic orientation, put great emphasis on individual effort and personal success. Their failure in this context gives rise to a combination of guilt, resignation, inferiority feelings and hatred towards authorities. The East European Jews are more pragmatic in their orientation. They face the challenges of everyday living through a practical tradition of skills in trade and economy and a literary tradition of transcendental reconstructions. (p. 143)

Esquit (2009) has studied the relationship between political action and the formation of the Indian Guatemalan Kaqchikel's concepts of *meb'ail* ("poverty"), *qawinaq* ("our people"), *poqonal* ("suffering"), and *consciousness* ("politically positioned"). For him, the Indians' notion of poverty—through which they define their social relations—can be understood when we examine their language and

the discourses about history and daily life. This analysis has shown that *qawinag* is a category that defines the Indian being and the solidarity kept because of *meb'ail* and distress they suffer facing the hegemonical culture. He has emphasized that to be poor and Indian are kind of synonymous because the differences between the Kaqchikel group and the dominant one always showed them as not having "house, food, clothes."

## Poverty as a Process

And one would not have given a fair representation of a world that, as the social cosmos, has the peculiarity of producing numerous representations of itself, without a place in the space of views for these groups particularly exposed to little misery which are all professions that have the task to treat or speak of their great misery, as all the distortions related to the peculiarity of their views.

(Bourdieu, 1997, p. 13)<sup>5</sup>

The approach to poverty developed by contemporary French sociologists is very relevant for understanding being poor as a living experience. Embracing the road opened by Bourdieu, Paugam can be recognized as the one who has developed a processual approach to poverty, as much as he focuses on trajectories built across ages and contexts where there is an increasing social disqualification. Taking into account the case of welfare policies in France, Paugam has worked with the notions of trajectory, identity (positive, negative), and territoriality (the spatial basis that houses socially excluding processes, such as segregation).

One could say that Paugam's analysis is based on categories that assume the standpoint of the poor: the kind of processes and situations people experience when crossing the several layers that constitute life in poverty.

The concepts involved in this debate often refer to job insecurity, lack of qualification, uncertainty toward the future, finally, to pauperism, coupled with the crisis of industrial society (from the nineteenth century to today) and the exclusion itself. Both refer to moral degradation as the new condition of material deprivation (...). There is a process which is progressively pushing to outside of the productive population those segments less qualified. It is, indeed, the disillusionment in the belief that progress would bring prosperity for all.

(Véras, 2003, p. 14)

Individual trajectories through poverty can be illustrated by the French example, where social policies, meant to integrate people under the welfare system, establish three conditions: the assisted (depending on welfare services), the fragile (still distant from welfare services), and the marginalized (who had severed social bonds). This system contributes also to stigmatization (each condition in a different way) and sets up conditions for a broad array of personal experiences and cultural tools for survival under poverty.

According to Véras (2003), Paugam's system shares some of Robert Castel's description of the process of disaffiliation, which starts from the *destabilization of the stable*, who become vulnerable and settle down in *precarious conditions* (long-term or recurrent unemployment). It is followed by the absence or deficit of places to be occupied in the social structure (*social uselessness*).

Paugam has worked on the concept of disqualification, related to social status and identity. One could say it is his way to approach poverty as a living experience:

To study disqualification, the discrediting of those who, at first glance, do not participate fully in economic and social life, means to study the diversity of status that defines personal identities, that is, the subjective feelings about their own situation along diverse social experiences, and finally the social relations that hold among themselves and with others.

(Paugam, 2003, p.47)

In the psychological field, diverse representations of poverty are present, sometimes implicitly, but nevertheless orienting the view and choices of the researcher. Obviously, these representations imply a certain concept of the psychologist as a scientist and as a practitioner. It is therefore possible to identify the social activist as the one who practices charity and philanthropy; the other who consents to work on explaining—for example, delinquency—for purposes of social control; and employees at institutions and funding agencies. These institutions and agencies are oriented by specific goals and adopt images of poverty from an outsider perspective, hardly taking into account the poor's own goals.

Ezequiel's report on Geremek's account of the representation of poverty between the years 1400 and 1700 recognizes that "the constructions of the cultural elite regarding the marginal elite were absorbed by the social elite as answers to its need to

be horrified in front of the dirt and the unknown. Such a strangeness was useful for praising their values and legitimizing the existing rules through the reversal of the discourse” (1998, p. 109).

Therefore, a curious mosaic of intertwined meanings is set up: representations and explanations of poverty are available that do not consider the needs and goals of those who live in poverty. The actions generated by the studies on poverty, for their part, are directed to the poor, offering them solutions that they internalize, and then comes the moment where the well-known questions on the ability of the poor for a subjective life, for agency, emerge in the field of psychological studies and practices (“Are the poor ready to go through psychotherapy?”, “Are they able to maintain autonomous thinking?” or “Are they condemned to be in a subordinated position?”). These kinds of questions appear with much distance and strangeness, as if referring to a different humankind, and are not without consequences, inasmuch as they regulate decisions and choices in the process of researching and intervening on human lives.

Actually, sociological thinking registers different images of poverty, connected to different times and paradigms, related to different dimensions of the process of being or becoming poor, and also present in the field of psychology. Bajoit (2006) offers the following sketch of these images:

1. “The poor as marginal: he is poor because of his bad socialization, or as he comes from a subculture different from that of the majority of persons. So, he cannot succeed because he is stigmatized (and cloistered inside his culture and his stigma by the view of the others). (Oscar Lewis, Richard Hoggart, G. Simmel);
2. The poor as exploited: he is poor because he is exploited by the upper class/ruling class, because he is alienated, impoverished, excluded by the way capitalism works, and he cannot succeed as he is not protected and is not aided (Jean Labbens, Paul Vercauteren);
3. The poor as dependent: he is poor because he has no autonomy and no success, and cannot succeed because he does not have sufficient capital – associability, information, training, trust, autonomy (Klinsberg, Tomassini, Putnam).
4. The poor as disaffiliated: he is poor because he is isolated, fragmented, and discouraged and he cannot succeed because he does not participate in organized forms of solidarity (R. Castel, S. Paugam).” (p. 92)

Although providing relevant cues, these images still do not fill in the blanks regarding being poor as a living experience. To consider just one of these portraits, social disqualification based on disaffiliation, it is necessary to analyze the diverse statuses and personal identities involved in impoverishment (Paugam, 2003); the personal feelings concerning one’s own situation, the social relationships.

In the field of cultural history, being poor as a living experience can be described by specific features:

Thinking of a cultural history of society, Chartier (1990:19) states that its subject is the understanding of shapes, motifs and representations of the social world, which, despite of social actors, reflect their interests and describe the social world as they think it is, or how they would like it to be. In consequence, the values, the conceptions of the self and the world and the images of the poor should be studied because they are constituents of the past as much as quantifiable information.

(Ezequiel, 1998, p. 104)

Balsa, Boneti, and Souler (2006) argue that the socio-anthropological analysis of poverty, unlike a historical and socio-institutional approach, is supposed to focus on

“The ways in which situations are rooted and the particular contexts and trajectories can be approached through the use of individual, family or group life histories. The goal here is to examine how poverty and its dimensions are grounded in personal biographies or how people experience and handle the events that lead to poverty and exclusion”.

(p. 22)

A similar direction can be found in some psychological studies, moving—more or less resolutely—toward constructing process models. For example, in Garbarino’s (1992) claim of the need to consider the “phenomenology of deprivation” (p. 231) starting from the evaluation all human beings do of their situation, comparing it with their surroundings. Therefore, to impoverish at recession times assumes specific connotations: “It leads to a growing sense of deprivation that stands in stark contrast to the ‘objective’ facts of modern affluence (pp. 230–231).” Garbarino concludes:

“The phenomenology of poverty is dominated by the experience of deprivation and exacerbated by widespread promulgation of highly monetarized affluence as the standard. Low-paying jobs can come to be interpreted as an affront in such a context,

the accoutrements of affluence a right. None of this contributes to the well-being of young children. All of it sustains rage and despair.”  
(p. 231)

Undoubtedly, variables linked to poverty as a situation (income, socio-economic status, environment, unemployment) have been exhaustively measured in psychological research, as predicting outcomes. Carr (2003) has presented an interesting synthesis of some milestones relevant to understanding the relationship between psychology and poverty since the late 1950s. He starts with the sociological account of poverty represented by the notion of a “culture of poverty” of Oscar Lewis and considers that a more psychological approach can be identified during the 1960s:

During the 1960s, the field moved toward a much more psychological approach, captured most succinctly in the concept of a Need of Achievement (McClelland, 1961). In a similarly psychological way, the 1970s were largely focused on attribution theory, and in particular on how the comparatively wealthy view the causes of poverty amongst the relatively deprived (Feagin, 1972). The 1980s, in turn, witnessed something of a crisis of confidence in this type and level of analysis, culminating in suggestions that psychology may be doing more harm than good (for examples, see Sinha & Holzman, 1984). During the 1990s however, tentative calls that psychology might be able to make a difference began to appear (e.g., Sloan & Montero, 1990; Carr & MacLachlan, 1998). By the new millennia, we are witnessing a renewed debate about the role of psychology in fostering critical awareness of the causes of, and solutions to, poverty (Cohen, 2001).  
(p. 2)

In the particular field of developmental psychology, we can see socio-economic variables often correlated to measures of development, with a predominance of linear, one-dimensional explanatory models. Some efforts, however, rely on different, more systemic grounds, such as Bornstein and Bradley (2003) and Tudge (2008),<sup>6</sup> who take into account the need of understanding the multiple levels of organization involved in human development.

New trends exemplifying processual approaches are also reflected in *Poverty and Psychology—From Global Perspective to Local Practice*, edited by Carr and Sloan (2003). This pioneer work, coming from what the authors name a positive and critical psychology, has to be considered and encompasses a

meaningful number of subjects relevant to analyze the scope and directions of psychological research and intervention addressing poverty—power and justice, place and community, wealth and crisis, psychopathology, and unemployment. We (Bastos & Rabinovich, 2009), in *Living in Poverty—Developmental Poetics of Cultural Reality*, cover the results of investigation of social realities and their public representation in Brazilian poor communities, with a particular emphasis on the use of cultural tools to survive and create psychological and social novelty under conditions of severe poverty.

### Cultural Tools for Survival

“The miserable ones are those who confess to be defeated. However, poor people do not surrender. Every day they find out unprecedented/novel ways to work and fight. Thus, they face their difficulties and search to overcome them. Having to be constantly alert, they do not have an intellectual rest. Memory would be their enemy. The heritage of the past is flavored by the feeling of urgency, this awareness of novelty that is also an engine of knowledge”.

—Milton Santos, 2000.<sup>7</sup>

The analysis of cultural tools for survival entails various conceptions about what survival is: What does it mean to be poor, to remain in poverty, to overcome poverty? In which directions and with which characteristics are cultural tools to be utilized?

When it comes to survival and to coping with poverty, two relevant alternatives are in place: survival and coping. They need to be understood in the direction of adaptation: is the desired goal conforming to or overcoming poverty? In each case, which cultural tools are available and likely to be handled?

The concept of cultural tools comes originally from Vygotsky and, from the beginning, has been defined by the quality of signs projected to master and improve natural human psychological processes. Signs are included in psychological operations just as tools are included in a work operation, and the metaphor of tools is just as appropriate (Valsiner & van der Veer, 1996). Cultural tools are, therefore, media of transformation (Cole et al., 2001; Wertsch, 2002). To properly understand them, studies need to focus on processes and not on outcomes. Using cultural tools entails a focus on psychological distancing, through the use of semiotic mediation for overcoming, temporal and spatially, the particular here-and-now situation.

## Collective Memory

Collective memory is among the most widely usable cultural tools. It is a concept originally developed by Maurice Halbwachs (1990), who claimed that there are as many collective memories as collectives. This concept contrasts with that often employed in psychological studies on memory, linked to the assumption that memory is a distinct phenomenon that can be studied isolated from other mental functions. Usually, it is studied as an individual phenomenon. Studies on collective memory, on the contrary, have the guiding assumption that it is a complex setting always bound with something else (Wertsch, 2009, p. 122). It is also seen as in the service of providing a usable past that serves some group identity (p. 123), and this has led to a view of remembering as contestation and negotiation in social and political spheres (p. 124). Because of the issues involving memory *in* the group and memory *of* the group, Wertsch (2009) proposes the concept of a “distributed version” of collective memory:

From this perspective, memory is viewed as being distributed: (a) socially in small group interaction; (b) “instrumentally” in the sense that it involves both active agents and instruments” (p. 119). Cultural tools belong to instrumental distribution. The author suggests two forms of mediation: explicit linguistic forms, especially narratives, and forms of mediation that rely more on embodied practices. Narratives are a crucial cultural tool for representing the past (*APUD* Bruner, 1990) and what makes collective memory collective is the fact that members of a group share the same narrative resources. (p. 120)

Wertsch (2009) proposes the concept of schematic narrative templates as they concern abstract and generalized functions. The organizing form is a narrative, and these abstract structures can underlie an entire set of specific narratives (p. 129). These narratives operate at a level that can be called “deep collective memory” because they:

“function to exert a conservative, yet unrecognized force on collective memory, making it resistant to change. This reflects the fact that they are deeply embedded, both in the sense of being transparent and unconscious, and in the sense of being part of deeply held identity commitments.” (p. 130)

Thus, cultural tools (either narratives or other means such as calendars, computers, etc.) can be

seen as mediators affording people the capacity to create distinct versions of their collective past and to share these versions that construct their “collective memory.” These memories are not about the past but about present interests and conflicts (p. 113). Belelli and Leone (2007) have argued that communities “have a memory” only in a metaphorical sense; still, collective memories can be a marker of community life, favoring belongingness.

As a kind of cultural tool, collective memory implies the possibility to organize and direct the struggle for survival, which has important political consequences.

## Resilience

Many studies centered on poverty have focused cultural tools from a conceptual perspective broadly called *resilience*. Resilience has been generally defined as overcoming adversity and seen through different lens, disciplines, and theory approaches. For example, Adger (2000), a geographer, has emphasized the connection between social and ecological resilience, pointing that the demand for diverse and resilient resources partially determines location for a settlement. But for Unger (2004, p. 344), a social worker and a family therapist, there are two discourses on resilience: a positivist one, the *ecological model*, that defines resilience as “health despite adversity”, and a *constructionist approach* that defines it as “the outcome from negotiations between individuals and their environments for the resources to define themselves as healthy amidst conditions collectively viewed as adverse.” And Payne’s methodological critics (2008) have highlighted the importance to capture the phenomenology of the studied person, which is not usually taken on account in studies about resilience.

Other concepts to describe correlate phenomena are vulnerability, risk and protective factor, coping, and empowerment. Risk may be defined as statuses that increase the probability of failure as a consequence of the imposition of structured constraints (O’Connor, 2002). Constraints are practices that systematically and/or institutionally limit the life chances of particular groups of people. However, Shih (2004, p. 180) opposes coping models to empowerment model: in the first, individuals are motivated to avoid negative consequences rather than to create positive ones; the second one proposes that overcoming adversity is not a depleting process but rather a replenishing and enriching process. In the same direction, Nicolas et al. (2009)

have used the concepts of strengths and resistance—not of resilience—to refer to active coping strategies that youths learn to use to alter environments or their reactions to adverse environmental contexts.

Nevertheless, one important notion is that of opportunity: it signifies the availability of specific institutional, material, or human resources that might be employed in the negotiation of structured constraints. Opportunity can be registered through the availability of institutionalized and non-institutionalized resources. Institutionalized resources reflect systematic and structured supports that counteract or circumscribe constraints. In contrast, non-institutionalized resources reflect those supports that mitigate the impact of circumstances but are acquired through idiosyncratic or informal mechanisms. (O'Connor, 2002).

As a consequence of opportunity social differentiation, Schoon et al. (2004, p. 399) concluded from their study about levels of adult adaptation that for the socially disadvantaged, secondary school adjustment was a more important predictor of successful adult adjustment than for their more privileged peers. Young people from disadvantaged backgrounds have to have the necessary credentials to succeed, whereas for their privileged peers, other factors, such as existing social networks and familial resources, might be more important. Bronfenbrenner's idea of a structure of opportunities and its components—mainly the differentiated degree of permeability at each level of the context and the differentiation by forms of social integration and participation (Goodnow, 1996)—was utilized by Bastos, Iriart, Alcântara, Milani, and Ferreira Santos (2008) to analyze mechanisms for social inclusion of Brazilian adolescents living in poverty.

The study of resilience started from an individualistic approach to a much more complex and social one. Historically, researchers relied on deficit models (Ceballos, 2004, p. 172). Poor families were seen as potentially confronting multiple stresses, such as unemployment, substandard housing, lack of health care, crime, violence, and substance abuse (Black & Lobo, 2008). Poverty was considered a risk factor for a multitude of reasons, including family exposure to parents with higher stress and greater propensity for negative parenting, and neighborhood factors, such as crime, violence, drug use, peer influences, and cultural pressure (Abelev, 2009). Despite these pressures, many low-income families not only met basic needs, but were able to avoid violence and crime involvement, kept their children in school, engaged

their children in enriching activities, and maintained family cohesion (Black & Lobo, 2008).

However, framed within a positivist paradigm, most of these studies choose arbitrary distinctions of what are to be accepted. "Such arbitrariness is more the result of ethnocentrism than of cross-cultural study that questions the hegemony of Western middle class norms" (Ungar, 2004, p. 345).

Payne has highlighted this issue (2008, p. 5), studying "street people" (Black men) and noting that traditional literatures on discussions of resiliency are typically grounded in four problematic assumptions: (1) a middle-class and upper-middle-class orientation, (2) an a-historical stance, (3) an individualized perspective that often holds the person solely responsible for the development of resiliency, and (4) a refusal to consider the overall social structural impact of economic conditions in the lived experiences.

Therefore, in contexts such as poverty, the significance of societal context has been minimized in resilience research (Bottrell, 2009a). Recently, research has centered on understanding processes to account for the complexity of factors and their correlated interactive effects (Abelev, 2009; Adger, 2000; Bottrell 2009b; Brown, 2008; Gomes, Rabinovich, & Bastos, 2005; Hernández, 2002; Jones, 2007; Payne, 2008; Seginer, 2008). That which may constitute risk in one cultural context may not apply to another or elsewhere may constitute a protective factor or process, based in specific conditions, cultural values, and norms (Ungar, 2004; Bastos et al., 2008). Moreover, criteria for assessment of positive or maladaptation may be embedded in socio-cultural assumptions and historically specific societal expectations.

Bottrell's study (2009b) has revealed that resilience goes beyond the protective factors currently highlighted within the resilience literature, noting that all her respondents also benefited from access to the *habitus* of the middle class, without which they would not have exhibited the same level of resilience. So, to become a middle class can be understood as one way to surpass the difficulties of being poor—even if it can conduct to other kinds of poverty, considering the restricted worlds and horizons of some typical middle classes.

Besides social class, gender and ethnicity have been related to poverty (Campbell, 2008; Hartman et al., 2009). O'Connor (2002, p. 878) has shown how constraints were expressly linked to the women's positioning as Blacks and women, as well as to

how the intersection of race, class, and space determined their access to educational opportunity. This point of view suggests the importance of resources to enhance both resilience and social capital because options and opportunities are constructed out of the unequal resources of multiple interdependent capitals (O'Connor, 2002). The role of social structure in risk decision making has been extended beyond social factors to include notions of power, opportunity, and constraint—for example, social exclusion, access, and use of social networks, and the range of “social capital” available to the decision maker to include the structure of opportunity itself and the range of choices and resources genuinely available (Kemshall, 2008). Therefore, Bottrell’s (2009b) study about Black student girls has shown that the students thrive on recognition within their own networks, but “their pride can readily transform to shame and anger in the face of outsider” (p. 499).

These two levels of focus (individual vs. collective) may not always be exclusive and contradictory. Stigmatized individuals who adopt an empowerment model tend to engage in efforts aimed at removing stigma at the collective level (Shih, 2004, p. 183). Those individuals believe that the stigma associated with the identity is unjust, and consequently, they are often spurred into action to remove the stigma from the identity.

Besides pride and relations of recognition that close down opportunities and resources for some and open them for others differentiating types of networks and their capacities for facilitating accrual of social rewards and resources, social institutions are subject to external pressures and shocks associated with both political and economic change. The ability to absorb these changes depends on social capital but also on the role of surprises and the characteristics of the resource system (Adger, 2000). At a still broader perspective, Saint-Arnaud and Bernard (2003) have accrued another perspective including welfare regimes. The authors have concluded that the stability of the welfare regimes reflects the strength of their resilience when confronted with the effects of the economic transformations caused by globalization.

So, either focusing on individual or social resources, the deficit model prevailed. More interestingly, the concept of paradoxical poverty has been used to refer to places that are poor in material resources yet rich in social, cultural, or environmental resources (Driskell, Bannerjee, & Chawla, 2001). The paradox of people’s culturally and emotionally

rich lives within the context of a poor and environmentally degraded place “is not a naïve story about poor people content with their low station in life. Such an interpretation would serve only the interests of those who wish to retain the inequities of the status quo” (Driskell, Bannerjee, & Chawla, 2001, p. 80). Driskell’s account of India Sathyanagar’s young people spoke of young people living under difficult circumstances: of 6- and 7-year-olds thrust into adult roles; of hours spent each day in household chores such as fetching potable water; of children exposed to open sewer drains in their daily play; of people’s lives cut short by disease and violence; and of social and political injustice. Yet they also spoke of young people with an astonishing degree of resilience. In many cases, the children of Sathyanagar could be described as confident, connected, and happy—words seldom used to describe young people in many other cities that enjoy much higher relative levels of well-being.

Some approaches to Black and Native American studies have turned their focus to cultural differences. Brown (2009, p. 45) concludes that the cultural practices of some Black American families and communities may have a significant role in their resiliency. Having the support of another person (e.g., family, peer, and community member) can be advantageous for African-Americans (Utsey, Bolden, Lanier, Williams, 2007, p. 77). The worldview of African-Americans is grounded in a strong spiritual/religious belief system, extended familial and fictive kinship bonds, a collective social orientation, and affective expressiveness. Studying the continuity as resistance of the Native American family, Gross (2003) has shown that “memory is a key source of self-destructive behavior, as well as of cultural resilience” (p. 31). So, cultural factors can have a significant impact on the level of resilience reported by participants.

The study of a gifted Black child living in rural poverty (Hébert & Beardsley, 2001, p. 98) also showed that the boy, besides solitude, “found that his quiet surroundings gave him high-quality thinking time and inspiration for his creative writing.” The authors note that educators need to appreciate and respect the cultural qualities of rural life to people born and raised in a rural culture. Related to an education process, Sartorello (2009) has proposed collaboration, interlearning and co-theorizing to arrive at a new curriculum in Chiapas, an Amerindian Mexican region. New Amerindian social movements related to education can be seen in Chiapas but also

in the whole Mexico and in Latin America. These new movements look for ethnic and solitary citizenship, supported by Amerindian cultures against the domination–submission balance between the national-mestizo culture and Amerindian cultures. He insists that educators must listen to the voices of their Indian collaborators and let themselves at some measure be guided by them so they can construct and express their educational proposal.

#### FOLK AND ORAL CULTURE

Santos (2009, p. 143), discussing the effects of globalization, opposes the resistance of the previous culture to the mass culture, dominated by the international market. This folk culture outlines the daily life of the poor people using the mass media tools. Even so, its content is not “global” because its base is grounded on the territory and on the traditional and local culture (p. 144). For this author, scarcity is again the main issue; as “the poor” do not have the instruments (material and others) to participate in the modern mass culture, their own culture, based on territory, work, and daily life, becomes strengthened and finds its way out. So, territoriality is important to consider how poor people manage to find solutions to their challenges. This is culture and how they do it, cultural tools.

Martins (2000) also stresses that poor people’s common sense is socially related shared knowledge (p. 59). Meaning comes before the relationship “because without shared meaning there is no interaction” (p. 59). Meaning is reciprocally perceived and negotiated by the participants. So, new meanings are continually re-invented and not only merely copied. An important contribution to understand cultural tools related to poverty comes from Denham (2008). His study focused on narratives of resilience of one Indian American family to understand historical trauma. Owing to the manner in which memories and ancestral identity are transmitted to future generations, family members constructed their sense of self from a network or chain of *intergenerational* memories and narratives situated within the larger socio-cultural, political, and historical context. Children are told: “Never forget who you are and where you come from.” The author concludes that the resilient dimensions of the narrative praxis of the family—that is, the active employment, telling, and interpretation of narratives—illustrate how personal situations or experiences are given meaning and often interpreted in relation to a specific narrative or an ancestor with whom the individual closely

identifies. That is, stories of individual experience are frequently employed in direct reference to the content or structure of family trauma experiences or oral history (p. 406).

Based on these considerations, our understanding of cultural tools and resilience related to poverty made us highlight the following features: belongingness; hope; destiny; cultural beliefs and values; spirituality; and strategic interpretations of social environment.

#### GROUP IDENTIFICATION: BELONGINGNESS AND SPIRITUALITY

Individuals that are highly identified with their group, despite the negative meaning associated with it, are more likely to be empowered. They interact with others from the same group and are more aware of the positive aspects of their group membership. As a result, they are less likely to buy into the negative messages received from society about their negative public identity (Shih, 2004, p. 181).

Hernández (2002) has defined *autogestión* as

“the name in Spanish to the processes in which communities develop agency and organize themselves to demand the fulfilling of their rights, restructure relationships of power within the community, or become political in society.”

(p. 343)

Social networks in communities living in poverty can be seen as a survival mechanism. Informal kinship is another manifestation of the value of interconnectedness and authenticity, present in the Afrocentric belief system. It is a manifestation of the collective social identity whereby one has a view of oneself as part of a community. As a result, the microsystem expands to include more than immediate and extended family members (Jones, 2007). Driskell et al. (2001) have shown that the children of Sathyanagar had the advantage of being part of a generally cohesive culture steeped in tradition, myth, and ritual that gave them a strong sense of identity. They knew who they were and had a strong sense of belonging, partly because of their extended family networks, strong ties of kinship, and a vibrant social and cultural context in which interaction with community members of all ages was an integral part of daily life. Analogous trends have been analyzed by Mahfoud and Massimi (2009), in a Brazilian semi-rural community that stands on religious traditions, particularly celebrations (“festas”) to relate with modernization without losing the sense of identity,

keeping the autonomy for making choices and positioning themselves. Belongingness and celebration of the history and the artistic resources of the community were found by Ferreira Santos (2009) to be the most important strengths in the struggle to survive for adolescents living in a slum of Salvador, Brazil.

Historically, spirituality has been defined as a search for universal truth and meaning or a form of belief that connects an individual to the world and provides meaning to one's existence (Jones, 2007, p. 131). Cultural resources are sources of external support, such as religion and spirituality and availability of extended family networks (Nicolas et al., 2009). The term *religiosity* historically has been associated with functional, institutionalized behaviors associated with religion. More recently, researchers have begun to minimize the polarized nature of these definitions and consider a more integrated definition of spirituality. Jones (2007) focused cultural beliefs and values that are used as coping mechanisms in the context of specific African-Americans. Participants in the study included 71 African-American children between the ages of 9 and 11 years who lived in a high-crime, high-poverty community in Houston, Texas. The results indicated that formal kinship and spirituality, along with high levels of combined supports, demonstrated buffering effects on exposure to violence. Utsey et al. (2007) concluded that spiritual and collective coping were statistically significant predictors of quality-of-life outcomes above and beyond the traditional predictive factors for African-Americans from high-risk urban communities.

In Driskell's et al. study (2001) in India, religion, with its symbols and rituals, also played an important role in community life. From Brazil, people living on the border of the Amazon River emphasized the importance of family, nature, work, and religiosity (Vasconcelos, 2009). The religiosity in this context legitimated the family and work relationships and demonstrated it to be strongly tied to the regional traditional values. And Terena (2009), a great Brazilian Indian leader, has said that spirituality is a criterion shared by every Amerindian together with oral, historical, and ancestral wisdom, which maintain the balance and the quality of life.

Spirituality is a broader term than religiosity, but both seem important when we consider them as cultural. Both also are related to belonging to a group, either transcendental or more socially based.

## HOPE AND DESTINY

Lothe and Heggen (2003), after their study in Ethiopia, raised the question: "Is resiliency sufficiently differentiated to fit cultural setting in the countries of the South? (p. 319), based on a possible cultural bias of the lack of attention paid to the significance of hope that "emerges as the most significant source for survival" (p. 320). For Hernández (2002), studying the meaning of hope and solidarity in Colombia Latin American context facing war and political repression, the locus of hope is located in the building of social networks and promoting agency. From Israel, studying the psychological factors that facilitate adolescent future orientation in times of political violence, Seginer (2008) has outlined an integrated model positing that the effect of challenge/resilience on future orientation is mediated by hope. She has defined hope as "a positive emotion specifically related to the feeling that things will turn for the best, and close to the meaning yet distinguished from optimism" (p. 277). Finally, Payne's (2008, p. 9) project has provided a social psychological examination of how street life as an ideology and set of relations and networks operate in the lives of low-income Black men as a space within which hope, friendships, violence, terror, risk, optimism, and struggles for survival are displayed.

A very interesting way of looking to destiny and to its underlying processes is proposed by Chaturvedi, Avinish, Chiu Chi-yue, and Viswanathan Madhubalan (2009) by using the concept of negotiable faith belief. This model accepts that the individual does not have direct control over one's fate and at the same time maintains that the individual can negotiate control with fate for better personal outcomes (p. 882). They differentiated it from disjoint agency "which boasts the ability of self-determine one's course of action and outcomes unconstrained circumstances" and from "fatalism, which holds that all events are predetermined by fate." Negotiable fate recognizes fate as a powerful causal agent through agentic actions (p. 881).

In their study, among relatively low literacy in Indians, the belief in negotiable fate was linked to a greater tendency to engage in decontextualized judgment and rule bases categorization (p. 890). This thinking style is privileged by Western culture and not in societies where contextualized, intuitive thinking is emphasized. They "speculate that, among these individuals, the belief in negotiable fate and its associated thinking style may support a focus on their personal agency despite the environmental

constraints. Specifically, this belief may help these individuals to identify the critical factors that create and remains the major constraints in their life” (p. 891) and motivate them to identify rules to maximize personal control without directly confronting the “nonmalleable” social reality.

There is a Brazilian’s expression, *jeitinho* (literally, “little way”), which is difficult to be translated but means “that a problem should be accepted as given” (Torres & Dessen, 2006, p. 262) but that at the end some solution will be anyway achieved. This expression is similar to the concept of negotiable faith belief in the sense that, even if fate exists, agency also plays a role and results depend on both.

Besides, there are other processes to overcome stressful poverty situations related to strategic interpretations of social environment. Individuals may switch their identity orientations across situations to strategically emphasize identities that are valued and de-emphasize identities that are not in any given social context. Work on identity adaptiveness has found that individuals orient themselves more positively toward identities that are adaptive in any given situation (Shih, 2004, p. 179). In a broader sense, orientation to the future and human capability of psychological distance respond for survival under adversity, as exemplified in the experience of Brazilian families living in poverty. There is a poetic dynamics involved here, in every shift that challenges *what is* and clearly promotes moving into the direction of what *could be* and *should be* (Bastos & Rabinovich, 2009).

Individuals can manipulate their interpretations of their environment to protect their sense of self-worth. By changing their standards of comparison, individuals are able to ameliorate perceptions of inequity and relative deprivation (Shih, 2004, p. 179). They also may manipulate the kind of attributions they make to explain social events.

These could be cultural tools that underlie some processes by which poor people manage to survive. As Kumar (2010, p. 16) has concluded, cultures remain an important variable in explaining phenomena linked to poverty and development, but daily culture is majorly responsible for structuring the responses to real-life situations.

## Future Directions

The issue of poverty, broadly considered, and for its implications for human lives in several senses and at multiple levels, cannot be reduced to a research topic or to a technical problem. It seems impossible

to dissociate research, theoretical understanding, and social change when it comes to poverty; similarly, poverty is a phenomenon that entails economic, social, psychological, cultural, and ethic dimensions. No wonder that so many initiatives to reduce or alleviate poverty fail. However, there are signs that justify some optimism.

To recognize this mixed, complex nature of poverty and the trials for interdisciplinary and intercultural approaches is an important, positive sign. The initiative of United Nations inviting 10 international journals of psychology to elaborate special issues on the subject of poverty is an interesting example in the search of a more complex, integrated view in the development of policies and strategies for poverty reduction. However, as Tripathi (2010) has observed, the possibility of halving poverty in the world in 2015, as a Millennium Development Goal, is not likely to be achieved then.

An effective criticism about conceptual perspectives on poverty has to be centered on the question of its relation with alterity. Everything is preceded by how poverty is perceived and by the way one relates to it (de Waal, 2005; Bastos, Rabinovich, & Almeida, 2010). Here, we need to consider the diverse discourses and to situate ourselves in relation to them. This challenge requires basic changes in the way of feeling, thinking, and acting of researchers and practitioners. The issues discussed in this chapter can help to delineate the nature and directions of these changes, and it may be worthy now to single out some of them.

The first issue concerns the cleavage between being poor as a living experience and as a focus for study and intervention, and the epistemic and ethic challenges to build different basis for the relationships I–Other, in a globalized world and at multiple levels—the person, the family, the community. New developments in the conception of poverty and in research methods are needed, articulating the study of micro- and macro-level processes and fostering the voices of the poor to be heard, taking advantage of cultural diversity.

Besides the two psychological models in understanding poverty presented by Tripathi (2010), *dispositional* (where the poor are held responsible for their fate and fall victim to stigmatization and prejudices that are based on social class or a social category) and *situational* (that holds the social, economic, and political conditions responsible for the emergence of the social class of the poor), it is also needed a different perspective on poverty, a perspective capable

of revealing the cultural tools that the poor wield for survival, and the developmental poetics present under adverse and paradoxical circumstances. Such an approach aims to overcome the blindness—still present in psychological research—toward the broad variability of modes of living, and in doing so, allow us to dialogically consider diversity and otherness.

A third set of questions is directly related to cultural tools, as we understand here. Which cultural tools are employed in the struggle for survival, and how does it happen? Cultural tools are media of transformation (Cole et al., 2001; Wertsch, 2002) and media for understanding social change itself. Research should also focus on the new cultural tools that continuously emerge from the struggle of the human being to survive, living in a world of poor and non-poor people, full of heterogeneous and ambivalent social directions.

We agree with Tripathi when he says that “poverty reduction requires approaches which are trans-disciplinary. Poverty alleviation cannot be left to be dealt with by any single discipline” (pp. 216–217). Furthermore, we would say that poverty reduction requires intercultural and intersectorial approaches, far beyond of the academics and governmental walls. Nothing will happen without the effective and agentic participation of the poor, at the social level and at the personal level as well. Whatever should be the role of the researcher in this process, he/she must be aware of the political implications of every decision and step taken. These implications start from the conceptions he/she holds about poverty and the relationship with the poor. In a certain way, we must also consider that the researcher has necessarily a political and a social inclusion that participates in his/her research. The possibility of investigating poverty depends on an honest, intense, and open practice of reflexivity considering the place occupied by the researcher allied to intervention as a way of knowledge. The participant of the research also must occupy the place of the knowledge constructor.

Finally, an intercultural perspective is important to identify general patterns of conditions, contexts, and ways of feeling, thinking, and acting that produce specific ways of survival. It would favor a broad vision of poverty as part of human experience—to be transformed toward dignity—but still a source of psychological and socio-cultural novelty and concerning every human being, poor and non-poor, for its multiple implications. Poverty must not be a stigma that superposes itself to richness and to

the poetry of a diversity of ways of life that still, in a certain measure, escape from homogenizing and impoverished models as, for example, the limits, paradoxes, and suffering of consumer society.

In this context, it is worthy to have in mind the goal stated by the United Nations—even if inscribed in the official discourse, which needs to fight very much to be recognized and legitimated from the standpoint of people living in poverty:

Promoting inclusion and reducing deprivation strengthens democratic institutions and processes, making social and economic relations more harmonious, and provides a firm foundation for long-term development and prosperity.

(UN, 2010, p. 7)

# Cultural Psychology of Racial Ideology in Historical Perspective: An Analytic Approach to Understanding Racialized Societies and Their Psychological Effects on Lives

Cynthia E. Winston and Michael R. Winston

## Abstract

Race as a label and idea has developed over time as part of science, philosophy, psychology, and other areas of scholarship. Its social uses have been notable—and often notorious—leading to treating race as a “thing.” Such ideological use of race as a “thing” has been discredited in our century. Nevertheless, the residual reality is that socially destructive ideological concepts of race have been embedded in racialized societies to varying degrees through social, economic, and political institutions and their practices. This reality has psychological consequences for human personality development, identity formation, and lives. Varied cultural historical conditions have buttressed systematic and institutionalized agents of power. This has motivated, manufactured, and sustained new forms of racial thinking and ideology. The goal of this chapter is to develop an analytic framework for cultural psychology that penetrates the historical surfaces of racialized societies so that the interactions among race, culture, and racist ideologies may be understood as a dynamic, rather than static, multidimensional system that varies over time and place. Although modern scholarship on race across the disciplines is vast and more than a century old, the Winston Framework provides a new organization and synthesis of cultural psychological concepts that operate at multiple systems and interindividual levels across time and different racialized systems of domination. It is proposed that a cultural historical psychology of race analytically requires a synthesis of race concepts appropriately placed in their historical context, including the dynamics of individuals, institutions, and societies.

**Keywords:** race, racialized societies, racial ideology, identity, master narratives, cultural historical, cultural psychology, comparative

Contemporary biological and social sciences recognize that human beings are a single species and that observable physical differentiations among them are not markers for traits, abilities, or intelligence. Moreover, genomic research has found that all humans are approximately 99.9% the same genetically (Collins, Green, Guttmacher, & Guyer, 2003). Since the end of World War II, an international scientific consensus has dismissed the idea of superior and inferior races as a myth. For more than 200 years, however, such ideas were a dominant although often challenged ideology,

especially in Europe and in the Americas. In those societies in which dominant and subordinate groups were classified racially, economic and social institutions were structured to maintain the existing disparities in power, wealth, and social development. Those aspects of the social structure in turn shaped patterns of behavior, forming cultures of dominance and subordination. Within such societies, behavior coded and regulated by race and or color became an integral component of the psychological development of dominant as well as subordinate groups.

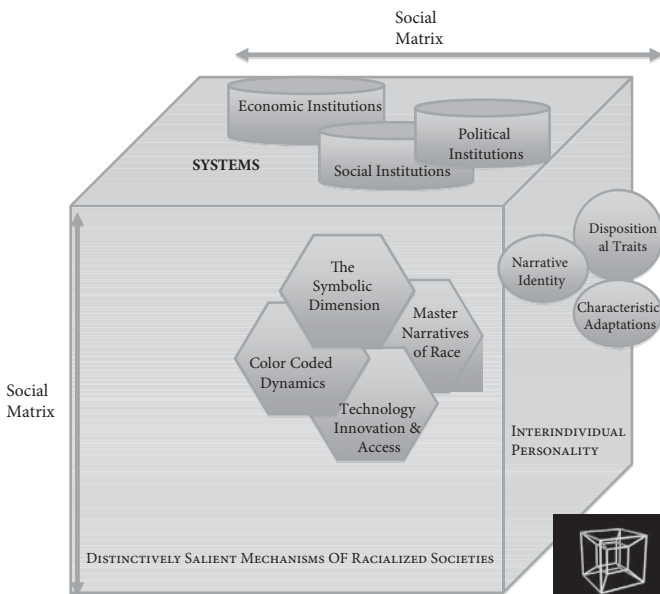

In this chapter, we propose an analytic framework for penetrating the historical surfaces of racialized societies for cultural psychology. It would enable researchers to view interactions between race, culture, and racist ideologies as a dynamic, rather than static, system that varies over time and place. A cultural psychology of race conceptualizes culture as central to the psychological meaning of race. Race's meaning is both constituted by and constitutive of culture. A cultural psychology of race fuses systems and identity development dynamics through mechanisms that are political, social, economic, and personal. It includes history as a tool to specify empirically the psychological mechanisms of domination, subordination, and equality.

There are several factors that distinguish our analytic framework from others within the field of psychology and other social sciences. Our framework allows for comparative analysis of racial systems across cultures and social types in different countries—such as the United States, South Africa, the Dominican Republic, and Brazil. As such, it allows for very specific factors to be compared across systems and cultures. For example, the date of emancipation varies across the British colonies (1834), the United States (1865), and Brazil (1888). In some instances, emancipation precipitated a search for other racial sources of labor, as in the case of the British Empire, where Asian (Chinese and Indian) contract labor was imported to replace local Black labor. The racial-cultural dynamic was thus made only more complicated but actually

facilitated colonial exploitation by the British system of “divide and rule.” In other instances, such as Brazil, color and class replaced the legal status of slavery as markers for social and economic subordination. In such a system, the cultural dimensions of class became a major component of the system of racial subordination, enabling supporters of the system to argue that it was not based on race or former slave status, but class.

Another example of a comparability measure is the degree of urbanization and proximity to seaports (e.g., coastal versus interior [Africa, Latin America, Caribbean]). For example, in pre-industrial societies, seaports were “zones of racial juxtaposition” because they attracted populations involved in various aspects of trade. These included slaves, textiles, spices, tobacco, and other commodities in trade between tropical areas, Europe, and the Americas. As cities grew in the coastal areas of the Americas, England, Europe, Africa, and Asia, work and commercial opportunity attracted populations that were highly differentiated racially.

The Winston Framework also allows for empirical data to be interpreted within a dynamic and scalable framework referring to linked concepts and phenomena that vary in their expression and intensity from society to society. The Winston Framework identifies such concepts as color coding, technology, and master narratives of race as being mutually relevant (see Fig. 25.1). Therefore, empirical data on the race

**Figure 25.1** The Winston Framework for the Cultural Psychology of Race in Historical Perspective (2010)

and or color and status or role of a particular racial group in a technical field may be examined as part of a socio-cultural system, rather than isolated demographic and employment data. It was the pattern in racialized societies, for example, for newly emerging technical fields of scientific importance or social prestige to exclude racially targeted groups. Aerospace programs, organ transplant programs in their early development, and militarily significant research programs (such as the development of nuclear weapons) are all examples of this phenomenon. Limiting the access of targeted groups to the relevant education and training is also, of course, a part of the institutional means for making some fields more exclusive, prestigious, and Whiter than others.

## Race As a Biological and Historical Phenomenon

### *The Basic Dualism of Race*

The term *race* has been used for centuries to categorize human groups. If it were no more than a convenience for generalizations about human variations, then it would have had no more historical or social significance than different classification systems in botany and zoology.

Analysis of race is often marred by confused reasoning caused by the tendency in some academic disciplines, and in certain aspects of public policy, to discuss race as if it were a concrete “thing.” On one level of analysis, “race” is a label with no universal definitions or intrinsic substance. On another level, race is implicated in a vast system of social and economic control and subordination. An understanding of these two aspects of race necessarily involves the history of how the use of the term race evolved and how it became more than a neutral label. In fact, it became a major social, political, and cultural force. The key distinction is between what race “is” objectively and what race “means” in different cultures and periods of history.

Just as there is a basic dualism in the *concept* of race, as a label and a “thing,” there is also a fundamental dualism in the *history* of race. On the one hand, race as a label, as a means of classifying humans, has continued to evolve over centuries in both science and scholarship. On the other hand, race has evolved as a component of various ideologies—some explicitly racist, others more nationalistic or cultural but with a strong racial element—for example, American White Supremacy, (Fredrickson, 1981, pp. 136–179), Russian Slavophilism, (Riasanovsky, 1963, pp. 401–404), German *Volkish*

ideology—the transcendental, unique essence of the German soul (Mosse, 1964, pp. 3–30); and *Yamato minzokuism*—the Japanese as the pure “leading race” (Dower, 1986, pp. 204–207).

The ideological use of race as a “thing” has been discredited in science and scholarship. The ideological manipulation of race, however, has often adapted to new social and political conditions, sometimes using politically potent proxies for race such as religion or immigration status. Despite the steadily narrowing appeal of overt racism since World War II, a residual, institutionalized reality continues to exert significant psychological influence on lives. Ideas, attitudes, and values now known to be erroneous have an embedded life in the economic and cultural patterns that continue to shape the interactions of people of different racial identifications in what the Winston Framework conceptualizes as “racialized” societies. This has psychological consequences for individual personality development (Winston, in press a) and for the study and understanding of lives affected by subsurface social ideologies from earlier periods of history (Drake, 1987).

### *Origins of Racial and Racist Thinking*

The physical differences among humans noted in early civilizations were variously explained by creation myths and legends. Claims to superiority were usually rooted in a belief that a given civilization or culture was superior to all others (e.g., Greece and China), which were characterized as “barbarian,” but not because of the physical differences themselves. As early as the time of Aristotle (384–322 B.C.), physical and temperamental differences were sometimes explained naturalistically as a result of climate and culture (Aristotle, *Politics*, Book X 1327b). When Christianity emerged as a syncretistic religion of the Roman Empire, transcending tribal and sectarian traditions, it acknowledged human differences but emphasized St. Paul’s statement that God “hath made of one blood all nations in the earth to dwell” (*Acts of the Apostles* 17:26). Later, in the early fifth century, St. Augustine argued (in *The City of God*) that differences in color or “quality of nature” did not mean that human beings did not all derive from the same divine source (Gossett, 1965, p. 9).

The spread of explicitly racist views is linked historically to the European conquest of large territories inhabited by non-White populations. It was observed initially in the Spanish conquest of Peru and Mexico in the sixteenth century, when Indians were enslaved to provide free labor for

mining and agriculture. Countering religiously based objections to slavery, most significantly those of Bartolome de Las Casas (1474–1566), defenders of the system asserted that Indians were inferior to Europeans, not because of climate or culture but because of unchanging “racial” differences. As other Europeans—notably the English, the French, and the Dutch—vied for the opportunity to extract wealth from their colonies in the Americas, racist ideas took firmer root with the expansion of the African slave trade. As late as the seventeenth century, these ideas were still far from systematic and did not generally have the sanction of the learned. As Thomas Gossett has pointed out, as slavery expanded as a system driven by economic gain, “there was a minimum of theory” (Gossett, 1965, p. 29). When slavery began to be attacked more frequently as immoral by Quakers, and contrary to Christian teaching by some Protestants, explicitly racist theory began to be developed in defense of the system (Frederickson, 2002).

Race gradually became more than a device for classifying human beings. Under the pressure of controversy, it evolved into something new, in which its social meaning was more important than any biological variations. Variations in physical appearance (phenotype) were interpreted to be markers for unchangeable abilities, temperaments, and traits. It was claimed that just as human groups differed in color, physical stature, and facial features, they differed fundamentally, as groups, in their “capacity for civilization,” their intelligence, general educability, capability in mathematics and the sciences, character traits such as industriousness, adaptability, as well as motor skills, sexual behavior, tolerance for particular diseases, pain thresholds, and aesthetic sensibilities (Hall, 1905, pp. 95–107).

### ***The Enlightenment Sources of Modern Racist and Anti-Racist Ideology***

During the eighteenth century, intensified contact among Europeans with Asians, Indians in the Americas, and Africans aroused increasing interest in the subject of human variations. Over the course of the century, two contrasting intellectual responses to the new information about non-European populations emerged. One approach continued the effort in botany and zoology to develop a scheme for classifying populations. This strain of thought was a type of proto-racial theory, classifying humans according to color or geography (usually white, red, yellow, brown, and black; or, alternatively, as

Europeans, Asians, Americans, and Africans). By mid-century, some writers in this camp ventured a stratifying notion of “the races” in a hierarchy, with Europeans at the apex and Africans at the base (Cohen, 1980). Equally prominent was their attempt to associate “character traits” with nations as well as races, identifying some as uniformly clever or dull, courageous or servile, militaristic or passive. The opposite approach, based on a broad conception of the formation of human cultures and societies, posited that there is a single “human nature” that is expressed variously in different cultures. Its adherents also argued that civilizations or societies evolved over time, from simpler forms and structures to more complex, with the range and variation in human behavior attributable to the type of society in which individuals and groups lived. The first approach tended toward a racial determinism in human behavior, expressed as unchangeable racial superiority or inferiority, whereas the second recognized human differences but left open the possibility of “savage” peoples evolving into “civilized” peoples. Two of the most prominent philosophers of the century, Immanuel Kant and David Hume, adopted the racist approach. The opposite view was prominently advanced by J. G. von Herder, Adam Smith, and Adam Ferguson (Broadie, 2003, pp. 88–90).

A vehicle for systematizing and disseminating knowledge was the creation of encyclopedias, the most influential of which were the *Encyclopédie ou Dictionnaire raisonné des sciences, des arts, et des métiers*, edited by Denis Diderot and Jean d’Alembert (published in parts, 1751–1772) and the *Encyclopaedia Britannica* (published in three volumes in 1771). What these works had to say about race reflects a distinct stage in its evolution as an organizing idea or concept in society and among the learned. *The French Encyclopedie* said that not only did color and facial traits distinguish Negroes from other men, but they “appear to constitute a new species of mankind.” The first American edition of the British version (1798) claimed that Negroes were “a variety of the human species” and identified them as *Homo pelli nigra*—black-skinned man (Eze, 1997, p. 91). After describing the color and physiognomy that was supposedly distinctive of Negroes, it ascribed to them a remarkable catalog of implicitly hereditary traits:

“Vices the most notorious seem to be the portion of this unhappy race: idleness, treachery, revenge,

cruelty, impudence, stealing, lying, profanity, debauchery, nastiness and intemperance, are said to have extinguished the principles of natural law, and to have silenced the reproofs of conscience. They are strangers to every sentiment of compassion, and are an awful example of the corruption of man when left to himself”

(Eze, 1997, pp. 91, 93–94)

Although it might be thought that such notions were more likely to flourish in societies heavily involved in the African slave trade, some of the most influential debates about race biologically and socially occurred in Germany, which had no colonial assets at the time and was only marginally in contact with non-White populations.

The most important German racial theorist was Immanuel Kant (1724–1804), whose influence as a philosopher was of European—not simply German—significance. Kant introduced a course on anthropology at the University of Königsberg in 1772, the first in any German university. Over the course of his career, Kant offered at least 72 courses in anthropology (compared with 28 in ethics and 54 in logic). The ideas developed in these courses became embedded in European racial theory for more than a century. In one early essay, “*On National Characters*” (1764), Kant wrote, for example, that “the Arab [is] the noblest man in the Orient,” whereas “the Persians are the French of Asia.” By contrast, he wrote:

“the Negroes of Africa have by nature no feeling that rises above the trifling. Mr. [David] Hume [in his essay, *Of National Characters*, (1754)] challenges anyone to cite a single example in which a Negro has shown talents . . . not a single one was ever found who presented anything great in art or science or any other praiseworthy quality . . . So fundamental is the difference between these two races of man [blacks and whites] it appears to be as great in mental capacities as in color.”

(Eze, 1997, p. 55)

In the same essay, Hume had also written that he was “apt to suspect” that there were four or five “species of men” who were naturally inferior to Whites.

“There never was a civilized nation of any other complexion than [W]hite, nor even any individual eminent either in action or speculation . . . On the other hand, the most rude and barbarous of the [W]hites, such as the ancient Germans, the present Tartars, have still something eminent about them . . .

Such a uniform and constant difference could not happen, in so many countries and ages if nature had not made an original distinction between the breeds of men.”

(Eze, 1997, p. 33)

The claims of Kant and Hume were countered by James Beattie (1735–1803) in his *Essay on the Nature and Immutability of Truth, in Opposition to Sophistry and Skepticism* (1770) on logical grounds: the only way to prove an inherent inferiority of Africans and American Indians would be to introduce arts and sciences among them to see whether they were “unsusceptible to cultivation.” “The inhabitants of Great Britain and France,” he wrote, “were as savage 2,000 years ago as those of Africa and America are to this day.” Adam Smith, another member of the Scottish Enlightenment, argued in *The Wealth of Nations* (1776) that geography, not individual abilities, was the underlying cause of the social and economic differentiation that led to personal achievement. All of the inland areas of Africa and Asia, he wrote, were in a “barbarous and uncivilized state” because they lacked waterways that supported internal “commerce and communication,” whereas all the civilizations of the past (his examples were Egypt, India, China) were built around great river systems. He added that Europe followed this pattern, with inland and other isolated areas having less developed populations than the sea coasts or the river systems (Smith, 1776, Chapter III, Section 8).

The large shifts in racial populations occasioned by slavery, contract labor systems, and the mobility associated with intensified transnational and intercontinental trade after the sixteenth century resulted in vast increases in mixed race populations. In the ancient and medieval worlds, such populations were clustered mainly on the Mediterranean rim (the Maghreb, Egypt, Western Anatolia, Sicily, Southern Italy, and Spain). In the early modern period, mixed race populations grew rapidly in the West Indies, Latin America, and North America. In some social systems of the Spanish Empire, the term *mestizo* included mixtures of Indians, Whites, and Africans, whereas in others there was an attempt to place racially mixed groups in a hierarchy based on the observable “amount of their White blood.” The Spanish colonies generally developed systems of psychological advantage and prestige attached to people of “pure Spanish blood” as the number of mixed race people grew, in most cases to a clear majority of the population. In such a triadic system (e.g., Cuba,

Puerto Rico, the Dominican Republic, Mexico), Whites were at the top of the hierarchy, mixed race people in the middle, and dark-skinned or Black-skinned people at the bottom, although some of them were indeed of mixed race. Thus, *color* became a major part of the psychosocial matrix affecting the distribution of education, occupations, wealth, and social prestige. Language also played a cultural role, with a premium placed on “correct speech” as opposed to the Creolized or pidgin speech associated with the lower classes and darker segments of the population.

The French colonies of the West Indies and North America followed some of the same mixed race and color-graded patterns of the Spanish but developed different attitudes about the acknowledged mulatto children of wealthy Whites. Those children, at times, inherited property, were provided educations in France, and returned to the colonies as a privileged segment of the population (e.g., Saint Domingue [later Haiti], Martinique, Guadeloupe, and Louisiana before 1803). As in the Spanish case, color was an important feature of the cultural matrix in the racial systems of the French colonies.

The British developed racial policies and practices in their colonies that varied. In India, racial theory was used as a dividing technique, classifying some groups as “martial races” (e.g., Sikhs and Gurkhas, although Sikhs were not racially different from Hindus or Muslims) and others as “backward.” Racial or “color bars” were imposed in establishing residential areas and clubs. In the settler colonies of Africa, such as Kenya and Rhodesia, racial segregation and racially limited educational opportunities followed the South African pattern, whereas in Egypt, Aden, and other places, racial discrimination was more muted. Theories of racial inferiority were, however, an essential part of the British, French, Dutch, Belgian, Spanish, and Portuguese systems of rule and the maintenance of White dominance.

In the United States, the juxtaposition of White, Black, and Indian populations resulted in a large mixed race population from the early seventeenth century to the end of the mid nineteenth century. This occurred, of course, before the U.S. Congress passed an Indian removal bill, signed into law by President Andrew Jackson in 1829, that mandated the forced removal of the Indians (principally in the Southeast) to territory west of the Mississippi River. Most demographers concluded by the early twentieth century that only a tiny fraction of the Negro population in the United States remained,

as a matter of biology wholly African. Because the racial system in the United States was regulated by law and the usual violence of slave societies, the racial definition of these populations became a matter of law rather than custom, cultural preference, or individual decision. Popularly known as “the one drop rule” because the legal and social definition as a Negro could be made if a person had any African ancestry, no matter how remote (*see* Frazier, 1949). As a result, in the racial system in the United States, many individuals who would have been classified as Whites in the West Indies, Brazil, or other parts of Latin American were classified as mulattos (one-half White), quadroons (one-fourth White), or octoroons (one-eighth White). In the nineteenth century, they were generally called “people of color” but remained legally an undifferentiated part of the “American Negro race”. From 1890 until 1920, there was a mulatto category in the U.S. Census. After that category was eliminated in the 1930 Census, some of those formerly identified as mulatto simply became White, as they were not counted as Negroes. Although color played a personal role in cultural preference among American Negroes, the fixed legal status of the race had the effect of creating a social and political solidarity that had no analog in Latin America or the West Indies. By contrast, in the South African system of Apartheid, laws succeeded in creating a system in which Whites, Coloreds, Indians (and other Asians), and Africans developed as separate populations in the racial system. The opposition to Apartheid eventually included members of all of these groups, but there was never the degree of solidarity between Black Africans and Coloreds as there was between those of various racial mixtures among American Negroes. This is mainly attributable to the fact that the Coloreds had privileges as a matter of law that were denied to Africans, whereas in the United States there was no legal or political difference based on racial mixture.

## **The Consolidation of Race Theory in the Era of Scientific Racism**

### ***From Racial Ideas to Racial Ideology***

The transformation of eighteenth-century speculations about race into an ideology that was regarded as solidly based knowledge and sound science was a process that stretched from the mid-nineteenth century to the early twentieth century. In this period, several developments accelerated interest in racial theory. One was the dramatic expansion of European imperialism in Africa and Asia. By

the end of the century, only two African countries remained independent: Ethiopia and Liberia; all the others were direct colonies of Britain, France, Germany, Belgium, Portugal, Italy, and Spain or were controlled less directly by European powers (e.g., Egypt and the Sudan). Holland, Britain, and France directly controlled colonies in Asia (e.g., Indonesia, India, French Indochina) and had spheres of influence in China. Another development of profound importance was the abolition of slavery in the United States after the Civil War (1861–1865) and the creation of a system of government-enforced White Supremacy in the South and various types and degrees of segregation in the North, all of which were sanctioned by the U.S. Congress, the Presidents of the United States, and the U.S. Supreme Court.

Both European Imperialism and White Supremacy in the United States (and South Africa) were buttressed by racial ideologies that posited the inherent inferiority of Africans, Asians, and American Negroes. Although it is an exaggeration to call Count Arthur de Gobineau (1816–1882) the “Father of Racism,” as he often is, he was the European thinker in the nineteenth century who wrote the most influential racist book of the era, the *Essai sur l'inégalité des races humaines* (1853–1855). He borrowed the racial classification schemes of the eighteenth century and followed the usual Hume–Kant hierarchy, placing Blacks at the lowest level and Whites at the highest. New in Gobineau’s ideology was his application of these ideas to a racial interpretation of all history, explaining the rise and fall of civilizations on the grounds of supposedly racial migrations, traits, and degrees of “purity.” Gobineau also popularized the idea that among Whites there were various “races,” with the “Nordics” being the most superior, whereas the Mediterranean and Slav groups were inferior. Of “the [W]hite races” as a whole, he wrote that they “are gifted with reflective energy, or rather with an energetic intelligence.” He added the following details:

“They have a feeling for utility, but in a sense far wider and higher, more courageous and ideal, than the yellow races; a perseverance that takes account of obstacles and ultimately finds a means of overcoming them; a greater physical power, an extraordinary instinct for order, not merely as a guarantee of peace and tranquility, but as an indispensable means of self-preservation. At the same time, they have a remarkable, and even extreme, love of liberty, and are openly hostile to the formalism under which the

Chinese are glad to vegetate, as well as to the strict despotism which is the only way of governing the Negro.”

(Gobineau, as in Biddiss, 1970, pp. 136–137)

In Gobineau’s theory, Northern Europeans were regarded as superior, intellectually and physically (the “Nordics” of Scandinavia and the “Celtic Germans” of Central Europe), whereas Slavs in Central Europe and Eastern Europe were “demonstrably” inferior, as shown by their often subordinate status in peasant societies. Those Europeans on the Mediterranean rim, southern Frenchmen, Spaniards who were not “of pure blood,” Greeks, and Italians were inferior. In the evolving racial theory of the nineteenth century, there were as many as 30 different “races” or “racial types” of Europeans, including a religious minority—Jews (Snyder, 1939).

Gobineau’s ideas were further popularized by Richard Wagner’s version of racism allied with German nationalism (his “Teutonism”), and by Wagner’s son-in-law, Houston Stewart Chamberlain (1855–1927). Chamberlain’s two-volume, *Foundations of the Nineteenth Century* (1899), fused racism with anti-Semitism, an amalgam exploited politically by Adolf Hitler in Germany (and enacted into law in 1934) and by the anti-immigration movement in the United States (enacted into law in the immigration quota system in 1924 and “the national origins plan” of 1929).

An important stage in the consolidation of race theory in the nineteenth century was the skewed importation of Darwin’s biological ideas (e.g., natural selection) into social theories in the newly developing social sciences. Herbert Spencer (1820–1903), for example, argued that just as there was a struggle for existence between animals in nature, there was a struggle between classes in society, between nations and between races. As in nature, he maintained, these struggles had the result that the strongest triumphed, and this was the key to overall human progress—the “survival of the fittest.”

Social Darwinism became not only an approach to society but was embedded in the social sciences as the most “realistic” way to think of the disparities in education and wealth in industrial societies and between Europe and other parts of the world. From this perspective, social inequality was a natural phenomenon, based on biological facts that could not be changed by education or other variables. It was, therefore, a “sentimental delusion” to believe that the “lower orders” of humanity could be improved

by better education, health services, or other social policy interventions.

In the same era, medical and physical anthropological research attempted to establish an anatomical and physiological foundation for theories of racial inferiority, especially of Blacks. The most consequential and prestigious American scientist to adopt rigidly racist views was Professor Louis Agassiz (1807–1873) of Harvard University. He was the founding scientist of Harvard's Lawrence Scientific School (1848), the first school in the United States to train scientific researchers. His popularity as a public lecturer and writer on scientific subjects propelled him to unprecedented influence as a shaper of scientific knowledge and public opinion. Supported not only by Harvard but by substantial research funds from the Massachusetts legislature (for his Museum of Comparative Zoology), Agassiz's work was influenced by Samuel George Morton, the leading American anthropologist, who believed that on the basis of his examination of human skulls, he had shown that Whites had the largest skulls, whereas Blacks and American Indians had the smallest skulls, proving to his satisfaction that Whites had more intellectual ability because of their presumptively larger brain size. Morton's results were achieved in part by arbitrary racial classification, deciding for example, that the ancient Egyptians were Caucasians. In his first year as Lowell Lecturer, Agassiz lectured in Charleston, South Carolina and maintained that as a matter of science, Negroes were a distinct species. Using Morton's work, Agassiz said that the "brain of the [adult] Negro is that of the imperfect brain of a 7-month's infant in the womb of a White" (Stanton, 1960, p. 100).

Agassiz developed his ideas into a theory, polygenism, that maintained that all of the races were separate creations and in an immutable hierarchy of abilities. Polygenism was a theory especially congenial to defenders of slavery. Agassiz's theory meant that the abolitionist and humanitarian views on slavery were false, because Negroes were not fully human and could not be included in the natural rights doctrine announced in the American Declaration of Independence or ever be entitled to citizenship or constitutional protections. Agassiz's ideas about race retained their scientific authority in the United States far beyond the slavery controversy and the Civil War because they became the foundation of the American School of Anthropology and part of standard medical research and teaching in the United States (Menand, 2001, pp. 97–116).

The most active and influential of Agassiz's successors in this area of research was Robert Bennett Bean, a professor of anatomy at the University of Virginia Medical School. The "Negro brain," he wrote in 1908, developed normally as far as perception, memory, and motor responses were concerned, but logical critical thinking or the comprehension of abstract ideas were beyond its grasp because of "arrested physiological development" (Bean, 1906, pp. 353–432). The significance of this development in science was, first, the assumption that it was objective and correct, and therefore not a matter of controversy, but fact. Second, its application to public policy had far-reaching consequences, especially in education and employment.

### ***From "Race Science" to Racialized Public Policy and Institutions***

The United States had the most sophisticated system of racial domination in the world. As a hard system, the United States maintained a structure of racialized power through legislation and judicial opinion. This distinguished it from European systems in which claims of racial difference were made, for example, about Italians, Germans, Poles, or Jews. When members of these groups immigrated to the United States, those European racial distinctions virtually vanished, as they were identified by U.S. law as White. As a result, the social use of race was redefined because of the use of the legal system to maintain a racial hierarchy after the abolition of slavery (Mangum, 1940). The question became, Who is Black and who is White? At the same time, in Europe, race theory was still based on the idea that there were multiple "races" within Europe (Goldstein, 2006). In England and Ireland, there was the development of the idea of an "Irish Race." Maintaining the European distinctions would not only have been too complicated legally but would have worked against the assimilation of immigrants so they could become "Americans," pure and simple.

Because of its size and distribution, the Negro population of the United States was always of public policy importance, during the slave era and afterward. Constituting about one-fifth of the national population in 1790, it remained a much larger proportion of the population in the southern states. By 1880, Negroes were 13% of the national population but in some southern states comprised as much as 50% or more of the total population (Bureau of the Census, 1918, pp. 46–49).

The Thirteenth, Fourteenth, and Fifteenth Amendments to the U.S. Constitution, and the Congressional policy of Reconstruction, had been intended to be the basis for the Freedmen to be citizens and participants in a democratic society. Although no government measures were taken to secure an economic base for the ex-slaves, the Freedmen's Bureau (a part of the War Department) was the government agency created to provide the recently emancipated slaves with education, health care, and other forms of assistance. With the defeat of Reconstruction (1876), southern Whites attempted to erase the progress that had been achieved by Blacks in the decade since the end of the war through Black Codes, Ku Klux Klan terrorism, and other violence. These methods were gradually superseded by changes in state constitutions and federal policy, principally by the U.S. Supreme Court, which removed Negroes from political participation in the South. Southern and northern Whites then created a system of legalized racial segregation and economic exploitation (Logan, 1954, pp. 3–11).

Between the 1880s and 1920s a new type of society was structured, one that was “modernizing” with respect to industrialization, commercial development, urban growth, expanded transportation, communications networks, and a rapidly growing system of public education, including higher education. At the same time, disparities based on race in education, income, and access to social resources were institutionalized through segregation laws and other forms of public policy that made it possible to limit the development of Negroes (segregated schools, libraries, hospitals, racial classification of jobs as “White jobs” and “Black jobs”) while advancing Whites at public expense.

The fusion of racial theory and institutional development made it possible to perpetuate inequalities based on race from generation to generation. An illustration of this trend is the expenditure of funds for education of Whites and Negroes in those states maintaining racial segregation of schools (the most crucial institution for social mobility in the American social system). Charles H. Thompson, head of the Bureau of Educational Research at Howard University, pointed out that in 1900 the disparity in per capita educational expenditures for the two racial groups was 60% in favor of Whites, but by 1930 had increased to 253% (Thompson, 1935, pp. 419–434) As such disparities were consolidated in all social and economic institutions,

including the military, the United States developed separate social and cultural environments that not only limited the development of the Black population but affected them psychologically. Race became a determinative aspect of the economic and social realities that shaped most Black lives, irrespective of the frequently enunciated egalitarian aspects of American ideals and democratic constitutional theory. The United States became a racialized society at the same time that the country rose to become one of the most powerful countries in the world, a social fact that did not begin to change until after World War II.

### ***The Scientific Error of Eighteenth- and Nineteenth-Century Race Theory***

The fundamental error of eighteenth- and nineteenth-century race theory, as science, was the assumption that naming a race and then attributing fixed abilities, behavioral traits, and physical characteristics to it was logically or empirically adequate. However, the intellectual weakness of this approach as science did not lessen the hold such ideas had on social thought, public policy, or popular culture. It was not, strictly speaking, an issue of science but of power and a need to find a cultural and social means to unify a majority of the people of the United States, even if at a terrible cost to the minority that was not White. The multiple traumas of the Civil War placed in high relief the divisions among the White population—by region, class, immigrant status, religious domination—so that hatred and exclusion of Blacks (to the extent possible) became a kind of social adhesive for people who increasingly thought of themselves as “White” rather than as ethnic immigrants, class opponents, or former enemies on the Union or Confederate side of the war.

### **A Racialized Society**

The racial ideas of the eighteenth century did not, of course, independently create the racialized societies of the nineteenth and twentieth centuries. In their time, they were primarily speculative conjectures. They gained importance later, when race-based systems of dominance operationalized them by the application of governmental power and private institutions.

A “racialized society” develops over time. It is not simply a society in which there is a sudden or transitory contact between different racial groups through conquest or immigration. In a racialized society, different groups that have been socially identified

as “races” are limited to social and economic roles according to their racial identification.

Racialized societies are historically a phenomenon of the early modern world (beginning in the sixteenth century) when western Europeans developed the technical and military means to conquer societies in Asia, Africa, and Latin America and extract mineral wealth and other natural resources from some of those areas using native labor. During a second stage, millions of laborers, either through slavery or contract labor systems, were moved to frontier societies, such as those in North and South America, the Caribbean, East Africa, and South Africa. There, Europeans imposed a caste system in which race was made a functional boundary for economic and social roles (Du Bois, 1945; Frazier, 1957).

The concept of a racialized society does not apply to all multiracial societies. In the ancient African and Mediterranean world (e.g., in Egypt, the Greek or the Roman Empires), Africans, West Asians, and Europeans were significant demographic components of those societies, making them multiracial. But there was no systematic or strict determination of social and economic roles by what would be later called race (Snowden, 1970, 1983). In the ancient world, slavery was a result of conquest, as it was in the Medieval Muslim and Christian realms, but slavery was not the product of a racialized economic system, as it would become in the era of the Indian Ocean Slave Trade, the Atlantic Slave Trade, and European colonization. Status as a slave or free person was not tied in the earlier historical periods to racial or ethnic identity. The mere existence of several races in the same society does not, therefore, make it conceptually a “racialized society.”

Is there a distinction to be drawn between a “racialized” society and a “racist” society? The Winston Framework uses “racialized” to designate societies in which race is used as a socially differentiating marker. Societies may use such markers in varying degrees. In “softer” systems, race and color may have more importance in the private than the public realm and historically were linked in some societies to class hierarchies. In such systems neither race nor color may have formal legal significance. The absence of a legalized, state-imposed racial regime does not, of course, mean that there is no racial prejudice or virtually hereditary racial stratification in a society, as was claimed by scholarly apologists for the Brazilian racial class system (Fernandes, 1969; Freyre, 1946; Ramos, 1939). In “softer” systems,

the prejudices of the private realm are extended by custom to the employment and civic realms, so that persons of the less socially privileged racial groups would not be absolutely barred from certain occupations or public offices but would attain them very rarely. In “harder” systems designated as “racist,” in the “racialized society” continuum, racial groups are defined formally by law. Limitations in the educational, economic, and political freedoms of those proscribed racial groups then become enforceable by law, including regulation of such private relations as marriage (Higginbotham, 1978; Mangum, 1940).

Historically, the societies of Latin America and the Caribbean were racialized but not racist in the sense defined here. In the United States and South Africa, the societies were racist as defined here because the status of racial groups was fixed and enforced by the power of the State through the formal mechanisms of legislation, judicial proceedings, and executive force. In the case of those regimes developed by such colonizing powers as the Dutch, the Portuguese, the English, and the French, racial policies and the distribution of educational and economic opportunities in the colonies were regulated by colonial administration, whereas in the metropolitan area such laws did not apply. Thus France, for example, maintained a racially stratified regime in its African and Caribbean colonies but provided legal equality in France itself for all racial groups. In such a system, it was possible for Negroes (as defined in the United States; in France they were mulatto), such as the Chevalier de St. Georges (1745–1799) and Alexandre Dumas Père (1802–1870), to become famous and distinguished “Frenchmen” in music and literature (Banat, 2006; McCloy, 1961).

The analytical significance of these distinctions derives from the fact that societies that may be classified along the “racialized–racist continuum” adapted different kinds of institutions and cultural systems to perpetuate racially stratified social and economic differentiations. Those differences, between customary regimes on the one hand and legalistic ones on the other, had varying kinds of impact on those who were within the racial nets maintained by political and social elites. Institutional and cultural variations, in turn, had different types and degrees of psychological and social consequences for individuals in those societies. By conceptualizing a “racialized–racist continuum” as a framework, it is possible to compare very different racial systems

across time and geography, one of the most difficult analytical problems in studies of the intersections between race, culture, and society.

### ***Master Narratives of Race***

Within racialized societies, master narratives of race emerged as a cultural psychological mechanism to “story” dominance, subordination, and equality ideology. Master narratives of race are dominant cultural stories and discourses that reflect racial ideas and ideologies within a racialized society. These stories include plotlines, characters, settings, and other narrative features that create a framework that individuals draw upon in thinking about the meaning of race within lives. Master narratives of race function as societal, symbolic meaning systems of culture. In a sense, they have a dramatic quality like all narratives that are constructed over time (see Bruner, 1990). Moreover, often based on the “point-making” motivation (see Bamberg, 2004) of the master narrative speaker or writer, only selected narrative features of the story are emphasized.

Although master narratives of race may at times appear to be elusive, they are omnipresent, producing images, symbols, storylines, and caricatures that reflect dominant racial ideas and ideologies within a racialized society. This can include storylines about the meaning of racial group membership, as well as explanations for racial group disparities. There is a rapidly growing body of research on implicit racial bias in social psychology that provides an example of how these master narratives of race can work to shape unconscious bias at the interindividual level (see Goff, Eberhardt, Williams, & Jackson, 2008). In this research, the symbolic meaning of race is often induced using cues associated with a particular group membership or stereotyped characteristic of racial group members.

Master narratives of race serve the function of configuring power dynamics through distortion of reality, gross overgeneralization, and extension of the ideas with origins or roots in scientific racism, racial thinking, and ideologies associated with racist and antiracist movements. In other words, within racialized societies, master narratives of race to varying degrees provide one of the most important mechanisms through which racialized habits of thinking are sustained and reinforced. The key vitality and sustainability of these master narratives of race is a pervasiveness of thickly embedded racism in American society and culture. Discourses, policies, and practices of individual, institutional, and

cultural racism (see Jones, 2003) can be combined within master narratives of race that reflect their influence on both social structures and individual cognitive structures. In many ways, they come to provide a distorted justification for the racial disparities that emerge not from individual sources but from collective constructions of institutions, systems, and customs.

The form that master narratives of race takes can be varied and complicated. Master narratives of race can present themselves as ideologies, plot constructions, storylines, and discourses. Plotlines for master narratives of race for African-Americans, for example, have been up from slavery/sharecroppers’ child, affirmative action unqualified, and Black exceptionality of excellence. These master narratives of race plotlines evolve over time, retaining the central essence of their meaning, grounded in racial ideas and ideology that are prevailing at a particular point in time. Characters in master narratives of race are contextualized in the format of exemplary actions by exemplary characters that are appropriated to act out and make relevant the claim. For example, Sterling A. Brown (1933, 1937, 1966) identified seven stereotypical characters that were prominent in fiction of the late 1800s and early 1900s which included the contented slave, the wretched Negro, the comic Negro, the brute Negro, the tragic mulatto, the local color Negro, and the exotic primitive. More contemporary characters in master narratives of race include the hip hop icon, the superhuman athlete, and the highly successful exception whose achievement, therefore, is not to be considered important vis-à-vis the low-achieving stereotype by its very exceptionality (Rice, 2010).

Master narratives of race act with storylines that have both static and dynamic features, making the master narrative of race a cultural historical construction that is recombinant at the level of the individual and society. Master narratives are temporary, like other narratives, of course. Bamberg (2004) asserts:

“[L]ooking at narrative at a different angle . . . there seems to be something special in their implementation, even at the level of mundane, conventional everyday interactions, because narratives order characters in space and time and therefore, as a format, narrative lends itself not only to connecting past events to present states (as well as imagined, desired states and events) but also to

revealing character transformations in the unfolding sequence from past to future.”

(Bamberg, 2004, p. 354).

The master narrative of race about the alleged intellectual superiority of White Americans and alleged intellectual inferiority of Black Americans is an illustration of one of the main features of master narratives of race. Within American society and culture, there is a master narrative or common “story” whose main characters are individuals who are Negro, Black, or African-American as well as typically White characters. One storyline develops the plot that intelligence is an exceptional or genetic impossibility for individuals who are non-White and particularly for those who are Black. A contemporary example of the plotline of exceptionality occurred when early in the 2008 U.S. Presidential Campaign, Senator Joe Biden referred to then Senator Barack Obama as “articulate” (see <http://www.cnn.com/2007/POLITICS/01/31/biden.obama>).

From a cultural-historical perspective, typically when the word “articulate” is used to describe someone who is Black, it may be interpreted as a coded way to indicate that he is an exception to the socially scripted inarticulate stereotype for Blacks in this race and intelligence master narrative. In other words, although the speaker’s motivation may be to pay a compliment, the symbolic meaning of the discourse is interpreted in the resonant context of the master narrative of race and intelligence.

In response to this master narrative about the alleged intellectual inferiority of individuals who are Black and African-American, powerful counter-master narratives have also emerged in American society and culture. These counter-narratives have been developed primarily among individuals who are the targets of the master narrative of intellectual inferiority. This counter-narrative script is that Black people are intelligent and at least equally as capable as their non-African-American counterparts. These counter-master narratives have evolved over time as part of a response to the ideologically driven, institutional, and culturally crafted explanations for structural disparities across racial groups, particularly related to public policy debates about compensatory education and affirmative action (e.g., Jensen, 1969, Herrnstein & Murray, 1994).

Within the counter-master narrative of race, there are features that act like other types of counter-narratives. For example, there are some elements of dominant narratives that Bamberg (2004) suggests

are left intact, whereas others are reshaped and reconfigured. To extend this idea further to a counter-narrative of race, the master narrative of race is reflected in the construction of counter-narratives of race, making it not a “simple counter-story”; rather, these counter-narratives juggle several story lines simultaneously (see Bamberg, 2004). The degree of psychological interactivity required to negotiate the meaning of race between the level of society and the individual is complex. As such, precise determination of the shifting meanings of race is analytically challenging given the current state of research in the field, the quality of the conceptual tools developed thus far, and the inadequacy of the research instruments and methods.

### ***Human Personality Development With Racialized Societies and the Centrality of Identity***

The complexity of master narratives of race inhere in their fusion of interindividual dynamics and systems level racial ideology that are within economic, social, and political institutions. Within the field of psychology, individuality is most often conceptualized in terms of the concept of personality and focuses on those psychological forces within the whole person.

The development of personality within all societies, racialized and non-racialized, involves the dynamic interplay between phenomena on three levels: (1) dispositional traits or the broad individual differences in behavior, thoughts and feelings that have longitudinal consistency across situations and developmental time; (2) characteristic adaptations or goals, values, motives, coping strategies, and stage specific tasks that are contextualized in time, place, and social role; (3) narrative identity or internalized and evolving narratives of the self that reflect the meaning of life experiences in time and culture. In fact, McAdams and Pals (2006) have argued that any science of the person should include conceptualization and corresponding methodological approaches of personality as “an individual’s unique variation on the general evolutionary design for human nature, expressed as developing patterns of dispositional traits, characteristic adaptations, and integrative life stories complexly and differentially situated in culture” (p. 212).

Culture impacts these different levels of personality in different ways. For example, different cultures may emphasize distinct characteristic adaptations, with individualistic cultures emphasizing

independent self-construals, in contrast to collectivist cultures that stress goals and values of interdependence (Markus & Kitayama, 1991). The most profound influence of culture on personality is arguably reflected within the psychological repertoire from which a person draws in making sense of past, present, and anticipated future experiences that comprise that person's identity construction. In answering the question *Who am I?*, people have agency in choosing from competing internal and external stories while rejecting many others. McAdams and Pals (2006) have described this process and the relation of culture and identity as self and culture coming together through narrative. This process of self-exploration occurs in the context of a person's dispositional trait profile and adaptive states. As such, it highlights the centrality of the identity dimension of personality in understanding the psychological effects of living in a racialized society.

### **Identity**

Within racialized societies, persons construct the personal, collective, and cultural dimensions of their identity, in part, within the context of the racial ideologies that present themselves in master narratives of race. The narrative features of these master narratives are reinforced by the institutional and structural features of society, as well as through the political and economic realities that automatically create limited opportunities distributed by race.

A person's identity is a psychological dimension of personality that functions to integrate past, present, and anticipated future life experiences to answer perplexing and complicated questions: *Who am I as a person? What does my life mean in the overall structure of the cultural contexts in which I live? How do I bring unity and purpose to my life through how I think about self and who I am? And how do I fit into the adult world?*

Identity is at the same time personal, social (Tajfel & Turner, 1979), hierarchical (Markus, 1977), storied (e.g., McAdams, 1985), and cultural (Erikson, 1968). Such simultaneously constructed elements make its development across the lifespan complex and both a product of and producer of culture. Within any type of society, identity drives psychological attachments to the values, attitudes, customs, cognitions, affect, and views of the self, others, and the world. Racialized societies present unique contexts in which complicated forms of identity develop, because master narratives of race

most often require individuals to reconcile psychologically contradictory characterizations of who they are in terms of a personal sense of self as persons, as well as with respect to their collective attachments within social, religious, and national groups. The narrative features of these master narratives of race are often omnipresent because they are reinforced by the economic, political, and social systems of society.

The human development of identity has a profound impact on all other aspects of a person's life-course. To understand comprehensively the magnitude of this impact, imagine if human beings did not strive to achieve and restore their identity. There would be no posing of questions and striving for answers to the question of *Who am I?* at any developmental stage of life, including adolescence and later adulthood. In this sense, all of the psychosocial tasks associated with resolving conflict, achieving psychological balance, developing trust, and choosing a life's occupation would be eliminated from what it means to be human.

The experiential elements specific to living in a racialized society contribute to a person's identity construction in the form of autobiographical memories of race (Winston, in press a; Winston, in press b). In her theory of race self complexity, Winston (in press a) argues that the meaning of race is processed narratively, and as such, there is a complex process of the self-system by which autobiographical memories of race are recalled and narratively organized. In the construction of autobiographical memories of race experiences, encoding of remembered emotion launches two core processes of the self-system: narrative processing and autobiographical reasoning (Mangum & Winston, 2008; Winston, 2011). This processing engages narrative sequencing and emotion. The processing also is triggered at different times across the life-course, and in various roles and environments. The narrative processing of autobiographical internal and external race-related stimuli requires channeling of a stream of thought into prescribed, narrative race meaning sequences. These narrative sequences rely on both cultural and personal templates, as well as the stimulation of affect. Often the stimuli and cultural templates are in the form of master narratives of race. Such dominant narratives in society serve as a mechanism for drawing up a personal meaning of race. Also, the human nature of individuals to categorize phenomena, objects, and people serves as a culturally universal mechanism that individuals

use in racialized societies to cultivate the meaning of race within their lives.

Emotion is an adaptive characteristic of personality that is also a core part of the narrative processing of race in identity construction (Mangum & Winston, 2008). Emotion enhances memory encoding and therefore serves to launch a person's narrative processing and autobiographical reasoning of race experiences, including those that are personal as well as those that are at the level of master narratives of race within the larger racialized society. In the process of identity construction, these experiential affect cues give rise to one of the psychological functions of autobiographical memories of race—to aid a person in organizing events of past life experiences of race in a temporal sequence and meaningful internal portrait of people, places, and events (Winston, in press a). In this regard, narrative is an organizing structure of personality, an idea advanced by both Singer (1995) and McAdams and Pals (2006). Self-protection, self-enhancement, and psychological balance (*see* Rice, 2008) are forms of self-regulation of the internal and external stimuli that operate within racialized societies. These three motives of the self serve important psychological functions of constructing autobiographical memories of race in the process of identity development.

Because identity is selective and constructed rather than fixed and genetically based, like other features of human personality such as dispositional traits, individuals within racialized societies have a wide range of ways they can choose to configure their identity. As a narrative of self, identity development within “harder” racialized systems may, for example, include elements of counter-racial or anti-racist ideology that have been influenced by familial and other primary socializers. This can be the socializing agenda for families from both dominant and subordinate groups. For members of groups that are subordinate within a racialized society, the intended result of such socialization is to help foster identity development that is adaptive and functional. For members of the dominant group, the function of such socialization is to normalize the presumption of privilege.

Within the field of psychology, for example, there has been a long history of debate about whether individuals who are Black living in the United States can form a healthy identity, given the pervasive racism within society. This debate began with the pioneering doll study research of Ruth Horowitz (1939), Mamie P. Clark and Kenneth B. Clark (1939),

whose findings had the single most important social science impact on the U.S. Supreme Court decision *Brown versus Board of Education* (1954), which held that the racial segregation of public education by law was unconstitutional (Kluger, 1976). Although the validity and reliability of these findings were later questioned, on interpretive and methodological grounds (Baldwin, 1979), this body of research continues to have a profound impact on the debate about the role of Black culture in the development of an identity that is not self-hating.

During the Black consciousness movement that began in the 1960s, Cross (1971) introduced his theory of Nigrescence (the process of becoming Black) to explore the stages of racial identity development shifts from an unhealthy sense of self as a Black person in the United States to a healthy identity. The impact of this stage model of identity development has been great. It has continued in various forms for more than 40 years, largely pursued by scholars who were students or collaborators of Cross (Parham & Helms, 1981). More recently, Black identity theorists, building on previous research, have shifted their focus from an emphasis on trying to understand the content of a “healthy” identity in a racist society to a focus on mental health correlates of the dimensions of racial centrality, racial regard of the public toward individuals who are Black, as well as Blacks' own regard for their group, racial salience, and racial ideology—mainstream, assimilationist, nationalist, and oppressed minority (*see* Sellers et al., 1998; Shelton & Sellers, 2003).

Another recent development in the study of identity within the United States has been to shift terminology from *racial identity* to *ethnic identity* for two reasons. One is to be more politically correct in the use of the term race, because the fallacy of its biological basis is widely recognized, and the second results from the racial and ethnic diversification of the participants in psychological studies beyond White male college students.

The complexities of identity construction within racialized societies have been formalized in the most sophisticated way in theories that focus on the psychological impacts of racially determined disadvantage on people of African descent. Jones (2003), for example, has proposed a theory of Time, Rhythm, Improvisation, Orality, and Spirituality (TRIOS) to explain the cultural dimensions of African culture that individuals of African descent use to adapt and cope with living in a universal context of racism. In so doing, his model identifies individual,

institutional, and cultural levels of racism that individuals have to negotiate in cultivating a sense of self and other. This negotiation can be linked to both self-enhancement and self-protective factors.

Similarly, Boykin (1986) has proposed a theory of identity dilemma in which individuals of African descent have to negotiate simultaneously three realms of psychological experience: the mainstream, minority, and Afro-cultural orientation. Harrell (1999) also has provided a theoretical orientation for describing the psychological consequences of racism on the minds of people of African descent. He describes three forms in which these consequences take shape: standards of beauty, European ideals, and miseducation. There are many other theorists who focus more explicitly on the psychological impacts of early forms of domination and oppression (particularly slavery) on the identity development of individuals of African descent (Akbar, 1984; Kambon, 2002; Cress-Welsing, 1991; Nobels, 1991).

Within the field of sociology, there is a class of theories called “Whiteness” theories (*see* Anderson, 2003; Bonnett, 1996; Lewis, 2004; Murano, 2004; Roediger, 2002) that posit a relationship between ideological and material components of race that afford individuals who are White automatic privileged social status within a societal racial hierarchy. Lewis (2004) asserts, “whether Whites have self-conscious racial identities may or may not matter as much for their life chances as external readings of them as White” (p. 624). Thus, she asserts, the social category Whiteness cannot be divorced from its role as a force of domination and subjugation. Moreover, whiteness theories suggest that the psychological negotiation that Whites must do in constructing their identity and corresponding behaviors and feelings is based on notions of privilege and entitlement.

Taken together, these theories about the psychological significance of race within lives suggest that the context of the racism within racialized societies and the simultaneous demands of psychological negotiation create complexities in a person’s quest to formulate answers to identity questions. Such complexities make it very challenging for researchers to uncover the meaning of race within lives. In addition, these theories and their important ideas have, for the most part, not been integrated theoretically or methodologically in the discipline of psychology and related fields.

To address this gap, the theory of race self complexity was developed. Race self complexity is a

new narrative theory of personality that posits that the meaning of race can be processed narratively (Winston, in press a). Within the framework of this theory, narrative theories of personality are integrated with psychological significance of race theories to describe and explain the nature, form, and psychological function of autobiographical memories of race specifically, and race narratives generally, across critical life periods within the lives of individuals in racialized societies. In other words, this theory provides a theoretical and accompanying methodological orientation to study, understand, and transform an individual’s identity construction process that includes making sense of race within racialized societies across critical life episodes. This allows for the incorporation of cultural psychological mechanisms through which systems and identity interact, change, or stabilize.

In sum, identity construction is fundamentally a cultural process. The amount of identity work in which a person engages shifts in developmental time, place, and role and in cultural dynamics that are made even more psychologically complicated by living within racialized societies. The demands of the broader cultural contexts in which the meaning of self and life experiences are cultivated may represent maneuvers simultaneously between complicity in and countering established master narratives of race. Those narratives give guidance to one’s actions, but at the same time constrain and delineate a person’s agency—where, for example, laws or entrenched customs prohibit access and movement to key institutions and opportunities of the society. Erik Erikson, psychology’s most influential identity theorist, has suggested that identity is “a process located at the core of the individual, and yet also in the core of his communal culture, a process which establishes, in fact the identity of those two identities” (Erikson, 1968, p. 22).

### **The Winston Framework for Inquiry: The Cultural Psychology of Systems and Human Personality Within Racialized Societies**

The concepts presented thus far comprise the Winston Framework for Inquiry. Racialized societies have specific generic features whose particular details will vary by culture, historical period, and the structure of political power and economic development. The Winston Framework is a conceptual framework for inquiry about the cultural historical intersection of interlocking societal systems and interindividual personality adaptations within

racialized societies (Fig. 25.1). It identifies, defines, and explains a collection of linked core concepts at both the macro- and micro-levels of reality within a racialized society. Regardless of discipline, these concepts are inherent and fundamental for all inquiry about or related to the meaning and impact of race on lives within racialized societies.

Although at one level the Winston Framework is systems-oriented, there is no intention of suggesting that what we describe as “racial systems” are mechanical, deterministic, or permanent. They are systems in the sense that they have structure, form, and stability across varying periods of time. Another characteristic of these systems is that they have identifiable uniformities and patterns. Moreover, a system itself is not necessarily a racial system *per se*. A system that is theoretically “race neutral” may be used for a racial purpose. This phenomenon is seen, for example, when the law is used to segregate schools, hospitals, or other public facilities or to use the power of eminent domain to eliminate the neighborhoods or businesses occupied or owned by disadvantaged racial groups. Another example would be the “special attention” policing applied to the non-White “Bidonvilles” of Paris or Marseilles or the immigrant slums of Manchester and Leeds. In other words, all societies have multiple systems that allow them to function as a whole, including economic, social, and political systems. In a racialized society, these systems operate differentially according to race. That is, those in a subordinate position do not benefit from the system in the way that individuals who are racially privileged have a probability of doing. Many debates have been launched about the greater significance of class to race, as well as arguments about race being more important than class in determining life experiences, as well as socio-economic outcomes (*see* Wilson, 1980).

At another level, the Winston Framework identifies processes used by the targets of racialized societies to establish their own identities, modes of independent action, and human flourishing. These processes of race self complexity include psychological manipulation of the plotlines of master narratives of race in the form of self-protection, self-enhancement, and psychological balance. In other words, there is an intra-active process by which meanings and personal actions are guided. The individual’s actions and internal processing have some degree of autonomy, but that autonomy has boundaries within the context of the interconnected systems of racialized societies.

Racialized culture is learned. A racialized society’s institutional arrangements, structured by racial stratification, induce the development of types of racially mediated, learned behavior—that is, they generate cultural mechanisms to perpetuate patterns of racial dominance and subordination. An example of this is the routine deference that a member of the subordinate group is expected to show to a member of the dominant group, whether it is expressed in the once entrenched southern custom of Blacks being expected to yield the sidewalk to Whites in small towns and cities during the segregation era or the cultural expectation in certain contemporary academic or corporate environments that the professional judgment of a member of a racial minority should count for less than a White colleague of the same training, experience, rank, or status.

A racialized society requires unwritten cultural codes because human institutions are not perpetually renegotiated in day-to-day living by individuals but fit, for the most part, into patterns that are governed more by implicit than explicit assumptions, beliefs, and habits (Doyle, 1937). These racialized cultural prisms of lived experience naturally refract psychological consequences. With some notable exceptions, scholars have focused more on the legislative, judicial, and public policy formulations of racial dominance and have given scant attention to the cultural plasma that allows racialized societies to actually work and escape socially paralyzing violence and disorder most of the time.

In a racialized society, culture also has the immensely important function of normalizing and rationalizing inequality and other aspects of the racial system, whether in a modern industrial state or, historically, in colonial environments as large as India or as small as the Caribbean islands. In all of these cases, the individual in the target group(s) must learn how to adapt psychologically to these cultural imperatives. These adaptations assume a range of forms, depending on the individual’s personality and access to a repertoire of coping resources and strategies. Within the limits imposed by a racialized society’s institutions and culture, such individuals engage in an evolving process of generating ways to give their own lives frames of meaning and significance that the dominant society’s racial postulates and practices deny or attenuate. Formation of such meaning-making resources is both a psychological and cognitive process that varies through an individual’s life span and differs in its details, but not in its function as a way to attain agency, integrity, and

personal fulfillment in the distorted social arrangements and cultural habits that characterize all racialized societies.

The most challenging element in developing the Winston Framework as a robust and appropriate model for inquiry is to make the connections between the social, cultural, political, and economic contexts and the individual without being simplistic or without denying agency to the individuals affected. This is a classic social science problem—filling the gap between what sociologists and historians do and what psychologists and others do who focus their research on individuals.

The Winston Framework serves as a heuristic device for researchers, practitioners, and the public to guide inquiry about racialized societies in terms of both systems and interindividual variables. It does so with an emphasis on global, complex, and cultural-historical conceptualization of the concept, structure, and psychology of race.

There are several key mechanisms that link systems and interindividual personality development within racialized societies. These include transportation, mass communications, color-calibrated social dynamics, master narratives of race, hierarchies of cultural prestige, access to technology, and academic scholarship.

### *Distinctively Salient Mechanisms of Systems and Interindividuality Personality Development*

#### **COLOR-CODED CALIBRATED SOCIAL DYNAMICS OF RACIALIZED SOCIETIES**

There are color-coded calibrated social dynamics of racialized societies in which race and color shape social experience and become a part of a society's culture. Although laws are used in some systems (e.g., the United States and South Africa) to establish racial and color boundaries, most systems function through culture and custom. In some systems, such as Brazil's, there has been more sensitivity to color and social class than to race (as defined in the United States). There were, for example, more than a dozen color classifications that calibrated skin shades between blanco (white), pardo (brown), and preto (black). Such color stratification affected employment opportunities; access to public spaces such as beaches, schools, and nightclubs; and were cultural rather than legal boundaries for the marriagability of women (Pierson, 1942, pp. 111–156). Similar cultural coding of color and physical appearance was a

salient feature in multiracial English-speaking colonies such as Jamaica, Trinidad, and British Guiana, or Spanish-speaking colonies such as Cuba, Puerto Rico, and the Dominican Republic. Within racialized societies, these types of color-coded calibrated social dynamics provide a mechanism for the social, economic, and political institutions and interindividual personality development to interact in ways that provide a multidimensional constellation of lived experiences.

#### **THE SYMBOLIC DIMENSIONS OF RACIALIZED SOCIETIES**

Modernization as a phenomenon always affects the *mode* of transmitting racial meaning in a racially stratified society. In pre-modern systems, force is more important than social or cultural systems. In modern systems (characterized by industrialization, urbanization, and the spread of mass media), racial symbols have become a primary cultural means for stabilizing a racial system. Thus, the portrayal of subordinate racial groups in mass circulation newspapers, magazines, radio, television, and films becomes a cultural mechanism for embedding stereotypes in a society. As those images become a stable form of representation, all racial groups in the society begin to accept those stereotypes as representations of reality for interindividual personality development and description. For the subordinate racial groups, this has an effect on motivation, education, standards of beauty, and achievement, thus reinforcing its racial stratification (see Harrell, 1999).

#### **TECHNOLOGY INNOVATION AND ACCESS IN RACIALIZED SOCIETIES**

Technology innovation and access tend to destabilize racial systems. Historically transportation was the first important change, as railroads, and later automobiles, enabled subordinate racial populations to migrate readily from rural to urban areas, from agricultural labor to industrial enterprise and better educational opportunities. As print media technology became more widespread, independent newspapers and book production by subordinate racial groups became possible, enabling them to mobilize for political and social action and to develop a counter-cultural racial consciousness (Winston, 1982). As mass media, like television, accelerated the spread of images and information, the shifting imagery of Blacks and other racial groups

destabilized racial attitudes and cultural boundaries (e.g., televised coverage of the U.S. civil rights movement of the 1960s versus earlier and limited print coverage, 1890s to 1950s).

#### MASTER NARRATIVES OF RACE

Master narratives of race as dominant cultural stories and discourses are a mechanism connecting systems-level racial ideas and ideologies to interindividual processing of the meaning of race. Most often, this kind of processing is required of the individual in developing motives, goals, and coping mechanisms, as well as in constructing an identity. In large part, these personality dynamics are adaptive responses to living in a racialized society and can work to create a continuum from psychological depletion to psychological stamina in overall well-being and functioning. Master narratives of race serve the function of maintaining power dynamics through distortion of reality, gross overgeneralization, and extension of the ideas with origins in scientific racism, racial thinking, and ideologies associated with racist and antiracist movements. In other words, within racialized societies, master narratives of race to varying degrees provide one of the most important mechanisms through which racialized habits of thinking are sustained and reinforced.

It is important conceptually to delineate the congruity between the political institutions of racialized societies and the dynamics of how master narratives of race are used. In the United States, for example, public opinion had an increasingly and at times decisive role in shaping race relations because elections are a fundamental part of the American political/power process. Although the defeat of federal Reconstruction policies enabled the White South to disenfranchise the Black population in those states, the continued national acquiescence in that system (supported by the U.S. Congress, the U.S. Supreme Court, and the presidents) depended on national public opinion, not only public opinion in the southern states. Therefore, the hostile portrayal of Blacks in developing a national market for mass circulation of newspapers and magazines was a significant component of the racial system and the master narratives of race that stabilized between the 1880s and 1950s (Logan, 1954; Winston, 1982). This is the reason that the most important intellectual and psychological response to scientific racism, White supremacy, and imperialism developed in the United States.

#### Counter-Cultural Racial Consciousness: The Intellectual Reconfiguration of Race and Social Action

There was a group of exceptionally well-trained Negro scholars who were clustered (although not exclusively) on the faculties of Atlanta University, Fisk University, and Howard University. They initially used the definition of race (of their time) and developed it as a mobilizing device. Many also redefined the concept of race and its consequences on lives. The trajectory of this change can be traced from Du Bois's work in the 1890s, in which "blood" was still a component of the concept of race, through Alain Locke's *Race and Inter-racial Relations* (1916), in which it was argued that race is a socially constructed, malleable concept, to the consensus views of E. Franklin Frazier and the United Nations statement on race in 1950.

In the United States, the foundation for anti-racist thought and action was created immediately after the Civil War when the Freedmen's Bureau, under the leadership of General Oliver Otis Howard (1830–1909) established a complete educational system from kindergarten to higher education for the former slaves (Bond, 1934; Holmes, 1934). This was the first such system of education in the American South, where educational opportunities among Whites were limited and prohibited by law for slaves and for Free Negroes. No similar system was created in any other former slave society. Spread over an area larger than Western Europe, these colleges and universities prepared generations of teachers, doctors, lawyers, and other professionals who became the core of a new middle class in the 1870s and 1880s. It is significant that the most important of the counter-cultural, antiracist intellectuals and scholars, W.E.B. Du Bois (1868–1963), was a graduate of Fisk University in Tennessee. Fisk was one of the institutions assisted by the Freedmen's Bureau and the American Missionary Association, a key educational agency founded and operated by northern White missionaries.

In his influential paper delivered to the American Negro Academy, the *Conservation of Races* (1897), Du Bois argued that American Negroes were the "advance guard of the Negro Race," whose mission it was to counter White racist thought, achieve racial equality within the American system, and ultimately liberate non-White colonies from European and American domination. Du Bois (Ph.D., Harvard, 1895), the fifth American Negro to earn a Ph.D. at an

American University (the first was Edward Bouchet in Physics from Yale, 1876), virtually created the field of objective science-based Negro Studies in the Atlanta University Studies (1896–1913).

DuBois's evolving racial theory converted the biological elements of Euro-American race theory into a historical-social construct that posited a global Negro race. In his view, Africans, all North Americans, and Latin Americans of any African descent (no matter how minute), as well as the mulattoes of the Caribbean and Latin America, constituted one race as a result of the shared historical experiences of slavery, emancipation, and economic exploitation.

A founder of sociology in the United States, Du Bois's *Philadelphia Negro* (1899) demonstrated that social conditions, rather than innate traits, accounted for much of the observed behavior in urban Blacks. His work became the inspiration for a generation of Black scholars in history and sociology (notably Charles S. Johnson, E. Franklin Frazier, and Horace Mann Bond). Du Bois had a clear concept of the intellectual mobilization of American Negroes to fight racial segregation, economic exploitation, and political domination by Whites. Carter G. Woodson (1875–1950), another early Harvard Ph.D. in History (1907), founded the Association for the Study of Negro Life and History in 1915 and the *Journal of Negro History* in 1916, both cornerstones of the Negro History Movement, perhaps the most effective fusion of scholarship and popular participation in the counter-cultural movement against racial ideas and policies. Through his books and other publications as well as his support for a younger generation of Negro historians (e.g., Charles H. Wesley, Rayford W. Logan, Luther P. Jackson, John Hope Franklin), Woodson decisively answered Hume's question about what Negroes had achieved over the centuries.

By the 1940s, Negroes in the United States had developed a national network of Civil Rights organizations; more than 100 accredited institutions of higher education; hundreds of newspapers; professional organizations of teachers, doctors, and lawyers; and a growing body of scholarship in the social sciences and humanities that was unparalleled in other racialized societies.

The largest and best supported of the Negro institutions of higher education was Howard University in Washington, DC, founded in 1867 with a multiracial administration, faculty, and student body. From Reconstruction to the end of the 1960s, it

produced nearly half of the Black physicians in the United States (the bulk of the other half was produced by Meharry Medical College in Nashville, Tennessee) and more than 90% of the country's Black lawyers, engineers, and architects. In the twentieth century, its faculty in the natural sciences, social sciences, and the humanities included the highest percentage of nationally recognized Black scholars and scientists of any institution of higher education in the country. The law and social science faculty (and their graduates) from the 1930s through the 1960s provided most of the intellectual leadership of the Civil Rights Movement. Equally important was the impact of the published scholarship of its leading faculty, which was instrumental in changing the global consensus on race, racial segregation, and White Supremacy (Winston, 1971). Howard University is an example of the institutionalization of a counter-racist micro-environment. Functionally, such an environment normalizes and legitimizes intellectual opposition to the prevailing social and cultural order. It also creates expectations of intellectual performance and achievement that are the opposite of the cultural stereotypes and expectations that reinforced the racial system imposed by Whites. An institution functioning in this way is one of the components for effective mobilization of a targeted racial group in a sophisticated system of racial dominance of the type developed in the United States.

### ***The Establishment of Black, Asian American, and Latino Psychology as Counter-Counter-Cultural Racial Consciousness Movements***

Within the field of psychology, a group of well-trained Black scholars cultivated a paradigm and associated publication outlets to counter the racist ideology that permeated much of the empirical science of mainstream psychology. In so doing, they established what has been recognized over time as the field of Black Psychology, the *Journal of Black Psychology*, and the Association of Black Psychologists.

The development of a new field of Black Psychology was stimulated by a desire of a group of Black psychologists "to move away from the pathology-oriented notions about the behavior of black people and toward creating, interpreting, and reinterpreting the psychological literature on Blacks" (Jones, 1972, p. xi). In 1972, *Black Psychology* was edited by Reginald Jones and was the very first

volume to bring together in a single volume writings of black psychologists. Prior to this publication, the feasibility of developing a journal of Black Psychology was discussed among this same group of Black psychologists at the Annual Meeting of the Association of Black Psychologists in 1970 (Jones, 1972). This book included both philosophical and empirical chapters that were designed to highlight re-interpretations and clarifications of the psychological literature on Black people related to the following topics: racism, psychological assessment, personality, motivation, counseling, education, and the training of Black psychologists for work in the Black community.

In June 1974, a group of Black psychologists held the first Conference on *Empirical Research in Black Psychology* at the University of Michigan in Ann Arbor. This conference was stimulated by the Association of Black Psychologists' charge to Black psychologists to focus their professional contribution toward service to the Black community. The primary purpose of this small conference, which currently continues in another form, was to cultivate in-depth exchange among Black psychologists whose primary interest was empirical research (Boykin, Franklin, & Yates, 1979). The University of Michigan conference (and the second in 1975 at Teachers College, Columbia University) resulted in the publication of a collection of revised and edited papers. Publication of *Research Directions of Black Psychologists* (by the Russell Sage Foundation) was a significant advancement toward establishing a field of Black Psychology. It is also significant that this book was edited by three early career psychologists—A. Wade Boykin, Anderson Franklin, and J. Frank Yates. Their careers had the potential to demonstrate the verifiable validity and research fruitfulness of the new modes of conceptualizing the field and its major research problems. The volume included sections on methodology, identity and adjustment, cognitive abilities, motivational issues, and problems for future research. These chapters were written by a collection of Black psychologists who later became some of the field's most influential theorists and researchers, including the following scholars: Oscar Barbarin, A. Wade Boykin; William Collins; William Cross, A.J. Franklin, James Jackson, James M. Jones, William Lawson, Diane Pollard, and J. Franklin Yates. The goals of the book as described by the editors were held together by an interest in empirical research in psychology but also included a concern for the growth and sustainability of this

work through the graduate and professional training of others:

“In particular, we hope this book will serve as an impetus to students and behavioral scientists to embrace research as one means of alleviating oppressive life conditions of Black people, and we visualize it as being especially encouraging to Black graduate students interested in pursuing systematically the difficult questions of ethnic pertinence so often confronted in professional training. Moreover, we expect to provide thesis advisors with a frame of reference for counseling students who adopt research proposals with themes that emanate from their professional interests and concerns about life conditions of Black people.”

(Boykin, Franklin, & Yates, 1979, p. xiv)

Within the field of psychology, a small group of well-trained Asian-American and Latino scholars organized through regional and later national conferences in ways similar to Black psychologists to counter the racist ideology that permeated much of the empirical science of mainstream psychology. In a recent article on the History of Asian American Psychology, Leong and Okazaki (2009) have identified the pioneering Asian-American psychologists and described the events that led to the founding of the Asian American Psychological Association. Similarly, Padilla and Olmedo (2009) have recently published a chapter on the History of Latino Psychology in the Handbook of Latino Psychology that describes the founding of the Association of Psychologists por la Raza in 1969 and the founding of the National Hispanic Association in 1980.

There were several significant historical events that created the momentum necessary for the establishment of a national movement for Latino/a Psychology. After 1969, when Edward Casavantes, an educational psychologist who worked for the U.S. Civil Rights Commission, founded the Association of Psychologists Por La Raza, an annual meeting of this association was held in conjunction with the annual American Psychological Association meeting. The first was held in Miami in 1970 and led to organization of a symposium for the following year that was to be the first on Chicano Psychology at APA (Padilla & Olmedo, 2009). In 1979, a National Conference of Hispanic Psychologists was held at the University of California Residential Conference Center at Lake Arrowhead. This conference was funded by a grant from the Division of Manpower and Training and the Center for Minority Group

Mental Health at the National Institutes of Mental Health. The goal of the conference was twofold: (1) to share information on needed training, services, and research from a Latino perspective; and (2) to determine if there was universal agreement to establish a national Latino association. This conference was significant in the history of Latino/a Psychology because it was the first time that a large number of Latinos/as representing different geographical regions, national origins, and disciplinary interests converged in a single location to develop an alliance for the empowerment of Latino/a psychologists and their communities (Padilla & Olmedo, 2009). More recently, the name of the National Hispanic Association was changed to the National Latino/a Psychological Association.

Like the Black Psychology and Latino/a Psychology movements, there were a few key historical events important to the momentum of Asian American Psychology. In 1972, a group of psychologists who lived in the San Francisco Bay area (including Derald Due, Stanley Sue, Roger Lum, Marion Tin-Loy, and Tina Tong Lee) founded the Asian American Psychological Association. The first national conference on Asian American mental health was held in San Francisco, California, and funded by the National Institutes of Mental Health. The conference was attended by more than 600 individuals from a wide diversity of Asian ethnic groups and types of organizations, including grassroots organizations, academia, and private practice. Leong and Okazaki (2009) have described how this diversity of backgrounds, views, and agendas led to some tensions and debates about the most pressing issues for a national Asian American psychological association to address. In 1976, Asian American psychologists organized a second conference in Long Beach California with the following objectives:

“(a) to gain a sense of mental health service needs of Asian Americans from individuals with active engagement with them; (b) to identify and recognize salient issues for various Asian American groups; (c) to abstract from participants’ backgrounds and experiences both instances and preparation that would facilitate work with Asian Americans and instances of inadequate or counterproductive training for such work; and (d) to organize information gathered into a series of recommendations for improving the training of Asian American psychologists.”

(Leong & Okazaki, 2009; p. 356)

Despite the widespread impact of this national organization of Asian American Psychologists that was stimulated largely by these two conferences, it was not until 2010, that *The Journal of Asian American Psychology* was established and published by the American Psychological Association.

### Future Directions

The human mind has the unique capacity of agency and adaptation. Racialized societies are complicated contexts in which the mind is called on to make these shifts of adaptation. The Winston Framework as a cultural psychology framework for analysis of systems level and interindividual level variables within racialized societies creates new opportunities for theoretical and methodological innovations within future research. Although clearly not an easy undertaking, scholars of the future will have unprecedented opportunities. They will have a new ease in gaining access to digital information across disciplines that provides insight into the economic, social, political, historical, and psychological dimensions of human life. This, coupled with the relative ease of travel, compared to the past, creates new ways to begin to formulate theories within the Winston Framework. Technological advances in digital data collection tools, all used within appropriate cultural boundaries, provide new opportunities to collect first-person accounts (*see* Winston in press b) with more ease in crossing geographic location, time, and resources to collect, process, and analyze the fusion of systems and interindividual personality data.

A derivative effect of the expansion of opportunities for theory development and methodological innovation are new emphases in research related to a cultural psychological analysis of race in historical perspective. For example, future research should examine the relationship between personality traits and identity construction within racialized societies. It is likely that racialized constraints within a society, driven by law or custom, for example, can cause tension and conflict if a person has personality traits that are more expressive or demanding than the system accommodates, making it more difficult to construct a balanced and adaptive identity.

### *The Significance of Comparative Analysis of Racial Systems*

It is now understood that race is a socially constructed category whose significance varies historically, socially, and psychologically by era, types of social and economic structures, cultures, and the

dynamics of individual and group adaptations to imposed racial boundaries. As scholarship about slavery, racial segregation, and personality development has matured, the importance of comparative studies has emerged, principally as a means of grasping the essential social and psychological mechanisms that perpetuate or destabilize racial regimes, and to separate fundamental structure from merely idiomatic or cultural features of systems of racial dominance (Holt, 2000). This realization underscores the importance of developing a provisional framework for the analysis of racial systems, regardless of geographic area, historical period, or the methods used to enforce dominance (e.g., a “hard” approach via government power or a “soft” one utilizing culture and private prejudices).

This chapter has posited the elements of a comparative framework for the analysis of racial systems but has deliberately avoided a purely schematic or theoretical approach, anchoring the framework in a historical, cultural, and psychological continuum. Thus, the core racist ideas have been identified, the process of their becoming embedded in institutions and culture described, and some of the social processes and intellectual movements mentioned that destabilized the late nineteenth- and twentieth-century racialized society system.

The Winston Framework emphasizes the issues of power, wealth, social development, and psychological adaptations because all racialized societies—regardless of culture—operated to reserve power, wealth, education, prestige, and social development to a dominant racial group, while systematically disadvantaging a subordinate racial group (or groups). It is the nexus between material advantages and racial identification that entrenched racial ideas in societies. Although the racist ideas themselves have been discredited, and the legal framework for racial segregation and other state-enforced discrimination has been destroyed, all societies with a racialized past or with later and weaker derivative variations have cultures and social habits that continue to have negative impacts on lives. The Winston Framework enables scholars and scientists to identify more readily the evolving adaptations of racially identified individuals to less racially restrictive (not “post-racial”) societies.

## Belonging to Gender: Social Identities, Symbolic Boundaries and Images

Ana Flávia do Amaral Madureira

### Abstract

Symbolic boundaries mark the differences between individuals and social groups in daily life. These symbolic boundaries are deeply connected with the feelings of belonging to specific social groups. What does *belonging to gender* mean? Social control related to the feminine body and sexuality is a field in which the study of reproduction of inequalities in the domain of gender relations is of interest. It is necessary to construct creative analytical and methodological strategies to investigate gender issues inserted in broad cultural meaning systems, historically constructed. In this paper, I consider the analytical and methodological relevance of images as data sources in the context of psychological science.

**Keywords:** gender, social identities, symbolic boundaries, meaning-making processes, images as cultural artifacts

... To affirm the identity means demark boundaries, means make distinctions between what is inside and what is outside. The identity is always connected within a strong separation and distinction, supposes and, at the same time, affirms and reaffirms power relations. 'We' and 'they' are not in this case only grammatical distinctions . . .

(Silva, 2000, p. 82)

What does it mean to be a man or to be a woman? What does *belonging to gender* mean? These questions are important in the analysis about the complex relations between the collective culture and the psychological development of each person. From a cultural psychology framework, this chapter focuses on the construction of symbolic boundaries that are deeply connected with the feelings of belonging to specific social groups. More precisely, our story is about symbolic boundaries related to the construction of gender identities.

It is not possible to properly understand the processes of the construction of gender identities from an isolated approach that treats cultural meanings

associated to femininity and masculinity as "linguistic atoms" (Madureira, 2007a). Therefore, it is necessary to construct creative analytical and methodological strategies that emphasize the importance of images, as cultural artifacts, in the inquiries about meaning-making processes and the construction of social identities.

### The Construction of Symbolic Boundaries and Feelings of Belonging to Specific Social Groups

From a cultural psychology framework, human conduct is conceived as behavior reorganized by *semiotic mediation* that is used by the intentional and active mediator, the person oneself (Valsiner, 2005, 2007a). Consequently, *understanding human conduct is essential to considering the central role of semiotic mediation*. Nevertheless, our relating with the world is not just a rational enterprise mediated by signs expressed by verbal language. Therefore, an important theoretical and analytical challenge is the overcoming of rationalistic and linguistic

reductionisms in the inquiries of social and psychological phenomena (Madureira, 2008). In this direction, the concept of *symbolic boundaries* could be a useful conceptual tool that expresses the necessity to construct an integrative view, a systemic approach that articulates cultural, affective, and cognitive aspects in the inquiries of important issues for psychology and social sciences in general.

In this chapter, I focus on the process of social identities. More precisely: the focus is on the construction of gender identities. In this sense, it is important to stress that social identities are always constructed on the ground of collective memories, historically situated. When we intend to analyze the construction of social identities, we move ourselves into the direction of crossing the boundaries between psychology and social sciences. After all, as Rosa, Bellelli, and Bakhurst state, the concept of identity “. . . is not a concept that pertains exclusively to psychology, but it is part of the heritage of all social sciences . . .” (2000, p. 57). Therefore, in order to understand the construction of symbolic boundaries and the feelings of belonging to specific groups present in our societies, it is necessary to establish interdisciplinary dialogues.

### ***Social Identities: The Construction of Affective Bridges between Individuals and Social Groups***

The metaphorical image of a boundary as semipermeable membrane (Valsiner, 2007b, 2009) is a promising path to study diverse phenomena like, for example, the construction of social identities and the related dynamics (and tensions) between in-group and out-group, stereotypes, prejudices, and discriminatory practices, as prejudices in action (Madureira, 2008, 2009a).

From a cultural psychology framework, it is central to recognize that without differences and ambiguities, meaning-making processes are impossible (Ferreira, Salgado, & Cunha, 2006; Valsiner, 2007a). In other words, the differences are central elements of classificatory systems through the meanings that are created (Woodward, 2000). Therefore, meaning-making processes are deeply related to the tension between sameness and difference. As Ferreira, Salgado, and Cunha (2006, p. 28) state: “. . . Human meaning, in that sense, is brought to being by difference, contrast, tension, disagreement. . . . In other words, meaning is always dependent on the play between sameness and difference.” Thus, marked differences are central in the

processes of meaning making in daily life, and symbolic boundaries have an important role in these processes. Tensions, ambiguities, and differences are in the heart of the meaning-making processes that involve the constant using of signs through the flow of personal experiences. It is important to stress that signs, visual and verbal, present a hybrid and recursive nature that increase the complexity of the meaning-making processes (Valsiner, 2007a). After all, there are many possible combinations between icons, indices, and symbols.

Making distinctions is important at different levels of analysis, including the biological level—for example, the differentiation of organ systems in embryogenesis, the “self/other” distinction in our immune systems (Valsiner & Rosa, 2007). In the biological sense, boundaries work as membranes. After all, “Boundaries as structures that unite standard in the biological world. All membranes are boundaries—and the livelihood of organisms depends on how well appropriate transpositions of chemicals through these membranes work” (Valsiner, 2007b, p. 221).

From a biological level to a sociological level of analysis—considering the societies as dynamic and open systems—we can notice that in diverse societies around the world, there are always symbolic boundaries that delimit the differences between individuals and social groups in a semipermeable way. Some of them do not present meaningful implications, but others present deep implications in different levels of analysis: (a) macrosocial level; (b) interpsychological level (social interactions); and (c) intrapsychological level (Madureira, 2008, 2009a).

The color of skin, for example, illustrates how symbolic boundaries can present relevant and concrete implications in daily life. This arbitrary criterion has been considered culturally meaningful to split individuals into different and hierarchical social domains in different societies. This arbitrary criterion is in the base of racism, a kind of prejudice that, frequently, is associated with elitism (contempt for poor people) in countries with slavery as a social practice in their past. There is obviously a long history of oppression and resistance in the process of the transformation of the arbitrary criterion “color of skin” into a culturally meaningful recognition of differences, which become connected with social power issues, understood as the relation between forces of oppression and resistance (Foucault, 1996). In few words, differences become inequalities.

When semipermeable symbolic boundaries become cultural barriers—understood as rigid, non-permeable boundaries—and come to qualify some groups at the cost of disqualifying others, we can perceive different kinds of prejudices in action (racism, sexism, homophobia, elitism, xenophobia, religious bigotry, and so on). When these rigid symbolic boundaries are targets of transgression, we see the violence and the intolerance underlying diverse discriminatory practices. For the constant reproduction of social inequalities and hierarchies, there are many social mechanisms that, in different ways, inform that these boundaries should be respected, whatever the cost in terms of psychological suffering: depression, anxiety, shame, and so on (Madureira, 2007a, 2007b, 2007c, 2008). In extreme cases, when the symbolic boundaries become more rigid, the “others” (they) are socially perceived as enemies that should be eliminated. Figure 26.1 shows a didactic view of the transformation of symbolic boundaries: (a) from differences to inequalities; and (b) from inequalities to intolerance.

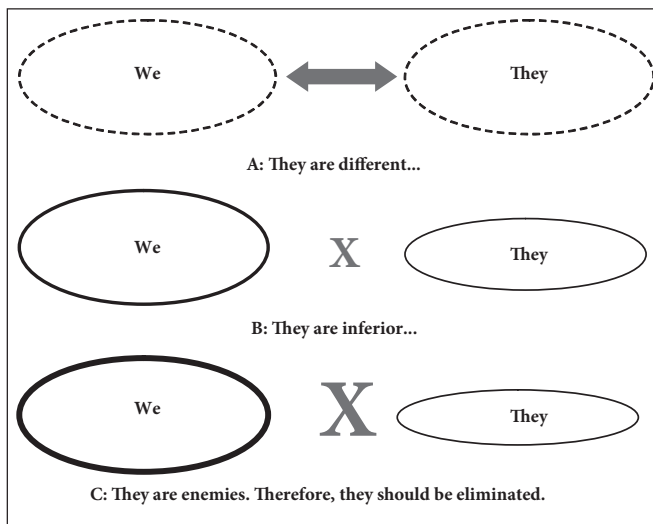

**THE FEELINGS OF BELONGING TO A SPECIFIC GROUP: THE TENSION BETWEEN THE HEIMWEH AND THE FERNWEH PROCESSES**

The feelings of belonging to a specific group provide a familiar and secure basis to face the ambiguities present in ordinary situations in our lives (Madureira, 2008, 2009a). In this direction, it is relevant to mention the notion of tension between two general processes, specified by Ernest Boesch, *Heimweh* (“homeward road”: striving toward the known and the secure) and the *Fernweh* (“road to

the far away”: adventure, encountering novelty and also risks). In general terms, while the perception of risks and dangers are related to the promotion of the *Heimweh* process, the feelings of pleasure and curiosity are related to the promotion of the *Fernweh* process. As we encounter in daily life many ambiguous situations, one possible solution could be avoided the experiences that put in risks the sense of stability of self-system, especially our personal values (Madureira, 2007b, 2007c). As Joerchel affirms,

... the relation between ‘home, secure’ and the ‘strange, unfamiliar’ is a key element in developing a self system. ... Thus, the self concept is comprised both of the familiar, the home environment, as well as of the strange and the unknown. It is within this tension that humans develop a self concept: the secure home environment provides the base for self confidence and self actualization, the strange and the unknown provides a platform for hopes, dreams, and desires, for potential actions and potential self concept as well as a platform for fears and threats to the self system. ... In this respect the construction of a social barrier can be seen as defense mechanisms in reaction to a perceived threat to the self concept. (2007, p. 257)

Therefore, when the *Heimweh* orientation is promoted, the symbolic boundaries between “us” and “others” tend to become rigid. It is important to clarify that we are not talking about a linear causal relation. Instead of we are talking about a tendency. In this sense, when the *Heimweh* orientation is promoted, a cultural barrier tends to be erected and the others come to be perceived as inferiors or enemies

**Figure 26.1** Prejudices as rigid symbolic boundaries: from differences to inequalities, from inequalities to intolerance.

who put at risk ourselves and, in a broader sense, the *status quo*. More than seeking strategies to deal with ambiguities from a secure and familiar basis, what emerges is the desire to eliminate all ambiguities, and all differences, to eliminate the others, perceived as the source of uncomfortable feelings (Madureira, 2008, 2009a).

An example can illustrate the discussion above: from (a) the secure basis of religious beliefs, values and practices in the case of religious individuals who respect other religious beliefs distinct of their religion; to (b) religious bigotry based on fundamentalist mentality (e.g., one's belief that everybody outside of the symbolic boundaries of his/her own religion is "unfaithful" and should be converted or combated and eliminated (Sim, 2004). Therefore, differences become inequalities, and intolerance, that underlying prejudice, becomes explicit through discriminatory practices against different social groups (Madureira, 2007c, 2007d, 2008).

*To summarize—the study of boundary processes challenge us in the direction of an integrative view that articulates cultural, affective, and cognitive aspects in the research of important issues for psychological and social sciences as, for example, social identities, stereotypes, prejudices, and discriminatory practices.*

From the previous discussion, it is possible to conclude that when we talk about the construction of social identities, we are talking about *affective bridges* (feelings of belonging) between the individual and the social groups present in society (Madureira, 2000, 2008, 2009a; Madureira & Branco, 2007). These processes are a political arena where tensions and contradictions are not the exception, but a common characteristic. In this sense, gender, class, and race become important interdependent axes in the approaches on social identities, as powerful social organizers in different societies (Barcinski, 2008; Oliveira, 1998). Therefore, the construction of gender identities always happens in connection with other social identities. Moreover, identity processes present a clear political dimension (Silva, 2000). Surely, we are not analyzing a neutral domain of social life.

### **What Does Belonging to Gender Mean? Social Identities, Symbolic Boundaries, and Cultural Canalization**

Between the (biological) concept of sex and the (cultural) concept of gender, there is a long way to be covered by each person. This "long way" is always covered from particular socio-cultural contexts, permeated by beliefs, values, stereotypes, prejudices, and

practices that mark what is socially expected regarding men and women. These social expectations delimit the symbolic boundaries of masculinity and femininity. Frequently, masculinity and femininity are conceptualized by the logic-exclusive separation. As Watzlawik (2009) demonstrated, the constructs of masculinity and femininity—based on the oversimplification and overlapping between different levels of analysis—are fragile in scientific terms. In this sense, to be a man or a woman is not a "natural fact." Instead, belonging to gender is a cultural construction.

In the cultural construction of gender identities, an important domain entails the beliefs, values, and practices related to sexuality (Blackwood, 2000). Thus, in this paper, we pay a special attention to the interfaces between gender and sexuality issues, including the deep connections between sexism and homophobia, which constitute boundary phenomena (Madureira, 2007b). The maintenance of gender inequalities in daily life is sustained by a complex power system (Foucault, 1996). Women, frequently, have a strategic and important position in the maintenance of this complex power system. The scornful talk among women about the sexual behavior of other women is, for example, a powerful informal social control strategy concerning feminine sexuality. More precisely, the social control related to feminine sexuality is a meaningful field to study hierarchical gender relations. In this sense, the feminine body, sexual pleasures, and desires play a strategic role in the context of the "power games" occurring within cultural contexts.

### ***Gender Identities: We Are Not Talking about "Natural Boundaries"***

The interdisciplinary studies of gender have questioned the biological essentialism diffused in daily life, and in scientific approaches based on the traditional biomedicine model (Costa, 1996). As previously mentioned, the construction of gender identities is permeated by beliefs, values, stereotypes, prejudices, and practices that mark what is socially expected regarding men and women in specific sociocultural contexts. These social expectations, with historical roots, are the "collective ground" where the symbolic boundaries of masculinity and femininity are delimited in daily life. In this sense, we can say that gender identities are:

(a) constructed not only in the relations between men and women, but also intragender relations from the cultural models and antimodels of masculinity and femininity (Parker, 1991);

(b) constructed in an articulated way within power relations that permeated our societies in their different levels, relations of force, oppression, and resistance (Foucault, 1996).

The development of the gender concept, from the 1980s, expresses the important exchange between the scientific enterprise and the feminist movement, which as a social and political movement, has fought against the sociohistorical inequalities between men and women in different domains of life (Louro, 1998). According to Joan Scott, "... Gender is the social organization of sexual difference. The concept [gender] is not a reflection of biological reality, but gender constructs the meaning of this reality ..." (Scott, 1995, p. 115).

Therefore, as an analytical and political tool, the concept of gender helps us to reject the assumptions—underlying discourses about the "natural" inequalities between men and women—that are based on biological differences. In this sense, the concept of gender has an important heuristic value concerning the understanding of the cultural and psychological basis of the process of becoming a man or a woman (Madureira, 2007b). We can say that gender issues have an important role concerning individual psychological development, in terms of cultural canalization (Golombok & Fivush, 1994; Madureira & Branco, 2004). Gender is, therefore, an interdisciplinary analytical tool that makes it possible to understand diverse phenomena studied by human sciences. Gender is a relational concept—best viewed as a field (Madureira, 2007b).

When we focus on identity processes and power relations, it is essential that we pay special attention to the role of scientific discourses in contemporary societies. As Foucault (1996) analyzed, there are intrinsic connections between scientific knowledge and power relations in our disciplinary Western societies. Historically, modern sciences broke the ancient distinction between *episteme* (theoretical knowledge) and *téchne* (applied knowledge) (Marcondes, 2000). Thus, modern sciences are not a kind of contemplative knowledge. In fact, the socially spreading myth of scientific neutrality hides this "practical" aspect of the production of scientific knowledge (Chauí, 1995). From the noticing that science is power in our societies, we should develop ethical and political reflections concerning our researches and recognize that we are not constructing neutral knowledge (Madureira, 2009b).

### ***Sexism and Homophobia: When Prejudices Meet Each Other and Become Stronger***

Since the beginning of Christianity, coherent with the ancient Greek one-sex model, and during all the medieval period in the Western Europe, "...the woman was defined from her deficiencies in relation to the human nature, that is was accomplished in the most complete form in man" (Zuber, 2002, p. 144). The adopting of the two-sexes model, at the end of eighteenth century and during the nineteenth century, was not just a consequence of "medical scientific progress", but resulted from deep social and political changes. As Costa claims: "... From the 'inverted man', the woman became the 'inverse of man', and the cause was in her sex. Firstly, the production of social and political inequalities happened, between men and women, legitimated by the natural norm of sex. Then, what is effect became cause..." (1996, p. 85, italics added).

The maintenance of a deep gap between masculinity and femininity has a strategic role in political terms, in order to reproduce the hierarchical structure between men and women. The transgression of symbolic boundaries related to gender is socially perceived as a threat to ordinary flow of life. For example, homosexuality is traditionally perceived as a defect of gender identity, as if gays and lesbians are men and women that "fail" in the construction of their gender identities. In the cases of transgender, the transgression of the gender boundaries is socially perceived as an even greater threat, because these cases question the existence of a "natural link" between biological sex and gender identity. It does not cause surprise that the amplification of differences between men and women is in the basis of sexism and homophobia.

Sexism corresponds to an *exclusive separation* (dualistic conception) of genders, prioritizing one over the other, and associating pejorative meanings to the other. In didactic terms: *sexism = rigid distinction of genders + unequal power relations + constructed prejudice to mark the unequal relation* (Madureira, 2007a, 2007b, 2009b). If we focus on the macrosocial level of analysis, we observe the reproduction of a hierarchical structure of gender that expresses inequalities between men and women in different domains, as autonomy, prestige, status, and so on (Bourdieu, 2005).

However, it is essential to recognize that sexism, as a kind of prejudice, is not present just "in men's minds." It can be found in institutional and informal practices, in different social relations in daily life. The

empirical example presented in this paper will illustrate the importance of the adoption of a relational perspective in gender studies. Beyond that, as recent studies have demonstrated, there are deep connections between sexism and homophobia (Andersen, 2000; Lionço & Diniz, 2009; Madureira, 2007b; Welzer-Lang, 2001). Sexism—as a rigid and hierarchical gender distinction—is directly related to the reproduction of nonpermeable boundaries between masculinity and femininity, between the heterosexual population and the Lesbian, Gay, Bisexual, and Transgender (LGBT) population.

### ***The Traditional Dualistic Gender View: Cultural Meanings Associated to Masculinity and Femininity***

There is a historical-cultural dualistic gender view in Brazilian society, like other Latin American, Mediterranean, Middle Eastern, and North African societies (González-López, 2005). According to this dualistic gender view, we can perceive strong connections between:

- (a) femininity, sexual passivity, and the value of female virginity *versus*
- (b) masculinity, sexual activity, and the value of diverse and precocious sexual experiences.

According to this dualistic meaning system, the antimodel of masculinity is the “passive man,” and the antimodel of femininity is the “active woman” (promiscuous) (Parker, 1991). The traditional cultural discourses about sexuality in Brazil have structured from this traditional dualistic gender view: masculinity—activity in social and sexual domains—*versus* femininity—passivity in social and sexual domains.

Therefore, the “major problem” concerning female sexuality would be the active conduct by women, many times perceived as a sign of promiscuity. In this sense, it is curious to note that of the women who participated in a qualitative research about the construction of nonhegemonic sexual identities in Brasília, Brazil (Madureira, 2000), all of them argued for a clear-cut difference between gays (out-group) and lesbians (in-group). In their opinions, comparing to men, women are more affective. Moreover, they claimed that men are totally sex-oriented, and depict men as promiscuous (out-group) whereas they are not. As Blackwood (2000, p. 232) claims: “. . . By establishing certain ideas about who and what men and women are, gender ideologies create different possibilities for men’s or women’s understanding of

their desires and their access to other sexual partners.” In fact, the label of promiscuity is a real danger for women in some contexts, especially where the traditional gender ideology is strong.

Sexual violence, more precisely, rape, does not correspond with a simple “individual pathology,” completely dissociated of power relations, beliefs, values, and cultural practices regarding gender issues. In this sense, it is pertinent to mention the research coordinated by the anthropologist Rita Segato (2003) about gender structure and sexual violence, from the analysis of interviews with prisoners of Complexo Penitenciário da Papuda (Distrito Federal, Brazil) who committed crimes against sexual freedom. This research shows that, in the rapists’ discourse, it is commonly a “moralizing accent” concerning the women’s behavior that is considered, in some way, immoral. Segato stresses that the rape is perceived by rapists:

... as a punishment or revenge *against* a generic woman who goes out of her place, that is, her subordinate position and ostensibly tutelage by a status system. . . . ‘Only the protestant woman [in Portuguese: *mulher crente, evangélica*] is good’, said to us a prisoner, which means: ‘only she does not deserve to be raped.’

(2003, p. 31)

According to the analysis carried out by Lloyd Vogelmann with rapists in South Africa (as cited in Segato, 2003, p. 30): “women who are not propriety of a man . . . are perceived as propriety of all men. In essence, they lose their physical and sexual autonomy.” Therefore, in traditional hierarchical gender structure, the notion of propriety of a man does not involve only material possessions, but also the possession of women. In other words, the woman is not socially perceived as citizen of her own sexuality and body, but as an object/property of the man: an “honorable” woman would be a possession of a unique man.

Without any doubt a rape is a case of extreme violence. However, it reveals subjacent cultural meanings associated to traditional gender relations in our societies. As it was analyzed by Segato (2003), the rapist fulfills a kind of mandate of society: the “deviated” women must be punished! They should not circulate freely in spaces designated to men, such as the public space of streets at “inappropriate times.” Indeed, as men socially perceived as “closer to women,” gays are also victims of sexual violence. *The maintenance of rigid symbolic boundaries*

between masculinity and femininity does not only imply “bad jokes” against the supposed transgressors, but also implies, in extreme cases, acts of physical violence against women and men who do not “respect” their biological sex. As if biological sex completely determines their actions, their thoughts, their feelings, their desires. As if the biological sex traces an inexorable destiny that must be respected.

#### **SOCIAL CONTROL ON THE BODY AND SEXUALITY OF OTHER WOMEN: AN EMPIRICAL EXAMPLE**

... Because gender includes beliefs about sexual behaviour, it is one of the primary crucibles within which sexuality is produced. Sexualities are informed by and embedded in conceptions of gender; that is, they are embedded in gender ideologies that enable and structure differential practices for women and men . . .

(Blackwood, 2000, p. 229)

This topic focus on the interfaces between gender and sexuality issues from an empirical example extracted from a broader research (Madureira, 2007a). The main objective of the research in focus was to analyze teachers’ beliefs and conceptualizations within the context of Brazilian public middle schools, located in Distrito Federal (DC, Brazil), about gender and sexuality issues, especially those concerning sexual and gender diversity. These issues were analyzed from the integration of different methods: (a) questionnaire; (b) individual semistructured interview; and (c) focus group. One hundred twenty-two teachers (n = 122) from seven different public schools in Distrito Federal participated of the first phase of the research (questionnaire). Ten teachers (n = 10), from two different schools that contributed in the first phase, participated in the second phase (individual semistructured interview and focus group). The age of their students was between the range of 11 to 15 years old. In the process of analyzing the “empirical indicators,” it was central to interpret the implicit connections between: (a) individual beliefs and values concerning the issues in focus; and (b) the broader cultural meanings system of gender and sexuality, historically established. In other words, *it was central to construct analytical strategies to integrate different levels of analysis in order to elaborate a more general understanding about the subject of the target research.*

The following empirical example was extracted from the individual interviews carried out at the second phase of the broader research (Madureira,

2007a). It is an insightful example to analyze how women, frequently, put in action the mechanisms of social control on the feminine body and sexuality. These mechanisms of social control are deeply connected within archaic cultural meanings about femininity, as it will be discussed later. Moreover, it illustrates the importance of adoption of a relational and political perspective (Louro, 1998; Scott, 1995) when we focus on gender issues.

*Example extracted from individual interview:*

Interviewee: Joanna (fictitious name).

Age: 34 years old.

Religion: Catholic.

**Ana Flávia (interviewer): Do you think today’s society expects different things from men and women? Why?**

– Joanna: I think that too much equality, also, is not good, you know?

– Ana Flávia: What do you mean? So I can better understand what you’re saying . . .

– Joanna: Well, I guess, like, too much equality, then we’d go like, then I don’t know. I’m going . . . I’m going . . . for instance, uh, the same rights. When you say, like, that women want to have the same rights as men, and everything. But then you have the sexual thing. You know, it’s too cheap, you see, like, what’s the problem if I go out with a guy this weekend and then with another in the next? You see? Because if all rights are the same, everything the same, at work, things are like this, you see? Then you have an equality, a sexual freedom, you know? A sexual freedom that I, like, sometimes I think that, it’s not worthy, you know?

– Ana Flávia: This sexual freedom you’re saying it’s not worthy, what do you mean by that?

– Joanna: I mean promiscuity.

– Ana Flávia: In relation to whom? Men or women?

– Joanna: To women.

In this excerpt of the interview with Joanna, she says that she disagrees with the idea of men and women having the same rights in all domains of life. She agrees about the same rights in the professional domain, but she really disagrees about the same rights concerning the sexual domain. Her position is made clear when she says:

*But then you have the sexual thing. You know, it’s too cheap, you see, like, what’s the problem if I go out with a guy this weekend and then with another in the next? You see? Because if all rights are the same, everything the same, at work, things are like this, you see? Then you have an equality, a sexual freedom, you know? A sexual*

*freedom that I, like, sometimes I think that, it's not worthy, you know?*

According to Joanna, sexual freedom is a real problem for women, but that is not so for men. Here we observe, in her discourse, the links between: (a) same rights for men and women in the sexual domain; (b) [women] become cheap; (c) [women's] sexual freedom; (d) [women's] promiscuity. Thus, we can conclude that, for her, the same rights between men and women at the sexual domain are not desirable; instead, it seems that the same sexual rights can be "dangerous." After all, for women, sexual freedom is interpreted by her as a sign of promiscuity. The personal values system seems to express a central role in the interpretation of what "sexual freedom" means. For example, for some women sexual freedom is interpreted as a sign of individual rights, while other women interpret sexual freedom as a sign of promiscuity. A sign that can present concrete implications in some contexts (especially sexist contexts): women who were marked with this sign (seen as promiscuous) become less worthy in the community's eyes.

What is particularly interesting here is that such a position was presented by a woman. Again, in order to develop our analytical strategies to interpret gender issues it is essential to go beyond generic assumptions about the "masculine oppression against women." *Gender inequalities are sustained by a complex power system that is built on cultural meanings and practices where women, frequently, have a strategic and important position in the maintenance of the oppression system.* For example, the scornful talk among women about the sexual behavior of other women is a very powerful social control strategy concerning feminine sexuality.

Here we have an example of the strong relations between gender and sexuality issues. More precisely, the social control (by men and women) related to feminine sexuality is a meaningful field to study hierarchical gender relations. The feminine body, sexual pleasures and desires play a strategic role in the context of the "power games" occurring within cultural contexts. Therefore, it is essential to integrate a critical view about gender relations with the interdisciplinary studies of sexuality, as illustrated in this empirical example.

For example, the pejorative view of Joanna about the "sexual freedom" of women (understood by her as a sign of "promiscuity") is inserted in the long Christian tradition that presents feminine sexuality as potentially dangerous. Thus, it should be

"controlled" by each woman, by other women, and by society in general. The pejorative view about the female body and sexuality is fed by social imaginary. The ways that each woman deals with her sexuality and body in daily life are socially interpreted from symbolic boundaries. *These symbolic boundaries split women in two different social groups: "honorable women" and "nonhonorable women." A central issue is: the honor of a woman is focused on her private life while the honor of a man is focused on his public life.*

### **The Feminine in the Medieval Christian Iconography: The Woman as a Devil**

When we focus on the construction of gender identities, it is necessary to promote interdisciplinary dialogues between psychological science and social sciences in general. For example, the current historical analysis about social imaginary in the Middle Ages can be a fertile ground for psychology. Jacques Le Goff and Jean-Claude Schmitt, two important contemporary historians, stress the necessity of integrating "...in our analyses and in our reflection a new orientation in history so present in the view of historians nowadays: the history of imaginary..." (2002, p. 14). In other words, it is important to articulate the analysis of the "historical facts" and the representation of these "facts." The authors note that "Around twenty years, an important part of these new ways appears under the label of 'historical anthropology'" (Le Goff & Schmitt, 2002, p. 18).

In this sense, the present topic analyzes some historical clues about the cultural pejorative view about the sexuality of women from the image of the feminine in the medieval Christian iconography. After all, our personal imagination is constantly fed by the images that circulate in social imaginary, and we should not disregard the force of the Christian cultural tradition in Western societies.

The European Middle Ages is, traditionally, divided in the following way: it began in the fifth-century, with the disintegration of Western Rome Empire in 476 AC, and continued until the fifteenth century, with the Turkish capture of Constantinople in 1453 (Pratas, 2009). It is important to remember that Catholic Church was the most powerful social institution in this historical period, especially during the last centuries of the Middle Ages (tenth to fifteenth centuries), when its economic, political, and cultural power reached its peak. The Earth was considered the center of universe, and the universe was considered as finite and unchanged. The image

of God was in the center of medieval societies and, therefore, philosophy and arts were simple servants of theology.

From the conception that images are cultural artifacts, this topic focuses on some elements of medieval Christian iconography<sup>1</sup> in order to seek clues about the historical roots of archaic meanings about femininity. These meanings are still present in the social imaginary in Brazil, a country with a strong Catholic tradition, but are also present in other Western countries.

### *Misogyny in the Medieval Social imaginary*

Misogyny, or hatred of women, was widespread in European medieval societies. Misogyny did not begin with Christianity in the Middle Ages; it corresponded to an appropriation of conceptions and beliefs that were already presented in the Ancient world. On another hand, misogyny became a project "...in the sense to encrust in the popular imaginary the belief in the inferiority of woman and femininity. In Western history, the period when this procedure was the most obvious was during the Middle Ages." (Gomes, 2009, p. 261). In this sense, some meaningful examples will be presented in order to illustrate how the social imaginary in this historical period was full of hostile images concerning women.

As the start point, we will focus on the holy book for Christianity, the Bible that comprised the Ancient (Old) and the New Testament. Then, other examples will be presented. The Bible presents at least three essential elements of the religious doctrine associated with femininity: (a) as the man and the woman were created (Ancient Testament, Genesis); (b) the figure of Eve (Ancient Testament, Genesis); and (c) the figure of Mary, mother of Christ (New Testament) (Gomes, 2009; Pratas, 2009).

According to Genesis, concerning the way that the man (Adam) and the woman (Eve) were created, it is interesting to note that "...the man is a direct descendent of God—a divine being—although the woman is a descendent of man's rib—a flesh being and, therefore, closer to what is profane, sensorial and corporal" (Gomes, 2009, p. 262). Thus, the human tendency to commit sins is interpreted by Christianity as stronger in women than men. In a similar way, the figure of Eve *per se* also expresses this pejorative view of femininity. More precisely, Genesis stresses "the incapacity of Eve to resist the temptation, the woman is also responsible to induce Adam to eat the forbidden fruit, which resulted in

the expulsion from the paradise and the establishment of original sin" (Gomes, 2009, p. 262). In the New Testament, the third important element of religious doctrine related to femininity is the figure of Mary, mother of Christ, who is in opposition to Eve. Although Eve has a sin essence, Mary receives the Holy Spirit. The Virgin Mary "...is the unique woman in the Christian ideology who is not essentially sin and of which the body is not vehicle of sin" (Gomes, 2009, p. 263). Moreover, the figure of Mary is perceived as something extraordinary, as an ideal of chastity and purity that transcends the reality of concrete women.

Between the fourth and sixth centuries, spread a literature for men, inspiring the practice of solitary life that already had been happening among Eastern Christians since the third century. It was a literature that presented accounts about the life in monasteries with the objective to persuade men to seek to chastity. For example, Athanasius (295–373 AC), archbishop of Alexandria, found refuse among the monks before writing his famous *Anton Life* (Vainfas, 1992). In this work, a "crowd of feminine faces and bodies, that assaulted the monks' imagination, is associated to devil. It was another image of woman that emerges in these works: the diabolic, fleshly, that must be execrated of the spirit ... demonic mask." (Vainfas, 1992, p. 16).

In the novel *The Name of the Rose* by Umberto Eco<sup>2</sup>, the plot of the novel happens in the last week of November 1327 in a Benedictine monastery in medieval Italy. Although the work was fictional in nature, the author reconstructs in detail the atmosphere of this historical period. In this sense, there are parts of this novel that express some of the images about women that circulated in medieval monasteries. In general lines—with the exception of Mary, mother of Christ—the images of other women are extremely pejorative (Eco, 1983).<sup>3</sup>

From the previous examples, it is possible to deduce that there is no salvation for women out of the model of chastity and purity that were personified by the image of the Virgin Mary. In this sense, women should sublime their femininity, essentially marked by the original sin introduced by Eve in paradise. Mary and Eve are, therefore, biblical figures that personalized the strong moral dualism regarding women present in Christian imaginary (Gomes, 2009; Pratas, 2009). This dualism is inserted in the long Christian historical tradition of pejorative meanings associated with the body and pleasures (Vainfas, 1992; Delumeau, 1990).

In this direction, Vainfas—after the accomplishment of historical analysis of marriage, love, and desire in the Christian West (since the beginning of Christianity until the end of the Middle Ages)—states that, although the moral diversity concerning sexual issues during many centuries of Christianity, if there was a characteristic trade of all these morals was: “. . .the refuse of pleasure . . . that presupposes that the pleasure is an evil itself and also is an obstacle to eternal salvation. . .” (1992, p. 81). Therefore, we find a true “angelical anthropology” (Delumeau, 1990) between the lines of the Christian religious tradition, based on the conception that human beings should get closer to angels, who would be celestial beings without body and sex. It is possible to deduce that, concerning the Christian ideal of asceticism, women—as “Eves in potential”—would already have been born in disadvantage.

### ***Telling Stories through Religious Images***

Marked by the original sin introduced by Eve, women, in principle, would be more distant from the Christian ideal of renunciation of body and pleasures of “the profane world” (in opposition to “the spiritual world”). As “Eves in potential,” the women should be the target of a strong social control. Their actions, their body, and their sexuality should be kept guard over with rigidity. Because of the supposed feminine proximity to diabolic forces, women were forbidden to cure diseases and their transgressions were to be punished with severity (Dall’Ava-Santucci, 2005). Thus, thousands of women were burned alive during the Inquisition.

The Christian ethos of refusal of pleasures, permeated by misogyny, found in the universe of visual<sup>4</sup> arts an important ally in doctrinaire terms. In the Western history of arts, in the period of transition between the Middle Ages and Modern Ages, the Gothic cathedrals occupied a space of prominence. As Strickland (1999) stresses, the Gothic cathedrals were true “Bibles in rock,” wonderful architectonic structures:

... In fact, these ‘Bibles in rock’ overcame even the classical architecture in terms of technological audacity. . . . The medieval theologians believed that the beauty of church inspired the meditation and faith of believers. Consequently, the churches are more than a simple combination of spaces. They are holy texts, with volume[s] of ornaments preaching the salvation way . . .

(Strickland, 1999, pp. 28–29)

The Gothic cathedrals illustrate how the architectonic structures can make real in their “rocks” all of the symbolic universe that embody some beliefs, values, narratives, and cultural practices that populated the medieval imaginary. In a social world where the analphabetism was the reality of the great majority of the population, *the sculptures, the paintings, the stained glass windows, and the tapestries in the Gothic cathedrals fulfilled a didactic function: telling, through images, biblical stories. Thus, these different forms of art have become more concrete and palpable beliefs and values coherent within the Christian view of the world.* There is a rich iconographic tradition in the West that was legated by Christianity. The Christian medieval iconography fulfilled, therefore, a strategic function in a historical period when the participation in the symbolic universe of reading and writing was not a right of each citizen, but a privilege of a reduced part of the population.

It is important to mention that the artistic style named “Gothic” developed in Europe between the thirteenth and fifteenth centuries, in the period of transition between the Middle Ages and the Modern Age (Strickland, 1999). In the Gothic style, that succeeded the Romanesque style, the sacred became, gradually, closer to human reality through a more naturalistic representation. According to León (2006), a common characteristic of Gothic painting was the increasing naturalism, stimulated by the scholastic philosophical thought, that had as one of the most representative name: Thomas Aquinas (1225–1274). He introduced a Christian version of the works by the Greek philosopher Aristotle (384–322 BC), focusing faith issues through the “light of reason” and defending that philosophy helps the work of theology (Marcondes, 2000). The scholasticism promoted an approximation between human beings and the surrounding world, seeing the reflex of God in each creature. This approximation stimulated the analysis of the details of nature and also a narrative sense in the different plastic manifestations of Gothic style (León, 2006).

Around 200 years after the death of Thomas Aquinas, western Europe passed through a deep revolution called cultural and artistic Renaissance, directly related to the increase of mercantile bourgeoisie and the increase of cities (urban Renaissance). A new view of the world started to delineate. Nevertheless, this Renaissance did not imply a radical rupture within the medieval mentality. For example, the diffusion of the international Gothic style—that happened at the end of the fourteenth

century and the first half of the fifteenth century—resulted in the development of Flemish painting in northern Europe (León, 2006). Although the Italian Renaissance sought inspiration from classical ancient works, the Flemish Renaissance sought inspiration from nature (Strickland, 1999). Both of them, however, followed a tendency present since the end of the Middle Ages: despite the increased naturalism in the plastic expressions, the majority of the themes represented were still religious.

We find the most original expression of the Flemish tradition in the paintings by *Hieronymus Bosch* (1450–1516), an artist considered to be the precursor of the surrealist movement of the twentieth century (Strickland, 1999). The principal interest of Bosch was shown in his paintings, with irony, the passions and vices of his epoch (León, 2006). Underlying his work, there is a moralizing discourse connected within the medieval imaginary, permeated by misogynic images that remitted to original sin and the punishment of hell. One of the most notorious paintings by Bosch is the triptych *The Garden of Earthly Delights*.<sup>5</sup>

There is no other Renaissance panel painting like so-called *Garden of Earthly Delights*. . . , Bosch's best-known work. When opened, the triptych reveals three scenes that, at first glimpse, present a straightforward Biblical account. Adam and Eve appear in the left panel, their many children in the centre, and a monstrous scene of hellfire and damnation in the right. However, upon closer inspection, things are not as they should be. To begin with, no descendants of the first parents ever lived so well! Instead of the thorns and thistles the Bible says were food for Eve's children, who were consigned to lives filled with pain and work, Bosch's handsome young people feast with abandon on huge berries and frolic naked among giant birds. They seem more like children at play, innocently taking exuberant advantage of a world devoid of any hint of danger or evil.

(Dixon, 2003, p. 227)

As commented by Dixon, on the left panel we see the representation of paradise. On the central lamina, we see the representation of the Garden of Earthly Delights. Finally, on the right panel, Bosch has represented hell. *There is a clearly narrative sense in this painting: a story is narrated through images based on Christian doctrine.* In the representation of paradise, the Creator gives Eve to Adam (left panel). Thus, it is through the feminine figure of Eve that

sin is introduced in the world. According to Torviso and Marías, Bosch “...did not more than reproduce plastically what the theologians and poets were writing during the fifteenth century, following the medieval patristic, ‘culpa of Eve’...” (1982, p. 163). If we “read” the images—from the paradise into direction to hell (from left to right, like a text)—we can see the development of a religious narrative in front of our eyes, a religious narrative with moralizing function that alerts individuals to the tragic consequences of sin and, especially, the luxuriance sin (Torviso & Marías, 1982).

Between the historical period when Bosch lived—around 1450–1516 (Charles, Manca, McShane, & Wigal, 2007)—and the beginning of twenty-first century there are, surely, innumerable economic, political, and cultural differences. However, the social imaginary in the contemporary Christian Western societies are still marked, in different ways, by archaic images about women that are reproduced, reactualized, and contested in daily life. In some sense the moral dualism expressed by the strong opposition between Mary and Eve is still alive. In the promotion of gender equality, in diverse social spaces (including relations in the private domain), an important challenge is, exactly how to overcome this strong moral dualism about women. As we see in this topic, this complex challenge is articulated to the long Christian iconographic tradition that has marked, in deep ways, the social imaginary in the West.

### **Culture, Semiotic Mediation, and Images: Cultural Canalizations of Human Experiences through Visual Signs**

Since the prehistoric period, people have been practicing painting. Through colors, light, and shapes, artists have expressed the conception of the world that surrounds them; they have become closer to the immaterial and have understood, controlled, and appreciated everyday life.

(León, 2006, p. 6)

From the image of the feminine in the medieval Christian iconography, some historical clues on the pejorative view about women's sexuality were analyzed in the previous topic. Surely, psychological science should not disregard the historical force of different religious traditions in the construction of social imaginary in diverse cultural contexts around the world. In the context of Western societies, for example, the long Christian cultural tradition, and

its rich iconography, can offer meaningful clues about different social and psychological phenomena. *After all, our personal imagination is constantly fed by the images that circulate in social imaginary.*

As Silva claims: “To affirm the identity means demark boundaries, means make distinctions between what is inside and what is outside...” (2000, p. 82). In the flow of everyday life experiences, each person uses implicit criterions to include or exclude in the symbolic boundaries of a particular group his/herself or other individuals. These implicit criterions are connected within the personal values system that involves beliefs with deep affective roots (Branco & Madureira, 2008; Branco, Branco, & Madureira, 2008). From a cultural psychology framework, the personal values system is not perceived as a simply individual creation. Instead, *a personal values system is created and changed by the tension between collective culture (and its complex mechanisms of canalization) and the active and intentional role of each person. In other words, even the most “personal” values have cultural roots.*

The construction and maintenance of these diverse symbolic boundaries is directly related to distinction, fluid or rigid, between insider and outsider (Kim, 2007). Who is responsible for “gatekeeping” of these symbolic boundaries? If we focus on the macrosocial level of analysis, we can suppose the fundamental role of social institutions (e.g., religion, media, science, schools, laws, etc.) in “gatekeeping” the symbolic boundaries between insiders and outsiders (Kim, 2007; Madureira, 2007c). An important strategy used by social institutions is the materialization of some conceptions, beliefs, values, and world views through images. Our distant ancestors in the prehistoric period already used images to become closer to the immaterial (León, 2006).

In this sense, we can suppose that visual signs have fulfilled a strategic role in the processes of cultural canalization of human experiences in different historical periods and different cultural contexts. Thus, the present topic focuses on the analytical and methodological relevance of images, as cultural artifacts, in psychological science.

### ***Semiotic Mediation and Visual Signs: Beyond the Verbal Language in the Study of Human Experience***

A central issue for cultural psychology is the relevance of individuals’ experiences in their relations with the social world and with themselves (Valsiner & Rosa, 2007). In other words, the

focus is on the human experience instead of the behavior itself (Valsiner, 2007b). The focus on human experiences—which always happen in culturally structured contexts—expresses the phenomenological approach present in researches carried out in the cultural psychology framework (Valsiner, 2007a)—*a cultural phenomenology of human experience.*

In the context of theoretical and empirical researches on the construction of human experience, we are in front of an important challenge: improving our analytical capacity in order to integrate biological, cultural, and subjective dimensions. After all, human experience, as cultural organized, is the result of a long *Homo Sapiens* phylogenesis (Rosa, 2007a, 2007b). Thus, human senses have a clear biological basis. At the same time, human senses are deeply changed from the individual immersion in a specific cultural context that promotes a constant and, frequently implicit, “education of senses” (Madureira, 2007a). In this sense, *it is not exaggeration the metaphorical statement: social control penetrates in the mind through the body and its sensations.* Therefore, “the body is the intimate place where nature and culture meet each other” (Nightingale & Crombyas cited in Araiza & Gisbert, 2007, p. 115).

As it was analyzed by Louro (1998, 1999, 2003), social institutions in general, and schools in particular, promote a continuous cultural education of senses in agreement with hegemonic social values. Thus, individuals present on their bodies the “marks” of years of schooling. It was not just their minds that were modified by schooling, but also their bodies.

According to Le Breton (2007), the sensory perceptions correspond to an ambitious and original research field that remains almost unexplored in social sciences. If we consider that: (a) the Western societies present a long and rich tradition of images; (b) in our contemporary societies, we are living a true “invasion of images” in daily life through outdoors, television programs, movies (in 2D and 3D), Internet, sophisticated video games, and so on; and (c) through vision, individuals classify other individuals in different social groups, then we can conclude that the sense of vision—organized through stereotypes—has a special value in the study of social identities, personal values, prejudices, and discriminatory practices. After all, in ordinary situations in daily life, individuals classify other individuals in different social groups from their first impression<sup>6</sup>. Frequently, that classification is not based on more accurate

information. The first impression is enough to construct symbolic boundaries that split people in different domains: man, woman, white, black, heterosexual, homosexual, rich, poor, and so on.

Surely, there are particularities related to the processes of classification concerning different social groups. Some social groups present clear “marks” on their bodies, although other groups do not present these marks in a clear way. For example, as analyzed by Bourdieu (2005), the symbolic domination against gays and lesbians is related to a specific stigma that, unlike the color of skin or femininity, could be hidden or revealed. However, there are strong social expectations that work as cultural canalization into the direction of dissimulation and/or discretion concerning nonhegemonic sexual orientations. Compared to sexism and racism, a specific feature of homophobia is the demand that all nonheterosexual people keep his/her sexual orientation secret. The rescue of legitimated public existence, including the domain of laws, is a relevant mark of homophobia (Madureira, 2007c).

The maintenance of this secret includes also other aspects related to personal sexual orientation, like the sexual and affective relationships. Frequently, it is a complicated task for nonheterosexual people to deal with the social expectation to maintain this secret. Therefore, there are deep connections between the social invisibility and the psychological suffering, expressed in feelings of discomfort, like anxiety, fear, depression, guilt, and shame by people who present nonhegemonic sexual identities (Madureira, 2000, 2007a, 2007b; Madureira & Branco, 2007). Thus, social invisibility is one of the mechanisms of social exclusion that ensures the maintenance of hierarchical relations between different groups in society.

In sum: *we should not disregard the corporal sensations and emotions embodied when we focus on the cultural and psychological basis of different phenomena like identity processes, values, and prejudices.* The accomplishment of theoretical and empirical studies of psychological functions as embodied processes—that is, integrated biological, cultural, and subjective aspects—is a central challenge for contemporary psychology. In order to deal with this complex challenge it is necessary to find some general mechanism. From cultural psychology framework, this general mechanism is found in *semiotic mediation* (Vygotsky, 1978/1991).

In order to avoid any linguistic reductionism, it is central to recognize that our relating with the world is not just a rational enterprise mediated by

signs and expressed by verbal language. Beyond this reductionistic concept, our relating to the world and to ourselves is affective embodiment (Madureira, 2007a, 2007b; Madureira & Branco, 2005b). Thus, affect, cognition, and action form a whole and complex unit, and human beings are semiotically mediated: “. . . the role of language-mediated relating with the world is not [the] highest level in the semiotic mediation hierarchy—but an intermediate one . . .” (Valsiner, 2003, p. 156). In other words: *the processes of semiotic mediation go beyond verbal language.*

Human experience, culturally structured, is based on complex recursive semiotics processes: semiosis (Rosa, 2007b). Iconic signs, because of their similarity to objects, are powerful signs in terms of cultural canalization. Contexts that involve specific activities—as, for example, religious rituals—are used in order to promote the generalization of some feelings, beyond the immediate contexts, “here and now” (Valsiner, 2005). *Architectural structures, paintings, sculptures, and visual arts in general also fulfill certain functions in this direction, working as a “social technique of feelings”* (Vygotsky, 1970/2007). They promote more general and abstract levels of cultural mediation connected, in different ways, within the symbolic universe in which they are inserted. The raw material of social identities, personal values, and prejudices are not only verbal languages, but also images.

### ***Images as Cultural Artifacts and Their Methodological Potential in Psychology***

Through the centuries, images have been created to fulfill diverse functions (religious, aesthetic, political, entertainment, etc.). Thus, as researchers, we should not ignore the force of images in terms of cultural canalization of human experience. It is important to recognize the methodological potential of images in our researches. In contemporary societies—marked by a true “invasion of images”<sup>7</sup> in our daily life—we can mention, as an example of a broad and fertile field of investigation in human sciences, the cultural meanings, beliefs, and values expressed by media. Through advertisements, television programs, magazines, journals, etc., the hegemonic cultural meanings related to femininity, masculinity, and sexuality are continuously (re) appearing. According to the analyses carried out by Sabat (2001), media presents, in its majority, images and texts that reinforce a stereotypic view of gender.

For example, in an essay about the content of masculine magazines, Nogueira (1986) analyzes the image of man expressed in these magazines: a “victorious man,” rich, surrounded by beautiful women, without existential problems and sadness. “Words as glory, successful, and power are the most found [in these magazines] ...” (Nogueira, 1986, p. 61). We can even conclude that the anguish and sadness would be the marks of “losers,” men who were at fault concerning the project of a successful masculinity, men who are closer to women, and their “emotional problems” and “unnecessary affective and relational demands.” After all, from the images and texts presented in these masculine magazines, happiness could be translated as: having a lot of money, expensive cars, beautiful and sensual women. Therefore, the “masculine happiness” would correspond to the possession of socially valued “power signs,” including beautiful and sensual women, according to the models of masculine desire stimulated by these magazines.

As previously discussed, the feelings of belonging to gender are directly related to the identity processes, to symbolic boundaries that delimit who pertains to the group of “men” and who pertains to the group of “women.” Moreover, inside the boundaries of femininity and masculinity, there are implicit boundaries that mark who are the “honorable men” (focus on public life) and who are the “honorable women” (focus on private life). *When we talk about identity processes (including gender identity), we are talking about boundary phenomena.*

It is pertinent to note that arts are a fertile cultural domain to the study, especially, affective and emotional aspects involved in human experience. If we promote a closer relation between sciences and arts, we will see a fertile (and less explored) ground that integrates cultural and affective aspects in inquiries on theoretical and socially relevant issues. Concerning the articulation between sciences and arts, Del Río and Álvarez stress the importance of the broad formation of Vygotsky—his intellectual and humanistic formation, his scientific formation allied with his artistic sensibility—in the establishment of the double challenge faced by Vygotsky along his life: “... reach an objective knowledge about human beings without resigning its subjective knowledge. Or vice-versa ...” (2007, p. 11). Vygotsky proposed as a central idea of psychology of art “... the recognizing of the overcoming of material by artistic form ... the recognizing of art as *social technique of feeling* ...” (1970/2007, p. 160).

Therefore, the arts involve diverse social techniques of feelings that promote new levels of cultural mediation of affective and emotional processes, integrated with cognitive processes. In other words, the artistic objects are cultural artifacts that mediate, especially, human feelings and emotions. Thus, *we can say that the artistic object is a cultural artifact produced to the creation of aesthetic experiences, to the contemplation. The artistic object would correspond to feelings incarnate in forms* (A. Rosa, personal communication, 2008). It is important to stress that in order to contemplate, for example, a painting, it is necessary to have a cultural education of vision that involves cognitive and affective aspects, as well aspects related to the knowledge actively internalized by the person along his/her life. The interpretation of a painting, as a cultural artifact, demands an elaborate process of apprenticeship that orients our look (Franz, 2003). After all, images are signs to be interpreted (Lonchuk & Rosa, 2008).

The colors, shapes, and composition of a painting bring in itself some social conventions that are culturally and historically situated. Moreover, it is important to not forget that there is “... a narrow connection between vision and power. The act of looking—that involves what we select to see and how to see—produces effects on the person, produces power relations, many times, in a subtle and seductive way ...” (Loponte, 2002, p. 290). In this sense, the use of images can be a fertile tool, in analytical and methodological terms, in researches about gender and sexuality issues inserted in broad cultural meaning systems, historically constructed. Broad cultural meaning systems are those that support and are supported by power relations that permeated all levels of society (Foucault, 1996). In sum: *images as cultural tools (paintings, photographs, drawings, etc.) can be used as an insightful methodological resource in empirical researches on diverse subjects, like identity processes, personal values, and prejudices.*

#### **IMAGES AS METHODOLOGICAL RESOURCES IN PSYCHOLOGY: AN EXAMPLE**

Historical images can be an interesting methodological resource in empirical researches on identity processes. In this direction, we can mention the PhD studies carried out by María Fernanda González (Carretero & González, 2006; González, 2005). This research focused on the construction of national identities from a sample formed by participants of different ages and from different

countries: Argentina (n=80), Chile (n=80), and Spain (n=80).

The author used, as a methodological resource, a historical image: a drawing by Theodore de Bry called “Disembarkation of Columbus in Guanahani,” included in the work “The Great Voyages.” It was one of the first works with illustrations about the colonization of America by Catholic and Protestant countries. From the size of this work (13 volumes edited between 1590 and 1634) and its broad divulgation, this work corresponds to an “iconographic invention” of America (Bucher, as cited in González, 2005). The historical image selected was the base for the interviews with the participants. The interviews were analyzed from a quantitative approach (statistical analysis) and qualitative approach.

It is interesting to note that historical images tend to rouse some “affective looks” (in the original: “miradas afectivas”). As González (2005, p. 106) claims: “In this way, we can sustain that historical images produce and convoke some affective looks that are linked with the definition of who we are, where we are pertained, who is part of our group and who is not . . .”. Historical images, such as the drawing by Theodore de Bry, can be promising methodological resources in the studies on affective aspects concerning identity processes.

More precisely, the analysis of affective aspects concerning the construction of national identities among the participants from Argentina, Chile, and Spain disclosed interesting issues. For example, it was asked for the participants that choose one group between the two groups that appeared in the image (Natives and Spanish people) that they have more sympathy, and choose the group that they identify themselves with, they fell closer, resembling. Beyond that, participants were asked to justify their choice. The results showed that:

... The image of the Pacific native, innocent, linked to earth and his/her traditions; selvage and backward, but respectful concerning his/her surroundings, convokes sympathy of the majority of participants. However, at time to seek references about identity the references related to European and Hispanic cultural heritage are stronger, in this way 48% of sample is situated in this crossroad: sympathize with somebody [Natives] and identify with another [Spanish people].  
(González, 2005, p. 143)

This result is meaningful because it demonstrates clearly the presence of ambiguity and conflicts in

identity processes. In other words, the actuations of identification (Rosa & Blanco, 2007) are not oriented by cognitive processes alone. The emotions, feelings, ambiguities, and conflicts are presented at one time to choose the social groups for whom we have sympathy and the social groups with whom we identify ourselves. The sympathy concerning marginalized groups does not imply, necessarily, personal identification with them. Surely, there are deep connections between identity processes and power relations. Connections that also foment prejudices concerning some groups present in our societies. There are implicit connections between: (a) the inequalities among different social groups, in a macrosocial level of analysis; and (b) discriminatory practices and the reproduction of psychological suffering, in interpsychological and intrapsychological levels of analysis (Madureira, 2007a).

#### IMAGES AS METHODOLOGICAL RESOURCES IN PSYCHOLOGY: OTHER POSSIBILITIES

In researches on identity processes, personal values, and prejudices it is necessary to construct analytical strategies to interpret cultural, affective, and cognitive aspects—all of them. Therefore, we are in front of a challenge: create new methodological resources in order to find meaningful clues concerning the subjects under scrutiny. This is an invitation to our analytical and methodological imagination. After all, as Alves (1993, p. 39) claims: “. . . the scientist is a hunter of the invisible.”

It is possible, for example, to construct two images: (a) one image formed by different photos of men (different social classes, ethnicities, ages, and so on); and (b) one image formed by different photos of women (different social classes, ethnicities, ages, and so on). Then, these images could be used in inquiries about the construction of gender identities and their connections within other social identities from questions like: (a) Who do you like to be? Why? (b) Who do you not like to be? Why?

It is also possible to investigate the interfaces between religious values, political ideology,<sup>8</sup> and gender issues from a different version of the famous religious image of *The Last Supper*, with Marilyn Monroe at the center—at the position of Jesus Christ—and actors of Hollywood at the right and at the left of the image—at the position of the apostles (see Fig. 26.2).

After the presentation of this image (see Fig. 26.2), it would be interesting to ask: (a) What do you see in this image? (How the participant describes this

**Figure 26.2** Photo of one version of *The Last Supper*, with Marilyn Monroe at the center (Image on display in a café, close to a movie theater in Madrid, Spain).

image); (b) Do you like this image (or not)? Why? (How the participant values this image—in terms of positively, neutrally, or negatively valued). In research on gender and sexuality issues, it is important to investigate religious values of the participants (Madureira, 2007a), and how these values orient their views about the feminine, the masculine, and about sexuality.

Figure 26.2 presents a possibility, among others, to focus on participants' religious values at the beginning of an investigation about identity processes (especially about gender identities) in a more fertile way than asking direct questions about the religion of participants. Beyond that, it is possible to analyze the motives why a participant may like or dislike the image presented. Thus, the valued dimension implicit in identity processes is also contemplated. Surely, this is just one methodological suggestion; there are many other possibilities. *The most important is: the creation of fertile methodological ways to properly investigate the phenomena in focus in our researches.*

## General Conclusion

*"A scientist without imagination is like a bird without wings."*

(Alves, 1993, p. 43)

Throughout this chapter, I focused on the construction of gender identities, as a boundary phenomenon, with special attention regarding the interfaces between gender and sexuality issues within a cultural psychology framework. The feelings of belonging to a specific gender are constructed from the beliefs, values, practices, stereotypes, and prejudices that culturally delimit the symbolic boundaries between femininity and masculinity. It is

important to notice that without a serious political analysis about gender issues: (a) in theoretical terms, we tend to develop a naïve approach and reinforce conceptions based on a biological determinism; and (b) in practical terms, we lose a fertile opportunity to contribute, in different ways, with the elaboration of concrete strategies against social inequalities. The knowledge produced from our theoretical and empirical researches can contribute to public policies in order to promote gender equality in different domains of our societies.

The studies of social identities (gender identities, sexual identities, ethnic identities, etc.) are a promising field to understand the complex connections between individuals and social groups. Therefore, in terms of future theoretical development, the present author suggests the construction of "conceptual bridges" between social-identity approaches and dialogical self-theory (Ferreira, Salgado, & Cunha, 2006; Hermans, 2001; Rosa, Duarte, & Gonçalves, 2008). As a cultural contextualized theoretical model of self, dialogical self-theory can provide insightful conceptual tools to better understand the development of the self-system in its psychological and sociological dimensions. Both of these dimensions are also essential in the construction of social identities. From the tension between the particular and the general, we are in front of a relevant challenge: improving our capacity to consistently integrate different levels of analysis regarding the development of the self-system and social identities.

## Future Direction

Concerning the theoretical implications of the inquiry in focus, it is important to mention the

relevance of future researches on how the cultural meanings concerning gender and sexuality are integrated in broader cultural meaning systems, historically constructed. *In a metaphorical sense, meanings are not "linguistics atoms" that can be properly analyzed in an isolated way* (Madureira, 2007a). Instead, if we intend to improve our understanding concerning the multiple connections of cultural meanings about gender and sexuality, we should investigate them from a systemic approach.

These multiple connections are inserted in the context of broader meaning systems marked by the tension between stability and change. This tension has always been present in the cultural development of societies throughout history (Madureira & Branco, 2005a). The continuous construction and reconstruction of cultural meanings is connected within hierarchical structures of power between different social groups present in any society. These hierarchical structures have historical roots that should not be disregarded by cultural psychology.

There are diverse methodological ways to investigate meaning-making processes regarding the construction of different social identities. Therefore, the use of images, as methodological resources, is just one possibility that seems fertile. The most important is to constantly feed our methodological imagination in order to construct creative ways to investigate the phenomena under focus in our researches. Sometimes, we find interesting clues to do that in our everyday life: in the architectural constructions on the street, in famous paintings, in anonymous images in books, cafes, bars, and so on. At the most ordinary places and moments, we feed our imagination.

## Acknowledgments

I want to thank the National Committee for Scientific and Technological Development—CNPq (Brazil) for the financial support of my PhD studies, including the period that I was Visiting Student of the Psychology Department at Clark University in Worcester, MA (USA). I also want to thank the National Committee for Academic Support—CAPES (Brazil) for the financial support of my postdoctorate at Universidad Autónoma de Madrid (Spain). This chapter brought some contributions from both my PhD and postdoctorate studies. I am grateful to Prof. Dr. Angela Branco (University of Brasília, Brazil), Prof. Dr. Jaan Valsiner (Clark University, USA) and Prof. Dr. Alberto Rosa (Universidad Autónoma de Madrid, Spain) for their important theoretical contributions and for their relevant role in my academic trajectory. I also thank Juliana Garcia Pacheco (PhD in Psychology, University of Brasília, Brazil) for

the fertile discussions about social imaginary and images in psychology.

## Notes

1. In an etymologic sense, the word "iconography" is derived from the Greek "*eikon*" (image) and "*graphia*" (description). See: <http://www.etymonline.com/>. This site was visited 01/20/2010.

2. Umberto Eco is Professor of Semiotics at the University of Bologna in Italy. His first works focused on medieval aesthetics, especially in the works of Thomas Aquinas (thirteenth century). *The Name of the Rose*, published firstly in 1980, was his first novel.

3. "... Eco's celebrated story combines elements of detective fiction, metaphysical thriller, postmodernist puzzle and historical novel in one of the few twentieth-century books that can be described as genuinely unique. Set in Italy in the Middle Ages, this is not only a narrative of a murder investigation in a monastery in 1327, but also a chronicle of the fourteenth-century religious wars, a history of monastic orders, and a compendium of heretical movements." See: <http://www.umbertoeco.com/en/the-name-of-the-rose-1983.html>. This site was visited 01/19/2010.

4. "... In fact, concerning the medieval Christianity, the notion of "image" seems to be a singular fertility notion even that we understand little every senses related to the Latin term *imago*. This notion is, with effect, in the center of medieval conception of world and man . . . . The notion of image is concerned, in short, to Christian anthropology as a whole, because is the man . . . that the Bible, since its first words, qualify as "image": Yahweh says that make the man '*ad imaginem et similitudinem nostram*' (*Genesis* 1:26). " (Schmitt, 2002, p. 592–593).

5. See: <http://arteuniversal.wordpress.com/2010/06/16/bosch-hieronimus/bosch-hieronimus-the-garden-of-earthly-delights-triptych/>. This site was visited 08/15/2010.

6. Stereotype is a "belief about the personal characteristics of a group of people. Stereotypes can be super generalized, imprecise and resistant to new information." (Myers, 1995, p. 346). The stereotypes are not prejudices, but they can work as a base to development of prejudices (Myers, 1995). On the one hand, the stereotypes offer a base, even super generalized, to the future development of a deeper understanding about individuals of a specific social group. On the other hand, the stereotypes can promote prejudices especially when [they] 'close the doors' to the appropriation of new knowledge that contradict[s] what the stereotypes inform about the social group in focus (Madureira, 2009a, 2009b).

7. New technologies of images have been developing faster nowadays. The new generations already born in a world with computers, Internet, sophisticated video games, and other technologies. At the end of nineteenth century, cinema appeared (images in movement). In modern times, the accomplishment of 3D movies has been stimulated by the success of the creative movie *Avatar*. It is not an exaggeration to affirm that we are living a "true invasion of images" in our daily life. Psychology should not ignore this aspect of our contemporary societies.

8. In Latin America countries, because of the cultural colonization by the United States since the second half of the twentieth century, there are social groups, especially groups that identify themselves with the left political ideology, that cultivate a mistrustful attitude regarding the movies produced by Hollywood. In this sense, cultural products, like movies, can be an interesting

methodological resource to investigate political ideology and its relationship to personal values.

## Risk and Culture

Bob Heyman

**Abstract**

This chapter explores the interrelationships between risk and culture with particular reference to 'late-modern' societies. In such societies, the benefits of technological progress are no longer taken routinely for granted, and the human predicament is understood in relation to the 'lens of risk'. The chapter homes in on the taken-for-granted presuppositions which underpin this interpretive framework. Following a brief mapping of leading social scientific risk theories, the chapter will address still neglected definitional issues. Risk-thinking will be considered as a specific way of constructing contingency; and contingency thinking as derivative from a universal human tendency to view events in relation to the potential infinity of what **might** happen. The unlimited scope of possibility will be contrasted with the necessary cultural selection of a small number of contingencies, viewed mostly as risks in late-modern societies, which become objects of organized concern. The lens of risk will then be unpacked by recasting each of the elements in a standard definition of risk (The Royal Society, 1992, with present author's additions in parentheses) as:

the probability (3) that a particular adverse (2) event (1) occurs during a stated period of time (4a), or results from a particular challenge (4b).

Each numbered element will be reframed in order to bring out its concealed interpretive underpinnings: events as categories; adversity as negative valuing; probabilities as rule-of-thumb derived expectations; and 'stated' time periods as time frames (indefinite and therefore incalculable in the case of condition 4b). It will be argued that societies and social groups must attempt to align their interpretations of the above elements in order to make organized risk management possible. It will be further argued that this interpretive work tends to be pushed to the background of social consciousness through a tacit process of 'deletion.' Without such unspoken but collective direction of attention away from the indefinitely large set of what might happen, social orders organized around selective attention to particular risks could not be sustained.

**Keywords:** probability, risk, culture, interpretation, escalation

Anthropological observations of the warning signs which festoon the environments of full-blown risk cultures provide an instructive introduction to

this bizarre yet taken-for-granted world. Readers are invited to guess the location of the signs reproduced in Figure 27.1, below.

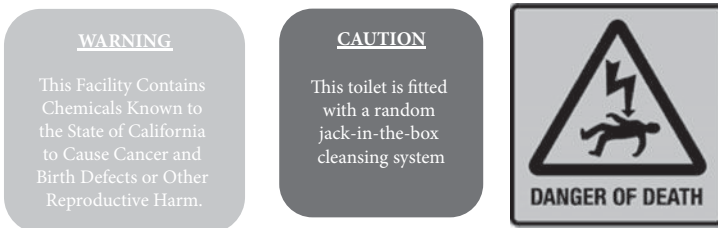

Figure 27.1 The weird and wonderful world of risk and its linguistic relatives.

The left sign (in tasteful pale blue) guards the entrance to one of the apparently most dangerous places in the world—an up-market San Francisco hotel! Its purpose is clearly to fend off potential litigation, rather than to warn individuals considering entry about consequential risks. In contrast, the third sign (in harsh yellow, nature's danger signal) was placed on a building site for an office block being erected in the City of London prior to the financial crash of 2007. It may well have been designed to discourage entry to a location which contained a large amount of expensive machinery. The middle sign could be observed in toilets on London to Brighton trains in 2009. Its pragmatic purpose is hard to fathom. But this sign shows up the esoteric nature of risk microcultures, since nobody appeared to have considered the sign's impact on users of the facility in question! The three signs also illustrate a small part of the rich linguistic family, of warnings, dangers, hazards, vulnerabilities, alarms etc., in which risk-thinking is embedded (Heyman et al., 2010, pp. 25–28). All are oriented in implicitly different ways toward possibilities of unwanted events, and convey unstated attitudes, for instance that hazardous **environments** should be made safe, or that vulnerable **persons** ought to be protected. Such lexical choices are used pragmatically, albeit unreflectively, in attempts to influence decision-making, rather than to merely describe contingencies.

The present chapter will analyze the relationship between risk and culture, focusing on late-modern developed societies in which contested issues of risk affect every sphere of organized life (Beck, 1992, 2009). It will be argued that this pervasive risk consciousness stands out historically and culturally from a much more general human concern with contingency (i.e. selective, symbolically mediated concern with what **might**, and by extension, what **might not** happen). The present preoccupation with risk is bound up with one particular approach to contingency which draws on probabilistic reasoning and the metaphor of randomness. It is found primarily in rich, science-based countries whose citizens can afford to invest the required resources into precaution (Bujra, 2000).

The author cannot offer anthropological expertise, a more general shortcoming of the risk social science literature (Caplan, 2000), but the chapter will address risk from a cultural perspective. The definition of risk will be given considerable

attention below. The term culture will be defined more cursorily as:

*the set of shared attitudes, values, goals, and practices that characterizes an institution, organization or group.*  
(Wikipedia, <http://en.wikipedia.org/wiki/culture>)

The chapter will home in on one critical form of this wide-ranging and ubiquitous phenomenon, namely the shared but unspoken presuppositions on which risk perceptions are unavoidably predicated. Unarticulated assumptions provide the buried, although by no means secure, foundations on which the vast edifices of cultures are built. They can be uncovered fairly easily, but only if attention is directed away from concrete cultural products and received problematics, toward the barely concealed collective mental processes which underlie their creation, maintenance, and dissolution. The material which follows will address these processes after a brief context-setting foray into social scientific theories of risk.

## Social Scientific Theories of Risk: A Brief Introduction

Major social scientific theories of risk offer distinctive, although not necessarily incompatible, analyses of why risk concerns have taken centre stage in contemporary developed societies. Despite their differences, these theories all point to complex organizational processes which the authors consider to be unrecognized by social actors who focus on particular risks. By way of background to the analysis offered in the present chapter, thumbnail sketches of four such approaches are offered below. For full accounts of risk society, cultural, systems theory, and governmentality theories, see Zinn (2008).

One variant, at least, of Beck's risk society thesis (Beck, 1992; 2009) anticipates that:

*in its mere continuity industrial society exits the stage of world history on the tip-toes of normality, via the back stairs of side effects.*  
(Beck, 1992, p. 11)

This vision of history sees developed societies gradually undermined by the cumulative force of the interacting, unintended consequences of technological development. The striking quotation suggests that accumulating ecological risks are backgrounded until they can no longer be ignored. Their pressure stimulates a transformation from modernity to late

modernity in which the benefits of technological 'progress' become contested.

Cultural theory, as developed by Douglas and colleagues (Douglas, 1966, 1992; Douglas & Wildavsky, 1983), equates risks with dangers, and views their collective selection as serving the function of buttressing structural weaknesses of a particular culture such as internal contradictions and unclear external boundaries. Although most apparent in small, undifferentiated and therefore fragile 'primitive' societies, this analysis can be applied to late-modern hang-ups, for example in relation to hostility toward immigrants, and panic about mentally disordered violent offenders and paedophiles. In contrast, risks which cause far greater total harm, such as those arising from traffic pollution and accidents, tend to be calmly accepted because they do not challenge the underlying cultural order.

Risk systems theory accounts for heightened societal risk consciousness as an unintended and unrecognized consequence of the ever-increasing role differentiation which results from societies becoming progressively more and more complex, specialized, and interdependent (Luhmann, 1993; Japp & Kusche, 2008). Each subsystem creates its own primary risk 'object' (e.g., loss of profit or patient safety failures), while decentering from those of others. The consequent multiplicity of risk orientations generates unrealized differences of perspective which make the organized coordination of social action more difficult to achieve, and more vulnerable to breakdown than in less differentiated forms. According to this theory, heightened generic sensitivity to risks in highly developed societies reflects the insecurity which arises from the increasing fragmentation required to carry an ever-expanding culture by means of indefinitely increasing levels of role specialization.

Finally, governmentality theory treats risk consciousness as a historically novel method of transmitting social power (O'Malley, 2008). The mechanism for social control becomes internalized within individual minds through acceptance of the imperative to manage risks responsibly, for instance by adopting a healthy lifestyle. This particular form of governmentality carries the concealed function of promoting a neoliberal social order in which responsibility for avoiding adverse outcomes is individualized. Within a Governmentality<sup>1</sup> framework, individuals are deemed to have placed

themselves voluntarily in designated higher risk categories such as obesity or illicit drug-taking, and to be morally accountable for officially disapproved 'choices'.

The above brief sketch will hopefully give readers unfamiliar with risk social science a sense of the diverse ways in which the relationship between risk and culture has been theorized. Conjointly, the four outlined approaches outlined can be used to construct a gloomy picture of near future risks for the prevailing science-based civilization and the billions of human beings who rely on it. In this envisaged future, the combined impact of runaway global warming and resource depletion overwhelms increasingly complex, interdependent and therefore fragile socio-economic systems. At the same time, raw cultural sensitivities, competition between nation states and the prevailing neo-liberalism preclude effective prophylaxis.

Some such hefty social scientific machinery is required to explain the yawning contrast between the vast resources spent fighting the 'war on terror' and the feeble global response to the looming catastrophe of human-induced climate change combined with unmanageable resource depletion. The risk of human activity causing catastrophic climate change has been much debated. Resource depletion has received less media attention. With respect to peak oil, for instance, according to one senior whistleblower from the International Energy Agency, this organization has presented unduly optimistic accounts of future supplies because the truth would destabilize stock markets (*The Guardian* newspaper, November 11, 2009). Risk arising from systems complexity is illustrated by analysis of the impact of severe solar storms (Marusek, 2007). The event of September 2, 1859 caused telegraph systems to collapse, with relatively trivial consequences. An equivalent event in the twenty-first century could bring about millions of deaths through the simultaneous destruction of electricity substations resulting in a lengthy loss of usable supplies and ensuing chaos. This example illustrates the potential for failure of a mundane but vital component of complex socio-technical systems to crash an entire civilization. The four processes of runaway global warming, resource depletion, systems failures and political paralysis may feed off each other with devastating consequences. Readers will share this doom-laden construction to a greater or lesser extent. What cannot

be disputed is that many different possible futures can be targeted for organized attention, the issue picked up below in relation to the key importance of contingency visualisation.

As noted above, the four major theories outlined above share one common feature despite their differences, namely the identification of key drivers for risk concerns which are claimed to operate outside the awareness of social actors: whether cumulating side effects of technological development (risk society theory); structural weaknesses in prevailing social orders (cultural theory); unintended consequences of increasing role differentiation (system theory); or the insidious operation of social power in a new form driven by individualized risk consciousness (Governmentality theory). Together, such work provides a rich and potentially complementary analysis of concealed societal processes. However, on the whole, social scientific theories do not systematically dissect risk thinking itself. Social scientists have, perhaps, been more concerned to highlight insight deficits than to analyze what people **do know**, or at least believe, when they think about a risk.

### *Goals for the Rest of the Chapter*

The remainder of the present chapter will not pursue the rich lines of analysis offered by social scientific theories of risk. Instead, the chapter will address the culturally mediated presuppositions which are carried by risk-thinking itself. The analysis will take off from the position that theories such as those presented above tend to take 'risk' for granted, and that this lacuna reflects more than a scholarly shortcoming, but derives from a wider cultural reflectivity shortfall. A degree of prevailing collective reticence about defining risk at all will first be diagnosed and accounted for in terms of the ambiguous 'reality' of risks. Risk-thinking will then be depicted as one historic form of a general human tendency to view events as contingent. A definition will be offered which allows risk to be decomposed into four components—events/categories, adversity/values, probabilities/uncertain expectations, and time periods/time frames, all influenced by cultural interpretive processes. It will be argued that risk differs from other forms of contingency thinking only in one respect: the grounding of uncertain expectation in the metaphor of randomness. These complex issues have been discussed in more detail elsewhere (Heyman,

1998; Heyman et al., 2010). The present chapter hones in particularly on the interrelationships between risk and culture. An adequate account of these relationships must illuminate **both** the generic existence of risk as a cultural phenomenon, **and** the construction and selection of particular risks such as climate change or terrorism for organized collective concern.

### **The Definition of 'Risk'**

#### *A Tendency toward Non-definition*

The idea that risk-thinking now influences all life domains in modern developed societies has acquired almost platitudinous status in the social science of risk, although its impact on public attitudes can sometimes be exaggerated by over-enthusiastic social scientists<sup>2</sup>. Indeed, it has become more interesting to comment on the contexts in which risks are apparently ignored, by mountaineers and other (fool)hardy adventurers, people ruining their livers with alcohol, or enjoying condomless sex with multiple partners. Such seeming exceptions must all be qualified in various ways. Mountaineers are expected to take high risks responsibly, particularly when their actions cause further risks for rescue services (Simon, 2003). Alcohol and sex are peddled by ruthless commercial interests, exposing potential consumers to profoundly conflicting cultural messages. Nevertheless, such behaviour appears to stand out as apparently anomalous in relation to the assumption of a pervading risk consciousness in late-modern societies.

The very ubiquity of risk-thinking in modern cultures challenges definitional efforts. It can be argued that use of the term has become stretched so far that it has lost much of any definitional purpose which it might once have possessed. Garland (2003) has eloquently noted that the wide range of substantive social domains in which risks are considered is cross-cut by a variety of approaches to risk, which can be applied in any domain.

*Today's accounts of risk are remarkable for their multiplicity and for the variety of senses they give to the term. Risk is a calculation. Risk is a commodity. Risk is a capital. Risk is a technique of government. Risk is objective and scientifically knowable. Risk is subjective and socially constructed. Risk is a problem, a threat, a source of insecurity. Risk is a pleasure, a thrill, a source of profit and freedom. Risk is the means by which we*

*colonize and control the future. 'Risk society' is our late modern world spinning out of control.*

(Garland, 2003, p. 49)

In this respect, risk may not differ from other widely used symbolic tools which acquire their usefulness because of their plasticity rather than their precision.

*Philosophers tell us that nouns are misleading because they suggest that a clear object exists when this is often not the case. In the case of 'risk' and 'risk management' we would do well to heed their advice. However, this book [Organized Uncertainty: Designing a World of Risk Management] takes as its point of departure the surely uncontested fact that the noun has grown in use and significance in organizational life.*

(Power, 2007, p. 3)

Similarly, another major contributor to the social science of risk, Hansson (2005) dismisses as the "*first myth of risk*", the idea that risk "*must have a single, well-defined meaning*". Althaus (2005) has argued persuasively that risk is conceptualized differently in a wide range of academic disciplines and subdisciplines, including economics, sociology, anthropology, psychology, medicine, legal studies, the arts, and philosophy. For instance, a long-standing line in economics, a discipline which took on risk much earlier than other social sciences, relates risk and uncertainty to entrepreneurship, with the successful entrepreneur 'beating the odds' through innovation (Knight, 1921). Medicine, in contrast, seeks to make practice evidence-based in line with empirically derived probabilities, turning conformity to statistical messages into the primary professional virtue. Such differences remain virtually unexplored because scholars tend to confine themselves to the voluminous but narrowly focused universe of their home discipline. A little discussed, embarrassing consequence of this breadth of focus is that not even the slickest polymath can internalize more than a small fraction of the current stock of risk knowledge on which the late-modern world turns<sup>3</sup>.

Students of risk should not naively assume that this word necessarily indicates the presence of a single entity possessing the same attributes. On the other hand, members of cultures in which risk-thinking plays a strategic role tend to implicitly presuppose that the term **does** possess a common core of meaning; that it somehow connects

widely diverse social contexts, including business, insurance, sport, weather, health care, crime prevention, child protection, war, and many others. The above quotations offer a debunking challenge to a mindset which connects the multitudinous contexts of late-modern life through the notion of risk. An alternative view is that the same term is used across social domains because it references a shared meaning which can be articulated. From this starting point, a social scientific failure to carefully consider what members of modern societies are actually doing when they use the term 'risk' to link together a vast range of organized activities can be diagnosed. Luhmann (1993) criticized "*carelessness in concept formation*". Rosa (2003) went further, identifying "*an intentional silence about defining risk at all.*" Most risk texts take the meaning of this heavily used term for granted, as documented by Heyman et al. (2010). Even a sharp, much-needed contribution to the "*sparsely populated*" field of risk philosophy, Lewens launches into a discussion of risks without reflecting on what the term refers to.

*Decision-makers of all kinds frequently face situations where they must choose one of several risky options.*

(Lewens, 2007, p. 2)

But what is a risk? And where do menus of "*risky options*" come from? Reticence about the meaning of the term 'risk' can be detected in the wider society as well as among social scientists who have tended to remain immersed in this unreflective conspiracy of silence. Definitional absence stands in sharp contrast to extended usage in every sphere of modern life. An extra-planetary anthropologist might be struck by the amount of energy invested by some of its wealthier inhabitants in managing a phenomenon which they cannot specify. An apparently sloppy or even conspiratorial approach to the concept of risk may be driven by its very ubiquity. Risks have become so much a part of the fabric of everyday life that they have acquired the aura of a fundamental natural force which can be directly observed. However, when attention is directed away from the practical management of particular risks toward the attributes of riskiness, its elusiveness becomes apparent. Probing the meaning of risk has a gently subversive effect, shaking the foundations of taken-for-granted cultural assumptions on which analyses of specific risks are

predicated. In particular, as argued in the next section, careful reflection about the core of meaning carried by the term 'risk' demonstrates that risks can never exist as material entities independently of an observer who has learned to view the world through the lens of risk. Definitional reflection undermines the apparent material substantiality of risks, and thereby opens up the indefinite number of alternatives which might become the focus of risk concern. Because the coordination of human action requires a limited number of risks to be selected from the infinity of possibility, such challenges threaten the underpinnings of organized risk societies.

### **On Contingency**

The best starting point for a conceptual analysis of risk is consideration of its relationship to contingency (Luhmann, 1993; Renn, 2008), the idea that one of two or more outcomes might happen (or might have happened while remaining unknown). Carefully uncoupling contingency and risk allows the latter to be put in its historical place as merely one variant, however currently significant, of the former. Risk-thinking can be distinguished from other ways of viewing the world contingency through its reliance on the **metaphor** of randomness, as argued below.

A contingency exists when an observer thinks that an event will fall into one of two or more categories<sup>4</sup>. For example, a child born on January 1<sup>st</sup> 2012 might or might not be alive 70 years later, and one and only one of these alternatives must hold true. An observer's sense of contingency is dissolved by eventually finding out the actual outcome, necessarily after, but perhaps not immediately after, an event has happened. In the practical, cookbook world of culturally mediated decision-making, contingency derives ultimately from uncertainty, not from indeterminacy, as demonstrated by the following consideration. An event which has already happened, and therefore is wholly determined (e.g. a sport outcome), can still be considered contingent by an observer who does not know what occurred. Conversely, for an observer who mistakenly believes that a particular outcome has already happened, the turnout no longer appears contingent.

Although contingency specification is mainly motivated by a pragmatic desire to influence outcomes, the concept can be logically uncoupled from perceived or actual prospects for human control. Contingency indicates merely a belief that specified outcomes might or might not happen. Thus, the

view that an uncomfortably close supernova might wipe out all life forms on earth refers to a contingency even though little or nothing could be done to prevent such a catastrophe. Similarly, at the personal level, a patient waiting to hear whether a suspicious lump is benign or malignant confronts a contingency specifying two alternative futures, but cannot influence which one will have their name written on it because the cancer process has already either started or not started. Contingency, as already argued, rests solely in an observer's uncertainty as to which of two or more outcome categories will hold true<sup>5</sup>.

The proposed separation of contingency from agency allows two interesting alternatives to be specified: contingencies perceived by some observers and not others; and contingencies which some observers, but not others, regard as fully or probabilistically controllable. With respect to global warming, for instance, an observer might hold that this future will simply not occur, or is too unlikely to be worth considering; or they could agree that global warming might occur while asserting that any such trend will be unconnected with human activity. As discussed further in the next section, contingencies cannot be thought about without categorization which requires boundaries to be set (e.g., warming above two degrees centigrade)<sup>6</sup>. Furthermore, value must be assigned to outcomes, allowing further differences of opinion—for example the view that global warming will confer as much benefit as cost. These and other potential areas of disagreement open up many challenges to the coordination of social action among observers who construe a contingency differently. They can be distinguished from the condition where a contingency which might be considered simply has not been thought about, a point taken up below and illustrated in Box 27.1 (p. 610).

### ***Some Esoteric Properties of Contingency***

The culturally universal ubiquity of contingency conceals the non-obviousness of its nature. As with gravity and time, its familiar practicality is misleading. Three important issues—the need for prior categorization, the infinite scale of possibility, and the creation of non-events—will be discussed here, before being taken up below in relation to risk.

### **Contingency and Prior Categorization**

The formulation of a contingency requires a prior interpretive act of categorization, without which multiple possible outcomes could not even be conceived

of. Outcome categories such as winning games or elections may be constituted by rule systems, or may be mapped onto qualitative disjunctions like death or heart attacks. Nevertheless, every individual event is unique. Classification transforms this natural variability into identical, distinctive, symbolic packages (Bowker & Star, 2000).

The infinite diversity of nature can be squeezed into an indefinite variety of category sets, yielding an unlimited number of potential contingencies. To count as a contingency, a category set must possess the three properties of possibility, exclusivity, and universality. For example a presently live person aged under 70 years might or might not die before their 70<sup>th</sup> birthday (possibility), can only experience one of the two or more categorized alternatives (exclusivity) and must undergo one or the other (universality). These properties do not appertain intrinsically to events, but arise from socially organized interpretive action. Many category schemes can be applied to the same domain of events. For instance, just considering binary distinctions for the sake of argument, deaths might be viewed as premature/of at least normal length, achieving/not achieving salvation, painful/peaceful, or brave/cowardly, depending upon the culturally mediated concerns of those applying a contingency. Once a contingency has been constructed, slotting cases into its alternatives requires simplification through the conjoint processes of homogenization within, and differentiation between, categories (Heyman et al., 2010, pp. 39–43), discussed further below in relation to risk categorization. These two processes direct attention away from both intracategory variability and intercategory similarity. This price must be paid in order to drive the diversity of events into unified alternative packages which can be generalized about. Allowing for a larger number of categories mitigates the distorting process of homogenization-differentiation, but at the price of extra complexity, and may fail pragmatically. For instance, screened individuals must either be offered or not offered further expensive and invasive diagnostic tests. In the practice of screening, the continuous scale of probability tends to be reduced to the two alternatives of higher and lower risk linked pragmatically to the action/inaction binary (Heyman, 2010).

#### POSSIBILITY CREATION

A second, crucially important property of all forms of contingency, not just risks, is that they conjure up possibilities through contemplation of

what might/might not happen, or might have happened/not happened while remaining unknown. A long-term cigarette smoker might or might not die of lung cancer, for instance. Thinking contingently by no means requires a risk-based interpretive framework which draws upon the metaphor of randomness. Thus, some religious belief systems hold that human beings are bound for either heaven or hell after death, with the outcome of this contingency determined by faith, repentance, or predestination. Two possible outcomes (or three if limbo is included) are specified. Every individual to whom the contingency applies must experience one of the specified trajectories generated by a chosen category system, but remains suspended between the constructed alternative categories until their fate becomes a matter of known historical fact.

If the Aztecs did carry out human sacrifices before dawn every day in order to appease the sun god (Meyer, Sherman, & Deeds, 2003), their view can be represented as a contingency. From this point of view, either the sun will rise following the present night or it will not, with the latter outcome potentially leading to eternal darkness if the sun god decided to depart for good (a second-order contingency). Similarly, at least with respect to its focus on what might happen, Tony Blair, the prime minister who took the UK into the second Iraq war (testimony to the Chilcot Inquiry, January 29, 2010, quoted in *the Guardian* newspaper, January 30, 2010), retrospectively accounted for this decision by appealing to contingency. He argued that “*What is important is not to ask the March 2003 question, but to ask the 2010 question. Supposing we had backed off this military action . . . ?*”. Blair maintained that the “*crucial thing after September 11 was that the calculus of risk changed*”. This instructive phrase distinguishes risk-thinking from other ways of reasoning contingently by attaching an aura of probabilistic scientific rationality to the mental activity of analyzing the inherently ethereal multiverse of possibility.

Examples drawn from cultures which seem exotic from a current science-based cultural perspective illustrate the infinite scale of the possible particularly well, showing that, in principle, anything might happen. Even the laws of physics do not curtail the potential bounds of contingency which require only that an observer should believe that a categorized outcome might possibly occur.

Culture plays the crucial roles, firstly, of shaping how contingency is understood (e.g., as risk

through the metaphor of randomness or as the will of the gods); and secondly, of specifying which small number of possibilities out of the infinite number of those which might be contemplated become foci of organized concern. Variants of contingency, in both its form and substance, should be located in the human mind, not in externally observable events which merely happen.

#### THE CURIOUS REALITY OF NON-EVENTS

In addition to selectively addressing what might or might have happened, thinking contingently allows the observer to ‘see’ an imagined outcome such as eternal darkness or runaway global warming ‘**not happening**’. To an observer who is not thinking about a contingency, the absence of an imagined possibility will simply not register. Thus, members of societies which recognize the risks of smoking can see a heavy lifetime smoker ‘not dying’ from a smoking-related disease, but this (non)event could not be ‘observed’ before smoking risks were flagged up. Non-events do not register to the senses or any measuring instrument, but cultural distancing is required for their ghostly nature to be recognized. In relation to an unmet expectation, non-occurrence is experienced as tangible. However, since anything might happen, the number of possible non-happenings is unlimited. The infinity of possibility, a crucial starting point for the analysis of contingency thinking, was emphasized by the nineteenth century philosophical psychologist Alexius Meinong<sup>7</sup> (Dölling, 2001, p. 63):

*In developing his theory of objects, Meinong was guided by the insight that the totality of what exists, including what has existed and will exist, is infinitely small in comparison with the totality of the objects of knowledge. This fact easily goes unnoticed, probably because the lively interest in reality which is part of our nature tends to favour that exaggeration which finds the non-real a mere nothing.*

Meinong’s assertion that there are “*objects of which it is true to say that there are no such objects*” caused considerable contention at the time (Dölling, 2001 p. 64), perhaps because it subverted the taken-for-granted assumptions of empiricist science. Contingency identification requires a semiotic “*preadaption*” (Josephs, Valsiner, & Surgan, 1999, p. 258) involving categorization, as argued above. For example, before smoking came to be viewed as a health issue, smoker longevity would not have been particularly noted, although, needless to say, many

smokers would have died prematurely. These events simply happened without becoming bound up with the machinery of what might be, or might have been. But smoking could have been, and sometimes still is, viewed contingently in many other ways (e.g., as an aid to digestion, an identity statement, or a facilitator of social bonding). Once a contingency has been constituted through outcome categorization, it automatically generates a counterpart type of non-event. Occurrence and non-occurrence are bound up in a figure-ground relationship in which each requires the other, although their dividing line may shift dynamically (Josephs, Valsiner, & Surgan, 1999, p. 265). Furthermore, the occurrence/non-occurrence binary structures time through differentiating an elusive present in which an outcome might or might not occur from a future in which one of these possibilities can be ruled out (Heyman et al., 2010, pp. 118–120). After an event, possibility immediately resolves itself into history, inviting retrospective forensic accounting, for instance if a serious accident has occurred.

To recap, contingency thinking depends upon the shoehorning of events into two or more possible, exclusive, and universal categories. Each contingency, realized as a category set, solidifies one issue from the unlimited fluidity of possibility. The notion that an outcome is contingent derives from observer uncertainty, not from the material existence of alternative trajectories, as does the remarkable but usually unnoticed human capacity to ‘observe’ what has not, but might have, occurred. **The crucial analytical step which enables the relationship between risk and culture to be adequately understood involves uncoupling the idea of contingency, originating in the human capacity to imagine possibilities, from its particular culturally derived forms, such as belief in divine justice or literal use of the randomness metaphor.**

The process through which imagining a contingency conjures it into existence, although without a guarantee of a lengthy or vigorous cultural life, is illustrated in Box 27.1, on p. 610, below.

#### ***The Problematic Status of Utility Calculation in Relation to Possibility***

The above analysis raises the question of whether some possibilities (e.g., the end of the world through divine retribution, invasion from another planet, a situation in which the UK or France would and could credibly threaten to use nuclear weapons independently of the United States) can

### Box 27.1 A Contingency Miscarriage

In 2009, an email concerning possible risks from compact disks (CDs) was circulated among forensic mental health service providers<sup>11</sup>. A patient had pointed out that CDs could be turned into sharp weapons, an outcome which the email writer had not previously considered. The email requested information from elsewhere as to whether others shared this concern, or knew of it happening. Nobody involved in the discussion group had come across a single case, but writers expressed concern that CDs or DVDs might be used as weapons in the future. Despite this fear, participants agreed that they should not be banned.

This example illustrates the risk-management implications of the conjectural status of contingency. Until the risk was envisaged, it could not be managed. Once articulated, it stimulated worry, which was not alleviated by recognizing that no cases had been locally recorded. Their absence did not preclude the possibility of adverse events having taken place elsewhere, or occurring subsequently. However, if preventative action had been initiated, patients would have been deprived of one of the few forms of recreation open to them, possibly generating new risks. At the same time, the overt contemplation of this contingency made those who considered it vulnerable to blame if the now imagined but never observed outcome actually occurred in the future.

rationally be given more or less weight than others. The present author has reviewed this complex question elsewhere (Heyman et al., 2010, pp. 65–76). In brief, the issue corresponds to that of measuring expected value, which has received gargantuan academic attention, particularly within the discipline of economics. The answer to the question posed above carries fundamental importance in science-based societies in relation to one of their principal strategic stumbling blocks, that of applying empirical methods outside the laboratory in conditions of real life complexity. Claims to rational grounding in risk-oriented societies depend heavily on the validity of utility quantification. It is easy to be mesmerized by the sheer volume of empirical work which relies on the assumption that expected value can be accurately measured.

Although not futile, the calculation of expected value can at best generate a variety of different, crudely plausible answers depending upon starting assumptions, for example about trade-offs between multiple values and about the temporal horizon to be taken into account (Peterson, 2007). Because expected value is so elusive, evidence for the charge of irrational contingency selection often draws upon the calibration of non-equivalence. For example, the contrast between the urgency given to the 2010 oil spill in the Gulf of Mexico and the long period of calm indifference to larger annual leakages in Nigeria and Ecuador can be used to support the view that environmental harm counts for more if it occurs in the United States than if it happens in a developing country. Since circumstances always

differ, such comparisons can always be contested. Fortunately, the question posed above can be largely ducked in the present analysis of risk and culture on the grounds that social groups respond to the contingencies which they collectively prioritize, usually unreflectively, regardless of any utilitarian calculations or accusations of non-equivalence which critics may throw at them.

### The Concept of Risk

Uncoupling the ideas of contingency and risk makes it possible to view risk as the label for merely one way of thinking contingently, which has acquired quasi-universalistic status in the modern, science-based world. This crucial step prevents the absurd conclusion, sometimes found in the risk literature, being drawn that only modern peoples have attempted to control the future. Risk-thinking provides a historically novel formulation of contingency as governed by the combination of empirically established causal factors and randomness. (However, the notion of randomness will be demoted in the next section to a merely metaphorical status at least in the domain of everyday objects.) The origins of the risk-based approach to contingency are associated with the linked developments of science and capitalism in Europe from the time of the Renaissance (Bernstein, 1996). Hacking (1975/2006) locates the birth of the modern concept of probability precisely in the Europe of the 1650s.

One way to explore the shared but tacit mental work underpinning the cultural presence of a

risk is to expose the implicit assumptions buried in standard definitions, which are themselves scarce. As presented in the Abstract and repeated here for the reader's convenience, the Royal Society (1992, p. 2, with present author's additions in parentheses) defined risk as:

*the probability (3) that a particular adverse (2) event (1) occurs during a stated period of time (4a), or results from a particular challenge (4b).*

The two variants of the fourth risk ingredient, which refer to limited and indefinite time periods respectively, both address the temporal aspect of risk. This formulation was designed to justify the objective measurement of risks. However, each of the four elements of risk enumerated above can be reframed in a way which brings out the implicit processes of interpretation that underpin them. This reframing is summarized schematically in Table 27.1, below, which also includes a similar reframing of risk management.

The four enumerated elements of risk tend to be **projected** onto the external world, so that features such as adversity come to be experienced as intrinsic attributes of events themselves. A person considering a risk plays an active, culturally mediated, judgmental role, which can sometimes be obscured by habit and social consensus, illustrated in the next

section. The risk observer cannot avoid implicitly or explicitly:

1. Categorizing the contingent outcomes which become a selected focus of risk analysis;
2. Making value judgments about these outcome categories;
3. Developing expectations about the likelihood of these consequences, using the past as a guide to the future;
4. Placing temporal boundaries around a risk, without which it cannot be assessed. (Condition 4b in the Royal Society definition precludes quantification because it encompasses consequences extending toward infinity.)

The bottom part of the table draws attention to the interpretive work which underpins standard risk management steps such as drawing practice conclusions from evidence, reframed as “*encoding*” (Alaszewski, 2010). Risk management will not be considered further in the present chapter. However, it should be noted that the crucial question of what to **do** about a risk cannot arise until it has been constituted, as shown in the first part of the table, and that this sort of question can only arise in cultures which frame contingencies as risks. The four elements of the risk compound will be considered further in the second part of the chapter.

**TABLE 27.1 Two Views of Risk Elements**

Naturalistic view of risk	Interpretative view of risk
<b>RISK CONSTITUTION</b>	
(1) Event	Category
(2) Adversity	Value
(3) Probability	Uncertain expectation
(4) Time period	Time frame
<b>RISK MANAGEMENT</b>	
<b>Service delivery</b>	<b>Service organization</b>
Evidence-based practice	Practice encoding
Information giving	Information representation
Regulation and safety	Control

## Four Components of Risk Thinking

As discussed in the previous section, perception of any contingency entails four usually implicit interpretive steps involving categorizing, valuing, expecting, and time-framing. Risk-thinking is differentiated from other ways of envisaging contingency only with respect to the third ingredient, through drawing upon the metaphor of randomness. These four components of risk-thinking have been analyzed at length elsewhere (Heyman et al., 2010). For the present purpose, each will be briefly illustrated with particular reference to the interrelationship of risk and culture.

### *The Categorization of Events*

Management of a particular risk will mostly be oriented not toward single outcomes, but toward constellations of linked predictive and causal antecedents and consequences. Regardless of the web of relationships in which any event will be enmeshed, risk management attention tends to foreground one negatively valued antecedent or consequent. For instance, a focus

on cigarette smoking as a risky behaviour would link this presumed causal antecedent to a greater chance of experiencing various diseases, directing attention away from benefits of smoking such as stress management and weight reduction. Alternatively, a negative outcome such as coronary heart disease might be considered in relation to multiple risk factors. The variable architecture of risk constellations has received little analytical attention, perhaps because the natural attitude toward risk does not lend itself to consideration of the socio-cognitive processes through which a risk is mentally carved out from the tangled web of causation.

Regardless of their position in a risk constellation, its constituent objects cannot exist without prior categorization, which will be considered in relation to a foregrounded outcome deemed adverse. Because events never repeat themselves identically, outcomes must be neatly packaged before they can become available to generalized risk analysis. This process entails three conjoint sub-processes, the **selection** of an outcome as worthy of attention, the **homogenization** of cases, and their **differentiation** from non-cases. For example, research into the risk of 'depression' is predicated on the assumption that this state can be clearly differentiated from everyday 'sadness' (Robertson, 2008). At the same time, estimating the probability that an individual will experience depression requires cases to be treated as equivalent so that their frequencies can be counted. But this step requires attention to be directed away from differences within a risk category, at least temporarily. McCormack, Levine, and Rangno (1997) provide "simple nomograms", essentially graphs with correction factors which doctors and patients can use to calculate a patient's probability of experiencing a "cardiovascular event" over 5- and 10-year periods in terms of known risk factors. These authors define "cardiovascular events" as including "angina, unstable angina, myocardial infarction or death from coronary artery disease." Thus, in order to quantify the chance of this 'event' occurring over a given time period, it must first be marked out by lumping together a diverse range of phenomena, as the above quotation demonstrates. However, this manoeuvre is not itself debated in the paper. Discussing category creation would direct attention toward the potential existence of alternatives which would generate different risk entities and probabilities of occurrence.

Inevitably, the categorization of risks generates dissonances in relation to the privileging of one contingency over another (selection), the suppression of

awareness of dissimilarities between cases (homogenization), and the exaggeration of boundaries between cases and non-cases (differentiation). The woman quoted below challenged the homogenization of Down's syndrome as a risk category (Heyman & Henriksen, 2001, p. 41).

**Pregnant woman:** *And it doesn't help, again, people making comments like, what he [acquaintance] just said, 'You could be changing someone's nappy at 21.' I mean, not all Down's syndrome are like that, are they? I have seen them walking around the town. And, apart from their visual looks, they are very intelligent, some of them.* (Research interview with pregnant woman, aged 39 years, who opted for amniocentesis)

Although the cause of Down's syndrome, three copies of the twenty-first chromosome instead of two, can be specified, its precise configurations and clinical manifestations vary immensely. The quotation points to a tension between the mental construction 'person with Down's syndrome', which enables its probability to be computed through counting its rate of occurrence, and the variability within this category, which its classification directs attention away from. In contrast, the next quotation from the same study (Heyman & Henriksen, 2001, p. 163) fends off challenges to the differentiation of Down's syndrome from the absence of the condition.

**Woman who had terminated pregnancy:** *I read a story [magazine article]. Reading this story has helped me cope with it [opting for pregnancy termination after Down's syndrome diagnosed] ... I think they [couple depicted in story] are bloody stupid ... They look like they are really over the moon because they are having this Down's baby.*

**Husband:** *I mean they will have been explained the same as everybody else as to what can happen, or what it is going to be like, and what it means for the future.*

**Woman:** *They can have chest infections ... I mean they are laughed, and they are scorned at.* (Research interview with woman aged 46 years and her husband after pregnancy termination for Down's syndrome)

This couple had been undergoing fertility treatment for many years, and had given up their last opportunity for biological parenthood, a loss which still distressed them deeply a year after the abortion had taken place. Understandably, they objected vehemently to a representation of Down's syndrome which undermined its differentiation from

non-cases, and thereby stimulated doubt about their painful personal decision.

The third conjoint component of risk construction alongside homogenization and differentiation, the selection and non-selection of outcome categories, can only occur for a risk category which has been created through homogenization and differentiation. Otherwise, there is nothing to accept. At the same time, the homogenization and differentiation of a risk category entails its selection as a candidate, at least, for organized concern. Hence, these three processes must operate together in order to bootstrap a risk into existence. Risk selection is illustrated in Box 27.2, below, in relation to a notorious case of risk blindness.

In conclusion, outcome homogenization, differentiation, and selection are undertaken conjointly. Mental representations of what might happen are simultaneously foregrounded, bestowed with common attributes and marked out from 'the rest'. This complex mental activity must be aligned for organized social interaction to be possible, but its grounding always remains fragile because outcome categorization can never capture the individuality of actual events.

### ***Value Judgments about Adversity***

The second component of risk-thinking mentioned in the Royal Society (1992) definition is reframed in the second column of Table 27.1 as negative valuing. The notion of a "*particular adverse event*" locates negativity in an observable property of the external world, like mass or temperature. However, badness can never reside in events themselves, but only in the perceptions of individuals who singly or collectively attribute negativity to outcomes (Rescher, 1983). The illusion

that adversity can be located in events rather than their perception arises from the **projection** of taken-for-granted, culturally shared values onto the external world, an unarticulated mental manoeuvre which leads to adversity being experienced as an intrinsic attribute. The Royal Society definition adopts this natural attitude, which unreflectively directs attention away from value questions.

The inescapable role of the observer in judgments about outcome adversity can be seen most clearly when the humanistic assumptions taken for granted (but not acted upon) in modern, developed societies are suspended. Aliens from another galaxy might view the demise of the entire human species as a positive event, a theme explored in countless science fiction movies. For racists, the destruction of 'inferior' ethnic groups is to be welcomed; whilst various religious groups have positively valued the destruction of the unfaithful. Conversely, believers in animal rights reject an implicit starting point in which humans are privileged above other species (Singer, 1990), thereby challenging the justification for animal experimentation. Such examples expose the unexamined presuppositions which any utilitarian calculation requires.

Even within the frame of Western liberalism, risk analysis is built upon many value assumptions which remain mostly unexamined. For the present purpose of exploring the interrelationships between culture and risk-thinking, one illustrative example of alternative values will have to suffice. Maternity services in the UK and many other countries are oriented toward preventing the birth of children with severe disabilities through screening and offering the option of pregnancy termination. Many parents wish to exercise this option, but some do not, and

### **BOX 27.2 An Example of Organized Risk Selection**

The Butler Inquiry (The Home Office/Department of Health and Social Security, 1975) dealt with a striking case of risk blindness, arising from selective risk perception, which stimulated the development of medium-security forensic mental health units in the UK. While confined to a high-security institution, Graham Young actively and openly pursued his interest in poisoning, for example borrowing library books on the topic. After being released, he promptly resumed his career as a poisoner. Physically and socially remote from wider society, staff working in high-security institutions may have become oriented toward internal risks such as patients harming themselves or others on the ward. They simply did not visualize an outcome which appeared glaringly obvious from outside the social system in which they were immersed.

Systems theory of risk (Japp & Kusche, 2008), outlined above, envisages endemic social disarray arising as an unintended consequence of increasing role differentiation. The Young case illustrates potentially tragic, but also blackly comical, consequences which can result when social actors selectively address different risk objects without appreciating their discordance.

experience may stimulate reappraisal. Oulton and Heyman (2009) found that some parents of children with severe and profound intellectual disabilities did not view their existence as an adverse event, a value judgment vividly illustrated by the following quotation.

*Her every little step she makes is just so phenomenal. And what grace she's got. And, ah, she's just a complete delight all the time.* (Research interview with mother of daughter with severe learning and physical disabilities)

Another quotation from the same study specifically articulates resonances, normally concealed, between outcome evaluation and wider cultural issues.

*There aren't many opportunities in twentieth century life in England to be a good person unless you seek it out. And, like a missionary or something, so caring for somebody, and the experience of loving somebody who is different, and damaged, and has certain problems is a very rewarding experience for me personally . . . it's a bit like Calvinism. You actually begin to feel as if you're of the elect, and of a very small banded set of special people who are different from everybody else . . . It's very dangerous to feel superior to other people. That's why you have to fight it.* (Research interview with the father of a daughter with severe learning and physical disabilities)

The brief exposition offered in this section has done no more than scratch the surface of the many complex value questions which underlie even the apparently simplest risk issue. That risk managers are not, like Shakespeare's Hamlet, paralyzed by doubt, attests to the quietly effective accomplishment of their culture, which supplies prepackaged, if not uncontested, answers to value pre-questions. The face validity of pragmatic assessments of 'what works' depends on such matters not being opened up to scrutiny and debate.

### **Probabilities/Expectations**

Probability is the third of the four components of risk-thinking alluded to in the Royal Society (1992) definition. It is reframed in Table 27.1 from an interpretive perspective as one approach to developing expectations. Categorization, valuing, and time-framing can be found in all forms of viewing possible events contingently. Probabilistic reasoning, in contrast, marks out risk-thinking as distinctive from other ways of viewing the world contingently. For this reason, it will be discussed in more detail

than the other three ingredients of risk-thinking. Reflecting its importance to risk, the Royal Society (1992) document immediately followed the definition of risk with a statement about probability.

*As a probability in the sense of statistical theory risk obeys all the formal laws of combining probabilities.*

This awkward, elliptical sentence unintentionally conveys the writers' unease whilst invoking abstruse mathematical "laws" as legitimation. Non-mathematicians, including the present author, tend to defer to such authoritative assertions which invoke a prestigious, mysterious world of science. Mary Douglas (1992, p. 50), challenged the prevailing official assumption that "*the ordinary lay person, the man in the street, is weak on probabilistic thinking*", arguing that human beings intuitively appreciate probabilities. Common mistakes in everyday probabilistic reasoning can indeed be diagnosed (Breakwell, 2007), for instance overgeneralizing from single cases, but should not distract attention from questioning this way of thinking, as the following quotation illustrates.

*Once upon a time I was an undergraduate majoring in mathematics and statistics. I attended many lectures on probability theory, and my lecturers taught me many nice theorems involving probability . . . One day I approached one of them after a lecture and asked him . . . "What is probability?". He looked at me like I needed medication, and he told me to go to the philosophy department.*

(Hájek, 2008, quoted author's emphasis)

This anecdote nicely captures the cultural process of deletion, discussed in the final main section of the chapter, through which unspoken shared presuppositions are kept away from reflective scrutiny. It will be argued below that probabilistic thinking draws upon the **metaphor** of randomness, and that its use to approximate the unknown but determinate carries very important consequences. Before this task is attempted, three ways in which qualitative or quantitative probabilities can be generated will be briefly distinguished, namely inductive reasoning, modelling, and motivation assessment.

### **THREE MODES OF PROBABILISTIC REASONING**

Firstly, when outcomes occur frequently, their probability can be estimated inductively, by using their past rate as a guide to the future. For instance, the chance of an individual dying from coronary heart disease (CHD) can be computed by counting

the number of such deaths in the recent past as the numerator, the total number of deaths as the denominator, and then calculating their ratio. More sophisticated conditional probabilities can be worked out for subcategories such as men versus women, or for different socio-economic strata. This rough and ready approach to grounding expectations directly in previous experience is not available for unusual events like nuclear accidents, which do not happen frequently enough to be reliably counted. In such cases, the quantification of probability, for instance the scientific consensus that there is a 90% chance of human activity causing catastrophic global warming during the present century, is based on mathematical modeling, a second mode of probabilistic reasoning.

Thirdly, when contingency involves voluntary action, expectation can be expressed in terms of a numerical probability, as when an individual asserts that he is 90% sure that he will turn up for a social event.

Expectations can be represented through numerical probabilities in each of these three strikingly different forms of reasoning, a difference which their common numerical representation obscures. Furthermore, their interrelationships, particularly that between statistical and psychological probabilities, are difficult to conceptualize. Human action can itself become the object of risk analysis at the collective level. Aggregate statistics such as an individual's chance of being a crime victim in a particular locality remain remarkably constant from year to year despite resulting from countless individual decisions. Similarly, the probability of an individual taking a risk-reducing action such as giving up smoking can itself be estimated inductively. The issue of genetic predisposition in relation to the attribution of criminal responsibility well illustrates the murkiness of the connection between voluntariness and randomness. Knowledge of statistical relationships between gene variants and crime rates can be used to argue **either** that the genetically predisposed should be given shorter sentences on the grounds that they cannot be blamed for their inheritance, **or** that they should be given longer sentences on account of their presumed greater propensity to offend (Farahany & Bernet, 2006).

The following discussion of probabilistic thinking will focus on the first of the three forms of probabilistic reasoning outlined above, inductive inference from frequently occurring events. But consideration of the very different cases outlined above demonstrates that probabilistic propositions

derive from expectations which can be grounded in diverse epistemological procedures.

#### PROBABILITY AND THE METAPHOR OF CHANCE

Risk-thinking invites its users to view the determinants of a negatively valued outcome as partitioned between risk factors and a residue of chance; and to regard this residue as resulting from indeterminacy rather than from prognostic limitations. Thus, uncertainty arising from lack of knowledge is **projected** onto events as the attribute of randomness, a process which parallels the perceptual metamorphosis of negative valuing into inherent adversity. The merely metaphorical status of chance in risk-thinking can be demonstrated through its application to historic but unknown events. For example, people who are screened for a condition such as colorectal cancer will be told their probability of experiencing an adverse outcome which has already occurred. 'Randomness' in such cases can only refer to the projection onto the external world of observer uncertainty about an outcome which has happened and is therefore utterly determined.

The same analysis can be applied to future outcomes which are clearly generated from the complex interactions of simpler forces, for instance, the end position of a spun roulette ball. Certain internet vendors claim to be able to provide systems of concealed cameras and computers which predict roulette outcomes with sufficient accuracy to beat the house odds, thus diminishing 'randomness'. In principle, there is no reason why such a system should not provide perfect accuracy, thereby banishing the scope for metaphorical randomness. In consequence, the probabilities of particular outcomes will change for anyone who is using this system. Meanwhile the roulette ball, although not the casino owners, will carry on blissfully unaffected by the changes to its chances of coming to rest on a particular number.

This outline of a classical closed causal system needs to be modified in two respects to take into account quantum uncertainty, and the indefiniteness of open systems such as the human body which are affected by an indefinitely large number of causal influences. Physics teaches that an irreducible randomness operates at the smallest scales of magnitude; and that, therefore, merely observing an attribute of a particle changes its behaviour so as to prevent the observer from obtaining 'forbidden' knowledge. Quantum processes may well

contribute to risk, for instance by tipping a cell into a cancerous state which the immune system fails to check. However, more generally, quantum effects and risks are connected only tenuously through shared use of the concept of chance. As argued in the next subsection, risk analysis, stripped of its pretensions, offers no more than useful cookbook pragmatism, and operates on a macro scale where quantum uncertainty can be ignored. Classical random systems and the more complex events which risk analysis addresses must be distinguished in one important respect, however. Whereas, the behaviour of a roulette wheel is determined by a small number of interacting forces, social and health phenomena are influenced by the interactions of a vast number of processes. Empirically grounded expectations about the latter can only be developed selectively. It is never possible to measure more than a small proportion of directly or proximally influential factors, and many different models with some predictive purchase can be put forward.

**CONSEQUENCES OF ADOPTING THE METAPHOR OF RANDOMNESS**

A number of practically important consequences follow from the projection of uncertainty as randomness. Their combined impact is not always appreciated because it is obscured by the tendency to take the metaphor of randomness literally. These consequences (Heyman et al., 2010, Chapter 5) are outlined in Table 27.2, and briefly illustrated below.

*Acceptance of the ecological fallacy:* The paradigm case of probabilistic reasoning involves counting rates in categories and attributing these statistics to future members, although, as discussed above, probability estimation does not always take this form. It, in effect, ‘spreads’ the calculated rates among

all members of a category, with each case deemed to ‘carry’ the same aggregate chance of incurring the predicted outcome. Refinement of predictive models can allow such demarcations of chance to be modified. For instance, personalized medicine, if its promise were ever met (Petersen, 2009), would allow those who will suffer side effects from a particular drug to be identified through genetic markers. At present, the chance of this undesired outcome is attributed to randomness equally affecting the entire population of medicine users. However, until perfect prediction is achieved, and risk thereby banished, a residue of unexplained variance will remain to be mopped up through tacit acceptance in practice of the ecological fallacy that all members of a nominated category share its aggregate statistics.

Two types of pragmatic gain can result from this usually unnoticed cognitive manoeuvring. Firstly, if presence in a marked risk category results from a causal link with the defining category attribute, as with smoking/lung cancer, and perhaps with obesity/coronary heart disease, modification of the risk factor will reduce the incidence of the risked condition in the sub-population flagged up as at higher risk. The belief that a causal connection, however imperfect, exists motivates the direct preventative endeavour targeted at the attribute category. The anticipated gains will only be achieved if the assumption of causality is correct. Secondly, even if no causal significance is attached to a category, its markers can be used predictively to target a class of individuals at greater risk for other forms of prevention, as with screening tests. However, such risk management gains come at the price of conflating the aggregated properties of a category with attributes of its individual members. Some further ramifications of this useful but crude heuristic (rule-of-thumb) are briefly outlined below.

*The ecological prevention paradox:* The ecological prevention paradox (Davison, Davey-Smith & Frankel, 1992) arises because every individual in a delineated category is deemed to possess the overall probability of experiencing the negatively valued outcome of concern, and, therefore, to merit the same risk management response. Moreover, this way of thinking is often applied even when high relative risk is combined with low absolute risk, indicating that a large majority of those in the higher risk category will not be affected. For instance, the finding of a raised rate of future hospitalization for schizophrenia among cannabis consumers (Zammit et al., 2002) has been employed to justify

**TABLE 27.2 Some Implications of Probabilistic Reasoning**

1. Acceptance of the ecological fallacy
2. The ecological prevention paradox
3. Multiple probabilities
4. The informational management of “personal” probabilities
5. Acceptance of the inductive fallacy
6. The inductive prevention paradox

its criminalization, even though the vast majority of users and non-users alike will not experience this outcome. Zammit et al. concluded that self-reported heavy cannabis users were 6.3 times more likely than self-reported non-users to be hospitalized for schizophrenia over a 25-year period. However, 3.8% of heavy users, compared with 0.6% of non-users, were found to have been hospitalized. High risk categorization spreads 'the problem' among the vast majority who are unaffected one way or the other.

*Multiple probabilities:* Because risks are attributed to individuals on account of their category membership, it follows that changing either the specification of categories or the assignment of individuals to them will alter 'personal' probabilities. In relation to category specification, for example, recent research has suggested that obesity risk is better captured by waist circumference than by the more widely used body mass index (BMI). BMI lumps together highly fit muscular individuals with those carrying larger amounts of fat (Janssen, Katzmarzyk, & Ross, 2004). The **category** of persons with high BMIs may experience a higher aggregate rate of health problems despite including some very fit persons. Although the choice of risk markers can be empirically grounded in selection of the most accurate predictors, suboptimal risk models may provide sufficient predictive purchase to justify their adoption. Until perfect prediction is achieved, banishing risk, stronger predictive models will remain to be discovered. Many alternative models may offer a similar degree of prognostic power while marking different attributes as markers of risk. Each will assign different probabilities to at least some individuals.

*The informational management of 'personal' probabilities:* Individual location within an established set of risk categories will depend upon the availability of information which assigns individuals to one or other alternative. Hence, individuals can change their risk status by deciding whether to inquire further (Heyman, Henriksen, & Maughan, 1998). For instance, the children of a parent with Huntington's disease may opt to undergo a genetic test which will establish with certainty whether or not they will develop the disease, or may choose not to be tested, leaving their probability at 50%. Some individuals make this choice because they do not want to risk having to live with knowing that they will definitely develop the condition in later life (Leontini, 2010). Similarly, pregnant women who are informed of their age-related probability of carrying a fetus with

Down's syndrome can choose to leave their probability at this level. Alternatively, they can choose to undergo a test which will either increase or decrease their risk. However, they cannot know in advance which of these probabilities will apply to them. The woman quoted below (Heyman & Henriksen, 2001, p. 153) had ruled out diagnostic tests and abortion, but, nevertheless, managed her personal probability (expectation) by gambling that a negative screening test would bring reassurance.

*And if I had the serum screening test, that would let me know when it was a high risk or a low risk. And if it were a low risk, well, I could practically rule out having a Down's baby anyway. So that was brilliant anyway because that gave me peace of mind.* (Research interview with pregnant woman, aged 37 years, who accepted serum screening for chromosomal anomalies)

Although unusual, this way of responding illustrates the possibilities for informational probability management particularly well. Since about 5% of women who underwent this form of screening were judged to be at higher risk, her strategy yielded a 95% chance of relocating her to a lower risk status. But if she had screened at higher risk, she would have had to live with this status until the birth because she had ruled out invasive diagnostic testing.

*Acceptance of the inductive fallacy:* Probabilistic reasoning based on frequency observation requires more than working acceptance of the ecological fallacy. In addition, a conceptual leap must be made from the past to the future. Without this assumption, expectations cannot be grounded in empirical observation. But its adoption requires pragmatic acceptance of the inductive fallacy. What happened in the past will not necessarily recur in the future, as the European discovery of black swans in Australia during the nineteenth century illustrates<sup>8</sup>.

Mortality risks provide a good example of familiar statistical 'facts' which contain implicit inductive assumptions. Individuals in marked categories such as those of gender, social class and lifestyle, are deemed to carry their aggregate rates of occurrence as personal probabilities, as discussed above<sup>9</sup>. But these statistics can only be estimated inductively through extrapolation into the future from the longevity of those who have already died. Direct extrapolation carries the fundamental limitation that it does not allow for historical increases or decreases in life expectancy. Even if such trends are taken into account, some sort of extrapolation

from the past to the future is inescapable. Observed regularities provide a practically indispensable rough guide to expectations. However, a price has to be paid for heuristic simplification, as with acceptance of the ecological fallacy, discussed above. If the past ceases to provide a guide to the future because some unknown causal condition has changed, inductive inference will systematically mislead.

It will be argued in the next section that this limitation becomes inherently inescapable when preventative efforts have themselves potentially altered the circumstances surrounding a risk.

*The inductive prevention paradox:* The inductive prevention paradox arises when preventative efforts remove from sight the pristine conditions which existed previously, precluding assessment of their future necessity. This predicament arises regardless of whether the harm-reducing measure is presently efficacious, as long as those managing a contingency think that it might be. If the Aztecs did carry out human sacrifices before dawn every day in order to appease the sun god, then their action would have prevented them from observing whether the sun would have risen regardless, as modern readers may suspect. Furthermore, their belief system about this contingency would have prevented them from putting the efficacy of human sacrifice to the test on account of the irreversible damage which they feared might have resulted if the sun god had taken umbrage and departed. Certainty is not required, merely fear about what might happen (i.e., about contingency).

Regardless of its historical accuracy, this esoteric example illustrates a predicament which equally affects modern risk management at both the individual and collective level. To illustrate the former, a frail older person who is injured in a fall outside their home might decide that they cannot risk going out again. By staying at home, this person cuts off the supply of evidence which might have suggested that such precautions were unnecessary. Similarly, patients with long-term conditions taking prophylactic drugs, for instance controlling Crone's disease with anti-inflammatory drugs, cannot know whether experimentally stopping their consumption would trigger irreversible flare-ups. At the collective level, the 'war on drugs' continues to be fought despite its evident failure, in case its abandonment would trigger an irreversible explosion of addict numbers (Califano, 2007). However the impact of decriminalization could only be observed if the present legal regime were to be suspended<sup>10</sup>. In the same way,

cervical cancer vaccination has been recently introduced in the UK and elsewhere alongside the established technology of screening. Whether screening will become unnecessary in a population with a high vaccination rate cannot be easily assessed as long as both are being provided (Kiviat, Hawes, & Feng, 2008). But the termination of screening programmes can hardly be contemplated because their withdrawal might generate serious consequences.

This section has analyzed the complex, implicit structure of probabilistic reasoning, identifying counterintuitive implications such as multiple probabilities, informational probability management and preventative inductive loops.

### ***Time Periods/Time Frames***

The analysis presented so far has attempted to unpick the interpretive work entailed by three embedded elements in risk-thinking: the categorization of contingent outcomes; negative valuing of at least one of the categorized alternatives; and the development of probabilistic expectations based on heuristic acceptance of the ecological and inductive fallacies. The final main section of this chapter will consider the fourth necessary component of risk-thinking, the segmentation of time within temporal horizons, without which probabilities could not be calculated.

The Royal Society (1992) definition refers to a risk spanning a "*stated period of time*," recast in Table 27.1 as a time frame. The definition also offers a variant on time periods, adverse events which result "*from a particular challenge*". The latter implies an open time frame encompassing all the future consequences of a risk. Given that consequences can extend indefinitely into the future through chains of causation, removing the outer limit would render the inductive estimation of probabilities impossible. For instance, radiation from nuclear waste might harm health directly for many thousands of years, but its consequences could extend even further through reproductive transmission of genetic damage. Not surprisingly, the nuclear industry has favoured assessing the health impact of storing radioactive waste over a relatively short 500 year period (Atherton & French, 1999), thereby placing longer-lasting radioactivity outside the temporal horizon for risk assessment, and reducing its apparent net disutility.

The metaphor of a temporal horizon suggests a boundary beyond which consequences become invisible. However, the distance to the horizon is

set by the observer's focus, which is determined by a mix of cultural, organizational, and personal influences (Heyman et al., 2010, Chapter 5). Although easy enough to recognize when attention is drawn in that direction, awareness of the unavoidable arbitrariness of time frames is particularly susceptible to collective taking for granted. Unless social actors are oriented toward similar time frames, organized coordination of their risk management efforts becomes almost impossible. In particular, those who set different time frames will draw different utilitarian conclusions even if they share the same values and probabilistic expectations, as illustrated above in relation to nuclear waste. However, this requirement to segment time in order to estimate expected value flies in the face of multiple causal pathways which do not fit into single time segments. For instance, women who decline prenatal screening for Down's syndrome in order to avoid the stress of being tested can argue that this stress would itself cause long-term risk to the baby on account of the link between pregnant women's emotional well-being and fetal health, a concern illustrated by the following quotation (Heyman & Henriksen, 2001, p. 150).

**Interviewer:** *How did you feel in the weeks that you were waiting for the results?*

**Pregnant woman:** *Oh it was awful. The result, waiting . . . Cos I was saying, "Ee, this baby will come out miserable little" . . . I mean, when you read the books and that, you think, "Oh well, you know, three, four weeks". But, like, you're wishing your life away, and it's awful, you know. (Research interview with pregnant woman aged 40 years who opted for amniocentesis)*

The juxtaposition of multiple time frames in the above quotation well illustrates the heuristic simplification required to confine outcome scanning within a particular time period. For the present purpose of reviewing the relationship between risk and culture, three further examples of time-framing drawn from the field of health care will be outlined below: randomized controlled trials; confidential suicide inquiries; and smoking cessation programs.

Randomized controlled drug trials for curative cancer treatments usually measure clinical effectiveness through 5-year survival rates. Adoption of this time frame makes research comparable, provides a cut-off which limits research costs, and allows timely product development. But a price has to be paid for this and any other time frame, in that it excludes longer-term effects which can only be identified

through the relatively ineffective method of post-approval adverse reaction reports. For instance, an annual recurrence rate of 1–2% after 10 years has been found for one form of testicular cancer (Dearnaley, Huddart, & Horwich, 2001).

In the UK, confidential inquiries into untoward deaths such as suicides of former mental health service users are undertaken if the person had been in contact with health or social care professionals less than a year before their death. Again, a cut-off, however necessary, interpretively dismembers the chain of causation at an arbitrary point. A mental health service manager (personal communication to the author) indicated that his trust would prefer a shorter risk ownership period, of 6 months. This shift would narrow the scope of service risk 'ownership', thereby reducing the number of adverse events for which they would be held accountable. The probability of discharged patients being involved in adverse events would be reduced, although, unfortunately, patient welfare would not be improved. Any apparent risk reduction would result solely from changing the temporal boundaries within which probabilities were calculated.

Finally, UK smoking cessation programs have adopted a *de facto* time horizon of 2 weeks for identifying "successful" quitting (The NHS Information Centre, 2008). This temporal cut-off ensures a high success rate because it excludes anyone who relapses more than 2 weeks after the outcome is assessed, thereby potentially inflating the 'chance' of success'.

The micro- and macropolitics of temporal horizon setting can easily be identified when attention is drawn to them. Although shorter time frames do not necessarily generate substantially different risk assessments, they do work against questions about longer term consequences being asked. Despite its significance, time framing remains largely invisible. Indeed, the collective *de facto* failure to extend global time framing beyond the next few decades is condemning the entire human species to almost certain disaster (hardly risk) through runaway climate change and resource depletion.

### **Risk, Culture, and Collective Deletion**

The final step in the present analysis of the interrelationships between risk and culture will gingerly explore one important implication of identifying the unexamined shared presuppositions on which all societal manifestations of risk must rest. Although more assumed than discussed in the social

sciences, the presence of a collective silencing process is implied by all interpretivist theories which point to concealed presuppositions at the heart of any social order. This issue is discussed below in relation to the idea of collective “*deletion*” (Law, 1995; Van Loon, 2002).

Risks, like all forms of contingency, are located in the minds of observers, in contrast to particular events which merely happen. Because absolutely anything might occur, individuals cannot avoid choosing which possibilities to concern themselves with. However, societies and social groups could not function if their members attended to wholly different risks. Cultures protect their members from this chaotic fate by encouraging them to share their orientations toward what might happen. Such alignments, however fragile and temporary, bestow an aura of materiality on the collective selection of some but not other contingencies. Social actors managing a particular risk tend to adopt the “*natural attitude*” (Schutz, 1962), treating it as a material entity, while directing attention away from the culturally shared interpretive steps without which it could not ‘exist’.

Van Loon (2002, p. 54), drawing on Law (1995), has argued that the societal establishment of a risk requires a collective deletion process which distances the necessary interpretive foundations from conscious scrutiny. Deletion transforms a small selection from the unbounded realm of possibility into ‘real’ and controllable risks, which are therefore worthy of organized attention, while backgrounding all others as either invisible or inevitable and so unmanageable. For a risk to acquire the status of an (apparently) material entity, the societal deletion process must itself be deleted, and so on, creating a fragile spiral of shared silence.

This analysis raises the further question of how deletion might be detected. Unfortunately for social scientists, the postulated silencing process works against its direct observation. Although inevitably controversial, it is possible to point to breathtaking risk blindness as evidence of culturally fuelled deletion on the grounds that individual human beings, left to themselves, could not display the required levels of stupidity! To put this point less pugnaously, an observer who detects massive discrepancies between social actors’ goals and utilitarian calculations might infer collective deletion. For instance, during economic bubbles, including the one which collapsed in 2007, financial players appear idiotically impervious to the inevitable credit crunch end-point, despite their historic

recurrence. Overwhelming non-urgency about the looming catastrophe of human induced runaway global warming provides the most alarming example because of its historic imminence and long-term disastrous consequences. In relation to public health, despite strong evidence from migration studies that *myopenigenic* urban environments greatly increase the prevalence of short-sightedness (Morgana & Rose, 2005), this now common childhood condition is not viewed as a risk to be managed. In these and many other cases, the absence of high level concern or resource mobilization provides false reassurance that there is not a contingency to be managed. Unfortunately, however, for this line of reasoning, what appears entirely rational from one cultural perspective will look insane from another. A snake-handling preacher in Tennessee, shocked that the author of *Salvation on Sand Mountain* did not have any snakes in his car, asked, “*What’s the matter with you boys? . . . Are you crazy?*” (Covington, 1995).

Qualitative research offers more direct glimpses of the postulated deletion process at the individual level through inviting reflectivity. The following extract from a research interview with a doctor who advised pregnant women about prenatal screening for Down’s syndrome (Heyman & Henriksen, 2001, p. 42), unusually, captures the deletion process in an answer to a thought-provoking question about clinical practice.

**Interviewer:** *Do you talk to them [pregnant women] about Down’s syndrome, about what Down’s syndrome is?*

**Doctor:** *No, I don’t actually . . . interesting. And yet, of course, that is addressed in the film [provided for pregnant women], isn’t it? Perhaps I should do.* (Research interview with doctor who advised women about chromosomal screening)

Another doctor working at the same hospital appeared more resistant to undeletion of questions about the nature of Down’s syndrome (Heyman & Henriksen, 2001, p. 42).

**Interviewer:** *Do you talk about Down’s syndrome?*

**Doctor:** *No.*

**Interviewer:** *What Down’s syndrome is?*

**Doctor:** *No. I assume that they understand, and they’ve read the leaflet before they came to see me, because we see about eight or nine new bookings every clinic. We don’t really have time to go through this.* (Research interview with doctor who advised women about chromosomal screening)

As these quotations illustrate, the cultural existence of a risk depends as much on what is kept off the agenda as with what is articulated.

## Conclusions

This chapter has explored the relationship between risk and culture. Given the vast scope of the latter, the analysis has been confined to late modern societies in which contested risk issues take centre stage. The discussion has focused on one aspect of culture, the implicit and partly shared presuppositions on which risk understandings are predicated. A concern with low visibility processes can be seen in major social scientific theories of risk, although conceptualized differently. Late-modern risk consciousness, has been variously viewed as resulting from struggles over recognition of the ecological crisis (Beck, 1992), the vulnerabilities of particular cultures (Douglas & Wildavsky, 1983), systemic role fragmentation (e.g., Japp & Kusche, 2008) and the evolution of a new mode for transmitting social power (O'Malley, 2008). The present chapter has homed in on the shared but unstated presuppositions underlying risk-thinking itself.

The best starting point for the analysis of risk-thinking is contingency, a universal, linguistically mediated human capacity to envisage multiple possible future, or past but unknown, outcomes. Although experienced as real, contingencies cannot exist in nature where events simply happen, but must be located in socially constituted minds. Given the unlimited scope of what might come to pass, cultures have to coordinate contingency selection in order to make coherent organized social interaction possible. This collective feat of alignment tends to be achieved outside conscious scrutiny, which would undermine the prevailing social order by invoking the infinity of possibility. The forging of sets of shared, although always fragile, working assumptions about contingencies occurs at two levels: firstly, the formulation of contingency itself (e.g., as the outcome of divine justice, predestined fate or quasi-random processes); and, secondly, the construction of specific contingencies within a generic interpretive framework. In relation to the present focus, the study of risk as a type of contingency can be differentiated from the study of particular risks.

For events to be viewed contingently, the unlimited variety of nature must be interpretively reduced to a small number of homogenized and differentiated categories, these categories valued (otherwise a

contingency would not matter), and analysis confined within a time frame which makes it quantifiable and manageable. Risk-thinking, the currently dominant approach to contingency, differs from others not in these three respects, but through its use of probabilistic reasoning. The universal numerical expression of probability as a proportion of unity conceals a variety of inference forms such as modelling and motivation assessment. The present chapter has focused on a third form, induction from observed frequencies, the most important method for grounding probabilities in health and other fields which deal with large numbers of cases. The ubiquity of probabilistic reasoning conceals its esoteric but required working assumptions: that members of an assigned category 'carry' its aggregated rate of risked outcome occurrence; that currently unpredicted variance within a category results from randomness; and that past patterns provide a reliable guide to the future.

This interpretive architecture involves more than a cultural curiosity. It has important implication for fields such as health and social care. Many probabilities of an outcome category can be derived from empirical observation, making chance itself (the merely metaphorical projection of uncertainty in the non-quantum world at least) open to management. Individuals can acquire higher risk status and all that may go with it, including anxiety, stigmatization, and moral imperatives, simply by being assigned to a category. Preventative endeavours can create self-sustaining epistemological loops. These and no doubt other non-obvious consequences of risk-thinking can easily be observed, but remain largely unexamined.

## Future Directions

An interstellar journalist depicting life on early twenty-first century earth might point out that a small proportion of its rampantly dominant species enjoy pampered lives, while many others struggle in abject poverty, and other forms of life become extinct at an ever-increasing rate. He might note the widespread although not globally universal influence of risk consciousness, but then contrast huge investment in warding off military threats with organized indifference toward looming climate change and resource depletion catastrophes.

Delving into human history, he might comment wryly on the well-known but ignored exemplar of Easter Island, whose inhabitants chopped down every tree, thereby depriving themselves of

a life-supporting environment, and even a means of escape. Finally, he would look to explain this breathtaking injustice and short-sightedness, pointing to the might of organized commercial interests and the collusion of both lobbied politicians and the prosperous minority. Seeking to illustrate his report with a topical story about ecological recklessness combined with global injustice, he might compare the justifiable outrage which greeted a catastrophic 2010 oil spill in the US waters of the Gulf of Mexico with relaxed indifference to much larger routine annual spillages in poor countries such as Nigeria and Ecuador.

Such gloomy reflections appear to overshadow the interpretive niceties analyzed in the present chapter, making the latter appear trivial by comparison. However, these soft considerations are directly connected to hard material realities. Looking at risk thinking as a form of contingency thinking reveals a fundamental contrast between the infinity of possibility and the organized selection of a few outcomes for organized attention. Analysis of the metaphorical lens of risk can draw attention to the narrowness of the light beam shed on possibility by any form of collectively activated risk management. It thereby serves a constructively anarchic function, transmitted via the potentially explosive power of ideas. Subversive questions can be asked about the ontology of risk objects (e.g. depression, terrorism), the value judgements implicit in perceptions of adversity (e.g. the birth of a disabled child), the soundness of probabilistic reasoning (e.g. the calculation of life expectancy) and the setting of time frames (e.g. 5-year survival for drug treatments). The considerations outlined in this chapter, and in more detail elsewhere (Heyman et al., 2010) point to important issues about risk, which the social sciences have neglected, perhaps because even the gurus of this field have tended in practice to neglect the prior question of what risk is.

## Notes

1. O'Malley (2008, p. 56) usefully distinguishes 'governmentality' from 'Governmentality'. The former generic term refers to the many interpretive frameworks within which social power is or has been transmitted (e.g. public torture and executions in medieval Europe). 'Governmentality' depicts a specific late-modern mode in which social power revolves around the internalization of risk-based moral imperatives directed at the behaviour of individuals.

2. A distinction needs to be made between the ubiquitous presence of risk-thinking in every domain of late-modern life and the variability of its influence. For example, the existence of risk prescriptions for eating does not mean that all individuals will view eating primarily or even partly from this perspective. But

a focus on risk-thinking does draw attention to one important, available interpretive slant with the potential to shape experience and decision-making about foods. Only in risk-oriented cultures is it even possible to actively take risks.

3. Professor Sir Roy Meadow was initially struck off the UK medical register for making gross statistical errors which led to the unsafe murder conviction of Sally Clark. Meadow had advised the court that the chance of a second, unexplained natural cot death in a family was about 73,000,000:1, but a case review concluded that this probability was actually 200:1. He was reinstated after appealing on the grounds that his expert testimony was given in good faith (Samanta, 2006). Meadow was considered to have erred by straying from medical to statistical matters about which he lacked competence. This tragic example illustrates the quagmires which all self-proclaimed risk 'experts', including critical social scientists, get themselves into. The above judgment also raises questions about the status of medical expertise itself since probabilistic reasoning plays a fundamental role in its knowledge base.

4. Readers who have undergone elementary statistics courses may recognize the term 'contingency table' in relation to the chi-square test. A two-dimensional contingency table relates two or more categories of two variables, allowing conditional probabilities to be inductively estimated (e.g., the chances of men versus women living beyond their 70<sup>th</sup> birthday). The computational simplicity of such calculations belies the complex and problematic tacit categorisation processes on which they are predicated..

5. Luhmann (1993, p. 23) takes a different view, arguing that, "*Only in the case of risk, does decision making (that is to say contingency) play a role*". One difficulty with this analysis is that it generates borderline cases which might or might not be awarded the status of contingency because opinions can differ as to whether outcome probabilities can be influenced. Luhmann (1993, p. 26) has to insist rather primly that this attribution does not depend "*on the whim of the observer*". Such awkwardness can be avoided in a way which remains true to the experience of contingency, for example, of somebody waiting to hear whether or not they have terminal cancer, by separating a sense of alternative outcomes being possible from views about their controllability; and by insisting that contingency is properly located in the mind, not in events, which merely happen.

6. Although not uncontroversial, this widely accepted boundary is empirically fragile, since nobody knows the point at which global warming will become self-sustaining and beyond human control. Boundary-setting, however dubious, provides the necessary starting point for the challenging task of mobilizing international prophylaxis. This coordinating function can only work effectively if doubts, however obvious, are tentatively set aside.

7. The present author is indebted to Jaan Valsiner for drawing his attention to this historical connection. The analysis of contingency also resonates with Sartre's *Nausea* (1938/2000) and *Being and Nothingness* (1943/2003), but the present author does not feel sufficiently knowledgeable to risk pursuing these connections.

8. Surprise may arise from event rarity (e.g., a large asteroid colliding with Earth), or from sampling limitations, as with Europeans not observing black swans before they discovered Australia. (However, the notion that all swans are white might be conserved through the classificatory manoeuvre of defining black swans as a separate categorical entity.) Both kinds of jolt to expectation arise from practical limitations to inductive reasoning, which can never show that non-observed events might not happen in the future, or be discovered elsewhere.

9. For example, people living in areas of greater socioeconomic deprivation can obtain better annuity rates because they are assigned the lower life expectancy associated with their locality.

10. Recent press reports (e.g., *Scientific American*, 7/04/09), have drawn attention to the decriminalization of previously illegal drug consumption in Portugal. As this example illustrates, the inductive prevention paradox can be broken, but only through a leap into the unknown, which may be justified through theoretical analysis. Others can then learn from the pioneers.

11. The author is indebted to Lisa Reynolds of City University for this instructive example.

### Abstract

In this chapter we discuss how people in present societies construct historical narratives. This topic, related to the field of the teaching and learning of history, extends to the debates in the last decade about the “history wars” maintained in numerous societies. All these cases share a process of consumption and production of historical narratives. To this respect, school history master narratives are analyzed in terms of six common features. On the other hand, a theoretical distinction between Romantic and Enlightened functions of teaching of history is presented. From this point of view, significant educational developments and research in this field are analyzed, showing the limitations and possibilities of both functions. Finally, the relevance of socio-cultural theories for the field of learning and teaching history is also presented, along with future developments in this area of study.

**Keywords:** learning history, historical narratives, national identities, constructivism

Questions regarding how people construct historical narratives in current societies have taken a center stage in recent public and academic discussion. Intense debates are taking place in different countries about the kind of historical contents that should be taught in the schools and through other formal and informal educational devices (Seixas, 2004). These debates started in the mid-1990s and are still alive in many countries. A vivid example is found in the recent controversy around the dictates of the Texas Board of Education in the United States. As a recent article in the *New York Times* (February 11, 2010) reports,

“Conservative activists on the Texas Board of Education say that the authors of the Constitution intended the United States to be a Christian nation. And they want America’s history textbooks to say so.” (Shorto, 2010)

The saliency and significance of this issue is revealed in the “History Wars” sustained in numerous societies

throughout the last decade (see Carretero, 2011, and Nakou and Barca, 2010 for comparative studies of different countries). As it will be shown below, these debates in different parts of the planet are the result of social and political changes related to the increasing globalization process and their implications on national identities (see Carretero, 2011, for Europe and Latin America; Eklof, Holmes, & Kaplan, 2005 for post-Soviet Russia; and The Academy of Korean Studies, 2005, for African and Asian countries).

### Inventing the Nation: Tailoring the Past

It is by no means casual that in a short span of time, the teaching of history—a topic often reserved to experts—became a prominent issue in furious public debates across the globe. History wars have led to the revision of the historical narratives in which, as Hobsbawm said, “the nation is invented” (1990; see also, Berger, Eriksonas, & Mycock, 2008). Research conducted in several

countries in the last 10 years has documented how the production of school historical narratives is closely related to the construction of national discourses (Carretero, 2011; Carretero & Kriger, 2011; Van Sledright, 2008). Interestingly, this revision of historical narratives coincides with, and probably originates from, the intensification of the globalization process and its social, political, and economic effects. Profound transformations such as the crisis of political identities, the emergence of new discussions about nationalisms, and the re-signification of the question “Who are we?” in any society affect the history that is taught to young people. In the context of the European Union, for example, several countries have undertaken a reinterpretation of the “national histories” taught in schools in light of the need to promote the notion of a common future. In a different context, Russia and the United States offer two salient examples of similar dynamics.

Within a very short period of time, from 1991 to 1992, all the history school contents in the former Soviet Union, as well as in many communist countries that were under its influence, were drastically modified (Ahonen, 1992, 1997). This entailed, among other things, that millions of students of different ages received a radically different version of their national past, and of the past in general, than what they had been taught in school up until then. After one decade and a half of introducing a liberal view of history in the schools, Russia is now again reconsidering its position about essential issues as Stalinism, in order to provide the Russian students a more positive view of their own past. Dramatic controversies have taken place in the last 5 years about the educational decision, originated in Vladimir Putin’s office, to require the use of an obligatory history textbook in any Russian secondary school (Halpin, 2007; Maier, 2005; Piattoeva, 2009).

In the United States, the neoconservative elite, which seized power in the 2000 and 2004 elections, impugned the new school-taught history contents, which had been designed by numerous specialists as a result of a meticulous, professional, and widely democratic work (NCHS, 1994; Symcox & Wilschut, 2009). The above-mentioned debate about the Texas Board of Education (Shorto, 2010) is clearly a continuation of these heated debates. Uncovering a new angle of this issue, Wineburg’s study on the communication across generations about the Vietnam War shows the process of

production of a national rhetoric that homogenizes popular views despite the complexities of the lived past. Wineburg explains how, “In a curious twist of historical revision, Vietnam, in the eyes of these young people, had become a war waged without supporters,” and uses the concept of “occlusion” to describe the process by which “stories, images, and cultural codes . . . become muted in the transmission from one generation to the next” (Wineburg et al., 2007, pp. 65–66).

That the history taught to young people is tailored to fit with current national discourses had already been evidenced in comparative analyses of the history curricula. Several of these studies show that the versions of the recent past taught to the citizens of historically related societies could not differ more from each other. In some cases, mandatory school contents are presented in an outright biased way and full of inexactitudes or falsities. In other cases, the interpretation of the past presents a vision that is hardly acceptable to the country to which the comparison is made. For example, Spanish school textbooks have traditionally omitted essential issues on the American colonization, such as the subjugation of indigenous people or slavery as generalized social and economic practices. In contrast, such issues are highlighted in Mexican or Brazilian textbooks (Carretero, Jacott, & López-Manjón, 2002). Similar findings are reported for France/Algeria, Great Britain/India, China/Japan (Ferro, 1984/2002) and Korea/Japan (The Academy of Korean Studies, 2005).

These different cases reveal intellectual and educational movements in which a reconsideration of the past is emerging, favoring the profound revision of national and local histories both at the academic level and at the school level. Despite the particularities of each case, they have certain features in common:

- a) The search for a significant relationship between the representation of the past and formation of identity, whether national, local, or cultural;
- b) The conflict between mythical and objectified histories;
- c) The social need to reelaborate past conflicts in function of the undertaking of future projects, and
- d) The still incipient utility of generating a comparison between alternative histories of the same past.

## ***Evolving Approaches to the Study of the Production of Historical Narratives***

Scholars in the field of history education have approached these phenomena in varied ways. Ferro's seminal study (1984/2002) on how the past is taught to children around the world introduced the important distinction between official and unofficial histories, the first being the narratives constructed and maintained by the Nation-State and the second being the counter-narratives of minority groups. Further studies have examined this distinction in more depth. The recent history wars revived an interest in studying the processes of ideological production and distribution of official histories, revealing through the analysis of curricula, textbooks, and the narratives of teachers and students how a hegemonic social and cultural device—the school history—contributes to create the cognitive and affective foundations of “imagined communities” (Wertsch & Rozin, 2000). Wineburg and colleagues (2007, p.70) in turn, discuss this in terms of Michael Schudson's (1992, p. 64) distinction between, *interest theories*, in which cultural meanings are predetermined by an underlying economic and political agenda, or *semiotic theories*, in which cultural products become, by definition, expressions of the search for meaning (see also Valsiner, 2010).

Building upon and extending this tradition of research, a new and important line of questioning has emerged: How do the conflicting narratives found in academic and public debates and in school textbooks, manifest in students' minds? How do the features characteristic of the process of social production of historical narratives translate into the processes of individual consumption of historical narratives? This paper expands on this last line of inquiry.

### **The Consumption of Historical Narratives *Pablos' Construction of the Reconquest: An Example***

The following example of a historical narrative offered by a Spanish college student illustrates the depth of these emerging questions. We will draw upon this example to discuss different layers of the problem, and corresponding lines of inquiry about the processes of production and consumption of historical narratives. The narrative in this example was collected during an interview conducted by one of the authors as part of a research project investigating the development of understanding of causal explanations in history (Carretero, López-Manjón,

& Jacott, 1997). The goal of the study was to determine if college students were able to understand significant historical events based on abstract socio-economic and political causes, as opposed to personalized motives that tend to be more concrete and typical of younger students. The interviewer asked a group of college students to explain what led to the defeat of the Arabs in the battle over Granada in 1492, when the last Muslim ruler surrendered his kingdom to Ferdinand II of Aragon and Isabella I of Castile. This victory, which led to the definitive expulsion of the Arabs from the Iberian Peninsula (the territory that is Spain and Portugal today), is considered an essential moment in Spanish history because it represents the starting point of the Spanish Empire, followed soon after by Columbus' “discovery” of America, in an expedition financed by the aforementioned king and queen.

Pablo, one of the interviewees (21 years old), provided an account of the victory of the Catholic monarchs that included most of the staple facts and motifs of current historiographic research that has made its way into high-school and college history courses. Dissecting the various pieces of his extensive account we learn that:

- The Arabs first arrived in 711 and expanded throughout the peninsula within a few years.
- They encountered a collection of disparate medieval Christian kingdoms that were establishing in the Iberian Peninsula since the collapse of the Roman Empire.
- There were many and frequent fights among Christians rulers, who on occasions allied with Muslim rulers in an attempt to defeat their opponents and conquer their territories.
- At other times Arabs, Christians, and Jews coexisted and developed peacefully.
- The frontiers of Arab and Christian domains ebbed and flowed as different kingdoms expanded and contracted throughout the 800 years in which the Arabs resided in the Iberian Peninsula.
- The Catholic king and queen were monarchs of the Kingdoms of Aragon and Castile, respectively.

Pablo's account displayed a relatively well-developed capacity to form complex causal explanations, which is not uncommon among students of his age and background. He considered multiple social, economic, and political factors, he weaved together long-term and mid-term processes with more immediate events, and he kept an accurate

record of the chronology of key events and turning points. Yet, shortly after completing this account Pablo paused for a few seconds and then offered an epilogue to his explanation that caught the attention of the interviewer: “Well, at any rate, the most important thing, which I didn’t mentioned before, is that nobody likes his own nation to be invaded.” The interviewer probed what he meant: “Which nation are you thinking about?” to which Pablo replied: “Spain! The Muslims had invaded Spain since 711. So really, what the Catholic King and Queen did was to finish up the Reconquest.”

Pablo’s epilogue revealed two competing narratives that coexisted in his mind. At this point, the narrative of the “Reconquest,” (or the Christian reconquering of the Iberian Peninsula from the Muslim invaders) displaced the more current historiographic version that organized the first part of his interview. Interested by this apparent contradiction, the interviewer probed further (see Carretero, Kriger, & Lopez, 2010; Lopez, 2010).

**Interviewer:** *Why did this happen (the Reconquest)?*

**Pablo:** *Well, because the Arabs had wounded, so to speak, the Spanish Christian pride. Then, as usual, you have to recover something that was taken away, at least you have to try, it doesn’t matter how long it takes.*

**Interviewer:** *And the area that you have drawn as al Andalus [Arab territory, about one-third of the Iberian Peninsula] was it, at that time, rightfully Arabic? What do you think?*

**Pablo:** *Well it is true that several centuries had passed, and it might be that they (the Arabs) had persuaded themselves that they had the same right as the Christians, or even more. But I still think that if that was at first a Christian territory ... what happened is that it took them a long time to regain their territory. I still think it’s legitimate Christian territory.*

**Interviewer:** *OK, we’ve been using about the word ‘Reconquest.’ Tell me a little about what that term means to you?*

**Pablo:** *Well, for me, to reconquer is to recover a territory that it was assumed it was mine. You know, if I have this whole table and I’m studying in it, and if you, or another guy comes along and ... if you ask me, then maybe I’d say half and half, maybe ... But if you just come and take over, pushing me out bit by bit, little by little ... if I put my books here but you still come a little closer ... Well, there has to come a time when I get angry and say: ‘Hey, what are you doing! Let me ...!’ But what we are talking about now is something of much more importance, because what’s mine is mine! Then, in my view, the goal of the*

*Reconquista was to retrieve something that was mine and had been forcibly taken away.*

On logical grounds, the first narrative undermines the second: The Christian kingdoms did not have control over the whole territory, and they did not conform to any sort of united entity. Thus, Spain, the historical subject of the Reconquest, did not exist when the Arabs arrived in 711, nor during the hundreds of years when they occupied the Iberian Peninsula. In consequence, strictly speaking, there was no territory to be reconquered. The first portion of Pablo’s account reflects this understanding. However, the very use of the concept of *Reconquista*, prominent in the more traditional historiography, determines how Pablo ultimately makes sense of the past. He draws upon the “natural anger” that anyone would experience when “having one’s nation invaded” to explain the moral force that drove the Catholic Queen and King to the final victory. Then, he redefines the unsteady and conflictive expansion of the Christian kingdoms as a long and concerted effort on the part of the Christian rulers guided by the shared ontological purpose of “recuperating” their vast territory lost to the Arabs since 711.

### ***Contradictions and Ruptures in the Construction of Historical Narratives***

How can Pablo sustain a complex causal explanation of this historical event together with a mythical account of it? The coexistence of these two competing historical narratives in Pablo’s mind suggests that the process of consumption, and the related attempts of meaning making, involve perhaps inevitable contradictions and ruptures. How do these happen? Where do they arise? How does the individual manage them? How do we account for them? These questions are central to the purpose of this paper, and the following pages discuss different approximations to them. Some emphasizes the socio-cultural processes that shape the individual’s construction of historical narratives, while other approximations emphasize the individual cognitive processes involved. We search also for interaction between the two.

#### **THE Pervasiveness of Ontological Narratives**

Although Pablo demonstrates a rather abstract and well-organized understanding of the past that derives from the recent circulation of a new historiographic narrative in school textbooks and public discourses, he simultaneously reveals a deep

internalization of an ontological and essentialist concept of the Spanish nation that is pervasive in his society. The following excerpt from a classical textbook (Alvarez, 1965/1997) captures that view that once dominated the teaching of history in Spain, and still today has a strong hold on a variety of cultural artifacts such as popular literature and movies, monuments, and casual conversations. See Box 28.1.

Demonstrating the pervasiveness and importance of this narrative of the *Reconquista*, former Prime Minister Jose María Aznar, claimed in a recent speech “the Arabs never apologized for having invaded Spain 13 centuries ago” (*El País*, September 23, 2006).

Content analysis of Spanish textbooks and their changes in the last decades (Carretero, 2011; Valls, 2007) coincide on the importance and ubiquity of the Reconquest narrative as a central constituent of the national identity. The construction of Spain and the Spaniards as heroic subjects, opposite to, and able to overcome the Arabs, is a purposeful cultural production. Spanish collective memory was first created during the eighteenth and nineteenth centuries as a basic support for the construction of a national identity, and it has since been maintained on a basic opposition to the Arab identity (Alvarez Junco, 2011; Boyd, 1996). Within it, the notion of “reconquering” serves to organize the past in a narrative structure that defines a heroic character (Spain) endowed with an intrinsic purpose (recuperating its

territory). Both elements are rooted in an ontological assumption: Spain, the essential national spirit, preexisted to the foundation of the nation itself and led the actions of its people toward a predefined destiny. Once the central motif of the Reconquest is introduced in the account of the 800-year presence of the Arabs in the Iberian Peninsula, the past is reorganized in such way that serves to justify past, present, and future actions. In a mere chronological sense, 800 years is quite a long process to “recuperate” a territory. Still, national narratives tend to use time in such a mythical way<sup>2</sup>.

### ***Narratives as Cultural Tools***

Socio-cultural analyses of school history contents show how closely these constitute “official narratives” that purposefully seek to determine subjects’ representations of the past. The nation’s past, present, and future are organized in official versions of the so-called “nation’s history” that are distributed by schools. These official versions carry an argumentative continuity: an “identitary us” is constituted, and the typical nineteenth-century conception of the “nation” as a community of destiny (Smith, 1991) is transmuted into new imagined communities. Hobsbawm (1990) defined this as “the nation’s programmatic mythology.”

“National histories” were born to be taught. They are contained in a variety of records such as monuments and patriotic celebrations. Patriotic rituals play an important role in many countries. The case of Latin America is telling. In countries like Argentina, Brazil, Chile, or Uruguay, at least four historical and patriotic commemorations take place in school every year. They consist of dramatizations and discussions about the events, battles, and national heroes related to the processes of independence of each of these countries. In the United States we find these kinds of activities in many historical sites and monuments (Beckstead, 2012), besides the activities performed at schools. These scenarios, rather ignored until now by researchers, convey an important amount of historical content that influences students’ understanding of the history contained in the formal curriculum and textbooks (Carretero, 2011). Students consume and use national historical narratives that they learn not only from the history textbooks but also from these kinds of events, in and out of the school. The school record contained in textbook narratives is probably one of the most important and effective means in determining how people consume the narratives produced in their respective societies. School

#### **Box 28.1 The Reconquest: Asturias, León, and Castile**

The Reconquest: this is how we recall the struggle sustained by Christians during almost eight centuries against the Arabs in order to expel them from Spain.

Spain is among the nations that have contributed the most to the world’s civilization and had greater influence in world history.

To prove this, it is enough to mention: its defense of Europe during the Reconquest, when she stood between Europe and the Arabs; the discovery, colonization and civilization of America, as well as the heroism she deployed in the Independence War, which contributed to Europe’s salvation from Napoleon’s Caesarism.

This Spain is your Motherland. Know her history. Always take from her the virtuous and heroic examples offered to you by your ancestors and try to be their continuator at all times.

versions, usually heroic and celebratory, unite stories with different degrees of importance in a long narrative chain that links them by virtue of the role they play in the construction of what we might call the nation's "saga." Most of these sagas adopt a teleological form; destiny is already contained in the origins, and knowledge of the "roots" of a nation is indispensable for knowing how to act in the future. As Alridge (2006) and Straub (2005) have shown, these "master narratives" pervade underneath a variety of specific contents and through time. Although specific narratives may change frequently, these underlying master narratives rarely change, and manifest once and again in subsequent revisions. From the perspective of socio-cultural psychology, official narratives on the nation's origin constitute cultural tools (Wertsch & Rozin, 2000) that configure schematic templates in students' minds. These schematic templates define the underlying structure of historical narratives and of people's understanding of them.

#### USES AND CONSEQUENCES OF INDIVIDUAL AND NATIONAL FORMATS OF HISTORICAL NARRATIVES

Although historical knowledge does not only occur in a narrative format, it often does. Barton and Levstik (2004) distinguish two specific types of narratives that appear prominently in education (and in other cultural practices): individual narratives and national narratives. The typical uses of these narrative formats have profound implications for students' construction of historical understanding.

Individual narratives focus on the personal lives of important historical figures, as opposed to those whose focus are more abstract entities and events such as economic systems, civilizations, processes of social change, and impersonal concepts of this kind. We can all recall these individual narratives from our own school experience: stories about Columbus, Julius Caesar, or Napoleon would be classic examples. Paxton (1999) and Alridge (2006), in comprehensive analyses of American textbooks, show that the narratives about "great" men and events that led America to an ideal of progress and civilization continue to be the prototypical way in which many historians and textbooks spread knowledge. Frequently, these figures are studied in isolation from other individuals and events that constitute its historical context, while the more controversial aspects of their lives are not reflected.

The use of these types of individual narratives is justified with the idea that a more abstract content

results in greater difficulty in understanding, and lower levels of student motivation. As pointed out by Barton and Levstik (2004) these individual narratives have the power to humanize historical contents. However, this kind of narrative greatly influences the way students understand and analyze information about the past, and they may result in a series of typical biases that hinder a more complex understanding. When the narratives are purely personal or individual, there is an absence of structural causal explanations based on social, political, or economic factors. In many instances they personify a historic event in a particular character, which is represented as the main actor and the cause of its development (Carretero et al., 1994; Hallden, 1994). We find examples of such embodiment in the "discovery" of America by Christopher Columbus, or the emancipation process by Abraham Lincoln (Alridge, 2006). This simplification of historical contents decontextualizes the events of the past, and relegates to oblivion other characters or social groups that participated in them.

National narratives are another type of narrative frequently found in schools and in daily life. In schools across the world, the study of history often focuses on the history of their own country. This is not surprising if we consider, as we will discuss later, how the teaching of history emerged at the end of the nineteenth century. National narratives diminish the importance of other stories: Students do not have access to the most controversial aspects of history, hindering their understanding of conflicts, dilemmas, and ultimately, the reality of democratic societies in which they live (Barton & McCully, 2010). In this way, they determine the type of explanations that students give to critical historical events. For example, in American textbooks, the vast majority of national narratives are organized around the concepts of progress and freedom, and students reuse these motifs to explain past events (Barton & Levstik, 2004). Thus, the resistance of Native Americans in the face of waves of European settlers is seen as an obstacle to achieve progress, and the Vietnam War is justified as an American response to the need to bring freedom to that country. In relation to other countries, where also native history is also part of the culture, similar contents can be found in both textbooks (Carretero, 2011; Clark, 2007) and students' minds (Carretero, Gonzalez, Rodriguez, & Carreño, 2010).

## *Features of the Production and Consumption of Historical Narratives*

Several studies (Carretero, 2011; Carretero & Kriger, 2011; Van Sledright, 2008) describe the features and functioning of historical narratives and explain their presence in the production of school history textbooks and other cultural artifacts that support the Nation-States. We can distinguish six salient characteristics:

- 1) Exclusion-inclusion as logical operation contributing to establish the historical subject.
- 2) Identity as both cognitive and affective anchor.
- 3) Mythical and heroic character.
- 4) Simplification of historical events around the main motive of search of freedom.
- 5) National narratives offer fundamental moral examples and directions.
- 6) Ontological and essentialist conception of the nation and its nationals.

Most of these features have been identified and explained in the process of production of historical narratives by cultural media (school history textbooks among others). What is less clear is how they manifest in minds of citizens who appropriate these narratives. A brief example will assist us in elucidating these features, both in the production and the consumption of these narratives.

Consider the following excerpt from a dialogue between Federico, a 6-year-old Argentinean boy who describes to a Spanish interviewer a school activity in which he and his friends dramatized the events of May 25th, celebrated in the country as the day of Independence from Spain. After recounting several details of their reenactment, the interviewer asked: "But, what was the celebration about?" to which Federico answered, "Well, I do not know really, but I think it was when we were able to be free." Probing his thinking, the Spanish interviewer paraphrased his words asking: "When *we* were able to free?" Immediately, Federico corrected "well . . . you were not. We were. This is to say, we, the Argentineans." "Oh, well, it is true," the Spanish visitor conceded, "you, the Argentineans, were free, but why, how did it happen?" Federico responded, in a very frank manner, "Well, I am not sure if I understood well the whole thing. I better ask the teacher again . . . but I think we were free when . . . we, the Argentineans, escaped from the Pharaoh" (Carretero, 2007, p. 127).

## **EXCLUSION-INCLUSION AS A LOGICAL OPERATION THAT CONTRIBUTES TO ESTABLISH THE HISTORICAL SUBJECT**

A salient feature of this example is the mastery of the distinction between "we" (in this case "Argentineans," but of course the historical subject could be of any nationality) and "the others" that the child shows. As different studies have shown, this distinction concerning the national "we" is already mastered by children between 6 and 8 years of age (Barret & Buchanan-Barrow, 2005), even though children are not able at that age to define precise attributes of this category. In our example, it is interesting to note that this national "we" is not only social and political, but also historical (Carretero, 2011). The very explicit "not you, but we, the Argentineans" evidences that Federico is already making a basic distinction based on a logical operation of inclusion vs. exclusion, which he will probably continue to use in his learning of history, in and out of school. Typically, this logical operation is performed in such a way that positive aspects are almost always assigned to the national "we," while any critical or negative aspects are assigned to "the others" (Todorov, 1998). Likewise, negative features of the national "we" tend to be ignored or justified. It is reasonable to presume that historical master narratives will be learned and developed later on based on this fundamental distinction (Barton and Levstik, 1998), where the national "we" is being used as very well-defined category.

## **IDENTITY AS BOTH COGNITIVE AND AFFECTIVE ANCHOR**

The distinctions concerning a national "we" vs. the "others" is probably based on emotional and affective features as much as on cognitive ones (Barret & Buchanan-Barrow, 2005). This emotional dimension facilitates a strong identification process. In this example, Federico uses the narrative in such way that includes him in a particular community, the Argentinean one. In this regard, it is also interesting to notice how the process of categorization in Federico's mind draws no distinction between past and present times: the "we" of the present that includes him (Argentineans) is the same "we" of the past (the patriots of the Virreinato del Rio de la Plata). This overlap, which makes no sense from a historical point of view (Argentina did not exist at the time of independence. *Sensu strictu* they were inhabitants of the Virreinato del Rio de la Plata,

not Argentines), makes perfect sense to Federico because, as the master narrative dictates, the essence of the Argentinean nation pre-existed the facts.

In order to fully understand how historical narratives are constructed it is essential to know much more precisely how these emotional and affective components of historical contents influence students' minds from an early age, and in particular, how they provide support to the logical distinctions of exclusion and inclusion.

#### MYTHICAL AND HEROIC CHARACTERS

One of the main differences between historical and mythical explanations is precisely the absence of time in the latter. It is totally irrelevant, for example, to know Oedipus' date of birth or any other specific temporal markers. Myths and mythical figures and narratives are usually free of time restrictions. In contrast, one can say that history is making its appearance when time and its constraints are introduced into a narrative. In our example, it is clear that Federico's understanding of Argentinean independence events does not include a firm grasp of the temporal dimension. Pharaoh's intrusion aside, it is telling that he links elements from a narrative of liberation in ancient Egyptian times with a narrative of liberation of the Latin American bourgeoisie during the nineteenth-century revolutions. In fact, this is a common characteristic of historical understanding at this age, in which children find it very difficult to understand and use chronologies and other conventional representations of time in history (Barton, 2002; Carretero, Asensio, & Pozo, 1991). The appeal of mythical national narratives probably builds on this developmental trait. Usually, children are not able to master chronological aspects of historical time until they are approximately 12 years of age.

One could hypothesize that as students grow and improve their understanding of historical time, core mythical elements of their historical narratives would subside. However, if we recall Pablo's account of the Reconquest of Spain from the Arabs, it is clear that mythical features remain in the historical narratives of children older than 6 years old. Although the temporal frame may adjust to disciplinary canons, the heroic tone and the essentialist understanding of the nation evidence the permanence of mythical narratives' core elements. This is, indeed, a striking permanence, at least from a developmental perspective. Besides the cognitive-developmental models of historical understanding, other developmental

theories would predict the gradual disappearance of mythical elements. For example, well-established theories of narrative development (Egan, 1997) claim that human beings develop a narrative ability that goes through a number of stages: somatic (0 to 2 years of age), mythical (3 to 6 years), heroic (7 to 10 years), philosophical (11 to 15 years) and ironic (15 years of age and onward). Thus, if national historical narratives often maintain their mythical and heroic components even during adolescence and adulthood, times at which individuals should be able to generate philosophical and ironic historical narratives, it is worth investigating what kind of socio-cultural mechanisms yield this result.

#### SIMPLIFICATION OF HISTORICAL EVENTS AROUND THE MAIN MOTIVE OF SEARCH FOR FREEDOM

National narratives tend to simplify the enormous complexity of historical processes and events around core common moral themes. These moral themes typically relate to the sense of destiny portrayed in teleological accounts of the past. Several studies have documented how this feature manifests in students' thinking. For example, Barton and Levstik (2004) and Penuel and Werstch (2000) studied how students understand the process of independence of their own nations, drawing upon a historical master narrative in which the search for freedom is the core theme, and the starting point of the new community. Their representations consist of a network of rather concrete concepts. Independence resulted from the intention of a group of individuals to be free from some form of domination. In the case of many American, African, and Asian countries, the independence narratives obviously relate to the domination of one of the European nations: Spain, the United Kingdom, France, and so forth (The Academy of Korean Studies, 2005; Ferro, 1984/2002). Abstracts and complex causal factors, such as economic relationships and interests, political developments, and international influences are basically absent of these narratives, even in the case of adolescents and adults (Carretero, López Manjón, & Jacott, 1997). The following examples (Carretero, Gonzalez et al., 2010) illustrate this feature as interviewees explain how the independence of their respective countries came to happen:

12-year-old Dario responded that: "*Yes, the Spanish dominated... It was when they used us as slaves, wasn't it? And we wanted independence.*"

Guillermo, one of the adult subjects interviewed expresses: “*Well, we said to ourselves, this is enough. And we were able to say this to the Spanish.*”

Moreover, it is common to find in such historical narratives that social groups and social conditions that put into question the central theme of the narrative are excluded or represented in misleading ways. For example, although a significant number of Argentinean children and adolescents think that Spaniards treated the American “colonists” as slaves, at the same time they ignore the enormous economic significance of the slavery of the African American population, which, in all countries, was maintained by the colonists well after the independence (Carretero, 2011).

Along similar lines, in the United States the historical master narrative of search for freedom organizes around the theme of progress (Barton & Levstik, 1998). This tendency to consider that society undergoes ever-increasing progress—both technological and in regards to the standards of living—is quite naïve and gives rise to oversimplification in historical understanding. Insofar progress is deemed as the teleological direction of a society, the complexity of a nation’s experience must be disguised.

#### **NATIONAL NARRATIVES OFFER FUNDAMENTAL MORAL EXAMPLES AND DIRECTIONS**

The moral dimension of historical master narratives is quite an obvious one, but unfortunately it has not been explored enough, particularly from an empirical point of view (Barton & Levstik, 2004). Interestingly enough, on the classical debates on the nature of historical knowledge, the view of White (1987) about historiography as a production of narratives having an important moral component has had an increasing influence. But this idea has not received much attention as an inspiring hypothesis in order to test if school master narratives are producing moral interpretations in students’ minds. To this respect, our expectation would be a positive one because historical contents are presented very often to students in a way closer to moral stories than to historiographical explanations.

National historical narratives, both in and out of school, play an important role as moral vectors, because they are designed with that goal in mind. This purpose is accomplished in at least two ways. First, the master narrative establishes the distinction between “good” and “bad” options, people, and decisions. Typically, the first one is associated with

the national “we,” and the second one is related to “they.” Thus, the logical and moral truth is always on the “we” side. For example, in our research (Carretero, Kriger, & Lopez, 2010) we have found how young adolescents considered that Christians have the right to “recuperate” the territory, inhabited by the Arabs for 800 years, because it was considered “Spanish territory.” On the contrary, according to the same students, the Christians have no right to conquer the American territories because they belonged to the natives.

Second, master narratives offer living examples of civic virtue, particularly of loyalty. As it can be easily inferred, this loyalty function was essential in the construction of the nation, and it can still be found in many symbolic forms. For example, if we consider the way that the World Soccer Championship is followed by any citizen in the world, it would be inconceivable that a citizen could support any team belonging to a different nation, even though that team may play better.

#### **ONTOLOGICAL AND ESSENTIALIST CONCEPTION OF THE NATION AND ITS NATIONALS**

In their effort to simplify the account of events, national narratives also reduce the subject of history to particular groups who participated in the events and achieved the predestined goals. This is an extension of the function of master narratives discussed earlier. The subject of national narratives may well be a collective one, but its features coincide with those of one single and particular group. We can anticipate that in the studies discussed above, the historical subjects of students’ narratives of Independence are influential Caucasian colonists, most of them established merchants and landowners. They are the sole protagonists of the narrative because they embody the struggle for freedom or progress. Interestingly, students tend to identify this generic and idealized subject with the present whole population of the nation, similar to what we saw earlier where students identify the “we” of the past with the “we” of the present. A clear example of this effect can be found in the historical meaning of the statement “We the people . . .” in the U.S. Constitution. Probably most students think that this subject included each and every inhabitant of the new nation, missing its rather restricted meaning that excluded the African American and Native American population, along with women.

Similarly, the end result or main achievement portrayed in these narratives is represented in ontological terms. This end result is the creation of the nation, but the nation is understood by most of the subjects as an essentialist entity that preexists the very process of creation. Pablo's account of the Reconquista, and Federico's account of the Independence, both illustrate this feature. Respectively, they consider that Spain and Argentina existed much before the historical formation of each nation. The national essence exists independently of historical developments. Thus, in one of our studies (Carretero, Gonzalez, et al., 2010), Argentinians (young students and adults) were asked if the colonists who participated in the first political demonstration in favor of a broader political autonomy by 1810 were Argentinians. As a matter of fact, and *sensu strictu* they were not Argentinians yet, because they were colonists questioning the political power of Spain. Thus, taking into account that this event happened 8 years before the Independence took place, our participants considered those colonists as definitely Argentinians because, as some expressed, they think Argentina and the Argentinians always existed. Thus, it can be concluded that the historical process of being member of a Nation-State tends to be seen as something that is already predetermined, in an ontological and essentialist way, and not as a result of different political, social, and economic influences (Leinhardt & Ravi, 2008).

### **The Hidden Tension of Romantic and Enlightened Goals of the Teaching of History**

So far we have discussed the construction of historical narratives, emphasizing the function they serve in supporting the construction of national identities. We have highlighted the mythical format that these narratives often adopt as they rely on ontological and essentialist concepts of the nation, and the resulting discursive functions they serve. But if national narratives were the only element in the picture, we would not see a rupture in Pablo's account, and in fact the process of construction of narratives would be far less interesting and intriguing.

What is interesting is the combination of discourses in his account, which reveals, among other things, that despite the pervasiveness of national historical narratives, and the influence they have in shaping peoples' understanding of the past, they have not gone uncontested in academic reflection

or in educational practice. The inconsistencies and ruptures present in Pablo's account of the victory of the Catholic King and Queen over the Arabs in the Iberian Peninsula in 1492 are an eloquent example of the deep contradictions that define the construction of historical narratives in the minds of individuals. In order to better understand this phenomenon, we must take a closer look at how historical knowledge became part of the school contents, and the kind of transformations that occurred to them since.

### ***The Coexistence of Goals***

History has been part of the national curricula since the late nineteenth century in almost any country that established a public educational system. In fact, the constitution of history as an academic discipline occurred very close to its presence in the school curriculum. What was the purpose of such early inception in the educational system? Most nations considered, since their very origins, that learning history was an essential part of the formation of their future citizens. History education was one of the pillars in the foundation of modern nations. However, from early on, this ultimate purpose of shaping the desired citizens translated into two parallel goals that generated and developed competing views of school history still present in today's practice and discourse.

Different researchers have considered the existence, implicit or explicit, of competing objectives of school history (Barton, 2008; Carretero, 2007; Cuban, 2002; Wineburg, 2001) In this chapter we redefine those objectives as *Romantic* and *Enlightened* because their features and functions stem from their respective intellectual roots in Romanticism and the Enlightenment. In other words, history is taught in any national school system attending to two different goals: to make students "love their country" (Nussbaum and Cohen, 2002) and to make them "understand their past." Based on this distinction, we analyze the continuous and seemingly irreducible tension that exists between the identity-formation function and the critical function played by historical knowledge in the construction of historical narratives (see Carretero, 2011 for an extended development of this idea). Can these two goals be simultaneously achieved? Can people love their own country, and at the same time develop a critical understanding of its functioning? This chapter attempts to make a contribution to understand these issues.

## THE ROMANTIC GOALS

From the very beginning, school history was inspired in the Romantic Goals of creating and maintaining a cohesive national identity that supported the emerging centralized political project of Nation-States. According to Anderson (1983), this process required the constitution of imagined communities whose members' uniform stories, symbolic representations, and abilities superposed to the territory and state administration. History education was a singular but fundamental strategy used to achieve this goal, and it is still today.

Research on the history of history education and school textbooks (Carretero, 2011; Ferro, 1984/2002; Foster & Crawford, 2006; Nakou & Barca, 2010) shows that history has been recurrently positioned in the school curriculum to instill in the future citizens, from a young age, the symbolic representations, the sentiments, and the values that guarantee:

- a) A positive assessment of their own social group's past, present, and future; both local and national.
- b) A positive assessment of the country's political evolution.
- c) Identification with past events and characters and national heroes.

Barton and Levstik (2008) synthesize the different ways of achieving these goals, by selecting topics that focus only on the groups with which students should identify, focusing the content of teaching on establishing a common origin, developing imagined communities around which such loyalties should form, glorifying the country's past, and providing historic models of civic virtue (pp. 358–361). As the French historian M. Ferro, author of a pioneering work in this field, has sentenced sparing no clarity: "The image of other people, or of ourselves for that matter, reflects the history we are taught as children. The history marks us for life" (1984, p. IX).

Why should these goals of history education be considered "Romantic"? There are at least two important reasons. First, because the emergence of the Nation-States cannot be fully understood without the influence of the Romantic ideas and their intellectual context. The whole idea of the nation as a specific ethnic group that is under a process of awakening and finally it constitutes itself in a community of destiny, cannot be conceived without the contribution of the Romantic ideal. Precisely historical narratives, in and out of schools, express

one essential component of that Romantic ideal. Secondly, the Romantic goal of history education is achieved through an intense and rapid process of identification with one's own nation through emotional, affective, and social-interaction mechanisms. To love a country is certainly an expression that does not denote specific reasoning or cognitive processes, but mainly affective ones. As a matter of fact, national identification processes and their final results are considered by political forces, such as nationalism or patriotism, as the necessary prerequisites to be willing, in case of necessity, to die for the motherland (fatherland).

## THE ENLIGHTENED GOALS

Aside from the Romantic focus, history education has also pursued enlightened goals of fostering critical citizens capable of informed and effective participation in the progress of the nation, including a possible criticism to the own local or national community (Adorno & Horkheimer, 2002; Habermas, 1990). From this perspective, the specific capacities that develop through the disciplined understanding of the past and its relations to the present are important contributions to the cultivation of a democratic mind that has great civic value in liberal societies. Barton and Levstik (2008) review several contributions that have been often attributed to the teaching and learning of history: The ability to form well-documented and plausible critical interpretations based on reasoned considerations of evidence from multiple sources, an understanding of societal systems of relationships and dynamics of continuity and change, the possibility of tracing the origins and evolution of current issues, the capacity to consider the value dimensions of public issues, and the ability to contextualize the differing perspectives of people (pp. 355–356). This Enlightened tradition places at the forefront the development of rational abilities; and it displaces the management of identities, values, and emotions that may cloud a critical understanding.

In its most current manifestation, Enlightened goals translate in several countries into disciplinary and cognitive objectives that generally consist of the following:

- a) To understand the past in a complex manner, according to age and educational level, which usually implies mastering the discipline's conceptual categories (Carretero & Voss, 1994).
- b) To distinguish different historic periods, through the appropriate comprehension of

historical time, in order to understand social problems and issues, situated at different periods and having distinct characteristics (Carretero, Asensio, & Pozo, 1991; Barton, 2002; Lee, 2005).

c) To understand the complex historical multicausality, in which individual and collective motivations interact with causal factors in intricate ways (Carretero et al., 1997; Bermudez & Jaramillo, 2001; Perkins, 2008).

d) To relate the past with the present and the future; this entails an important link with other social sciences and also with civic education (Von Borries, 1994).

e) To approach the methodology used by historians in ways that allow the student to learn history in an intellectually active way and to understand historical knowledge as a depository of problems that can be solved with objectification systems (Perfetti, 1994; Wineburg, 2001).

These Romantic and Enlightened goals of history education coexisted from the very beginning and developed over time. Often, when Romantic goals took the center stage, the Enlightened goals receded to a side stage, and vice versa. Yet, this ebb and flow defined a long century of pedagogical practice and academic reflection, that help us understand how citizens in present societies consume and construct historical narratives, and how we understand and explain that phenomenon.

The Romantic approach to the teaching of history was the dominant discourse and practice in different countries up until the postwar era. As we discussed at length earlier, this approach placed at the forefront of the teaching and learning of history the management of values and sentiments for the sake of building homogeneous national identities. Simultaneously, it displaced the idea of fostering through the teaching of history any form of critical rationality that threatened the cohesiveness of the national projects.

Beginning in the 1970s an Enlightened approach reemerged and dominated the field for the next three decades, installing a new perspective on the nature of historical knowledge and the purposes of teaching and learning it. Countering the Romantic tradition, Enlightened approaches in different countries advocated from early on for a teaching of history that explored the complexity of historical developments, recognized divergent experiences and multiples perspectives, contested national myths, scrutinized

the darker episodes of the national past, and challenged the celebratory narratives (Barton & Levstik, 2008, p. 361). Taken as a whole, the Enlightened approach highlights reasoning and the development of thinking skills, and the mastery of explanation and plausible argumentation.

### **Different Ways of Explaining Ruptures**

The evolution or transformations in the goals of history education explain how we account today for the ruptures and contradictions in the construction of historical narratives.

#### ***The Early Version***

Early manifestations of the Enlightened goals appeared during the first decades of the twentieth century in Europe and the United States. In the spirit of progressive movements it was proposed that history education should serve purposes other than furnishing the cultural memory of youth with glittering heroes, robust political landmarks, and other patriotic symbols. The idea of developing a rational understanding of the past through school curriculum and pedagogical practice were part of the progressive effort to open the classroom to the pressing complexities of social life (industrialization, urbanization, and immigration at that time) and to reframe the role of schooling (the teaching of history and social studies included) as the formation of habits of mind and thinking skills necessary for a reflective engagement in democratic citizenship (Dewey, 1910/1933, 1916; Rugg, 1921; Osborn, 1939; Griffin, 1942).

In the late 1950s and 1960s several programs for the teaching of social studies and history were developed following these Enlightened goals. Two prominent influential forces shaped this. In the United States, new developments in the social sciences made their way to the school context, when the “new social studies movement” engulfed the teaching of history. By and large, this approach saw the discussion of controversial issues as the necessary strategy to educate reflective citizens, and grounded its practical models on an *inquiry-based pedagogy*.

The emerging discourses of the “new social studies” recommended practices for teaching that proposed to help students acquire the knowledge and methods of inquiry of the social sciences. For example, the now classical work of Hunt & Metcalf (1955, 1968) outlined a curriculum for a “rational inquiry on problematic areas of culture.” Massialas and Cox (1966) insisted on an “emphasis on ideas

and hypothesis,” “a stress on analytical rather than descriptive processes,” and “the functional use of facts.” Terms like “value analysis,” “evaluation of data,” “skills of definition, classification, and generalization” were the typical language of proposals that claimed that these were the kind of abilities that competent citizens would need in a democracy, and the teaching of history and other social studies could and should develop those capacities in citizens.

“The revolution in education has at last reached the field of social studies,” wrote Massialas and Cox (1966)—with great enthusiasm. In their view, “the conditions of the society made it imperative that the schools accept as its role the ‘progressive reconstruction’ of the culture” rather than affirm itself as “a conserving agent of the past achievements of the culture” (p. 21). “Today’s society presents the school with conditions of change, instability, and disjunction. Although many of these conditions have historic roots, many others are new configurations, which are direct products of industrialization and technology” (p. 6). In the face of these challenges, they questioned the conservative Romantic approach because “this position minimizes or totally discounts cultural changes or the growing edge of the culture in deference to that which is traditionally good, classical, or ‘established truth.’” Instead, the school should be “deliberatively critical and creative in its selection and examination of the values of the society, carefully avoiding an over-identification with any segment of the culture” (p. 21). Accordingly, the function of social studies instruction should be to “furnish the forum for the analysis and evaluation of normative propositions or value judgments about man and society,” and the end result of such practice of inquiry should be “the production of a body of tested principles and generalizations about human relations and societies” (p. 24).

Similar proposals in the fashion of the Enlightened perspective can be found in other contexts, but this example from the American context suffices to illustrate the tension existing from early on between the Romantic and the Enlightened goals of the teaching and learning of history.

### **Constructivist Developments**

Despite the early appearance of these and other critical efforts, an Enlightened approach to the teaching of history only began to settle in a more generalized way in the 1970s. Exploratory and innovative pedagogical practices transcended to the wider curricular frameworks in several countries,

hand in hand with the development of constructivist and developmental theories of learning and education. Importantly, the decades of 1980s to 1990s saw not only new pedagogical practices and curriculum developments based on Enlightened goals, but also a developing research program. Research on history teaching and learning flourished during these last two decades. A significant body of literature emerged on how children and youth come to understand the complexities of the past and how they make sense of the process of knowing history.

For the most part, this work was influenced by the developing research in cognitive and developmental psychology. Basic psychological principles and concepts imported from Piagetian theory influenced research on the process of understanding historical knowledge (Burston & Thompson, 1967; Carretero, Asensio, & Pozo, 1991; Coltham, 1971; Hallam, 1967, 1970; Peel, 1967). For example:

- 1) Research was aimed to describe the development of underlying cognitive structures (general structures across disciplines, not specific to history).
- 2) Phenomena were analyzed as to how structures of reasoning support or create obstacles to mature understanding of core concepts (Time, abstract categories, hypothesis testing).
- 3) The stress was on the difficulties of teaching abstract history at young ages.
- 4) The importance of developing general cognitive skills that could transfer and be applied to the learning of history was emphasized.
- 5) Advanced research on common misinterpretation and challenges of conceptual change in history and social sciences contexts was carried out.

These constructivist and developmental views of the teaching and learning of history had an influential impact on the Enlightened research program. This, however, involved important debates and transformations. Already in the mid-1970s, but most consistently throughout the 1980s and 1990s, research that had begun in Britain established what is commonly known as the *discipline-specific approaches* that advocated for a constructive teaching of history that is organized around core historical concepts, and recognizes the particularities of history as a discipline that has developed specific ways of knowing society and knowing the past. Much of this work wanted to challenge the overbearing generalization of Piagetian models as proposed by Peel

(1967) or Hallam (1967, 1970). This discussion is evident in work by Dickinson and Lee (1978) or Booth (1987). Based on this claim about the epistemological specificity of historical knowledge and inquiry, research in this tradition investigated how young people learn to master core historical concepts such as causality, time, change, or empathy, and learn to think about the past in disciplined ways (Dickinson, Gordon, & Lee, 2001; Lee, Dickinson, & Rogers, 1984; Lee, Dickinson, & Ashby, 2001; Portal, 1987; Shemilt, 1980, 1984, 1987)

Simultaneously, research in other countries in Europe and in the United States progressed in a somewhat different direction. Influenced by cognitive research, studies on how students come to understand the complexity of historical knowledge tracked changes in students' ideas typically representing intellectual growth as a progression from naïve to expert models of reasoning (Carretero & Voss, 1994; Leinhardt, Stainton, Virji, & Odoroff, 1994; Limón & Carretero, 1999). For example, as it has been well-established in this research program, adolescents develop their causal explanations going from intentional and concrete forms to more abstract ones where political and socio-economic aspects play a more important role. Also, early adolescents tend to consider only one or two causes in order to explain a historical problem, whereas young students and adults usually are able to provide more complex multicausal explanations of historical phenomena.

These different traditions within the Enlightened research program have established some dialog and basic consensus. Three decades of international theoretical reflection and empirical research have left us with rich models of how children and adolescents develop the competencies needed to engage in "rigorous historical inquiry," including an understanding of the intricacies of historical evidence, the differences and similarities between past and present, the short- and long-term processes of social change, the layered webs of historical multicausality, and the contextual meaning of beliefs and practices that appear foreign today (Carretero & Voss, 1994; Stearns, Seixas, & Wineburg, 2000).

These constructivist developments contributed to the growing tensions between the Romantic and the Enlightened views of the teaching and learning of history, and the construction of historical narratives. Different progressive movements in the social sciences were already questioning the elitist and biased representations of the past contained in

Romantic narratives, and advocated for more inclusive, pluralist, and critical accounts. Adding to this, constructivist and developmental research emerging in the 1970s provided a psychological rationale that supported the proposal of Enlightened goals, and questioned the notions of a passive consumer of social narratives and the unidirectional process of meaning making that typically underlies to much of the Romantic tradition. Furthermore, advocates of the Enlightened goals increasingly pushed for school history contents that adopted a "scientific" explanatory and expository format. To be sure, these expository accounts are also cultural artifacts, socially produced and transmitted by the schools. Yet, they distanced the Enlightened pedagogy from the use of the traditional personal and national narratives typical of the Romantic approach, forever changing our understanding what it means to construct historical narratives.

### ***Limitations of the Enlightened Approach to Teaching and Learning History***

The wealth of constructivist research on the progression of historical thinking provides us with valuable conceptual tools to examine Pablo's account of the defeat of the Arabs in Granada in 1492, and to understand the strengths and limitations of his explanation. Based on this research we can say that Pablo has the precise chronology of the changing occupation of the Iberian territory by Christians and Muslims, holds a fairly sophisticated understanding of the interplay of multiple causal factors leading to the final expulsion of the Arabs, and reconstructs the changing power dynamics. It is also clear that what happens in Pablo's case is that he superposes an expository account focused on causal factors to a narrative account focused on the motivations that lead the Christians to victory. But, why does Pablo, who demonstrates a fairly sophisticated critical ability, ultimately resorts to an essentialist narrative that, in its very basic assumptions, contradicts the logical argument of his "historiographic account"?

Constructivist research falls short when it comes to make sense of this kind of incongruence. The argument put forward from this perspective would typically be that the *previous ideas and misconceptions derived from cultural narratives stand in the way of effective conceptual change* needed to construct accurate representations (Limón & Carretero, 2000). In fact, in much of the research on the development of historical thinking capacity, the introduction of values and emotions that emanate from

these narratives are regarded as cognitive obstacles that hinder the development of explanatory complexity, and ultimately stagnate the development of a *mature understanding of the past*.

To be sure, throughout the transformations described above, values, emotions, and identity discourses continued to be inseparable ingredients of the historical contents taught in the classroom, but exactly how they appeared was open to change. In the curricular domain, positions were split. Several constructivist curricular reforms in the fields of social studies and history continued to justify their new approaches by stressing civic value of historical thinking skills. The belief was that students would develop critical attitudes and commitment to democratic values such as supporting judgments with evidence or considering different perspectives that would then apply to their action as citizens (Barton & Levstik, 2008, Oliver & Shaver, 1966, 1974). To a certain extent, values and emotions become objects of rational analysis. Yet, others argued that the purpose of the history curriculum should be the development of historical understanding rather than any current civic purpose (Barton & Levstik, 2008, p. 362; Lee, 1984) The rationale for this position is that if history is taught for the sake of present purposes, history may be instrumentalized and denaturalized. An unqualified integration of moral questions may distort both the authenticity of historical experience, and the rigor of historical thinking. These concerns are long-lived among historians who coined two terms to name the greatest sins that a historian may be tempted to commit: presentism and anachronism.

The situation in the field of research was different. Questions about the role of values, emotions, and identity lost prominence in a research program concerned with the reconstruction of the cognitive structures and processes that underlies to the development of understanding (or misunderstanding). With few exceptions (see for example Von Borries, 1994; Hahn, 1994), researchers in the Enlightened tradition displaced these themes to the backstage, when they did not entirely dismiss the role they play in learning and knowing the past.

The constructivist claims may hold some truth, but they still cannot explain why individuals reach these obstacles and struggle to overcome them. In our view, the problem lays in that the theoretical apparatus of constructivist research is limited. Interestingly, it is precisely the features that define its strength that also constrain it. The strength of

the constructivist paradigm rests on its capacity to describe the cognitive or logical structures underpinning a historical account (e.g., number of causal factors considered, accurate representation of change and continuity, coordination of a variety of sources, etc.), and to map the pathways of transformation they undergo as they develop. In order to capture these structural features, and the similarities, differences, continuities, or transformations between them, constructivists separate form from content, and the structures of logical reasoning from the substance of meaning making. As a result, the process of reasoning is abstracted from the social and cultural context in which the individual reasons.

Indeed, the selective focus on the cognitive or logical structures underpinning a historical account allows us to grasp its disciplinary adequacy. However, in doing so, it overlooks three important dynamics of meaning making: (a) how individuals draw upon narratives available in their society and culture in order to make meaning of the concepts and facts learned in school (Haste, 1992); (b) how they engage in a variety of discursive activities through which they negotiate the implications of new historical knowledge for their personal and collective identities, and for the interpersonal and social relationships they participate in (Antaki & Widdicombe, 1998; Billig, 1987, Harré & Gillet, 1994; Harré & van Langehove, 1999), and (c) how they mobilize and manage a host of values and sentiments that link the process of knowing to the process of negotiating identities and social positions in a particular context. The constructivist research formula lacks the conceptual tools necessary to explain the role that socio-cultural context, identity, values, and sentiments play in historical understanding.

Within this paradigm, we are at a loss when we try to understand why Pablo does not extend his critical skills to examine the narrative of reconquest that was socially transmitted to him. This is not a minor limitation if we consider that much of the constructivist paradigm rests on the assumption that students will transfer the thinking skills developed in the history classroom to real-life situations in which a disciplined historical perspective can afford them a better understanding of the social issues and questions they encounter in their daily lives. In fact, there is no empirical evidence that shows that the transference of skills from the classroom to the everyday life actually happens (Barton & Levstik, 2008). Despite the efforts of teachers and researchers to engage students in the mastery of core historical

concepts, this does not effectively lead students to change the historical narratives they bring to school. In fact, people do not change their theories but rather pick and choose conveniently. Evidence shows that students do not readily modify their prior narrative understanding when they encounter new or conflicting information (Limón & Carretero, 1999). For example, Barton and Levstik (1998) have found that U.S. students, who struggle to reconcile their knowledge of topics such as the Great Depression, the Vietnam War, and continuing instances of racism and sexism with the overarching historical narratives of progress, tend to reinterpret such events to more closely match the broad theme that dominates American culture. Similarly, research conducted by Barton and McCully (2005) shows how students in Northern Ireland draw selectively from the curriculum in order to bolster the sectarian narratives that they encounter outside of school. Other authors point to the similar conclusion that students use religiously grounded narratives to ignore, reinterpret, or distort historical information so that it does not conflict with the prior ideas (Mosborg, 2002; Porat, 2004).

Where do we go from here? What are we left with? Are the identity and the critical dynamics in construction of historical narratives irremediably antagonistic? Are the Romantic and Enlightened traditions necessarily at odds with each other in their efforts to explain how and why historical narratives are constructed? The body of research on historical understanding has generated a number of questions about the knowing of history and the construction of historical accounts/narratives that cannot be addressed from within its own Enlightened paradigm. However, in our view, the latest wave of research informed by a variety of socio-cultural perspectives in psychology and social sciences challenge these dichotomies and open new possibilities for research and understanding.

### ***The Reemergence of Romantic Goals***

After three decades in which Enlightened goals and assumptions extended throughout pedagogical practice and constructivist research, the interest in the Romantic themes of identity and the role of values and sentiments is moving back to the center stage of the current research agenda.

Not surprisingly, these interests have reemerged in two different ways: within a neoconservative tradition on one hand and within a critical socio-cultural tradition on the other. Both approaches highlight

the narrative structure of historical knowledge, they stress the connection between the processes of knowing the past and constructing identities in the present, and they reposition sentiments and values at the core of knowing the past. Yet, they do so from very different perspectives and with significantly different implications.

#### **ROMANTIC GOALS IN A NEOCONSERVATIVE TRADITION**

In the neoconservative tradition, the reemergence of Romantic goals continues to be coupled with patriotic and nationalist concerns that emphasize issues of loyalty, attachments, and unity. For example, in recent years in the United States, several authors have argued that the liberal views of teaching history (i.e., the constructivist views), in which the past is made object of critical analysis, have eroded the *cultural literacy* that is the basis of cohesion of a national identity and the sense of civic virtue (Bloom, 1987; Hirsch, Kett, & Trefil, 1988; Cheney, 1988; Ravitch & Finn, Jr., 1988). In their view, the renewal of the nation depends on reestablishing a shared historical narrative and on enacting the values that this narrative embodies. Such reaffirmation of national unity is deemed fundamental in the face of external threats, as well as internal threats such as the challenges brought by ethnic and linguistic pluralism. This approach is generally didactic, and students are told what traits are embodied by historical figures and why they are good (Barton & Levstik, 2008). Here again, there is little room for interpretation or ambiguity, and little role for critical rationality that is repelled for having scrutinized and destroyed the creeds that sustained community and nation.

#### **ROMANTIC GOALS IN A CRITICAL SOCIO-CULTURAL TRADITION**

The socio-cultural approach contrasts with the conservative version in at least four important ways:

- (a) It tends to portray historical narratives as cultural artifacts rather than as essential distillations of national character, or a set of basic objective facts.
- (b) Because of that, it usually recognizes diverse and contentious views of the past rather than positing the existence of one shared narrative.
- (c) It claims an active rather than a passive role for the individual in the process of constructing

historical narratives, and locates this process in its socio-cultural context.

(d) Because of that, it tends to examine the interplay of rationality, values, and emotions, rather than dismissing one or the other.

Interestingly, some of these characteristics also explain that the current socio-cultural approach has new tools that constructivist views lacked, which afford the possibility of solving some of its limitations. In the pages that remain we will discuss some of these features in terms of the potential contributions that the current socio-cultural approach to the Romantic goals of teaching history can make to the research on the construction of historical narratives.

### ***Contributions of the Socio-Cultural Approach to Romantic Goals***

The latest generation of research and discussion on the teaching and learning of history is marked by a strong influence of socio-cultural theories. Recasting history to a narrative format, emphasizing the connection between the processes of knowing the past and the processes of constructing identities, and repositioning sentiments and values and the core of historical consciousness, socio-cultural approaches come as a refreshing force, raising new questions, shedding light on new phenomena, foregrounding new controversies, and suggesting new dilemmas.

Interestingly, much of this transformation in the research agenda has been propelled by the adoption of socio-cultural approaches without abandoning the basic constructivist tenets, either because researchers draw upon a *Vygotskian tradition* that organically integrates both, or because constructivist researchers migrated, bringing some of their conceptual heritage. For example, Barton and McCully discuss one of their recent pieces of work in the following terms:

“This study is grounded in a constructivist and socio-cultural perspective on historical understanding. For most of the last two decades, theory and research in history education has been part of the larger constructivist tradition in education and psychology. From this perspective, neither children nor adults passively absorb information, whether at school or elsewhere. Rather, they engage in a process of active construction in which they interpret new information—encountered in a variety of formats and settings—in light of their prior

ideas and their ongoing attempts to make sense of the world (Levstik & Barton, 2001). A student’s historical understanding, then, is not simply a mirror of external information but a unique set of mental schemata resulting from the interaction between the individual and environment. Yet, socio-cultural theory emphasizes that this process is necessarily situated in social contexts, and that the information to which students are exposed has been historically and socially constructed.”

(2005, p. 90)

The recognition of the active role of the individual in the process of construction of historical narratives has important implications. For one thing, it has propelled the distinction between the processes of production and consumption of historical narratives (Wertsch, 1997). The former refers to how history textbooks, mass media and other sources deliver official history versions (Ahonen, 1997; Luczynski, 1997) and the latter has to do with the process by which individuals appropriate those historical narratives, even though their narratives may not necessarily be identical to those produced.

Research conducted in different countries in the last 10 years has documented, along these lines, how students engage with a variety of historical narratives in active processes of negotiation that involve stances of endorsement, resistance, or challenge—as they construct the meaning and of their own identities. In the work cited, Barton and McCully call into question any simplistic notion of the relationship between historically grounded identities and formal study at school: “students neither reject school history outright nor use it to replace prior, community-based historical narratives. Rather, they draw selectively from the school curriculum (and other sources) to support a range of developing historical identities” (2005, p. 85).

While recognizing an active role for the individual in the process of constructing historical narratives, socio-cultural research also addresses the social and cultural processes involved in learning history, knowing the past, and constructing historical narratives.

Haste (1993), in her research about people’s construction of notions of self and morality, makes an argument that proves helpful here. In her view, “there is a major, and for some irreconcilable debate in developmental psychology . . . between those who search for the basic process of morality inside the head of the individual and those who search for it

in the interaction between persons, between those who assume that meaning is constructed by the individual and those who assume that it is a social construction transferred to the individual" (p. 175). "No one denies that there is interaction," Haste clarifies, but in the face of debate there is "a fundamental, almost ideological, division between those who view the individual as the phenomenon to be explained and those who treat the individual as the end of the social process" (p. 184).

Constructivist models in the research of history teaching and learning, which tend to adopt the first position in this conflict, assume indeed that other individuals play a role in providing challenges and generating disequilibrium. However, such "interactions among individuals" are not analyzed as embedded in social and cultural processes. In fact, social and cultural context are seen as unproblematic. In contrast, conservative and neoconservative approaches to the study of history education rest on principles akin to the second position described by Haste. These traditions tend to conceptualize the self and knowledge as products of socialization, and therefore, argue that the primary process to be explained is "that of inculcating the growing child into a socially constructed world of meaning." As Haste explains, "the social context provides frameworks for concepts and values, and this is regarded as sufficient explanation of an individual's development, with no need to address actual processes at the individual level" (Haste, 1993, p. 176, 182).

Among other things, the dichotomy described by Haste helps to explain why plain constructivist research has had little room to consider that "Identity matters" matter when it comes to constructing histories. Likewise, it sheds light on why the traditional Romantic perspectives rarely recognize that historical narratives have an active mind behind them. In contrast with the limitations of the Romantic and Enlightened traditions of research in their conventional forms, it becomes clear that what is needed to understand the construction of historical narratives in its full complexity is a synthesis that renders as problematic, or in need of explanation, both the process of individual active consumption of historical narratives, and the social and cultural processes of production of those historical narratives and their meaning.

### Future Directions

Our synthetic approach implies the investigation of three important dynamics of meaning making in

the construction of historical narratives, and we have begun to see work emerging in some of these areas:

a) How individuals draw upon social and cultural narratives in order to make meaning of the concepts and facts learned in school, as shown in the works of already cited authors as Barton, Seixas, Van Sledright, Wineburg, and others. In our opinion, a number of aspects of school history narratives need to be studied more deeply in the future not only in school settings but in informal learning environments, particularly museums, exhibitions, TV shows, etc. Particularly, in relation to the six features presented in this chapter. For example, we do not know in detail what is the influence of cognitive development on the processes of construction and consumption of historical narratives. It could be hypothesized that older students could understand and use historical narratives in a more complex manner than younger ones, following a progression from mythical and concrete narratives to ironic and abstract ones. To this respect, also teaching and learning factors should be taken into account. Thus, it is important to consider that very often school history education is carried out in order to promote Romantic and patriotic values and not really historiographical understanding. This implies the possibility of not having a real disciplinary progress in student's minds. To this respect, it would be very important to study in a very detailed way the possible influence of social and cultural factors in the process of interiorization of the mentioned narratives. Particularly the influence of the Nation-States educational policies, which are very often interested in developing just mythical and heroic historic representations.

b) How citizens mobilize and manage a host of values and sentiments that link the process knowing to the process of negotiating identities and social positions in a particular context. To this respect, we think the moral dimensions of historical master narratives should be explored in more detailed way, particularly in relation to the consumption process. A number of theoretical (White, 1987) and empirical contributions permit to expect a strong influence of moral issues on the way citizens consider historical narratives. It is plausible to expect that this moral influence would be very much related to the process of belonging to a certain national, ethnic or cultural group. To this

respect, the relation between national or cultural identity and citizens' moral interpretation of historical issues is, in our opinion, a very promising hypothesis to be explored in the future.

c) How individuals engage in a variety of discursive activities through which they negotiate the implications of new historical knowledge for their personal and collective identities, and for the interpersonal and social relationships they participate in. Coming back to the example of Pablo's narrative about the Reconquest in Spain, presented above, we think much more work is necessary about how the interaction between production and consumption of school historical narratives is being produced. A recent paper (Hammack, 2010) considers the strong influence of these narratives on youths' collective identity, suggesting that identity is both a burden and a benefit at the same time. This shows how complex and counterintuitive the mentioned interaction could be.

The location of individual meaning within socio-cultural contexts affords these new approaches the possibility of examining the interplay of rationality, values, and emotions, rather than dismissing one or the other. Hence, a salient contribution of the socio-cultural approaches is its potential to explore a variety of possible interactions between Romantic and Enlightened traditions and goals that have largely been kept separate in previous work.

## Notes

1. This chapter was written with the support of Projects PICT 2005–34778 and 2008–1217 (Agencia de Investigacion de Argentina), and Projects SEJ2006–15461 and EDU2010–17725 (Agencia de Investigacion, Spain), and the Fellowship at the D. Rockefeller Center for Latin American Studies (Harvard University) to the first author during 2009–2010. We would like express our gratitude for that support.

2. Consider, for example, the Israeli narrative about Palestinian territories arguing the need to recuperate a land from where the Israeli people were expelled 2,000 years ago. Sand (2010) has brilliantly studied the “invention of the Jewish nation.”

PART 7

# Emergence of Culture

*This page intentionally left blank*

Riin Magnus and Kalevi Kull

**Abstract**

This chapter begins by introducing the background, basic constituents and principles of the *umwelt* model and theory developed by the Baltic German biologist Jakob von Uexküll (1864–1944) in the first decades of the twentieth century. This is followed by a discussion of the features of the *umwelt* concept that has provided the impetus for interpretations of human activities and cultural processes. The once biology-bound model has by now found its way into very diverse traditions of thought. We concentrate on four major trends in interpreting cultural phenomena with the help of *umwelt* theory: (1) the Uexküllian functional circle model of perception and action as a predecessor of models that couple human forms of impression and expression; (2) the mediated versus immediate character of human in contrast with animal worlds; (3) the bridging of natural and cultural phenomena via semiotic processes; (4) the integration of the cognitive and the social interpretations of (human) mind via two facets of *umwelt*. The chapter includes some hints on the aspects of the *umwelt* model that could be elaborated further in the analysis of culture.

**Keywords:** functional circle, impression and expression, modeling systems, semiosphere, Uexküll, *umwelt*

**Culture, Semiosphere, Umwelt**

According to the semiotician and culturologist Juri Lotman, cultures have a structure that is analogous to individual human minds in several of its fundamental features. In some of their general structural aspects, as well as in some rules of their dynamics, these complex semiotic systems are isomorphic to each other (Lotman, 1984, 1990). Both a culture and an individual world are fields of sign processes. Both entail many codes, several sign systems, translation processes, heterogeneity, asymmetry, borders, center and periphery, continuity and discreteness, unpredictability, and a certain processual logic. Both are embedded and molded by communication and dialogue, which are primary in respect with individual languages. The general model Lotman proposed for describing personalities, texts, and cultures as semiotic systems and their

interweaving in a common semiotic space is named the *semiosphere* (Lotman 2005).

The semiosphere is a necessary medium for all sign processes as well as the totality of sign processes itself. Like the biosphere, which is the organic totality of living matter as well as the precondition for the persistence of life, the semiosphere is the result as well as the precondition for the development of culture (Lotman, 2000, p. 125). Departing from Thomas A. Sebeok's (1920–2001) thesis, according to which the origin of *semiosis* (sign process) coincides with the origin of life, we can assume that sign processes (as the basis of recognition, discrimination, signification) characterize human minds as well as animal minds. We can therefore describe the semiosphere of the worlds of organisms, all living organisms included. This is how the concept of semiosphere is used in contemporary *biosemiotics*—the branch

of semiotics dealing with the organic part of the semiosphere (Cobley, 2010; Hoffmeyer, 2008).

A predecessor of such a semiotic view in biology was the Baltic German biologist Jakob von Uexküll (1864–1944) with his concept of *umwelt*. Umwelt is the world an organism creates, in which it lives. It is the meaningful world based on sign relations. A quite common definition states that *umwelt* is the personal world of an organism, or a self-centered world, “the world as known or modelled” (Cobley, 2010, p. 348). This definition, although correct in itself, may not emphasize the relational aspect of the *umwelt* concept enough. Therefore we can also complementarily define *umwelt* as a set of sign relations an organism has in an ecosystem (as in a semiosphere) (Kull, 2010b).

Thus, if *umwelt* is made of relations, of semiotic bonds, we can conclude that organisms are derivatives of (sign) relations. Umwelt (as a relational, i.e., a meaningful world) exists even prior to the capacity to use representations, since organisms can often be involved in sign processes without building representations. Conversely, of course, there cannot be an *umwelt* without life. Life is centered on organisms, in their agency; therefore, *umwelten* are also individual and individualized.

All organisms participate in the construction of their *umwelten*. Organisms participate in making their *umwelten* because this is generally a communication (including autocommunication) process that modifies and constructs *umwelten*. Building and modifying one’s *umwelt* is simultaneously a communicative process and a modeling process.

As Thomas Sebeok has pointed out regarding the scientific use of the term “*umwelt*,” “the closest equivalent in English is manifestly “model” (Sebeok, 2001, p. 75). The description of a particular *umwelt* will mean the demonstration of how the organism maps the world, and what, for that organism, the meanings of the objects are within it. How the formation of individual worlds entails meaningful operations was likewise described by Jakob von Uexküll in his *Theory of Meaning (Bedeutungslehre)* (Uexküll, 1982 [1940], pp. 64, 69):

Meaning in nature’s score serves as a connecting link, or rather as a bridge, and takes the place of harmony in a musical score; it joins two of nature’s factors. [...] Each meaning-carrier was always confronted with a meaning-receiver, even in [...] earlier *umwelten*. Meaning ruled them all. Meaning tied changing organs to a changing medium. Meaning connected

food and the destroyer of food, enemy and prey, and above all, male and female in astonishing variations.

That semiotic systems are simultaneously modeling systems was also emphasized in the 1960s by the Tartu-Moscow School of semiotics (Lotman, 1967; Levchenko & Salupere 1999; Kull, 2010a). Here modeling systems (which encompassed languages as well as arts) were understood as the structure of elements and the rules of their combination that stood in an analogical relationship to some object of cognition (Lotman, 1967, p. 130). Modeling systems provide the means for comprehending the outside world and yet, they are themselves the primary sources of world formation.

Connecting the ideas of Jakob von Uexküll and Juri Lotman, we could also say that culture is continuously created via human *umwelt* making. Cultural modeling as *umwelt* making includes all of the building, shaping, and design humans do in their surroundings (i.e., besides “texts” in a narrow sense, also clothes, tools, technologies, architecture, and landscape). The *umwelt*-based semiotic approach to culture may further widen the understanding of the borders of culture by including semiotic processes of an ecosystem into a single whole with human culture proper. This means widening the basis of culture from language to semiosis.

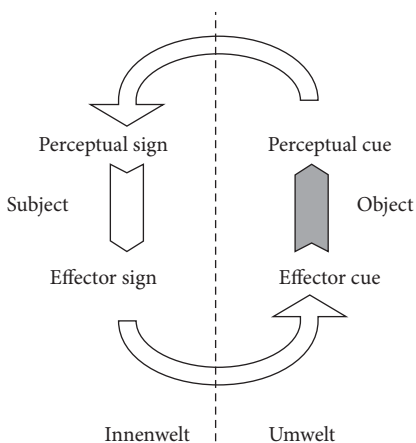

A semiotic interpretation, to which we will come back later, is just one way of linking the idea of *umwelt* with culture-specific constructions. In order to bring forth the variety of those links, we will further sketch the chief impetuses the *umwelt* idea has provided for interpretations of human activities and cultural processes. We shall demonstrate how different interpretations of the *umwelt* concept allow the integration of otherwise contradictory approaches to culture.

### Jakob von Uexküll’s Umwelt Model and Its Constituents

Although the common German word “*umwelt*” is traditionally translated into English as “environment,” its use as a loanword refers to the specific concept worked out by Jakob von Uexküll in the first decades of the twentieth century.<sup>1</sup>

*Umwelt* is the world as accessed and formed by the organism via its specific sensory and motor devices. The section of reality that a biologist should describe, according to Uexküll, is thus of the organism’s own making. In other words, *umwelt* is the set of perceptual and action-based distinctions, shared in a large extent by the members of one species and described by an external observer.

Umwelt as the world of meaningful objects, is always paired by its intraorganismic counterpart—*Innenwelt* (inner world). If *umwelt* denotes the outside world as it appears to the animal via its perceptual and motor apparatus, then *Innenwelt* refers to the experience side of the phenomena as experienced by the organism. However, the organism never feels itself as such. What is felt is some object of the *umwelt*, which indirectly refers to the subjective center of world formation via the meaning it carries to the animal. It is also the external object that serves as a ground for the species-specific coordination between the perceptual and motor apparatus. “Just like the factors of *umwelt* are objective, also the effects that they bring about in the nervous system have to be treated in the same manner. These effects are also organized and regulated by the building plan. They together form the *Innenwelt* of the animal”<sup>2</sup> (Uexküll, 1909, p. 6). The overarching principle that binds *umwelt* with *Innenwelt* is mentioned here as *Bauplan* (building plan)—the specific anatomical and physiological structure of the animal. The *Bauplan* concept encompasses both the developmental pathways of the organism as well as the functional aspect of the organism’s perceptions and actions. Although the focus for this *umwelt* concept is on the operation of sense organs and motor systems, when the formation of the *umwelt* is described, these systems are always to be seen as embedded in the totality of the organism itself. The key elements and characteristics of the *umwelt* formation process were modeled by Uexküll as a schema, which he called a functional circle (*Funktionskreis*) (see an adaptation of Uexküll’s schema in Figure 29.1).

**Figure 29.1** An adaptation of Jakob von Uexküll’s functional circle model.

When in contact with some object, a particular perceptual sign (e.g., a sweet taste) is first received by the organism and then projected to the outside world as a perceptual cue of that object (the sweetness of a fruit). The complex of the perceptual sign and perceptual cue further induces the formation of an effector sign. The effector sign is the image of the action that is to be carried out in respect with the object (e.g., biting the fruit). Like the perceptual sign, also the effector sign is projected outside as a cue or property of the object (the “bitability” of the fruit). If the necessary action is accomplished, a new perceptual sign can emerge and a new circle will begin. The circles of perception and action follow one another until the need that initiated them has been satisfied (e.g., until the animal has satisfied its hunger).

The model can also be seen as a hybrid of reflex arc schemes from biology and later communication models. At first glance, the *Innenwelt* part of Uexküll’s model could be interpreted as a unification of the afferent and efferent pathways of the reflex arc. The perceptual and motor cues, in turn, could be termed as equivalents of stimuli, initiators of irritation. As a remarkable difference from the reflex arc scheme, linear logic models do not work here. The explanation needed is therefore closer to the one used by complex systems theory, where downward and upward causation have to be accounted for simultaneously (see Gilbert & Sarkar, 2000). Incorporating all elements of the functional circle under the word *welt* denotes that the departure point for the observer of the animal’s behavior should be the whole set of meanings with all the characteristic relationships between them just as well as particular acts of perception and action. Individual causes and effects, and the extraction of single stimulus and response pairs, can be derived only from an already understood set of possible meanings, but the world-formation is itself observable and accessible only via the individual acts. We will return to this principle of part-whole mutual conditioning when describing the Romantic philosophical roots of Uexküll’s *umwelt* theory.

Comparing the functional circle model with classical models of communication<sup>3</sup> may allow us to see the subject as both a sender of messages about its physiological state to the outside world and as a receiver of responses to those states by the object-as-a-sender. However, the functional circle model does not articulate the difference between the active and passive object in the process. It does not therefore

permit a distinction between the acts of perception and communication.

### *From Reflections to Coordination: How the Umwelt Concept Emerged*

In order to track the road from umwelt to culture and to explain how some principles of cultural existence are to be viewed if umwelt is seen as their predecessor, we need to visualize the road leading to the basic model of umwelt theory itself. Jakob von Uexküll started his career by researching the physiology of marine invertebrates. While working in the physiology laboratories in Heidelberg and Naples, he concentrated on the muscular movements of sea urchins, brittle stars, octopuses, etc. (cf. Rütting 2004, p. 39; Mildenerger, 2007). It is exactly here that the empirical grounds of the developed umwelt theory are to be found: in those early works on muscular tonus accompanied by research on reflex movements and the nearly 200 years of debate about the exact mechanisms behind them.

The eighteenth-century explanations of involuntary movement that preceded the nineteenth-century reflex concept, exhibited disagreements on several grounds. One set of disagreements concerned the (in)applicability of optical theories of reflection to the biological relations of irritation and movement. Georges Canguilhem has demonstrated how the period encountered on the one hand convictions that the irritation-movement pair functions according to the mirror law.<sup>4</sup> According to this principle, the texture of the medulla serves as a “mirror” upon which the incident irritation falls and reflects back to the motor nerves. Those claims were countered by authors (e.g., George Prochaska and Robert Whytt) who denied the sufficiency of optical parallels for explaining medullary mediation of irritation and movement and who asked for the formulation of specific biological laws in order to clarify the issue (Canguilhem, 1994, pp. 179–202).

Several classical models of a reflex arc in the second half of the nineteenth century followed the physicalist line of thought while explaining the organism as a thing among things, comparable to a physical body by which the same impulses always result in the same reaction. Reflex arc models, which depicted the nervous system as a mechanism of simple motion transfer (cf. Bains, 2006, p. 61), received significant criticism already at the time of their wider distribution. The earlier critical fronts came not just from physiology, but also from

psychology and philosophy (esp. pragmatism) (cf. Phillips, 1971; Bredo, 1998).

John Dewey’s 1896 article “The reflex arc concept in psychology” identified the persistence of two kinds of older dualisms in the dominant models of the reflex arc: (1) the dualism between sensation and idea—as being repeated in the dualism of peripheral and central structures, and (2) the dualism of body and soul—as still present in the dualism of stimulus and response (Dewey, 1896). Dewey argued against the separation of stimulus-response as two distinct physical absolutes, tied to sensation and reaction respectively.

What shall we term that which is not sensation-followed-by-movement, but which is primary; which is, as it were, the psychical organism of which sensation, idea and movement are the chief organs? Stated on the physiological side, this reality may most conveniently be termed coordination.

(Dewey, 1972 [1896], p. 97)

Coordination is always present in each act of sensation or reaction as an “ideal” from which the two have deviated as conflicting parties and try to regain the initial state of coordination. Coordination is thus presented by Dewey as a process whereby the dynamic stability of the organism is achieved.

Jakob von Uexküll and his colleagues Theodor Beer and Albert Bethe published in 1899 an article where they suggest a new objective nomenclature for physiology. In the article they claim that physiology should be purified from the ambiguous terms like “light” or “sound” and terms indicating the physical origin and properties of objective stimuli should be used instead (Beer, Bethe & Uexküll, 1899). Here they seem to identify themselves with the tradition of a physics-bound physiology rather than with the more organism-specific perspective. Solely because of the position presented in this article, Uexküll’s research was received as a representative of the mechanistic-behaviorist physiology, even in his later career when he distanced himself from his earlier theoretical grounds (see Mildenerger, 2006; Mildenerger, 2007, p. 58).

Closer examination reveals that even this objectivist manifesto already contains ontological threads leading to the later *umweltlehre*. What is lacking in the latter and saliently present in the manifesto is a significant discrepancy between the ontological and the epistemological standpoints. While proposing a new nomenclature for sensory physiology, the authors differentiate between the objective stimulus,

the physiological proceeding, and the eventual sensation. The footnote to the objective stimulus, however, states:

We admit that the stimulus is nothing but an objectified sensation, but we stay by the conviction that natural scientists, in order to retain a stable ground, should take an unbiased standpoint, from where one could observe the outwards projected *Erscheinungswelt*<sup>5</sup> as materially present. (Beer, Bethé & Uexküll, 1899, p. 517)

The new nomenclature is therefore suggested because of merely heuristic reasons; the authors attempt to deny asserting any reality to the objective stimulus. Uexküll's later writing on *umweltlehre* resolved this former discrepancy by adjusting the theoretical framework according to his ontological axioms.

How could such a step be taken? What enabled the initially self-determined scientific methodology to be attuned to the “demands” of biological reality?

Above all, this leap in Uexküll's ontological commitments is caused by the synthesis of philosophical and scientific standpoints. The philosophical perspective, traditionally bracketed out from strictly scientific investigations, was brought in to take part in the explorations of the living world. Only through the coordination and integration of ideas belonging to different realms of human knowledge (either to scientific, philosophical, or artistic) could organisms be understood as entities who themselves base their existence on coordination and integration.<sup>6</sup> This synthetic understanding of human knowledge, which formed the epistemological foundation of the *umwelt* idea, was the legacy of Romantic theories of human mind. First, it followed the Romantic ideals of the entwined architectonics of human comprehension. Secondly, it considered the principle of the isomorphic relations between the object and the tools of research. Goethe figuratively expressed the latter in the introduction to his *Colour Theory (Zur Farbenlehre)*, quoted also by Uexküll: “If the eye were not sun-like, it could never behold the sun. If the sun were not eye-like, it could not shine in any sky,”<sup>7</sup> and in his statement that “similar can be recognized only by a similar” (*nur von Gleichem werde Gleiches erkannt*) (Goethe, 1810, p. xxxviii). The structural principles of the object and the descriptive system have to match with each other. Such matching and likeness of the observer and the observed does not require an overlap or

superimposition of one of the systems on the other. On the contrary, the central concept for describing these relations is *punctus contra punctum*—they have to match like two notes in a chord. The principle of responsive, counterpoint-like correspondence is central for understanding how it is possible to proceed from the perceptual systems to the communicative, dialogical ones. This key factor also opens up the possibility for *umwelt*-based research to serve not just as a descriptive system, but also as a tool for understanding. The animal in this case is not merely an object of scientific observation but a response to the research question posed by the researcher's own perceptual and cognitive schemes. Partaking in the communicative act provides the researcher with as much knowledge about his own mind as it does about the communicatively observed animal. And the more conscious one becomes of one's own perceptual restrictions, clarifying thus the structure of one's own research tools, the more the understanding of the other will correspond to the features of the other. Scientific truth in this case does not need to choose sides between idealistic or realistic premises—it is formed only while participating in the mutual exchange of information, where the object explicates the subject's characteristics and vice versa.

### *Umwelt Theory as a Springboard for Models of Culture*

Uexküll himself did not provide significant reflections on how his *umwelt* theory could be applied particularly to human beings (setting aside his constant reminder that all researchers are bound with their own perceptual boundaries, even when talking about the *umwelt* of another species, and his rather loose transfer of the *umwelt* concept to describe the characters of his friends). But Uexküll's writings on the *umwelt* concept have served as an impetus for later philosophers and representatives of other humanities to delve on the issue of its applicability to human beings.

For the sake of conciseness, we are not aiming at describing all directions of influence, as the idea has found its way into very diverse traditions of thought (*for overviews see* Kull, 2001; Mildnerberger, 2007; *on the additional aspects, see* Berthoz & Christen, 2009; Chang, 2009; Kliková & Kleisner, 2006; Magnus, 2008). We therefore focus on four kinds of topics in *umwelt* theory that have triggered discussions on the question of specifically human *umwelten*: (1) the perception-action pairing as a fundamental

property of “being alive” and as a source for the further developments of human-specific impressions and expressions; (2) the immediacy vs. mediatedness of animal and human action; (3) the semiotic embeddedness of all living beings, which leads to the view of life as the primary threshold of semiotic activity; (4) the integration of the perspective of the subject and the perspective of the system.

#### THE PRINCIPLE OF COUNTERPOINTS: RELATING IMPRESSION WITH EXPRESSION

Let us first examine the first of those four—to what extent is the basic model of the functional circle applicable to human sensations and expressions? According to Uexküll, all objects enter the animal’s *umwelt* via their perceptual as well as effector cues by inducing clearly distinguished perceptual and effector responses. Such a twofold process of receiving information followed by returning it reworked in an organism-specific form is characteristic for all living beings. Although there is a long evolutionary distance between the recognitions carried out by the cellular receptor proteins and signaling molecules (as perception), and corresponding genetic expressions, metabolic changes, or apoptotic behavior (as effects), and the orientation of vertebrates via highly differentiated sense organs (as receptors) and the limbic system (as effectors), both systems involve the establishment of a coded correspondence between the receptor and effector activities as their basis. This does not amount to stating that the same impulse always results in the same response. The organism with its specific form and current physiological state serves as a translation matrix that uses the correspondence between the perceptual and the motor systems in order to preserve its own organic form with each object-oriented functional circle. The coded duality of perception and action is simply a device via which the organism encounters meanings essential for its specific form of existence. Interpreting the organism as a translational matrix means that it provides an interpretational framework, in which all perceived objects are approached as actionable and actioned objects as perceivable.

We may thus infer from this that the specific linkage between what the organism perceives about the environment and how it responds can be formed only via a common meaningful framework between the two. Further, it is important to note that once such a relation has been established, its functioning becomes a necessity for preserving the meaningful framework itself. Thus the particular form, as well as

activities of an organism, rely on the encoded difference between its perception and action, impression and expression. The latter principle—the necessity of twofold activities for the preservation of complex phenomena or forms—is a topic that has provided common discussion ground for the philosophy of biology on the one hand and phenomenology of perception and philosophy of art on the other. One of the central authors uniting those two fields is Maurice Merleau-Ponty who also found a strong impetus from Uexküll’s *umwelt* theory, particularly for his courses on nature held at the Collège de France from 1956 to 1958.

Merleau-Ponty’s idea about the compulsory twofold nature of the body as a perceiver and as perceived can be summed up with his central motive of the “double sensation,” when my one hand touches my other hand (*see* Merleau-Ponty, 2002 [1945], p. 106, 1968 [1964], p. 141, 2003 [1995], pp. 74–75). It explains how one and the same body serves as a ground for acting and being acted upon and yet can never be in the two positions simultaneously. This temporal hiatus between the always reversible states of touching and being touched, seeing and being visible, as Merleau-Ponty explains, does not result in an ontological void between the two states, but “is spanned by the total being of my body, and by that of the world, it is the zero of pressure between two solids that makes them adhere to one another” (Merleau-Ponty, 1968 [1964], p. 148). Merleau-Ponty further postulated that the principle of reversibility does not reside just in one’s own body, but also among different organisms, which he designated with the word *intercorporeity*. By perceiving we thus also perceive the others as perceiving, as far as sensibility is unbound from its belonging to one and the same consciousness. This sort of a possibility for the perception of the other as a perceiving subject is absent in the Uexküllian *umwelt* model. Here, the reversibility of *umwelt* and *Innenvwelt*, of the perceived objects and the perceiving subject, is not possible, as the subject’s identity is solely based on the specific contacts with the objects as counterstructures. All objects in the world of an animal are directed toward its own existence; there is no object for another. Uexküll thereby remained true to the Kantian treatment of the subject, where “I can grasp the unity of the I only through its productions” (Merleau-Ponty, 2003 [1995], p. 22). In the Uexküllian approach, there is a correspondence between the different *umwelten*, but it is not caused by the subject’s perception of the other as a subject

and an object simultaneously, but it is caused by a general, supra-subjective plan of nature.

The function of presenting oneself as a perceivable object can be elaborated by special organs which exteriorize the organism in the same manner as the sense organs interiorize the world. This is the manner in which the Swiss zoologist Adolf Portmann discussed the function of the skin and other body surfaces as phenomena that have developed with the potential of being perceived by someone else (Portmann, 1990; cf. Kleisner, 2008). Firstly, the merely physiological function of several morphological traits has been enriched with a communicative function during evolution. The hair and plumage of warm-blooded animals became organs of communication besides their initial role of fixing stable body temperature; the skin's capillary network intensifies the color of the skin and thus serves as a sign for the psychosomatic state of the animal (Portmann, 1961, pp. 77–97). Secondly, there are multiple examples of morphological features that have never served any specific physiological function for the organism at all and to which Portmann attributes the role of the “self-expression/ or presentation” of the organism. Those traits may also attain a communicative function in the course of time, as is the case with some color patterns that acquire a mimetic value or begin to operate as warning signals.

Yet another variation on the topic of the anticipation of action in perception (and vice versa) as a binding phenomenon of humans and other living beings is provided by the American philosopher of art, Susanne Langer. Like Merleau-Ponty, Langer turned to biophilosophical questions in her later works while also integrating critical accounts of the *umwelt* theory (Langer, 1986 [1967]). The central notion upon which Langer builds her theory of the rootedness of artistic expression in the biological experience is “feeling.” As for an organism, what is felt is an action in the organism, either in the form of an impact or as autogenic action (Langer, 1986 [1967] pp. 23–24). Prior to the arousal of feelings, the simpler organisms already based their existence on perception containing “values for action.” With the development of the nervous system, feeling arises not as a property, but as a phase of vital activity (like ice is a phase of water), providing thus several physiological processes with the new status of “being felt.” The arousal of the domain of feeling is necessarily accompanied by its transfiguration into an expression. Thus if the organism's condition

prior to feeling adhered perception to action, feeling then becomes attached to its reverse in the form of expression. This kind of a “felt life” unites and serves as a foundation both for biological expressions such as gestures, postures, etc., as well as for artistic presentational symbols (see Weber, 2002). The latter are distinguished from discursive symbols, as they express not merely ideas, providing access to the more basic levels of organic existence.

Biological expressions as well as presentational symbols both express a certain significance and value that impressions have for the particular form of life. By filtering and sorting out only those bits of information that are meaningful for the particular living being, the peripheral organs already act toward the preservation of the form of which they constitute a part. Langer (1988 [1972], p. 55) has noted:

[...] The primary characteristics which animals see are values, and all the qualities of form, color, shape, sound, warmth, and even smell, by which we would naturally expect them to recognize things, enter into their perceptual acts only as they enter into their overt behaviour as values for action.

Susanne Langer's philosophy of presentational forms highlights the role of perception in opening up the world for signs, taking sense-data as receptacles of meaning (Langer, 1956 [1942]). “Eyes that did not see forms could never furnish it [the human mind] with images; ears that did not hear articulated sounds could never open it to words” (Langer, 1956 [1942], p. 73). However, in the Uexküllian *umwelt*, the meanings occur always together with forms. As far as all forms are functional and function is based on meaning, there is no before or after the meaning, as those categories are already abstractions unattainable to the animal itself.

#### POOR ANIMALS AND DEFICIENT HUMANS

Both Maurice Merleau-Ponty and Susanne Langer had explicated a particular organism-centric mode of existence that opens the organism up for the world and yet, at the same time, encloses the organism in its specific modes of appearance. Both had stressed the importance of seeing the anticipation of action in even the most primitive perceptual contacts with the world; perception was understood as already being attuned to the behavioral setting and to the set of possible actions, (Merleau-Ponty, 2002 [1945]; cf. also Harney, 2007) or carrying values for the subsequent activities (Langer, 1988 [1972]; cf. Weber, 2002).

The *umwelt* theory provided quite a different impetus for two other thinkers—Martin Heidegger and Arnold Gehlen. Although using different arguments and bodies of knowledge, they both maintained the impossibility of departing from the notion of *umwelt* while tackling any of the essential questions concerning human beings. They both appreciate Uexküll's contribution to the description of the fundamental conditions of "being an animal," but demand a new contrastive principle for the explication of human conduct.

Gehlen found that human imperfection (*der Mensch als Mängelwesen*) in relation to any specific environmental condition is striking when comparing it with the perfect matching of the animal and its environment.<sup>8</sup> He traced the idea of the deficient human being, lacking all means that would allow him to attach, to fix himself to any environmental affordances, back to J. G. Herder's reflections on the origin of culture (Gehlen, 1997 [1940]). Inapt to face any demands of the environment by means of specialized organs, humans had to choose a different strategy for getting by. Culture was thus established as a compensatory mechanism for biological insufficiencies. In the biological sense, man is not yet ready, according to Gehlen; he is a task for himself.

Unlike Arnold Gehlen, Max Scheler, and Adolf Portmann, philosophers Martin Heidegger and Ernst Cassirer<sup>9</sup> did not take specific morphological traits of man nor the adaptive inaptness accompanying them as a departure point for describing man's exceptional position among other living beings. Both Cassirer and Heidegger focused more strictly on man's specific mental modes of relating to the outer world. In broad terms, they both disclosed the semiotic or symbolic hiatus between man and animal, the human escape from the restraints of immediate physiological reactions. In his "An Essay on Man: An Introduction to a Philosophy of Human Culture," Cassirer, when discussing the human entrance to the world of symbolic forms, also considers the new coercion that is thereby set on man (Cassirer, 1944). Once the novel sphere of symbolic interactions is opened up, man becomes fully enmeshed and enclosed in it. From then on, symbolic filtering becomes the single pathway leading from the self to the world, although, in essence, it always results in auto-communication, with man being caught in the forms of knowledge that establish his own identity.

Martin Heidegger's concern with the human world, free from the captivity of the immediacy that

is characteristic to all nonhuman worlds (Heidegger, 1983), is echoed also in the work of his otherwise critical student, Czech phenomenologist Jan Patočka (Patočka, 1998 [1995]). Patočka contrasts the animal, embedded in the relations of immediate relevancy, forced into the constraints of constant presence, with the human, who is open not just to the domains of past and future, but also to all possible forms of past and future, which he calls quasi-structures (quasi-future, quasi-present) (Patočka, 1998 [1995], p. 32).

Excluding the aspects of past and future from the activity of any living being is highly problematic if the preservation of organic form is to be explained. Each act and activity of an organism already anticipates some further biological state, thus contributing to the presence of the specific organic form in the future. Each value and meaning that an animal encounters in the objects of its environment is at the same time an encounter with a possible future state. The "not yet" of the organism is touched upon with each perceptual act, giving way to the continuation of the self without reducing duration to an extracted present. A living being, therefore, is never a point in space, but an ontogenetic as well as phylogenetic extension, without a fixed moment of beginning and end, but with definite choices for the self-specific persistence.

All interpretations of Uexküll's *umwelt* concept introduced in this chapter, refer to it as a model that explicates the strict adaptations and deterministic, although species-specific, attachment of animal to its environment. In the next chapter, we return to the semiotic interpretations and see how the above-mentioned versions were challenged by a number of authors who questioned the claim that mediated access to the world is a privilege of humankind.

#### ACROSS THE SEMIOTIC PASS

A new merging of *umweltlehre* and the humanities in the form of a semiotic synthesis took place in the mid-1970s. It was a time when the language- and culture-bound discipline of semiotics started to seriously question its scope and extent. The coming years featured intensive discussions on the need to lower the semiotic threshold, i.e., to realize that the human mind and language are not the first instances of semiotic activity, but that animals, plants and in fact the whole living domain is based on the use of signs and the functioning of sign processes. Those new questions and research perspectives led to the establishment of a field called *biosemiotics*, which

concentrates specifically on the semiotic character of various biological processes (from immunological recognition to animal communication).

As the establishment of any new field is accompanied by the awakening and construction of its dormant historic background, so was the case for biosemiotics. After clarifying its basic principles, biosemiotics began with a search for the confirmational past. One of the founders of biosemiotics, Thomas A. Sebeok, with his primary interest in animal cognition and communication, found his predecessors mostly from ethological circles (Heini Hediger, Jakob von Uexküll) (Sebeok, 1999, 2001). The list of forefathers grew with the expansion of the field itself to include scientists from a number of subfields of biology; for example the embryologist Karl Ernst von Baer and the psychologist James Mark Baldwin. This biosemiotic quest for ancestors stemming from biology ran parallel with the rereadings of the classical authors of semiotics. Although American pragmatist philosopher Charles Sanders Peirce was to become the historical mentor for a significant part of biosemiotic research (Thomas Sebeok had called him the loadstar of semiotics (cf. Deely, 2004)), it is perhaps even more interesting to see how authors strictly bound to the humanities were linked to discussions of biosemiotics and to biological *umwelt* models.

Thus Jakob von Uexküll's son, Thure von Uexküll (1908–2004), who related the *umwelt* theory to very different models of semiotic processes, linked it even with a theory that is otherwise considered to be in opposition with biosemiotic principles. He explicated a homomorphic relationship between the principles of Jakob von Uexküll's *umweltlehre* and the structural semiotics of Ferdinand de Saussure.<sup>10</sup> According to T. von Uexküll, Saussure's distinction between the abstract language system (*langue*) and the concrete speech acts (*parole*) (Saussure, 1998 [1916]) might be seen as corresponding to Jakob von Uexküll's differentiation between plan of nature and its concrete realizations in life activity (T. v. Uexküll, 1992, pp. 4–6). T. von Uexküll made an important distinction between biological and linguistic sign systems, however, naming the former *perceptual or monological systems* (based on innate codes) and the latter *dialogical systems* (based on learned cultural codes). The classical authors of semiotics whose ideas Thure von Uexküll integrated with those of Jakob von Uexküll, included Charles Morris, Gottlob Frege and C. S. Peirce (T. von Uexküll, 1982, 1992, 1999).

## THE INTEGRATION OF TWO MEANINGS OF UMWELT

Despite centuries of debate, contemporary sciences of man still find themselves in what have been called the “turf wars between sociology and psychology” (Watson & Coulter, 2008, p. 2), i.e., the debates between the social versus cognitive interpretations of the human mind. Whereas the contradiction inside the humanities has gained further support from a corresponding institutional segregation, a number of philosophical endeavors, from phenomenology to pragmatism, have aimed at undermining the battleground. Extending and contextualizing the problem of mind, incorporating knowledge from areas separated by disciplinary borders, and inventing fully novel research arenas have all granted some assuagement, to a certain extent at least. Seen in the light of these developments, the theory of *umwelt* and its later cultural theoretical adaptations also face two alternatives—to join the debaters on either side of the cognitive-social divide or to adhere to the challenging efforts.

The *umwelt* concept could contribute to either one of the sides, if suitable threads of thought are extracted from the full web of the theory. Thus the cognitive enclosure of an animal (including humans) results in fully one-sided construction of all objects, unless the organism itself is simultaneously explained as a product of the constitutive ecological or social relations. On the other hand, the (biological) subject's meaning-initiated activity dissolves into a chain of causal reactions to environmental stimuli, unless the role of the organism as an active center of meaning formation is taken into account. In order to not thereby tear apart the subject-as-meaning-provider and subject-as-relations-induced, it is essential to find a framework of analysis that would maintain the two meanings of *umwelt*: as a world initiated and comprehended by the subject and as a node in the set of ecological relations encompassing the whole biosphere. Those two could also be referred to as the phenomenological and ecological facets of the theory of the *umwelt*. Only the simultaneous presence and usage of the two can guarantee a steady position outside the above-mentioned dilemma.

The essential question therefore is whether we could indicate some primary integrative mechanism that guarantees and produces the coherence of the two, and that logically explains their simultaneous presence? Uexküll himself has suggested what he called *planmäßigkeit*, as a ground for the synthesis (Uexküll, 1927, 1973 [1928]). As the word

seems to hint to a metaphysical grounding based on a preestablished harmony, preformationism, teleology, and an idealized state of affairs, it has not found many elaborations by later authors (*although see Hoffmeyer, 2004, 2008, pp. 172–173; Cheung, 2004*). However, several additional processes have been suggested for what could also ground the integration of the phenomenal and the ecological in *umwelt* theory, irrespective of whether *planmäßigkeit* is accepted or not. They can all be seen as mechanisms capable of establishing the relative autonomy of some entity, applicable at the same time to a number of natural and cultural phenomena (thus the phenomena of mind just as well as cells, organisms, and whole ecosystems can be included).

Frederick Stjernfelt, for example, has used subject-dependent categorical perception as a bonding mechanism between different species-specific phenomenal worlds:

[...] the condition of possibility for nature to link up in these strange ‘harmonies’ between different species’ *umwelten* depends precisely on categorical perception: the perceptual categories form the tones in the metaphor, and it is their categoricity only that permits them to enter into counterpoint between the single *umwelten*. (Stjernfelt, 2007, p. 236)

The traces of categorization and the complementarity of the categories of different species are observable by any kind of spatial and temporal discreteness. Unless the form and expressions of one species and the perception of another—e.g., the movement speed of the prey animal and the predator animal’s perceptual time-sectioning, the resolution of the insect’s eye and the size of its food object, the sound range of the male bird’s voice organs and the female’s hearing range—correspond to each other, the two species or organisms lack the means to enter one another’s *umwelt*. The dependence of ecological relations on perceptual units and categories appears thereby evident.

Individual percepts and categories never operate as individual units, as though demanding some extra mechanism for their integration. They never appear outside of the regulative and homeostatic self-maintenance process of the whole organism. Although the latter terms are mostly used for describing how the ontogenetic continuity of one organism is preserved in the fixed limits of certain parameters, self-regulation of the individual organism would not be possible unless it is supported by the coupled constancy of the environment, the

two constancies calling forth one another. The self-regulative and self-maintaining capacities of the organism had been a research interest of physiologists at least since the works of Claude Bernard in the mid-nineteenth century. Observations and discussions about the corresponding properties of ecosystems, however, were just emerging in the 1920s and 1930s (in the works of, e.g., Frederic Clements, John F. V. Phillips, Victor Shelford), at the time Uexküll wrote his major works. As the theories of the self-regulation of ecosystems were still in their outset in the first decades of the twentieth century, it may have been one of the reasons why Uexküll, in an organicist manner, used at some occasions the metaphor of the organism for describing the regularities in whole ecosystems, instead of discussing the characteristics of the ecosystems proper (cf. Uexküll, 1909, p. 196).

## Conclusion

We indicated a variety of ways in which Jakob von Uexküll’s theory of the species-specific *umwelt* has been thus far applied to the analysis of culture and the human mind. These concrete derivations have departed from different aspects of the theory while using it as a springboard for inferences concerning man. The following associations between *umwelt* theory and its cultural implications can hence be brought out:

1. If *umwelt* theory is interpreted as a demonstration of how biological form and behavior expose the sensory impressions an organism is capable of receiving, it may also draw attention to questions of the coupling of artistic forms of expression and the underlying impressions;
2. If *umwelt* theory is read as a theory of ideal biological adaptations and specialization of all living beings, except man, then culture appears to be an extension of the same vital need to cope with the environment, although of a different kind than all the previous morphological and physiological ones;
3. If we direct attention to the questions of meaning and sign-relations as expressed in the concept of *umwelt*, then research on the common semiotic footing of all living beings is to follow;
4. If *umwelt* theory is seen as a way of integrating the subjective and the systemic perspectives, then a possible solution to the cognitive-social divide in humanities may be suggested.

All this has given umwelt theory a remarkable place in several approaches to culture. The foundations of umwelt theory have passed through significant transformations every time they have entered a new cultural theoretical paradigm. In the face of this, we don't see a reason to strive for a purified essence of the theory, independent of all its interpretations and therefore suggest that umwelt theory itself can be seen as a good indicator of cultural theoretical change. It offers a number of culture-bound elaborations, the character and concrete realization of which is specified by the cultural and philosophical environment where it finds itself.

### Future Directions

Bearing in mind what we inferred in the conclusion, we can only rather generally suppose, what could further be the culture-bound questions, whereby umwelt theory can be employed.

First, there is still enough work for cultural studies to be done on how language itself functions as a system of perception and action and what are its relations to other sign systems that humans possess. A number of studies belonging to the field of embodied cognition, situated cognition, enactivism that have in the past decades demonstrated the sensorimotoric embeddedness of linguistic categories provide a strong foothold for further studies that might also encompass the principles Jakob von Uexküll delineated in respect with sensorimotoric coupling and its role in the formation of meanings. All those theories have paid attention to how the symbolic domain of language is strongly tied with the human bodily reactions and perceptions and Uexküll's contribution might help to clarify how the connections of the latter are brought about in the first place.

Another possible future investigation thread may lead to the questions about the transitions from perception to communication. Is Jakob von Uexküll's model of the functional circle still applicable, when the two interconnected entities are mutually "talkative," both carrying their own values and meanings? To think that there is always another who has a say toward a subject's actions, does not concern only situations where two or more living beings are directly involved. It comprises any situations where interests are in play. The other may therefore be present only indirectly, through the claim he may have for the same thing the subject is striving for. This means while making a choice (whether it's a living place, a piece of food or something else) taking

into consideration for whom else may the object in question be valuable. The acknowledgement of the interest fields that surround the objects should not be seen as a source of competition, though. That might rather lead to the establishment of shared interests and to a search for creative solutions for how the interest fields could further accommodate the diversity of subjects that they attract. That would also mean seeing other subjects behind oneself's actions, to the recognition that no activity can be only self-directed.

### Notes

1. The term "umwelt," if used as a loanword in English, may also refer to the milieu concept of the French philosopher and historian Hippolyte Taine (as the outer world that affects the organisms) and to the modern common-sense meaning of umwelt in German (Sutrop, 2001, p. 458). For the historic overview of the development of the terms "milieu," "environment," and "umwelt" see, e.g., Canguilhem (2001 [1948]) and Chien (2005).

2. "Ebenso objektiv wie die Faktoren der Umwelt sind, müssen die von ihnen hervorgerufenen Wirkungen im Nervensystem aufgefaßt werden. Diese Wirkungen sind ebenfalls durch den Bauplan gesichtet und geregelt. Sie bilden zusammen die Innenwelt der Tiere."

3. Under the classical models we understand here the linear models of communication (e.g., Wilbur-Shramm's, Shannon-Weaver's, and Jakobson's communication models). Although we are aware of the differences between them, such differences may be discarded in the context they are used here.

4. The mirror law or the law of reflection in physics characterises specular reflection, where the angle of incidence equals the angle of reflection.

5. *Erscheinungswelt* (the world of appearances) is the world of meaningful objects as it appears to the subject. Unlike umwelt, it is not accessible to the external observer.

6. From Uexküll's legacy, we find a significant number of articles and essays on philosophical issues in science. These writings touch first and foremost on the differences in the physiologist's and the biologist's approaches to living phenomena. As Uexküll described the physiological approach as a mechanical one, he identified his own position with the one of biologist.

7. *Wär' nicht das Auge sonnenhaft / Wie könnten wir das Licht erblicken?* (Goethe, 1810, p. xxxviii).

8. Max Scheler (1874–1928), who like Gehlen, belonged to the circles of German philosophical anthropology, reflected upon the same principle of nonadaptation as a biological impetus for the evolution of human species. Scheler called the latter an *organological dilettantism* (*organologische Dilettantismus*). He relied hereby on the evolutionary theories of the German physical anthropologist Hermann Klaatsch (1863–1916) (Scheler, 2001).

9. For in-depth studies on the relations of Uexküll's Umwelt theory and Cassirer's philosophy see Chien (2006), Krois (2004), Heusden (2001), Weber (2004); for the relations of Uexküll and Heidegger, see Buchanan (2008), Chien (2006).

10. Thure von Uexküll defines homomorphic relations as based on "[...] a fundamental conformity repeated on various levels of complexity, each time in a different way, but basically always in the same form [...]" (T. v. Uexküll, 1982, p. 5).

## Culture and Epigenesis: A Waddingtonian View

Iddo Tavory, Eva Jablonka and Simona Ginsburg

### Abstract

The relationship between biology and socio-cultural phenomena can be studied within either causal or metaphoric frameworks. Although *causal* analyses try to isolate biological factors and processes associated with cultural phenomena and work out how they bring them about, the *metaphoric* approach uses models and metaphors in one field to advance the other. This chapter outlines a metaphoric approach to studying socio-cultural phenomena that is based on the epigenetic landscape model developed by Waddington. The dynamic stability of socio-cultural phenomena is seen as a result of interrelated patterns of plasticity and canalization operating at different levels of organization and working through different mechanisms: social-structural, cultural, and biological. The chapter begins by distinguishing our view from other prevalent approaches, and then proceeds to explain Waddington's epigenetic approach and apply it to a well-researched sociological question—the reproduction of urban poverty.

**Keywords:** cultural evolution, epigenetic landscape, canalization, plasticity, Waddington

The relation between biology and culture—the effect of human culture on human biology, and the effect of human biology on human cultures—has received a great deal of attention in recent years. A cluster of approaches, differing in some ways, yet all inspired by biological evolutionary theory, is particularly influential (*see* Richerson & Boyd, 2005). Far less attention is given to analogies between developmental (e.g., embryological) processes and cultural processes. The open-ended nature of cultural transformations and the highly constrained, seemingly deterministic nature of developmental processes seem at first sight to make such an analogy inappropriate and no less problematic than that offered by approaches that stress specific genetic bases for culture. However, the problems facing studies of culture and society, and those facing studies of biological development are often similar.

Researchers studying embryological development, like those who study the dynamics of culture,

face an extremely complex system of relationships. In both cases, from an array of contingencies and interacting processes, a relatively coherent complex of phenomena emerges. For example, although both developmental biological and socio-cultural systems are in permanent flux, there is also a great deal of stability—what sociologists have been calling, for quite some time, “the problem of order.” We suggest that recent changes in the way biologists regard development—a greater stress on open-ended plasticity on the one hand, and on processes of canalization on the other (West-Eberhard, 2003)—make such biology “good to think with,” as Levi-Strauss would have put it.

In this paper, we outline such an approach inspired by developmental epigenetic research, and use insights from this field as metaphors that may be useful for thinking about some socio-cultural dynamics. We suggest that a nonreductive analysis of cultural phenomena can benefit from using

Waddington's (1957, 1968) view of developmental dynamics. We use Waddington's schema as a generative metaphor for socio-cultural dynamics; we do not assume that embryological dynamics can be seen as causal agents for cultural determination. Rather, we argue that, confronted by similar questions, sociologists and cultural anthropologists may benefit from the schema developed by Waddington.

We start by presenting and criticizing some of the most influential ways of thinking about the relation between biological determinants and socio-cultural configurations. We then move to define key concepts developed within the framework inspired by Waddington and discuss their application to cultural processes, focusing on a particular case—the reproduction of poverty. Throughout this chapter we make the point that since the relationship between the biological and socio-cultural levels is complex, “plastic,” and based on many (non-linear) feedbacks, any direct determination of a causal link from the biological to the cultural would be very partial, and often theoretically reckless. Biological and socio-cultural studies should, however, trade metaphors. Because they are engaged with similar dynamics—a study of multiple causes, of regularities and changes in a complex system—such trade, as we demonstrate, would be a fruitful endeavor.

### **Causal and Metaphoric Links between Culture and Biology**

Our approach stresses the “metaphoric links” between culture and biology. Although we agree that specific causal relationships between biology and culture may exist (in both directions) and although it is both clear and trivial that biology offers a template upon which culture evolves, this template is itself far from rigid, primarily providing a set of affordances that people socially and culturally mold in a variety of ways (Gibson, 1977). We argue that even in those cases where biological factors are to be taken into consideration as causally relevant for enabling cultural dynamics, they should be considered as inputs into a rich web of relationships in which they do not have a privileged status. Our approach is therefore close to that recently developed by Wimsatt and Griesemer (2007), who advocate a view of culture that focuses on processes of reproduction and co-reproduction among biological agents and cultural artifacts, rather than processes of replication and diffusion. Although they use the metaphor of *scaffolding*—social processes and embodied products that support and facilitate

the reproduction of complex behaviors—we focus on the processes that generate trajectories that lead to the reproduction of the same social-cultural state, even when these trajectories and many of the specific social products that are generated are variable. Thus, we see Wimsatt and Griesemer as providing a view that complements our own by specifying one class of stabilizing mechanisms.

Our view is, however, different from the dominant evolution-inspired approaches to culture, which we discuss in the sections below, so we first need to clearly distinguish it from them. In each case, having summarized the views put forward by the advocates of other approaches, we point to the kind of problems that make that view, in our eyes, partial, problematic, or even untenable. We differentiate between three major evolutionary approaches:

- a. A *memetic* approach, which regards cultural evolution as the result of the selection of memes, units of culture that are analogous to genes (Dawkins, 1976; Blackmore, 1999);
- b. The *massive modularity* view, which sees culture and cultural processes as powerfully influenced by preexisting mental cognitive and affective modules (Tooby & Cosmides, 1992, 1995; Pinker, 1997). This approach, which takes several forms, assumes strong, domain-specific, and partially encapsulated psychological processing devices, which are evoked by external social inputs;
- c. The *dual inheritance population* approach—an approach that focuses on selection by individuals of cultural variants, inspired by population genetics and quantitative genetics models, but not committed to distinct replicatable cultural units (Cavalli-Sforza & Feldman, 1981; Boyd & Richerson, 1985; Richerson & Boyd, 2005). It uses general social-cognitive biases, such as the tendency of people to follow the majority habit or copy prestigious individuals, as important determining factors of cultural dynamics.

### ***The Memetic View of Cultural Evolution***

This evolutionary approach is inspired by Dawkins' selfish gene idea and can be seen as an (analogical) extension of this view into the cultural domain (Dawkins, 1976; Blackmore, 1999). According to this view, cultural units, *memes*, are cultural replicators, and cultural evolution is governed by the selection of memes. Memes are determined by cognitive neural processes within individuals,

which may control the evolution of their carriers in a way similar to that in which viruses control their hosts. Like the selfish gene approach, where genes are the units of analysis, the memetic view suggests that ideas are the replicatable units for the analysis of culture, and people are but the carriers of such “replicators.”

This metaphor, however, has several serious problems. First, the nature of the memes is extremely fuzzy—memes are sometimes thought of as transmissible behaviors, sometimes as cultural products, and sometimes as circuits in the brain. Secondly, and most importantly, the idea that cultural behavior is “replicated” involves unrealistic assumptions about the way cultural meanings are acquired, a view that sees learning as a simple process of imitation, rather than as a pragmatic reworking of a given problem. This approach is therefore misleading—cultural behaviors are not replicated. Rather, culturally meaningful behaviors are developmentally acquired and constructed during individual ontogeny and social history. Since we regard developmental construction and reconstruction as an elementary aspect of culture and socio-cultural processes, disregarding it means, in our opinion, that the meme theory cannot properly explain the most fundamental facts about cultural dynamics—innovation, dynamic stability, and change (*for detailed critiques see* Sperber, 1996, 2011; Avital & Jablonka, 2000; Jablonka & Lamb, 2005).

### ***Evolutionary Psychology and the Massive Modularity Thesis***

The second approach is held by most twenty-first-century evolutionary psychologists. On the basis of widespread similarities in human behavior across different cultures, this view holds that “human nature” is reflected as a large collection of specific psychological adaptations that evolved about two million years ago, when our ancestors appeared and lived as hunter-gatherers (Pinker, 1997, p. 21). Following James (1890), who thought that human beings are flexible and intelligent because they have more, not fewer, instincts than other animals, evolutionary psychologists believe that the variety of problems faced by our ancestors led to the evolution of many specific modules: “hundreds or thousands of modules,” to quote Tooby and Cosmides (1995, p. xiii).

The idea that biological biases in psychological processes are organized as modules is taken from Fodor’s treatment of perceptual modules (Fodor,

1983). Modules are assumed to be functionally and neurologically distinguishable from each other, with each module having its own database, its own set of inputs that is specific to a particular empirical domain and that acts as a trigger, often during a critical period of development. In addition, modules have dedicated processing procedures, and domain-specific outputs (Fodor, 1983; Sperber, 2005). Evolutionary psychologists generalized this view, so that every strong behavioral human-specific tendency or behavioral bias is referred to as a module. Humans are supposed to have modules for humor, for mate choice, for food sharing, for cheater detection, and so on. According to this massive modularity thesis, then, the reaction to inputs is a process of evocation rather than construction (Tooby & Cosmides, 1992). The specificity and number of modules is the weakest point in this thesis (*for detailed criticisms, see* Karmiloff-Smith, 1994; Uttal, 2003; Sterelny, 2003; Jablonka & Lamb, 2005). Although some domain-general mechanisms (e.g., working memory) are accepted as important, and it is acknowledged that modules may have complex interactions with environmental inputs (*see* Buss & Reeve, 2003; Sperber, 2005), the assumption of massive modularity is maintained. In other words, evolutionary psychologists resist the idea that many of the “modules” they posit can be the effects of an interaction between a small number of domain-general procedures with socially constructed stimuli and processes. According to the massive modularity approach, instead of the interactions, the modules themselves are understood as specific.

Although the modular organization of some biological structures is not in doubt (West-Eberhard, 2003), this does not mean that specific psychological regularities must result from a specific modular cluster, or that these clusters have the properties assigned to them by such evolutionary psychology. The metaphor of the brain as a collection of modular “organs” is associated with several problematic assumptions. First, the difference between a species-specific organ-like module that requires little learning (such as inborn fear of snakes in some birds), and a module that requires substantial active learning is not very clear (Mameli & Bateson, 2006). Most normal people exposed to schooling who can read and write develop what may be viewed as a “literacy module” which can be selectively impaired, as cases of dyslexia prove; however, it is clear that “triggering” and “evoking” cannot describe the complex and learning-dependent process of constructing

literacy practices. There was no genetic evolution specific to literacy, and this is clearly a case of a specific interaction between more general cognitive-biological affordances and a specific social situation. Secondly, it seems that entrenched *individual* habits may have a cognitive structure which is quite similar to that attributed to a module. For example, a chess master may develop something resembling a “chess module”, and a professional football player can be said to develop a “football module.” In fact, every learned habit or cognitive obsession, with its developmentally constructed semispecialized and semilocalized brain mechanisms, can be described as a module, with more or less genetically guided aspects. Assuming that these modules are all specifically evolved is an unwarranted stretch of the imagination. Finally, the evidence from neurobiology for the existence of innate specialized cognitive modules is almost nonexistent. The only good example is the “language module”, and this too can be interpreted in less rigid terms than required by a massive modularity view, stressing the emotive, social, and learning-dependent aspects of language evolution (Tomasello & Slobin, 2005).

In short, the hypothesis that there are cognitive, sensory, and motor biases in humans, as in other animals, seems valid and nonproblematic (although, of course, such biases cannot be invoked at will); the assumption that they must be organized as distinct modules—with all the baggage that the term carries—is, however, unwarranted. The massive modularity approach downplays the significance of the formation of a vast number of new and changing neural connections between different areas in the brain during conscious behavior, the great open-ended plasticity of human behavior, and the major role of social factors.

### ***Dual-Inheritance Theory (DIT) Approaches***

A third approach, which is related to the view we take in this chapter, stresses mostly the analogies between the dynamics of social and cultural change and biological-genetic population processes. The proponents of this view (see Cavalli-Sforza & Feldman, 1981; Boyd & Richerson, 1985; Richerson & Boyd, 2005), revive parts of the diffusionist approach to cultural evolution, which was prevalent during the late nineteenth century, but add to it a rigorous methodology and a theoretical rationale. They argue that population thinking is the key to understanding cultural dynamics. Individuals acquire and use cultural information,

modify it (either accidentally or deliberately), and transmit it to others, both kin and nonkin. Some of the cultural information is beneficial or gratifying at some level, and persists. Other types of information are deleterious and are weeded out. However, simple benefits that enhance biological fitness are not sufficient, for there are additional processes that affect cultural dynamics, such as the tendency to act as the majority of people do (a conformity bias), and the tendency to imitate powerful individuals (a prestige bias).

The evolutionary effects of culture according to DIT are modeled by using (appropriately modified) population and quantitative genetics models. A well-known example is the selection of the alleles for breaking down the lactose sugar in milk, a trait that was favored in some human populations following the domestication of cattle (*for a basic review, see Jablonka & Lamb, 2005, Chapter 8; for a recent ramification, see Tishkoff et al., 2007*). According to the DIT theorists, the basic cognitive architecture of human beings constrains culture, but this constraint is far looser than that suggested by evolutionary psychologists. Instead of an encapsulated module in the massive modularity model sense, it is a bias or an affordance.

The DIT approach assumes that culture and genetics act upon each other, rather than that there is a uni-causal direction from genes to culture, and it uses population genetics models for thinking about cultural diffusion. Although we sympathize with both of these positions, we believe that as far as the metaphor goes, the DIT model can be improved. Population genetics models do indeed throw light on some aspects of cultural dynamics, but they provide only a partial account. The assumption that meaning diffuses because it is better “adapted” at the biological or cultural level is debatable. It seems to overlook some of the important ways through which cultural diffusion has worked throughout history—through forced diffusion, coercion, and conquest. Catholicism, for example, is not better “adapted” than Incan religion; it did, however, use guns—something that had a very tangential relationship to Catholicism. Although DIT theorists accept force (and other macrosocial phenomena) as the initial context for change in populations, they analyze it in terms of within-population dynamics and not in terms of global politics and macroeconomics, a perspective that is undoubtedly of importance for such cases.

In other words, the mapping of the relation between cultural “parents” and cultural “offspring”

provides only a partial view of cultural dynamics: the way that institutional practices, social products, political coercion, and economic constraints affect individual behavior is not just a background and a “selective environment.” These structural constraints are produced by individuals but can also direct and overwhelm transmission biases. *Macroevolutionary* processes like wars and global political processes are ever-present, always affecting the *microevolutionary* processes of diffusion within populations. Although DIT theorists focus on the diffusion of practices, propensities, etc. within populations, with the large-scale economic and political processes being construed as a background of necessary initial conditions, it may be more useful to situate the economic and political factors in the foreground as dynamic processes, no less important than the mechanisms of transmission of cultural practices among individuals within a population. Indeed, although the diffusion of cultural meaning cannot be reduced to political/economic conditions (*see* Alexander, 2003), these conditions always co-constitute the processes of diffusion. Thus, although the dynamics of transmission/acquisition are, as the DIT theorists claim, a constitutive part of cultural processes, they are one set of mechanisms, interacting in complex ways with other factors and mechanisms.

### Summary of Criticisms

In summary, we regard the lack of a developmental perspective in the memeticists’ and most evolutionary psychologists’ approaches as a serious flaw. We sympathize with the DIT approach, and think that many of the insights and methodologies it offers are useful, but we do not think that a population view is sufficient for explaining cultural phenomena and processes. Although, as we explain in the next section, processes of selective stabilization are central to our development-oriented approach, Darwinian population genetics describes only one type of such stabilization, and is not sufficient for the explanation of cultural dynamics. Indeed, in many situations it may be detrimental, leading us to think about adaptability of meaning where no such adaptive edge exists. In some ways our view is close to Sperber’s, although we do not subscribe to his massive-modularity assumption. In order to explain our view, we start by presenting Waddington’s epigenetic approach to the development of organisms and the assumptions underlying his model of an “epigenetic landscape.”

### Waddington’s Epigenetic View

The term *epigenesis*, which is the inspiration for the modern term *epigenetics*, refers to the Aristotelian view (although Aristotle himself never used it) that the characteristics of offspring are not preformed in the material transmitted by their parents, but rather arise sequentially during embryological development through qualitative changes in both material and organization. This approach was an alternative to what became known as the *preformationist* view, which posited that development consists of an unfolding of preexisting organization (Fry, 2000).

In the 1940s and 1950s, Waddington (1940, 1957) in Great Britain, and Schmalhausen (1949) in the Soviet Union, initiated studies of development and evolution that were centered on the complementary aspects of developmental canalization and phenotypic plasticity, two processes that decouple genetic and phenotypic variations. This view is known as an epigenetic view. The term epigenetics was suggested by Waddington who wrote in retrospect:

Some years ago (i.e. 1947) I introduced the word ‘epigenetics’, derived from the Aristotelian word ‘epigenesis’, which had more or less passed into disuse, as a suitable name for the branch of biology which studies the causal interactions between genes and their products which bring the phenotype into being. (Waddington, 1968, p. 12)

The “genetics” part of “epigenetics” points to Waddington’s awareness of the crucial role of genes in development, while the “epi” part of the term, which means “upon” or “over,” reflects Waddington’s intention to study developmental processes that go “over” or “beyond” the gene.

This epigenetic approach, which was somewhat neglected during the 1970s and 1980s, has recently been revived and expanded by a growing number of theoretical and experimental biologists. Modern epigenetic approaches stress the importance of the developmental dynamics of cellular and intercellular networks of interactions during the individual’s development, and sometimes also between generations of individuals. In addition to the emphasis on development and on the relation between genetic and extragenetic factors, the current epigenetic approach is guided by a set of heuristic concepts that are associated with Waddington’s views. The most important of these include “plasticity,” “canalization,” and “phenotypic accommodation.” Since

our approach to culture should be seen in the light of these, we first define and describe them.

*Plasticity* is defined in biology today as the ability of a single genotype to generate variant forms of morphology, physiology, and/or behavior, in response to different environmental circumstances. The responses can be reversible or irreversible, adaptive or nonadaptive, active or passive, continuous or discontinuous (West–Eberhard, 2003). The repertoire of alternative plastic responses to new conditions may be limited and predictable, as it is, for example, with seasonal changes in the color and patterns of butterflies' wings. Plasticity can also be, however, broad and relatively open-ended. Such open-ended plastic responses include unpredictable, novel adaptive responses, as seen when animals learn new behaviors through trial and error, or when humans engage in cultural behaviors such as building cathedrals or writing novels. Such open-ended plasticity is of central importance for understanding cognitive and cultural behaviors.

The mirror image of plasticity is canalization. *Canalization* is defined as “the adjustment of developmental pathways so as to bring about a uniform result in spite of genetic and environmental variations” (Jablonka & Lamb, 1995, p. 290, based on Waddington, 1957). In other words, canalization leads to the production of a stable output despite changes in inputs and/or in developmental trajectories. It leads to robustness and stability in a “noisy” world in which both the genetic milieu and the external environment are constantly changing. A single typical phenotype is generated by many different underlying genotypes and in many environmental conditions.

Canalization and plasticity are closely and intimately related: almost every case of canalized development (in the face of genetic and environmental “noise”) assumes plasticity at underlying or overlying levels of organization. There are many examples of this. Thus, to take an example from neurobiological research, it has been established that inputs from other brain areas during early embryonic development, influence the formation of specific cortical areas. For example, if retinal input is rerouted to the auditory cortex, the latter develops visual properties (Roe, Kwon, & Sur, 1992). Similarly, the ability of the adult neocortex to change its structure during the lifespan of an individual is also quite striking, and many examples of experiential modifications in the organization of the brain have been reported, in both normal and sick subjects. Following various

injuries, cortical areas devoted to certain functions undergo rearrangements, as is found after limb amputation or stroke episodes. In stroke patients, measurements employing brain imaging techniques during finger movements in a previously paralyzed hand have demonstrated complex patterns of brain reactivation; activity in certain areas of the cortex increases (Weiller, Chollet, Friston, Wise, & Frackowiak, 1992; Weiller, Ramsay, Wise, Friston, & Frackowiak, 1993), as changes follow rehabilitation treatments (Liepert, Bauder, Miltner, Taub, & Weiller, 2000).

Moreover, the plasticity mechanisms that enable brain reorganization have more than compensatory functions. Novel functional organization, which has never been seen in the ontogenetic or phylogenetic past of the individual, can become evident. The set of developmental processes that lead to novel phenotypic outputs has been called *phenotypic accommodation* (West-Eberhard, 2003, pp. 140, 146). The notion is perhaps best exemplified by a morphological example, the case of a two-legged goat that was described by Slijper in 1942. This goat was born without forelegs, and with the help of a caring farmer adopted a semi-upright posture, ending up hopping, kangaroo-like, bipedally and independently, on its hind legs. After its death, postmortem examination revealed many coordinated changes in its morphology, which were the consequence of its unusual mode of locomotion. In addition to a changed hind leg and pelvic structure, it had a curved spine, an unusually thick and large neck, and various functionally correlated changes in its skeleton and musculature (*see* West-Eberhard, 2003). Less spectacular, but still striking examples of phenotypic accommodation are found in normal subjects challenged with unusual tasks: for example, in the case of skilled string players, who use their left hand in playing music, the sensorimotor cortical areas in the right (but not in the left) hemisphere are enlarged (Elbert, Pantev, Wienbruch, Rockstroh, & Taub, 1995). Similarly, expanded sensorimotor cortical finger areas are seen in healthy Braille readers (Pascual-Leone & Torres, 1993).

Phenotypic accommodation is a consequence of general biological properties such as mechanical flexibility—the many partially overlapping regulatory elements—and, crucially, processes of “exploration” and “selective stabilization,” not only at the cellular and physiological levels, but also at behavioral and social levels. Exploration and selective

stabilization processes are based on a common principle—the generation of a large set of local variations and interactions, from which only a small subset is eventually stabilized and manifested. Which particular output is realized depends on the initial conditions, the ease with which developmental trajectories can be deflected away from their current paths, and the number of possible points around which development can be stably organized. Following convention, we refer to these points as “attractors,” since they are stabilizing end-states toward which the system seems to “strive.” This, of course, should not be understood as a classical teleological view, because the end points do not literally attract the processes leading to it. Rather, “attractor” is a shorthand to describe a process in which a large number of interacting factors tend to co-regulate and to reinforce each other in ways that regularly produce a specific end point. There could be different permutations and plastic shifts in many of the underlying processes, creating a number of variations in trajectories, but the end point would be similar. Put concisely, the selective stabilization processes that lead to an attractor involve both canalization (at the output level) and extensive plasticity manifested as extensive exploration and trajectory variability.

An example of a selective stabilization is the exploratory behavior of unicellular organisms, like bacteria or paramecia. A paramecium that has its path blocked starts moving in random directions. Its movement is only stabilized and directed when it encounters an attracting stimulus, such as light or food. Exploratory, initially random, behavior is also observed in plants’ growth trajectories: for example

the movements of the stem of a plant that is grown in the dark are erratic, and growth only becomes directional when the plant encounters the directing stimulus (light in this example), which leads to the stabilization of growth in the direction of the light (West-Eberhard, 2003, pp. 38–39). Other examples are the selective stabilization of synaptic connections during development and learning (Changeux, Courge, & Danchin, 1973; Edelman, 1987), and, at the behavioral level, trial-and-error learning in animals. Sperber highlights the role of attractors—both cognitive biases, and cultural structures and products—in the evolution of culture (Sperber, 1996, 2005, 2011; Claidière & Sperber, 2007). He argues that attraction can lead to cultural stability even in the face of variations and a low fidelity of copying.

The dynamic stability of the macrolevel in the face of microlevel variations and processes is the key feature of canalization and is best understood through Waddington’s diagrams of his “epigenetic landscape” model of development (Waddington, 1957; see Fig. 30.1 and Fig. 30.2).

Development is represented as a ball rolling down a tilted landscape, with many hills and branching valleys descending from a high plateau, which represents the initial state of the fertilized egg (Fig. 30.1). The attractor toward which the ball rolls is a morphological, physiological, or behavioral state, which is relatively stable: A functioning heart, a functioning eye, locomotor ability in a human child (see Thelen, 1995). The downward slope represents temporal movement, with the bottom representing the final state of affairs and the top representing the initial state. The steepness of a valley can be thought of as biases and propensities, constraints and specific

**Figure 30.1** An epigenetic landscape. Taken from Figure 4, entitled “Part of an Epigenetic Landscape” on p. 29 of Waddington’s *The Strategy of the Genes* (1957).

affordances, and it indicates how much the system can vary—how well-buffered it is.

The landscape is underlain by a network of interacting elements (Fig. 30.2). It is shaped by the tension of guy ropes that are tied to pegs in the ground. As can be seen in the figure, which is like an X-ray picture of the hidden dynamics below the surface, the topological relations of the interacting pegs and guy ropes determine the architecture of the visible undulating landscape (Figs. 30.1 and 30.2). These interactions could be described by network-theory models, in that the different pegs are themselves related to each other in complex ways that make some pegs more “central” than others, because they have connections with many other pegs, while other pegs are more “redundant.” As stressed in network theory, it is not only the number of different pegs (different interacting units) that is important, but the way they interact (*see, for example*, Bonacich, 1987; Brandes & Erlebach, 2005). In Waddington’s schema, the pegs represent genes, and the guy ropes represent their biochemical and regulatory effects. The specific developmental trajectory toward the attractor can change—there are many routes that can be taken, processes of exploration generate alternative routes that stabilize once the attractor is reached, whatever the route and trajectory taken and whatever the precise initial conditions. Although in certain circumstances the existing biases and propensities may be overcome and a different attractor may be reached, this requires that a new challenge (e.g., strong stress) alters the multiple interactions among the elements, and generates a new network of interactions that divert the ball from its normal course. The steepness of the valleys, and hence the

outcome of development, can be altered through natural selection. In other words, attractors, and the ease or difficulty of reaching them, can change during evolution.

### *Social Landscapes and Cultural Attractors*

We can use this visual model to describe the formation of new behavioral and cultural attractors. We must, of course, spell out what this social-epigenetic landscape may stand for, what the time axis is, and what the underlying interacting factors are. Unlike the embryological landscape, the social landscape in Figure 30.1 is not one of unfolding differentiation from a relatively simple to an increasingly differentiated state, but rather the outcome of the dynamics of the processes underlying it. Unlike the pegs in Waddington’s picture, which are usually different from the guy ropes emanating from them (in Waddington’s landscape, pegs are genes and guy ropes are proteins and different types of regulatory elements), there is no such clear distinction between social pegs and their effect. For example, if the quality of the school in a poor neighborhood is a “peg” in a landscape that depicts the reproduction of poverty (*see next section*) the behaviors of the pupils, their parents and their teachers both constitute the peg and are the guy ropes emanating from it. Figure 30.2 shows just part of a larger network (aspects of the social environment in the wide sense). The inclining slope leads to several large attractors (not seen in the picture) that are different socio-cultural phenomena. Depending on the initial conditions and the specifics of the landscape from which it starts, an individual is likely to reach one particular attractor state.

**Figure 30.2** The networks underlying and constructing the landscape.

Taken from Figure 5, entitled “The complex system of interactions underlying the epigenetic landscape” on p. 36 of Waddington’s *The Strategy of the Genes* (1957).

As a preliminary example, let us look at the cultural stability of a particular hypothetical culinary culture. Imagine a society with a culinary tradition in which salty and spicy, well-cooked food is strongly preferred, and assume that in this society the tradition, which involves the preparation and consumption of specific dishes, has been stable for many generations. What are the interacting factors, and why does the network they form lead to a stable, persistent, tradition? In this case the interacting factors are likely to be ecological, social, and biological:

a. *Ecological factors*: The area is hot, food spoils easily and the well-cooked, salted, spicy food is safer than food prepared differently. Plants from which spices can be made grow in the area, and the use of spices, and the cooking methods, enhance the safety of the consumed food.

b. *Social factors*: Spicy food has come to be identified with this society, and begins to identify individuals as members of this particular group. Specific dishes come to have important social-symbolic (e.g., religious) meaning, being eaten during festivities or other important occasions (weddings, funerals). Eating very spicy food gives an individual special prestige, as does preparing spicy dishes. The food is therefore related to a whole network of significant social activities and processes, which are mutually dependent. Economic activities that are centered on the growth, selling/buying, and preparation of the food used for cooking reinforce its value. Some spices that are not readily available are imported from several other localities. Economic activity is also associated with medicinal practices, since the spices have, or are believed to have, specific medicinal effects, used in the local physicians' practices.

c. *Biological and psychological factors*: Young children are exposed to the food during early childhood, and develop a lifelong preference for it. Moreover, pregnant women transmit food traces to their offspring through the placenta and through milk, and the offspring develop food preferences similar to those of their mothers (Mennella, Jagnow & Beauchamps, 2001). Exposure at early stages (in utero, as neonates, during early childhood), reinforces the same food preference, which becomes dominant (for a review of animal examples, see Jablonka & Lamb, 2005, Chapter 5). It is possible that in some populations, where the culture has persisted for a long time, there has been some

selection for genes coding for proteins that are related to the reaction to food intake.

The example above already includes some of the elements of a metaphoric use of Waddington's schema. Clearly, and contrary to Waddington's own use of the model, we do not assume that the pegs are all genetic. Rather, the pegs are the interacting processes and factors (in which individuals and groups are active agents) that lead, in this example, to cultural stability. Some of these may be the ecological, epigenetic, and genetic factors that biologists feel comfortable talking about, but others are symbolic, economic, and social aspects that cannot be reduced to the biological. What ties them together in an epigenetic-like landscape is that these are all mutually reinforcing mechanisms that lead the individual to a shared outcome (or "attractor"), namely eating spicy food. We can imagine a situation in which an individual leaves the community, breaking with the symbolic aspects of liking spicy food (even thinking that it is silly to treat spicy food as a symbolic boundary), but nevertheless still likes spicy food because of the preferences garnered in utero and early life. Similarly, we can imagine an individual who absolutely detests spicy food, but will still eat it, because she wants to be considered a competent member of the community. In both examples, the underlying variability in preferences and specific behaviors is still strongly canalized, leading to the attractor.

In the example above, the attractor state has biological adaptive significance for the individual because we assumed that the ecological factors make the consumption of the food beneficial (it is "healthy"). However, it is easy to relax this assumption, by assuming, for example, that a group of immigrants from the locality settled down in a different place, where medical care renders the consumption of spices completely irrelevant for health. But even though the spicy food is no longer beneficial, the tradition will still persist. In fact, one of the interesting aspects of the landscape model is that it can be used to interpret not only cases where there are some benefits to the outcome (when the attractor provides a positive selective advantage at the physiological level, the cultural level, or both). Rather, it can also be used to interpret cases where the attractor is clearly nonadaptive. The regulatory architecture of the dynamic network may have properties that overwhelm the chances of reaching alternative, more adaptive attractors. A representative case that can be interpreted in these terms is the reproduction of urban poverty.

## Realizing the Metaphor: The Case of Urban Poverty

We now move to consider ways in which thinking in epigenetic terms—specifically through Waddington’s epigenetic landscape metaphor—may help sociologists and anthropologists who deal with meaning and social structures to make sense of the patterns of action that people construct and decode, and into which they find themselves born. One thing that makes Waddington’s model useful is its similarity to current thinking about stability and change. Thus, whereas order was once seen as a non-problematic social point of reference, and change and conflict were seen as the phenomena we needed to explain, current theorizations of social life focus on the dynamics of both change and stability. As in Waddington’s model, the assumption is that any outcome is an end point in a long series of interactions, many of them highly contingent. Structure is not something that exists independent of these contingent interactions, and indeed, if structure “exists,” it exists as a process (Bourdieu, 1977; Giddens, 1984; Sewell, 1992). Thus, like Waddington, sociologists have moved to think about the *dynamics of stability* as much as about the dynamics of change.

Thinking along these lines, we take one general problem that has been central to urban anthropologists and sociologists—the reproduction of urban poverty. This is a potentially useful topic to think through, because, as will become apparent, it displays the two “Waddingtonian” dynamics we have presented above: A highly complex system that is constantly shifting, and a relatively stable outcome. Additionally, the question of urban poverty has received sustained attention, which allows us to bring together different claims made in this context.

Although some mobility exists, and people do move from one socioeconomic category to another, urban poverty can be thought of as “hereditary.” This “heredity” does not work in any biological sense, but simply in the sense that people who grow up poor tend to stay poor, the myth of the self-made man notwithstanding. Indeed, the degree of income correlation between generations is extremely high in the United States, and children born in the lowest quintile (20%) of the socioeconomic ladder have only a 1% chance to end up in the highest 5% (Herz, 2006). This is compounded in the case of poor blacks in the United States, where 63% of black children born into the lower-income quarter,

will remain there as adults (Herz, 2006), and this percentage is higher if we make our scale finer, and go lower down the socioeconomic status ladder. In other words, remaining poor can be seen as a strong attractor, a dynamically stable point people tend to reach if they are born into a specific economic stratum—although replication is not perfect, poverty is a strong attractor.

Why, exactly, poverty is such an end point is of course a matter of some debate. Some aspects are obvious. Poorer people don’t have the family connections that often provide good jobs, they usually live in blighted areas in which the only available jobs are rotten, the schools are bad, and children are expected to be working-class when they grow up, rather than being expected to go on to be lawyers, businessmen, etc. The parents’ position also affects their children through education. Thus, if there are no books in the home, or if parents cannot (or do not have time to) help children with their homework, and do not have the money to have them tutored, the effects can be predicted. Systematic discrimination, where it is harder for blacks to even obtain jobs, does not help (Pager & Shepherd, 2008).

Other aspects that work into the reproduction of poverty are less widely recognized. Wilson (1987), for instance, argued that the low socioeconomic mobility of poor blacks in the United States is directly related to the decisions of the few that actually “make it out” of the ghetto. Simply put, they disappear. They move out to middle class neighborhoods, and often sever the friendships (and kinship) and ties they had with their poorer social network. In effect, there is no collective efficacy, and the poor are now worse off, as those elements in their social network that could have helped them gain mobility are no longer there.

So far, the evidence for canalization is clear, but the evidence for plasticity is missing—the stability of poverty seems inevitable and mostly divorced from the question of meaning. A series of studies of the black ghetto and other working-class contexts, however, shows how poor urban blacks and other working-class residents attempt to “make it” in their environment; how they imbue their surroundings with meaning, and try to make sense of themselves as actors in such an environment. Thus, Newman (1999) shows that many residents in these blighted neighborhoods try to yank themselves up by their bootstraps, fostering a middle-class ethic of work, which they put into the worst jobs available—the “McJobs” at food establishments.

Other studies (Bourgois, 2003) show how drug dealers are attempting to realize a dream of mobility through their dealings, while simultaneously fostering a street “savvy” that gains them respect on the streets (*see also* Anderson, 1999).

People also try to cope with the poverty, constructing “niches” of respectability within it. Thus, for example, Duneier (1999) shows how homeless men and women in New York’s Greenwich Village make sense of their surrounding, selling magazines that they pick up from the trash of others, building up an ecology in which they can both survive and make sense of themselves as moral individuals. In other words, the end point of poverty is dealt with in different ways; there is quite a lot of plasticity and variation in the ways that people deal with their surroundings.

However, what makes Waddington’s metaphor “work” in this context is that these different strategies are all canalized. Thus, workers in McJobs, where there is very little occupational mobility between ranks, remain poor. They may get a sense of themselves as decent breadwinners, or see their jobs as “slaving” (Newman, 1999, p. 133), but they will almost certainly remain poor, with jobs that pay minimum wages. On the other hand, upon close inspection the “lucrative” allure of drug dealing turns out to be a myth. Not only is there the constant danger of being shot or arrested, but most drug dealers, if they carefully counted their earnings, would realize that they make little more than the minimum wage. Drug dealers’ illusions that they make “fast cash” stem from the fact that their work involves sudden cash flows, but this is punctuated by long lulls where they make nothing. Although the lives of drug dealers and McWorkers are different, both “plastic” adaptations are thus canalized into the same general socioeconomic outcome.

This relationship between plasticity and canalization can perhaps be best seen in Willis’ (1981) study “learning to labor.” One of the poignant points in Willis’ work is that the sons and daughters of working-class families often rebel at school. Knowing that their life trajectories are predetermined (and overdetermined), they try to kick in all directions, flunking school and fostering a masculine image of themselves as rebels in the process. Yet, without having a high school diploma or credentials, they are doomed to follow in the footsteps of their parents; it is exactly through their attempts to rebel against their condition that their condition is reproduced.

The striking point in all these cases is that different strategies and contingencies end up reproducing a specific socioeconomic position. In Waddington’s terms, the variations among the cases show that there is a high degree of plasticity, but the emergent consequences are strongly canalized. The “lads” in Willis’ work remain working-class, the unhoused remain poor, and those who develop a “code of the street” often find this code to be highly problematic when they look for jobs outside the ghetto; each of these strategies ends up flowing into the same set of conditions. On a larger structural level, urban poverty is reproduced. But the point is not only that without reorganization “from above” poverty will end up reproducing itself (*cf.* Wacquant, 2002), but that urban poverty is overdetermined, and—at least on a statistical level—each of the permutations ends up flowing to the same attractor: urban poverty.

Using Waddington’s metaphor, we then shift the way we think of the “pegs” from genes to different (in this case almost exclusively social) processes and mechanisms. Thus, in the case of urban poverty, we can distinguish between at least three different kinds of pegs. First, there are social-structural pegs. These include the kinds of jobs available, the education of parents, the quality of schools in the inner city, the structure of the state welfare system. A second order of pegs includes the meaning-making processes people use in order to make sense of the conditions they find themselves in, their ways to define themselves and their relationships. These pegs are not uniform and range from the rebellion of teenagers and selling drugs to the attempt to find steady employment in a McJob and other ways of handling the situation. Where the first kind of pegs relates to social structures, the second denotes local cultural and subcultural meaning structures. Another set of “pegs,” which is probably not very salient in this case, may include some biological factors—e.g., where the cheapest food is junk food, mothers’ and even fathers’ poor nutrition may have a lasting effect on the life chances of their children.

Of course, sociologists know this. Using different vocabularies—of “overdetermination of causes,” to take one example—they make a very similar point. Why then would the Waddingtonian schema be useful? We think it is useful in several ways. First, thinking through this metaphor would force researchers to explicitly study the complementary dynamics of change and stability. Adopting this viewpoint, “the problem of order” is not seen as somehow opposed to the constant dynamics of

change. Rather, in a complex system, certain outcomes are reproduced both in situations where one mechanism works against others (as when poor people try to “better themselves” through minimum-wage labor), but also *through* changing internal dynamics. These dynamics of stability are not deterministic, so that although canalization means that certain social conditions (“genotypes”) tend to produce the same social “phenotypic” outcome, this is not necessary. This probabilistic view needs to be kept in mind especially in the social world—where 63% of reproduction is considered very high.

Secondly, students of culture are often seeking for the “golden practice”—the piece of the puzzle that would explain the difference between conditions. Raised on Mill’s (1843/2002) “method of difference,” they (like other scientists) often look for the *one* practice that would account for the difference between conditions. Thinking through Waddington’s metaphor, however, would make this project highly dubious. If indeed sets of practices are canalized toward a specific outcome, then the comparative study of meaning should not focus on specific practices, but rather on the system of canalized relationships, and the combinations that may subvert a well-canalized attractor. Although one well-placed change can cause a different course to be more common, this would be rare. In most cases, it is only a combination of changing relationships that produces change. The task shifts from a specification of cause, to thinking about networks of relationships that produce a similar effect. A good example of the need to think in terms of networks of interacting processes that can lead to change (rather than of a single “major” cause) is the dynamics of persistence of famine in Northern Ethiopia. In this case, described and analyzed by De Waal (1997, Chapters 5 and 6) complex political/religious struggles for power play a decisive role in the maintenance of famine; sadly and ironically, foreign aid, which may be naively seen as a measure to relieve famine, has been used to sustain the political interactions that maintain the famine state.

The interactive, network-focused aspect of Waddington’s schema resembles recent developments in “Actor-Network Theory” in the sociology of science. Latour (1987) and others (e.g., Callon, 1986) focus on networks of relationships among different actors as the basis of their analyses. Within each specific situation, actors pursue their own ends through constructing a network of other actors (both human and nonhuman) that they manage to

align with their project. The Waddingtonian landscape may be seen as a further specification of this theoretical thrust in two ways. First, the networks we are led to think about through this metaphor are networks of relationships, not actors. Secondly, focusing on the temporal movement toward an attractor, and on the complementary nature of plasticity and canalization, moves us to think not only about process, but about the kinds of regularities that appear in overdetermined, canalized, structural dynamics.

Lastly, thinking about social phenomena in terms of plasticity and canalization would be useful in providing a spectrum of different conditions—a scale that goes from the well-canalized process (such as the reproduction of poverty) to more precariously canalized phenomena that are thus reproduced with less fidelity. Thinking along this continuum would allow sociologists to create a scale of effect-canalization, and thus a comparative tool, without making the unrealistic assumptions that Mill’s method of difference implies; at the very least, it would take this question of difference to a higher level of organization.

## Discussion and Conclusions

We have suggested linking biological and socio-cultural processes through the developmental metaphor of the epigenetic landscape. This bridging metaphor allows us to consider the many factors and processes that make up the social landscape without a priori granting a privileged position to one type of factor or process. We do not wish to downplay the role of biological factors, as they may indeed be important in some circumstances, providing “a difference which makes a difference” (Bateson, 1979). However, in most cases these factors may play only a very minor role. This role, when there is one, is overwhelmed by more dominant social factors. In fact, even when the existence of specific biological biases in a certain direction is demonstrated, it is still a long way from explaining symbolic culture. Indeed, an analysis of cultural processes may show that many aspects of culture go against the grain of our biological-cognitive biases. Our approach therefore incorporates these aspects, but does not prejudge their significance. Crucially, the adoption of the model is not intended to suggest a causal analysis of culture starting with genes and cellular epigenetic regulation processes, but its use as a metaphor highlights the similarities between the processes described by developmental biologists and

those described by anthropologists and sociologists (*see also* Wimsatt & Griesemer, 2007).

We use Waddington's model of epigenetic landscape as a way of thinking about the dynamics of stability and change in complex sociocultural matrixes. Like Waddington, we assume that there is very rarely, if ever, a situation in which an attractor, or a recurrent state of affairs, is underlain by one causal process. Waddington's schema assumes that any stable attractor is the effect of a dynamic network of processes. This schema describes the dynamics of social structures as a pattern of interactions among pegs supporting a landscape. The regulatory structure of these interactions raises the chances of a particular outcome, so that even if any one of the pegs changes or disappears altogether, and even when the landscape changes (in the sense that the ridges and valleys are altered), the final stable state will nevertheless be reached.

As we pointed out, the pegs and guy ropes in the social landscape belong to different domains, and what the pegs are in a given landscape depends on the kind of question we want to ask. If our question is about why spicy food is preferred in a certain society, we will have one attractor, and set of specific pegs (including possibly but not necessarily some genetic pegs, some epigenetic pegs, some ecological pegs, and many social/symbolic and economic pegs). In the case of the reproduction of urban poverty, our pegs would be very different, with no genetic pegs and with very different sets of social and economic pegs. Moreover, something that is an attractor for one question may be a peg for another. For example, in the case of the cycle of poverty we described, we could conceivably ask a question regarding the culture of masculinity in the ghetto. In this case, the cycle of poverty will be considered a peg (albeit a very central one).

We believe that the epigenetic landscape metaphor can be useful for thinking about cultural and social relations. By providing a landscape model of dynamic stability, we suggest a way for thinking about the relative stability of social and cultural phenomena as an emergent property of different mechanisms working simultaneously. We do not assume that processes are necessarily complicit, in the sense that they strengthen one another or depend on one another to work (*see* Bourdieu, 1984), nor that any one mechanism, or a priori assigned category, holds primacy over the social process. Both for questions of change and of stability, the interaction and dynamic stabilization of multiple processes, occurring at different levels, provides a tool for understanding how

the dizzying array of social mechanisms come to reproduce relatively stable social phenomena.

Although the landscape metaphor is a very general way of thinking about cultural development, a *particular* social landscape (such as that underlying the reconstruction of urban poverty) provides a framework for hypotheses about the particular nature and interactions among the underlying factors. A hypothesis has to account for the observed specifics of the architecture of the particular landscape, and for the specifics of its observed temporal dynamics (in the case of urban poverty—its dynamic stability). The landscape metaphor, like any other good metaphor, therefore provides a framework for articulating and testing hypotheses.

### Future Directions

In this chapter we have taken first steps toward translating Waddington's epigenetic approach in a way that makes it suitable for tackling questions in the study of culture. In order to further develop this approach, there are several questions that need specification and other areas that need to be addressed. Although we are sure that more issues will come up as researchers use the metaphor, some preliminary questions include the following:

- What is the strength of canalization for different phenomena? This is a question that needs to be addressed both for every particular case, and comparatively. On the comparative level, are there regularities in the strength of canalization of particular kinds of phenomena (such as inequality)? Is there a relationship between the structure of the landscape and the constraints on its change across different kinds of phenomena?
- What is the relative closure, or the relative autonomy of the part of the global landscape we focus on? In many cases we may find that within the immense, global network of social mechanisms, which are all interconnected to some extent, there are areas with a lot more interactions, clusters that lead to a specific attractor. What might these areas be?
- What are the relative effects of different kinds of pegs and what do they depend on? In what conditions are different types of pegs (social-structural elements, cultural meanings, ecological constraints and affordances, epigenetic inheritance, and genetic inheritance) more important than others? This question needs to be answered empirically for different domains.

- How are the pegs themselves constructed and how do they change? The pegs may be composite and have their own construction rules. What are they?

This chapter suggested a metaphor that researchers of sociocultural phenomena may find useful in tackling the kinds of questions they routinely face—questions regarding the intersection of different mechanisms, and regarding the dynamics of reproduction and regularities they observe. Like any metaphor, its usefulness lies in orienting researchers to specific kinds of problems. Like the “tool-kit,” the “network,” or the “game,” the strength of a metaphor is not in providing answers, but as a way to provide more, and hopefully better, questions.

## Glossary and List of Abbreviations

- Attractor:** The set of properties that the system tends to reach (the state it tends eventually to settle in), regardless of the conditions from which it started and the specific trajectory taken.
- Canalization:** The adjustment of developmental pathways so as to bring about a uniform result in spite of genetic and environmental variations.
- Dual-Inheritance Theory (DIT) approach:** A theoretical approach to evolution and cultural diffusion that assumes a two-way causal relationship between culture and genetics, and that takes population genetics as its model for cultural diffusion.
- Epigenetic Landscape:** A visual model suggested by C. H. Waddington to describe the dynamics of embryological development and its underlying genetic network of interactions.
- Exploration and Selective Stabilization:** The generation of a large set of local variations from which only a small subset is eventually stabilized. Selective stabilization occurs when the system reaches an attractor.
- Massive-Modularity Thesis:** The view that the mind is made up of many different, innate, domain-specific computational mechanisms or “modules.”
- Memetic View:** The view that culture can be conceived as a set of replicatable units, analogous to genetic replicators, and that selection of memes underlies cultural evolution. People are seen as “carriers” of replicatable cultural “memes.”
- Phenotypic Accommodation:** The set of developmental processes that lead to novel phenotypic outputs. Phenotypic accommodation is based on the plasticity of existing biological affordances interacting with (physical, biological, and social) environmental inputs.
- Plasticity:** The ability of a single genotype to generate variable forms of morphology, physiology, and/or behavior in response to different environmental circumstances.

# From Material to Symbolic Cultures: Culture in Primates

**Christophe Boesch**

## Abstract

Recent wild animal studies have led to the realization that some of the population differences observed in some species possess close similarities to human cultures. This has inflamed a long-standing debate about the uniqueness of human cultural abilities. The accumulation of such detailed observations from wild animal populations has provided more and more convincing details about the cultural skills in different animal populations, which has resulted in a shift away from the question, “do animals possess culture?” to the question, “what differentiates humans’ cultural abilities from other animals?” The growing body of evidence of cultural differences, not only in chimpanzees but also in macaques, capuchin monkeys, orangutans, and other primate species, opens the way to a precise ethnography of culture in different species. Chimpanzee culture is observed as well in the material domain as in the symbolic and social ones and is disseminating by social-learning mechanisms, allowing in some cases for cumulative cultural evolution. To further a precise understanding of the social-transmission mechanisms involved in cultural transmission combining detailed field observations with ecologically and socially valid experimental studies would be timely and welcome.

**Keywords:** Culture, symbols, cooperation, cumulative cultural evolution, ecological validity, chimpanzees, humans, primates.

*Culture* is probably the single most central concept in twentieth-century anthropology, as noted by the *Oxford Encyclopedia of Social and Cultural Anthropology* (1996). Although not wanting to attempt to formally define “culture,” this encyclopedia mentioned that “culture is what a person ought to acquire in order to become a fully worthwhile moral agent” (p. 136). This illustrates one side of the culture debate, which has been raging for decades as a consequence of the increasing number of observations of behavioral differences seen between populations in different primate species. Although these have been labeled as “cultural differences” by primatologists (Goodall, 1970; Boesch, 1996, 2003; McGrew, 2004; Panger et al., 2002; Perry & Mason, 2003; Van Schaik et al., 2007; Whiten et al., 1999), for many anthropologists and psychologists,

culture applies only to human beings, and, therefore, a direct reference to ourselves is often implicitly made when defining the concept (e.g., Barnard, 2000; Kuper, 1999; Galef, 1992; Tomasello, 1999; Povinelli, 2000). For many others, however, culture is first and foremost a social process and should be defined as such without reference to any particular species (e.g., Borner, 1980; Kummer, 1971; Boesch & Tomasello, 1998; Whiten & Boesch, 2001).

The tone of the culture debate has, in a sense, been set by Marshall Sahlins, in his famous 1976 book titled *The Use and Abuse of Biology*, in which the reluctance of some in the human sciences to discuss humans with an open comparative eye was clearly formulated. This seems to reflect some people’s fear that by opening anthropological concepts to other species, human beings might be “threatened” in their humanity. For

example, when the famous anthropologist Louis Leakey learned about spontaneous tool use in wild chimpanzees in the early 1960s, he remarked, “Ah, now we must redefine tool, redefine man—or accept chimpanzees as humans!” A century earlier, after learning about Darwin’s theory of evolution, the wife of the Bishop of Worcester said, “Humans descended from the apes! My dear, let us hope that it is not true, but if it is, let us pray that it will not become generally known.” Interestingly enough, this view was still expressed in a paper published in *Science* in 2009 when White et al. (2009) wrote that a new description of *Ardipithecus ramidus* showed that “humans did not evolve from chimpanzees.” However, this is a view that biologists have never expressed. As Desmond Morris said so wisely in his book *The Naked Ape*, humans’ “climb to the top has been a get-rich-quick story, and, like all nouveaux riches, we are very sensitive about our background.” At the same time, we may very well be the only species that is curious to know what makes us different from other species, and, therefore, many biologists and anthropologists feel that it is important to keep an open approach. Only in this way can we progress in answering the question, “what makes us human?”—instead of relying on just-so stories that do not reflect our humanity.

### **Culture as It Happens**

I shall adopt this last attitude in the present chapter and will present some of the knowledge that has been gained in the last three decades, as a result of field studies of primates in their natural environments. For the first time in history, this research has allowed us to gain a detailed view of what primates really do in the wild. For this purpose, following a broad consensus, a behavioral trait is considered to be cultural once we have shown it to be a group-specific socially acquired trait (e.g., Kummer, 1971; Bonner, 1980; Galef, 1992; Kuper, 1999; Barnard, 2000). It is often also required that these behavioral traits should be independent of any genetic and ecological factors; however, if the first aspect make sense, the second is never required when talking about humans and its relevance to the cultural debate should therefore be questioned (Boesch, 1996, 2003; Laland & Hoppitt, 2003). The example of potato washing in Japanese macaques will nicely illustrate this aspect of the cultural debate.

### ***Imo the Culture Wall-Breaker***

Imo, a juvenile female Japanese macaque, was a member of the Koshima troop, which lived on a

small islet in the Japanese archipelago. This troop was provisioned by animal keepers, who threw sweet potatoes on the beach for them daily. The macaques rapidly learned to come to the beach and eat the potatoes, and at the same time tolerated the close presence of human observers. One day, Imo carried a sweet potato from the sandy beach into the water, and after washing the sand off the potato, ate it. This new behavior, which resulted in sand-free and saltier-tasting potatoes, was performed by Imo again the next morning. Interestingly, until this time, the macaques avoided the water, but this new innovation required that they now, at a minimum, come into contact with water. The peer playmates of Imo were the first to copy her behavior, and next were the infants in the troop. Later, the mothers of the different potato washers also learned the behavior. In the end, other than some of the large adult males from the troop, everyone acquired Imo’s innovation. Remarkably, while potato washing, the macaques started to enter deeper and deeper into the water, so that the newborn babies lost any kind of aversion to the water, and started to play and swim. A few years later, the same Imo invented a new behavior: she collected a handful of wheat grains that the caretakers were throwing on the sand and carried them to the water where she threw them all in. Only the wheat grains floated on the surface of the water and she was able to eat them much more rapidly than if she had had to sort them from the sand, as before. This new invention also propagated to the majority of the group. Thanks to Imo’s innovations, several new cultural traits, including potato washing, wheat grain throwing, and bathing, playing, and swimming in water, spread through the troop.

When reporting these observations as far back as the 1950s, the Japanese observers did not hesitate to use the word “culture” without limiting its application to humans (Imanishi, 1952; Kawai, 1965; Kawamura, 1959, 1965). This was because they were less affected by the anthropocentric glasses that we tended to wear in the occidental world (de Waal, 2001). They were not disturbed by the fact that such changes resulted from human interventions, as, for generations, the macaques had been living in contact with humans in Japan and they had become part of the Japanese culture. To them and to many others in the fields of anthropology and psychology throughout the world, Imo and her playmates’ behavior opened the door to discussions of culture in animal species other than humans for the first time. However, not everybody shared our enthusiasm!

Some recent reviews of the concept of culture in the field of anthropology do not even mention these observations, and consequently, there is also no hint of a discussion about the possibility that cultures might be observed in other animal species (Kuper, 1999; Barnard, 2000). Others have looked carefully at the speed of acquisition of these new behaviors and have suggested that the transmission was too slow to warrant the designation of cultural transmission (Galef, 1990, 1992; Heyes, 1994; Tomasello, 1999; Laland & Hoppitt, 2003; *but see* McGrew, 1992; Boesch, 2003 for alternative social explanations for this).

It remains impressive that Imo invented two new techniques that spread through her social group and that resulted in a series of behavioral changes related to water. If precise analyses of the spread of the behavior are important to characterize how innovation spreads in macaques, it should not distract us from the fact that macaques have this ability to learn from others, and totally new behavior patterns can be acquired by most group members within a few years. These observations show that macaques exhibit important behavioral flexibility that was previously thought to be restricted to humans. To many, this is a nice example of cultural change!

### ***The Cultural Debate after Imo's Breakthrough***

Although the primatological community reacted positively to such new developments, some psychologists adopted a more critical stance and reminded us that, as cultural traits disseminate within social groups through a social-learning process, we should expect this to happen “relatively” quickly (Galef, 1990, 1992; Heyes, 1994). This has led to endless discussions about how quickly a behavioral trait should spread within a social group when it is supposed to be cultural transmission, and how we can differentiate such a social-transmission mechanism from a pure individual learning process (e.g., Lefebvre, 1995; Boesch, 1996; Tomasello, 1999; Laland & Janik, 2006). It should come as no surprise that in the absence of any rational argument about the expected speed of such a spread, opinions would diverge; some believed that the macaque observations show that the speed of spread indicates the absence of cultural transmission (e.g., Galef, 1990, 1992; Heyes, 1994; Tomasello, 1990), while others saw it as strong support for a cultural spread as the spread followed precisely the social interactions network prevailing within a macaque

group (e.g., Kawai, 1965; Whiten, 2005; Boesch, 1996; Leca et al., 2007).

From another perspective, some psychologists have argued that cultural transmission requires *faithful copying* of the behavioral trait and have claimed that this can only be guaranteed through imitation or teaching (Galef, 1992; Heyes, 1994; Tomasello et al., 1993). They argued that other social-learning mechanisms, such as social facilitation or emulation, whereby individuals copy the context or the way objects are used but not the behavior itself, might lead to the acquisition of a behavior but with much less fidelity. In their view, neither had been shown in the case of the Japanese macaques and, therefore, that although the acquisition of potato washing was impressive, it could not be labeled as “cultural.” Others rapidly argued that human data did not show that cultural transmission required either of these mechanisms but, instead, that other forms of social learning equally contributed to cultural transmissions (Boesch, 1996; Waal, 2001). Following the arguments of the Japanese researchers, biologists, on the other hand, have argued that the sheer presence of such invention and propagation within a social group is strong evidence of the cultural abilities of this species (Bonner, 1980; Waal, 2001).

More generally, psychologists tend to argue that animals' abilities to adapt to the ecological constraints they face in their daily life are well-documented, and that both present and past small *ecological factors* could have affected the occurrence of specific behavioral patterns. Furthermore, they suggest that, in natural settings, it would be almost impossible to exclude such ecological effects and that natural observations, therefore, do not allow us to make any claims about the cultural abilities of animals (Galef, 1990, 1992; Heyes, 1994; Tomasello, 1990, 1999). This view has become dominant in some circles of experimental and comparative psychology and has led to an increase in studies done in captive settings.

### **PROBLEMS WITH “CULTURE OUTSIDE OF CULTURE” STUDIES**

However, such studies of “culture outside of culture” falter on their two key assumptions. First, they assume that captive animals face the same social-learning challenges as their wild counterparts, and second, they assume that all behavior patterns are learned via the same learning mechanism, independent of the ecological relevance of the behavior. For example, they would argue that captive macaques

would learn to rake food within arm reach of a human model based on the same copying mechanism and motivation as Imo's playmates learn to wash potatoes. The stance a scientist takes toward experimental data with captive animals is a function of their stance on these two assumptions. For a number of experimental psychologists, these assumptions are perfectly reasonable and broad claims made from such experimental studies have been thought to reveal limitations in the cultural abilities of different animal species.

On the other side, the validity of this "culture outside of culture" approach has been viewed much more critically by the majority of behavioral ecologists, anthropologists, and philosophers, and the broad claims made from such artificial studies with animals who are often socially impaired are greeted with skepticism (Byrne, 1995, 2007; de Waal, 2001, 2006; Bekoff et al., 2002; Allen, 2002, 2004; Boesch, 2007, 2008; McGrew, 2004). For one, the "artificial" nature of the ecology of captive settings has no parallel in nature and, therefore, no one can really assess the "ecological validity" of such studies. To some, this renders captive experiments useless. Furthermore, the artificial nature of the social groups in captive settings is patent and the effect of this is again very difficult to assess, although we know that early social upbringing conditions have a large influence on later cognitive development. At the very least, this should require one to carefully assess the validity of captive studies in contributing to our understanding of the culture phenomenon in primates.

### Chimpanzees as Culture Generalists

As this debate was developing, new data was being published on what has emerged as the most major discovery in chimpanzee behavior of the two last decades, namely the unexpectedly large behavioral diversity observed among different wild populations. This was observed in a diverse assortment of contexts, including the sexual, social, demographic, tool-use, and hunting contexts. This important dimension of chimpanzee behavior was the center of three international conferences, which each resulted in an edited volume. These were titled *Understanding Chimpanzees* (Heltne & Marquardt, 1989), *Chimpanzee Cultures* (Wrangham et al., 1994), and *Great Apes Societies* (McGrew et al., 1996). This has progressively placed the chimpanzee in a special position, as the more we are learning about wild chimpanzee population diversity, the more similarities we are finding

between chimpanzee and human cultures. This has been mainly possible thanks to the special treatment of chimpanzee studies in primatology; because of the genuine interest we have in our closest living relatives, more different populations living in diverse habitats have been studied in chimpanzees than in any other primate species.

It is important to realize from the start that the study of culture in chimpanzees has followed a different approach than the one adopted with macaques; if a *dynamic diffusion approach* based on the acquisition of novel behavior caused by human intervention was central to the study of culture in macaques, an *ethnographic approach*, in which established behavior patterns in different populations were compared, has been taken with the study of culture in chimpanzees. Such an ethnographic approach to culture proceeds by exclusion, whereby ecological and genetic influences must be excluded before any behavior is proposed to be cultural (see Goodall, 1973; Nishida, 1987; Boesch & Boesch, 1990; Nishida et al., 1993; Boesch, 1995, 1996, 2003; McGrew, 1992; Boesch & Tomasello, 1998). The main rationale for utilizing such a different approach lies in the fact that, since wild animal populations live in stable ecological conditions, it is extremely rare to see the acquisition and dissemination of new behavior elements within a social group. Hence, the ethnographic approach is often the only one available.

In the case of the chimpanzees, this approach has proven very successful, in the sense that it has allowed for the first time to gain more precise knowledge of important characteristics of the cultural phenomenon in this species. Here, I will go through what researchers have seen as some of the key elements of the culture phenomenon in chimpanzees over the years:

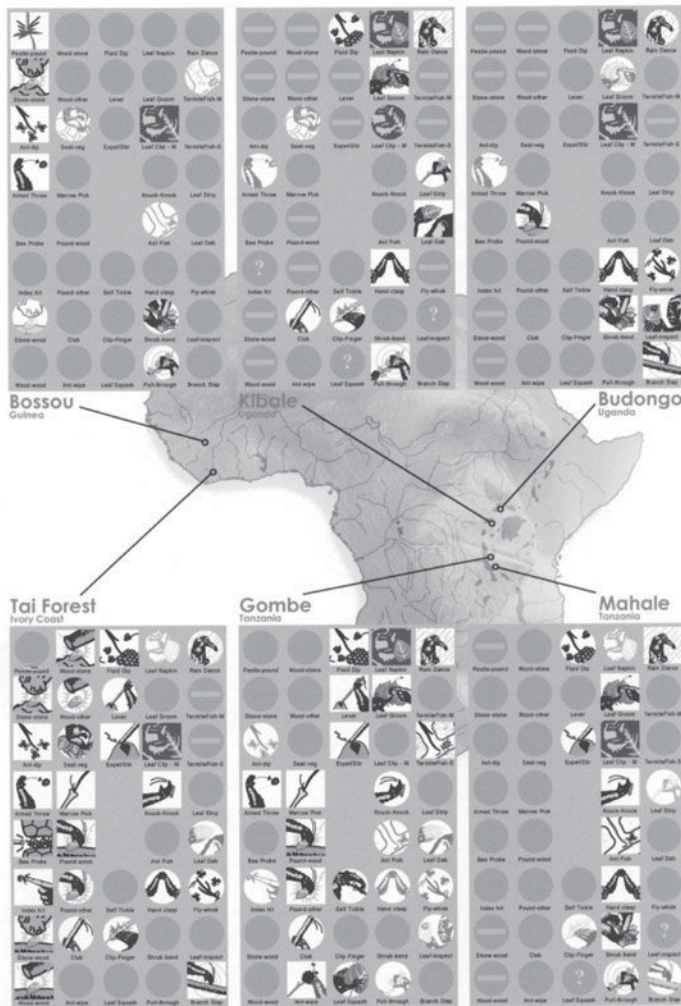

1) *Large cultural repertoire*: First, field researchers have started to compare aspects of the behavioral repertoires of their study populations with the knowledge gained by others on other populations and have proposed an ever-growing list of potential cultural elements (Goodall, 1973; McGrew, 1992; Boesch, 1996). Then, in an attempt to understand the breadth of the variability in the cultural repertoire of each population, field workers who followed eight different populations of wild chimpanzees in different regions of Africa gathered together to compare their knowledge about chimpanzees. This resulted in a preliminary list with 38 behavioral traits that were proposed to be cultural in the

species and independent of any ecological influences (Whiten et al., 1999, 2001). At the time of writing, a second similar exchange between field workers is underway. This meeting includes the addition of researchers who study three new chimpanzee populations, so that a much more extensive list of putative cultural elements is being produced (Whiten et al., in prep.).

The main lesson to be taken from such a listing exercise is that, in chimpanzees, *each* population can be distinguished from the others thanks to a specific cultural repertoire, which always includes a multiple complex of different behavioral elements. Like a fingerprint, knowledge of these elements makes it possible to determine the population origin of any individual chimpanzee with certainty. The map of the original publications presented here illustrates the distribution of the 38 cultural elements across six wild chimpanzee populations (Fig. 31.1). For

example, Tāi chimpanzees exhibit 26 of the 38 cultural traits, while Gombe chimpanzees perform 24 of them, but only 16 of these are shared with the Tāi chimpanzees. Similarly, the Bossou chimpanzees, whose territory is only 200 kilometers north of the Tāi forest, exhibit 11 of the 38 elements, and share only six with Tāi and four with Gombe chimpanzees. So, each population of chimpanzees is characterized by multiple different cultural elements, and it is this mix that is population-specific.

The second point is that cultural differences are not merely a question of presence or absence of a trait, but also a question of the *form and context* under which the trait is performed in each population. For example, ant dipping (the third icon from the top of the map, in the left column of each population cultural card) is performed with short sticks and one hand in Tāi chimpanzees, but with longer sticks and both hands in Gombe chimpanzees

**Figure 31.1** The cultural repertoire of six different chimpanzee populations (Whiten et al., 1999). For each population, the repertoire is synthesized on a card with the 38 potential behavior elements, where each element present in that population is earmarked with a colorful icon; a square icon stands for the element being observed in the population, a circle icon stands for an alternative form of the behavior element, and a blue circle indicates the element was not seen in the population with no obvious ecological reason. When a clear ecological reason explained the absence of the element, a horizontal minus bar is marked in the blue circle.

(Goodall, 1968, 1970; Boesch & Boesch, 1990). This is illustrated by the icon on the map with a squared or round shape, as can be seen for ant-dip. On the other side, for example, leaf-clip (the second to last icon from the right in the third row from the top) is performed in a very similar way in each population but the context and its attached meaning varies extensively (see below).

2) *Cultural fidelity*: In some limited instances, researchers have followed and made detailed observations about two neighboring chimpanzee groups living in the same forest block. For example, in the Mahale Mountains of Tanzania, field researchers followed two neighboring chimpanzee communities, the K- and the M-Group, and the larger of the two, the M-Group, was seen to push the smaller K-Group out of their range during certain seasons of the year (Kawanaka & Nishida, 1968). They have found

behavioral differences that persist despite the very close proximity of the two groups, and exchanges of individuals between the two groups have been recorded. As such groups are neighbors, we can be certain that genetic differences do not explain these observations, and additionally, it is straightforward to control for possible ecological differences. This has allowed researchers to make strong claims about cultural differences (Boesch, 2003, in press; Whiten et al., 1999; Langergraber et al., 2010).

In the Taï forest, three neighboring communities have been followed and reveal strikingly important cultural differences in 11 behavior elements. These behavior elements have been seen as well in the material domain, related to the acquisition of food, as in the symbolic domain, related to courtship and play initiation (Fig. 31.2) (Boesch, 2003).

The important aspect here is that, in chimpanzees, *cultural transmission and fidelity within groups*

**Figure 31.2** Map of the territories of the three neighboring chimpanzee communities in Taï National Park, Côte d'Ivoire, with a preliminary list of their specific cultural elements (Boesch, 2003). In addition to the general specific cultural elements shown already in Figure 31.1, Taï chimpanzees possess community-specific cultural elements, both in the material and social domain, that show a high level of conformity, being observed in all community members, and a strong level of fidelity, prevailing for many years.

*persist for extended periods of time*, despite females transferring between communities at menarche. This dispersal pattern could lead to a homogenization of the behavior patterns across neighboring communities over a very short period of time, as females who transfer from their natal community to a new one, at an age when they have already acquired the full behavioral repertoire of their natal group, could continue to perform it in their new group. However, the opposite was observed in both Mahale and Taï chimpanzees, in the sense that community-specific culture elements remain extremely stable and the new immigrants adapt rapidly to the culture of the new group (Luncz & Boesch, in prep.). It is too early to say anything about either the mechanisms making the immigrant females adopt the behavioral culture of their new community or about the benefits of doing so. In conclusion, high fidelity to group-specific cultural traits and conformity to new group-specific cultural habits are characteristics of chimpanzee culture.

3) Cultural history: An important part of culture is its historical dimension as this also emphasizes the social transmission aspect of the behavior trait. Many of the claims about human cultural fidelity rest on archaeological studies that have shown that some cultural products, like arrows, hammers, or

shelters, have maintained themselves for numerous generations in human groups. However, detecting the age of a behavior pattern is impossible, unless it produces long-lasting artifacts. The nut-cracking behavior of chimpanzees may well be the only primate behavior that might allow for such a study, as it is a cultural behavior in which chimpanzees often use stone hammers or anvils to crack nuts.

To answer the question of how long nut-cracking behavior has been present in chimpanzees, we initiated an archaeological project with the hope of uncovering some old nut-cracking sites (Mercader et al., 2002, 2007). By applying traditional archaeological methods to a *Panda* tree, where we had seen regularly chimpanzees crack nuts, we could show that they had been cracking at that particular tree for over 150 years (Panda 100 in Fig. 31.3), and had left hundreds of stone flakes behind. In a closely adjacent area, we were able to reach old soil layers dated to 6,000 years old, and found stone artifacts produced by cracking nuts in layers that were between 2,200 and 4,300 years old (site Noulo in Fig. 31.3) (Mercader et al., 2007). These artifacts were found mixed with some typical Iron Age human artifacts and the older samples were found below the human occupation layer. This represents a first estimate that could be shifted back in time once excavations are

**Figure 31.3 Stratigraphy of two excavation sites in the Taï Forest.** The first on the left represents a known recent Panda nut-cracking site (Panda 100), and the second is at an old nut-cracking site (Noulo), where chimpanzee stone artifacts that were uncovered were partly mixed with and below human artifacts typical from the Iron Age (after Mercader et al., 2002, 2007).

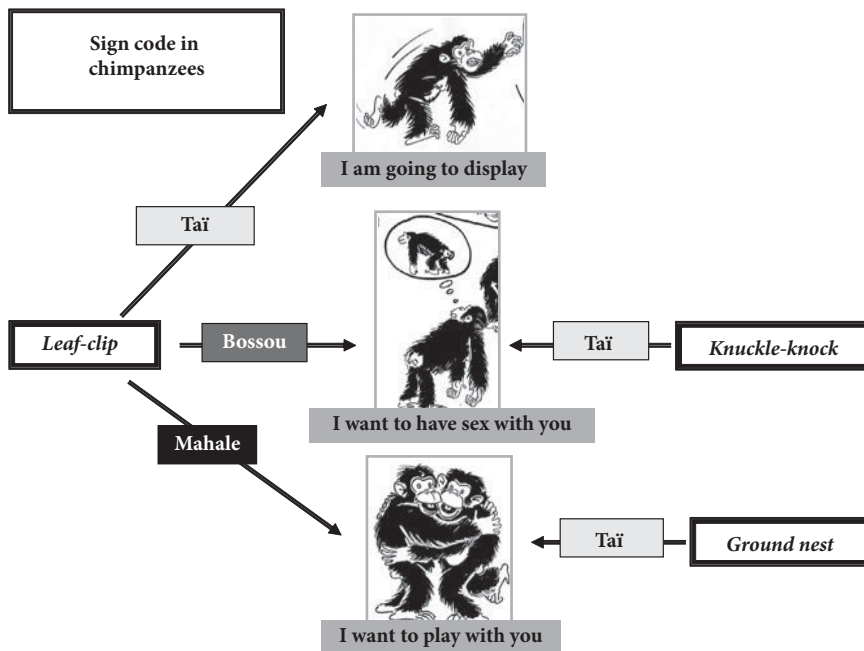

done on older soil layers. However, this result already shows that, in the case of nut cracking, chimpanzees have used a cultural behavior in a very similar way for over 200 generations. To give an idea of the time interval this represents, the human Iron Age began in this region of Africa about 2,500 years ago, and so the *Chimpanzee Stone Age predated the Human Iron Age* by some thousands of years.

This behavior remains the only cultural behavior trait where it is possible to show that chimpanzee culture has been transmitted over hundreds of generations. However, that simple observation suggests that the ability to copy a behavior pattern over generations is present in chimpanzees and may be observed in many other cultural traits.

4) *Symbolic culture*: Communicative behavior elements are used to convey information between social group members and, therefore, by definition are based on some shared meaning if they are to be of any use. In chimpanzees, some communicative traits follow some group-specific norms, by which it is the meaning of the trait that differs and not the form (Boesch, 1995, 1996, 2003, 2008). The most complex example is the leaf-clipping behavior element that is present in three of the six well-studied populations: In Tāi chimpanzees, leaf-clip is used

by adult males just before a display to signal their intention; in Bossou chimpanzees, it is often used by youngsters to get others' attention and invite others to play; and in Mahale chimpanzees, it is used by sexually active males to attract estrus female to mate with them (Nishida, 1987; Sugiyama & Koman, 1979; Boesch, 1995) (see Fig. 31.4). So, within a group, one behavioral element can acquire a specific meaning that is shared between all members, although the form of the behavior and the sounds produced remain exactly the same and do not refer to the meaning. In other words, the meaning of a behavior element results from a social construct that is shared between group members in chimpanzees.

The flexibility of these social meanings in chimpanzees is further revealed by the fact that a similar meaning can be expressed by different behavior elements in different social groups (Fig. 31.4). For example, although leaf-clip means "I want to have sex with you" in Mahale chimpanzees, this specific meaning is expressed by knuckle-knock in Tāi chimpanzees. Leaf-clip in Tāi chimpanzees means something different than in Mahale chimpanzees, while this last meaning is performed by knuckle-knock. To complicate this further, leaf-clip in Bossou chimpanzees, which means "I want to play with you" is

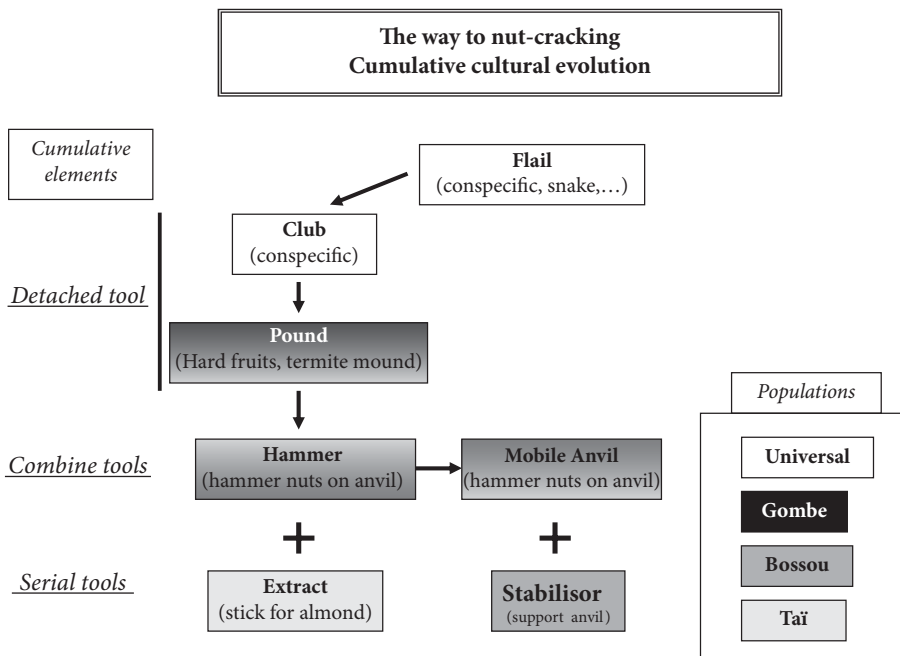

**Figure 31.4 Symbolic culture in wild chimpanzees.** The three behavioral elements performed by chimpanzees in three populations are framed in bold with the name of the population indicated on the arrow specifying the meaning the element has in this population. Two of the meanings have been seen to be supported by different signs in different populations.

also used by Tāi chimpanzees, but is expressed by making a coarse day-nest on the ground (Boesch, 1995, 2003).

Arbitrary shared meanings that are group-specific are obviously among the main characteristics of human language, and it is very intriguing to find that behavior signs in wild chimpanzee populations have similar properties. If the example of leaf-clip is still a long way from being a language, we need to keep in mind that uncovering such a “sign code” (see Boesch, in press) in another species requires from the human observers an expertise in this code, something no one anticipated to be present. In other words, if it was hard for Europeans to decipher Egyptian hieroglyphs, doing so for sign code differences between Tāi and Gombe chimpanzees may prove even harder. Thus, the leaf-clip sign codes might be just the tip of the iceberg in a new dimension of chimpanzee communication still unknown to us, or it may remain what it appears to be now—an intriguing sophistication that never developed. Until specific studies comparing chimpanzee populations are done with expert eyes, we will not know.

5) *Cumulative cultural evolution*: Some of the cultural elements proposed in chimpanzees are characterized by a relatively high level of technological complexity, in the sense that they incorporate different elements that each produce a behavior element that fulfills a function on its own and is seen to be used in only some populations. For example, all chimpanzees in all studied populations pound hard-shelled fruits against hard surfaces in order to break them open and get at the seeds or the flesh found inside. Some chimpanzee populations in Western and Central Africa have incorporated the use of a hard tool in this universal behavior pattern, whereby the tool is hammered against the hard-shelled fruit to pound it open (Fig. 31.5) (Boesch & Boesch, 1984, 1990; Morgan & Abe, 2006). The integration of a second object in the pounding movements, as seen in Bossou and Tāi chimpanzees, allows the chimpanzee to crack open much smaller and harder fruits that would not have been accessible with the first, simpler technique. Finally, in regions where roots, which are used as anvils, are hard to find, as in Bossou, chimpanzees have been seen to place nuts on mobile stone anvils instead (Fig. 31.5) (Matsuzawa, 1999).

**Figure 31.5 Cumulative cultural evolution in chimpanzees:** All chimpanzees in all wild populations have been seen to use branches, clubs, or saplings to hit at conspecific or dangerous species, such as snakes or wild cats. This object can be attached or detached from their substrate. As a second innovation, a food source could directly be pounded against a hard surface, as seen in Gombe, Bossou, and Tāi chimpanzees. Third, a hammer has been added to the behavioral sequence to pound harder food sources in Bossou and Tāi chimpanzees, while only Bossou chimpanzees have been observed to use mobile anvils that they can transport to the nut-producing trees. Furthermore, chimpanzees in Tāi and Bossou have been seen to use other tools to either extract more of the kernel out of the shell or to stabilize the mobile anvil.

But from there on, we saw two additional incorporations that are possible, either the use of sticks to empty nuts as seen in Tai chimpanzees, or the use of a second stone to stabilize mobile anvils in Bossou chimpanzees (Fig. 31.5).

An additional, very complex example of cumulative cultural evolution in chimpanzees is seen in the honey-extracting techniques performed by Central African chimpanzees (see review Boesch et al., 2009; Sanz & Morgan, 2009). Here, different elements have again been progressively integrated in the technique, so that each step in this cumulative process produces an efficient technique seen to be used in some chimpanzee populations (Boesch et al., 2009). As seen in the nut-cracking example, chimpanzees add innovations to a universal technique, in this case, the common behavior for chimpanzees extracting a food resource from a hole in either a tree trunk or the ground with their hands. In some chimpanzee populations, we observed the first incorporation of a tool in the technique, either a twig for ant dipping in Gombe, Goulougo, and Tai chimpanzees, or a sturdy branch, a pounder, to break open bee nests for honey in Goulougo, Loango, and Tai chimpanzees. Then, after they succeeded in breaking open the nest with the first tool to extract tree honey, a second tool, a collector, was added by the Loango and Goulougo chimpanzees. This was not, however, seen in Tai chimpanzees. Finally, a third tool can be incorporated for large nests. In Loango, the accumulation of elements can go in another direction for terrestrial bee nests. The Loango chimpanzees use a perforator, a complexity not seen in Goulougo chimpanzees, to extract honey (see Boesch et al., 2009).

New observations of nut cracking and honey extraction present some of the most detailed cases of cumulative cultural evolution in chimpanzees, analogous to those proposed for human artifacts, such as the hammer or a screwdriver. Boesch (in press) has emphasized the fact that such cumulative processes were also apparent in different communicative cultural traits.

### **Orangutans, Capuchins Follow the Culture Track**

Once described only in macaques and chimpanzees, the idea of animal culture has gained credibility in larger circles in science, and biologists have garnered the courage to look for culture in other animal species and have adopted a similar approach by comparing behavior patterns in different populations.

It follows then that ideas about the uniqueness of human culture have lost some of their preeminence, and in their place, the urge to understand the distribution of different animal species' cultural practices has arisen. The legitimacy of culture in animals was gained through an ethnographic approach, by which the behavioral repertoire of different populations within one species was compared to the ecological conditions they were facing. By excluding ecological factors, the ethnographic approach suggested that the potential differences were of a cultural nature. The main requisite to the implementation of such an approach is the necessity of detailed studies on enough different wild populations in a given species. Even today, this situation exists for only a handful of species, and, therefore, our understanding of the real distribution of the cultural phenomenon in animals remains limited by definition.

The ethnographic approach applied to wild populations has uncovered fascinating new facts about important population differences that exist within a species, and cultural abilities have been proposed in such diverse species as orangutans (van Schaik et al. 2001), capuchin monkeys (Perry & Manson, 2003; Panger et al., 2002; Visalberghi et al., 2007), macaques (Leca et al., 2007), as well as in whales and dolphins (Rendell & Whiteside, 2001). Not only does the ethnographic approach stimulate the incorporation of a comparative approach in different animal species, but, when observing one population, such approaches allow us to discover what is population-specific and what is representative of the species as a whole. This further stresses the complexity of the interactions between ecology and culture.

Capuchin monkeys are particularly interesting as, in some ways, they present very similar patterns to the ones observed in chimpanzees. A handful of wild-bearded capuchin monkey (*Cebus libidinosus*) populations have been seen to crack wild nuts in Brazil, while this behavior pattern is absent in others (Visalberghi et al., 2007; Canale et al., 2009). In another species, the white-faced capuchins (*Cebus capucinus*), a series of differences have been observed between three populations in the way they process 20 food species before eating them (Panger et al., 2002). In addition, a certain number of social behavioral traits have also been observed to differ between populations, such as hand sniffing of others, sucking on the body parts of others, and the "finger-in-mouth" game (Perry & Manson, 2003). Some cases of new social games were invented when researchers were around and the diffusion within the

group could be followed (Perry & Manson, 2003). From these and other primate species observations, we see that some of the simpler forms of cultural abilities seem to have been present very early on in our evolutionary history and that abilities proposed to be uniquely human in the past are possibly shared with many in the primate family lineage.

### **The Cultural Debate after the Wild Animal Culture Explosion**

The important progress made in recent years to our understanding of the cultural phenomenon in different animal species has led to a second shift, one that is still in progress. The central question in the culture debate has become, “what distinguishes the cultural practices in different species?” rather than, “is culture a uniquely human ability?” This shift in focus in the culture debate has been enthusiastically adopted by primatologists and some behavioral ecologists, while contemplated with more skepticism in some human science circles (Boesch, 2003; Whiten et al., 2003; Laland & Janik, 2003; Byrne, 2007).

This shift in trying to understand the width of cultural diversity in different species is still underway but there are many stumbling blocks. The first is sample size, as this differs dramatically between species. In humans, we have access to observations from hundreds of different populations or more, while we have detailed observations from only 12 populations of chimpanzees, the second-most-studied animal species. There are only six populations of orangutans, the third on the list. In other words, because of the terrible paucity of data on nonhuman animal species, cultural breadth and abilities might by definition be much less-developed.

An additional hurdle to comparing cultural abilities across species is that, since adaptation to ecological conditions has long been observed in animal species, including insects and fish, ecological influences must be excluded for a behavior to be recognized as cultural in nonhuman animals (Galef, 1992; Tomasello, 1990; Laland & Hoppitt, 2003). The addition of this criterion, never considered in humans, has by definition decreased the number of potential behavioral elements that could be considered as cultural in animals (Boesch, 1996; Boesch & Tomasello, 1998; Whiten et al., 1999; Van Schaik et al., 2003). However, we all know that a vast part of human culture includes artifacts, clothes, foraging tools, and many other items that are all related to the specific ecological conditions a population faces. For example, many of the differences in material

culture between Eskimos and Pygmies are, first and foremost, because of the drastically different ecological conditions that they face. It is important to bear in mind that if we want to compare cultural abilities between different species, we need to use the same set of criteria to define culture. Sadly, such an aspect has rarely been considered in the conclusions made when comparing the cultural abilities of humans with other species.

Two ways of progressing toward a fairer comparison have been pursued. The first solution to narrowing this gap was to address the sample size issue by studying more and new groups of wild populations belonging to species known for their cultural abilities. The gaps in our knowledge in chimpanzees have been especially dramatic, as the largest population of this species lives in Central Africa, and they have been totally neglected for decades. It is only very recently that two long-term studies have been initiated to fulfill this gap, the first in the Goualougo Triangle in the Republic of Congo (Sanz & Morgan, 2007, 2009; Sanz et al., 2004) and the second in the Loango National Park in Gabon (Boesch et al., 2007, 2009). Both have already unraveled surprising new and sophisticated forms of tool use that have not been described before. This nicely illustrates how much our knowledge of chimpanzees, a species who we have studied so much, is still very fragmentary. Similarly, new studies with capuchin monkeys have adopted a much more comparative approach and included many more populations (e.g., Canale et al., 2009).

The second solution directly addressed the shortcomings of experimental approaches. For many psychologists, a transmission mechanistic approach should be favored over the ethnographic approach, based on the argument that what counts in the culture phenomenon is not necessarily the end result of population-specific behavioral patterns but, instead, how a behavior is transmitted between individuals. Furthermore, they argue that only an experimental approach is able to identify such a mechanism, as individuals in the wild are exposed to so many simulations and experiences that it would be almost impossible to identify the precise mechanisms at work (Galef, 1992; Heyes, 1994; Tomasello & Call, 1997). However, it has been difficult to interpret the results of experimental studies on social learning of novel behavior patterns, which showed strong limitations in this ability in captive chimpanzees (Tomasello et al., 1987; Heyes, 1994; Povinelli & Vonk, 2003). The favored experimental procedure

was to present a single individual in an isolated room with a demonstrator located in another room through a window. To prevent any uncontrolled influences, the social dimension of cultural learning was completely excluded. Furthermore, the novelty of the tasks was more important than their ecological validity, so individuals were tested with artificial tasks such as throwing sand or raking food (Tomasello et al., 1987). Nevertheless, to some, a consensus developed that such experiments were enough to prove that culture, as understood in humans, was not present in nonhuman primates and that the population-specific behavior observed should be based on a totally different process (Povinelli, 2000; Tomasello & Call, 1997; Tomasello, 1999). However, such a conclusion remained in strong contrast to observations in the wild and no attempt was made to explain the differences between the ethnographic approach and the captive experimental studies.

The impressive array of cultural behavior differences documented in wild primates concerning group-specific socially learned behaviors has led other psychologists to question the validity of the above-mentioned experimental procedures and to develop alternative ones, in which some of the aspects presented to the tested individuals would be as similar as possible to the situations faced by wild animals in the cultural domain. One of the most innovative procedures was done by keeping the individuals within their normal social setting during the experiments rather than isolating them. In this way, the social transmission of a novel behavior as well as the development of group-specific traditions could be mimicked in captive social groups (*see* Whiten et al., 2005, 2007, 2009; Horner et al., 2006; Hopper et al., 2007, 2008; McGuigan et al., 2007). This proved to be very successful as it was possible to follow the whole chain of social transmission from one expert individual to all group members and then from one group to up to four different neighboring groups. Such dispersal of novel behavior was accompanied by a strong fidelity to the expert's behavior, which maintained itself over long periods of time and during the dispersal process between groups. In other words, some of the key aspects of cultural transmission could be reproduced in such innovative cultural diffusion experiments.

This success has led the team to explore another aspect of culture that was proposed to be unique to humans, namely the ability to imitate one another. Some have proposed that culture can develop only

as a result of imitation, as this was suggested to be the only social-learning process that guaranteed a high level of fidelity in the copied behavior (Galef, 1990, 1992; Heyes, 1994; Tomasello, 1990; Tomasello et al., 1993). However, in the absence of a complete theory as to when and why imitation should be used within a species, experimenters have been looking for imitative evidence with behavioral tasks selected randomly with mixed results. Although the results of group diffusion experiments have convincingly shown that imitation is not required to reach a high level of fidelity in copying a behavior pattern in chimpanzees, it was found that chimpanzees copy more by imitation when the individual cannot understand all the physical complexities of a task (e.g., when copying the way to get access to food contained in an opaque version of a box), while they will use more individual skills if they can understand them (e.g., when facing a similar but transparent version of a box with food inside) (McGuigan et al., 2007). In both cases, the demonstrator was the highest-ranking female of the group and therefore a trustful social partner. This convincingly showed that imitation and transmission are social behaviors and that chimpanzees are very sensitive to this. Without taking great care to preserve the social dimension, the results of experiments are not very helpful.

The main lesson about such studies is that culture is a social phenomenon and that the "culture outside of culture" approach adopted in so many captive studies has shown very strong limitations in its ability to understand the cultural abilities in nonhuman animal species (Boesch, 2007, 2010; de Waal, 2001). The main progress to experimentally understand some aspects of cultural transmission was achieved when the social dimension could be reintroduced into the experiment paradigm. This social approach was so successful that it could be replicated in other primate species, such as capuchin monkeys (Dindo et al., 2009). Field studies remain the prime source of information about the breadth of the culture spectrum and the cultural abilities.

## Conclusion

Being as selfish as we are, the question of human uniqueness has always drawn a lot of attention and been an area with numerous unsupported strong claims (e.g., de Waal, 2001; Whiten et al., 2003; Boesch, 2009). To avoid such well-known pitfalls, I shall try to limit myself to comparisons between species for areas where direct observations are available,

as reviewed above, and avoid anthropocentric claims as much as is humanly possible. The newest data on wild animals reveal that, in many species, cultural differences are present. Such cultural traits that are concentrated on feeding techniques and therefore contribute directly to an individual's survival represent important characteristics of life. In other cases, cultural traits are also observed in the social and communicative domains but these tend to be less common than those seen in the material domain (Boesch, in press). For the first time, this progress offers some hope toward a resolution of what parts of the culture phenomenon are uniquely human.

This review would open the way to distinguishing some of the differences observed between animal species in their cultural abilities. To do this, I tried to include all we know about wild animal cultural behavior as well as some important experimental results. This review allows us to propose that, at a minimum, humans share the following attributes with many animal species:

- Acquisition of spontaneous group-specific behavior traits,
- Presence of cultural traits that are not influenced by ecological and genetic conditions,
- Social learning of cultural traits from group members,
- Persistence of cultural traits for extended period of time,
- Presence of nonadaptive cultural traits.

In addition, I propose that the overlap between human and chimpanzee cultural abilities is larger, as they include the following attributes:

- Cultural cumulative evolutions in material and social domains,
- Multi-generational history in cultural traits,
- Faithful copying from dominant prestige-carrying models,
- Conformity to new social groups,
- Active teaching and imitation of cultural traits,
- Symbolic social norms in cultural behavioral traits.

At this stage, it would be tempting to argue that those cultural abilities not listed here are uniquely human. This may be true, but we should not forget that our knowledge of other animal species fares very poorly compared to what we know about humans, and, therefore, more observations will certainly increase the list of similarities. I fully realize

that such a statement is very frustrating, as all primate species are threatened in one way or another, and because of this, we may never fully know how similar our abilities are.

Wild animal studies have led to the realization that some of the population differences observed in some species possess close similarities to human cultures. The accumulation of such detailed observations from wild animal populations have provided more and more convincing details about the cultural skills in different animal populations, which has resulted in a shift away from the question, "do animals possess culture?" to the question, "what differentiates human cultural abilities from other animals?" The growing body of evidence of cultural differences, not only in chimpanzees but also in macaques, capuchin monkeys, orangutans, and other primate species, opens the way to a precise ethnography of culture in different species.

By turning away from wild animal studies, comparative psychology faces the risk of eventually reaching an impasse, as only experimental studies with captive animals are considered without any concern for the ecological validity of such approaches. Luckily, studies have recently been started that will, in complement to wild animal studies, help us to address the question of animal cultural abilities. However, time is running out and all primate species suffer from habitat degradation and direct hunting against them, which could prevent us from collecting enough data on them before we can determine the specific cultural abilities of human and nonhuman primate species.

### **Future Directions: Toward a Resolution of Understanding Human Uniqueness**

One way to find a provisional answer to the question of human uniqueness is to look for cognitive abilities unique to humans that are important for cultural transmission and acquisition. This would include speech, which is notably absent in other animal species, as well as modern human means of communication like writing, radio, and Internet. These communication media allow for the transmission of cultural traits between individuals who do not meet face-to-face, either because they are not visible to one another or because one of them might already be dead (Boesch, 2008). In addition, even in a face-to-face situation, such improved communication permits the cultural transmission of skills out of context, namely without having to demonstrate or practice the skill. Such cultural transmission modes,

which are not available to any other animal species, would facilitate the transmission of more complex cultural traits.

Another possible way to answer such a question will come from careful and ecologically valid comparisons between how chimpanzees and humans learn social skills from group members. Recent work on imitation reveals that, although both species readily imitate, humans have a much stronger tendency to overimitate than chimpanzees, in the sense that they will faithfully copy unnecessary or irrelevant actions (Lions et al., 2007; Whiten et al., 2009). This tendency to blindly imitate irrelevant actions in adults might contribute to a stronger tendency in humans to adopt irrelevant and maladaptive cultural traits (Whiten et al., 2009). In a process similar to mate choice in birds, where individuals have been seen to simply copy the choice of others rather than to select the best mate, humans may be copying what they see group members doing without going through the time-consuming process of evaluating the benefit of each cultural trait, and thereby nonadaptive or opaque cultural traits can spread more readily in humans than in chimpanzees.

## Encountering Alterity: Geographic and Semantic Movements

Alex Gillespie, Irimi Kadianaki, and Ria O'Sullivan-Lago

### Abstract

This chapter analyzes the semantic consequences of crossing national borders. When crossing borders, identities change, and alterity is encountered. We ask: what are the semantic structures, or meanings, that enable alterity to be either embraced or resisted? We start by distinguishing between movements in geographic space and semantic movements of meaning. Our aim is to link geographic movements to semantic movements, but not in a linear way. The semantic consequences of geographical movement can be diverse and reverberate for many years. We draw upon empirical examples from studies of immigration in Greece and Ireland to show how alterity is resisted, how representations of nationality and belonging are used to stabilize identities, and how feelings of being stigmatized can be deflected without leading to reciprocal denigration. We speculate about the potential role of geographic movement in providing people with externality over their own experiences, as it enables them to step out of themselves and see themselves from the perspective of others. The chapter concludes with suggestions for future research.

**Keywords:** Immigration, dialogism, identity, semantic barriers, movement

Humans move. They move from one place to another, from one job to another, from one social group to another, from one life stage to another. It is therefore overly simplistic to consider contemporary society as a collection of people and groups belonging to mutually exclusive identities. Movement can make locals become migrants and in-groups become out-groups. The present chapter analyzes the relation between geographic movements on the one hand, and the meanings that such movement generates on the other. This relation is complex because geographic movement does not have a linear effect on the way in which self and other are re-represented. Movement across national borders usually has different meanings for the people who move compared to those who are either left behind or those in the host community. The extent to which people who move are aware of these different meanings and integrate them into more general meanings is one of

our concerns. Movement between geographic locations is mutually exclusive: our bodies cannot yet be in two places at once. Meanings, however, even when contradictory, are rarely mutually exclusive: our thoughts can be in many places at once. In the present chapter we will examine how the multiple meanings are not only present within the thoughts of people who move, but also how these multiple meanings interact.

Starting with a discussion of the extent to which people travel across national borders, we move on to the impact of those movements on how people are identified and identify themselves. We then introduce data from two studies and demonstrate the ways in which crossing national borders disrupts and redraws identity boundaries. Our analysis places emphasis on the way in which geographic movement leads to encounters with alterity: other individuals and other groups. We analyze semantic structures

(i.e., at the level of meaning and not discursive practice) that enable alterity to be resisted, identity boundaries to be stabilized, and also those that create an openness to alterity. Our key question is: what are the semantic structures, or meanings, that enable the alterity encountered through geographic movement to be either resisted or embraced?

### **People on the Move**

Commercial aircraft transport over one billion passengers per year. Most of these passengers are making trips of relatively short duration, with over 922 million international tourist arrivals worldwide in 2008 (UNWTO, 2009). However, some international travelers have one-way tickets. Although it is difficult to estimate the exact number of migrants in the world today, a recent UN report (UNDP, 2009) has estimated that there are over 190 million worldwide. Clearly, geographic movement is an important phenomenon for a large portion of humanity. Moreover, a recent survey by Gallup (Esipova & Ray, 2009) indicates that 16% of the world's population, or 700 million people, would move to another country permanently if they had the chance. Actual geographic movement must be considered alongside the larger pool of hopes, dreams, and fears that motivate people to actually move, whether for touristic pleasure or making a new life.

While geographic movement may have reached new heights, the phenomenon is not new. For example, the heterogeneous makeup of people living in the so-called "New World" is evidence of a long history of movement. According to the U.S. Census Bureau (Luke, 2004), the U.S. population is made up of 70% non-Hispanic European descent, 12.5% Hispanic descent, 12.3% African descent, 3.8% Asian descent, and over 2% mixed descent. Less than 1% of the population are of Native American descent. What this latter fact also reveals is that even if one does not move, the geographic relocation of others can have an enormous impact. The Native American group became "natives," hosts to those that migrated, and later, because of the volume of individuals who arrived, a minority group in their own land.

### ***Social Psychological Consequences***

The movement of people across national and cultural borders has been shown to have large-scale social and political consequences (Mountz, 2004; Ellis, 2005; Hubbard, 2005; Abu-Laban & Garber, 2005; MacÉinrí, 2006). But, what about

the social-psychological impact of such movement? From a social-psychological point of view, geographic movement is interesting because it is a basis for encountering alterity, that is, other people and alternative ways of viewing the world and one's own position within it. Theories of human development and identity put significant emphasis on interactions with alterity. Researchers developing the work of Mead (Hobson, 2002; Gillespie, 2006; Martin, 2006), Vygotsky (Valsiner, 1998; Wertsch, 1991), and the early Piaget (Perret-Clermont, 1980; Psaltis & Duveen, 2007) have argued and shown that social relations are central to the development of higher mental functions, the capacity for self-regulation, and the transition to more differentiated and integrated psychological processes. In addition, researchers working in the field of identity have argued, on the basis of countless studies, that alterity is central to the emergence and transformation of self-definitions (e.g., Howarth, 2002; Jovchelovitch, 2007). If we accept that encountering alterity is a basis for human development, what implications does the unprecedented movement of people across national borders have for how people think about themselves and others?

There is an established body of research examining the relation between geographic movement and identity. Encountering the other, particularly cultural others when individuals relocate, is not a simple task for the self. Be they immigrants, asylum seekers, refugees (O'Sullivan-Lago, Abreu, & Burgess, 2008; Kadianaki, 2010a), tourists (Gillespie, 2006), or international students (Märtsin, 2009), the action of moving in geographic space and coming into contact with alterity forces individuals to construct new identities (Moghaddam, 2002) and engage in processes of identity negotiation. This is caused by their encounters with novel social others, and also because of direct or indirect encounters with their home communities (Bhatia & Ram, 2001; Kadianaki, 2010a, 2010b). As they move, individuals must come to terms with the identity transitions from being a "local" in their home culture to being a "foreigner" and "immigrant" in the new culture. How they are positioned in their home communities is also altered, however: there is, as such, "no home to go back to" (Hall, 1987, p. 44).

Because of their geographic movement, individuals encounter previously unfamiliar identities that are often racialized and devalued in the particular social context (Deaux, 2006). Yarbrough (2009) describes how migrants coming from Latin

American countries to Atlanta, USA, encounter a previously unfamiliar identity, that of Hispanic/Latino(a), in their everyday social interactions with native-born residents. Physical characteristics and language accent are often used by native-born residents to build racialized assumptions about the new migrants, which lump together all Latin American nationalities into an overarching identity or misattribute all of these nationalities as being Mexican. In the new situation, the migrants also move into positions of “immigrant” or “asylum seeker,” identities that are often highly stigmatized and laden with social meanings that need to be negotiated (O’ Sullivan-Lago & Abreu, 2009; Kadianaki, 2010a). Verkuyten and Steenhuis (2005) point out that although the “asylum seeker” category is often misinterpreted, it is very socially meaningful, featuring in everyday thinking and raising emotional reactions. Often, particularly in the case of “asylum seekers,” the label is applied to, and must be negotiated by, individuals who do not even belong to that category (O’ Sullivan-Lago, 2009).

Immigrant identity can be seen to be caught between asymmetrical social discourses and stigmatized representations in the community of residence and “contradictory discourses related to home, tradition, community, nation and loyalty” to the community of origin (Bhatia & Ram, 2001, p. 304). The immigrant self often constitutes ambivalent and conflicting identity positions (Bhatia, 2002; Hermans, 2001). In the next section we analyze more closely the relation between geographic movement and the semantics of identity.

### Theorizing Geographic and Semantic Movement

Our distinction between geographic and semantic movements is based on Koffka’s (1935) differentiation of the geographic and behavioral environment of organisms. Koffka pointed out that there can be a difference between the geographic environment (the physical environment as it is independent of its perception) and the routines and meanings that organisms associate with that environment. The *behavioral environment* refers to the meanings, that is, *semantic associations*, that organisms have with the geographic environment. In what follows we develop Koffka’s distinction to theorize movement within the geographic and behavioral, or semantic, environments. Simply put, we want to theorize the relation between the movement of human bodies

in geographic space and the movements of self and other at the level of meaning and representation.

While it is accepted that identities are bound into geographic and social contexts (Dixon & Durrheim, 2000), it does not follow that as people move from one context to the next they take up new identities and completely disregard their previous identities. While bodies can be only here or there, at the level of identity and representation we can occupy multiple and even contradictory positions. For example, before immigrants-to-be actually move, they think about moving, they imagine their possible future in another country, and thus before they have physically moved they have engaged in semantic movements. Instead of describing people as moving from one identity to the next, it has been argued that it is more accurate to describe them as accumulating identities that, in relation to each other, stand in various states of tension and harmony (Gillespie, 2007a). The self stretches back to encompass all the positions we have occupied and it can stretch forward to imagine future ones we may occupy. For example, in his analysis of Malcolm X’s dialogical identity, Gillespie (2005) has shown that in his trajectory through the social world and movement between different social contexts, Malcolm X accumulated the identities of being oppressed, a hustler, minister, and human-rights activist. Toward the end of his life, it was the interaction between these accumulated identities that characterized his uniqueness.

In further opposition to the geographic body, the semantic world enables us to move between and occupy many social, temporal, and imagined geographic positions simultaneously or in rapid sequence. At a semantic and psychological level, the past, present, and future can coexist along with counterfactual presents, imagined pasts, and wished-for or feared futures. For example, tourists in Northern India have been shown to inhabit a semantic world in which what is observed and experienced merges with what has been seen in films and books (Gillespie, 2007b).

In the geographic world, the difference between self and other is absolute because self and other occupy mutually exclusive space-time trajectories (Mead, 1932). However, at a semantic level, the oppositions between self and other; between us and them; between me and you; can shift and slide, sometimes collapse or even reverse (Gillespie, 2007a). We live in a perspectival social world: a world in which other people and groups have

different ideas and identities, and what is key is that as social actors, we are to some extent aware of their different ideas and identities. The difference is not only “out there;” it is also within us. Humans experience alterity, represent it, and position themselves in relation to it.

### *The Relation between Self and Other*

The distinction between geographic and semantic environments provides conceptual clarity when talking about the relation between self and other. While self and other are fundamentally distinct in the geographic world, they are inter-related in the semantic world, gaining meaning through their relationship. At a semantic and psychological level, others are an important part of the self: this includes not only one’s friends but also one’s enemies. Insofar as the self is defined in dialogical relation to the other (Marková, Chapter 22), the other is an essential part of the self. To make the same assumption of groups, that the out-group exists “out there,” apart from the in-group, is to commit the psychologist’s fallacy and confuse what is in the mind of participants with what is in the mind of researchers (James, 1890). In a context of intergroup conflict, the out-group is central to the in-group’s identity: it structures the way in which in-group members think about themselves and their world. Within the dialogical self, the other is a central counterpoint: not only a point of comparison, but also a perspective from which to view the self (Simão, Chapter 18).

Thus, at a semantic level the other can be within the self. At an empirical level this manifests when someone refers directly or indirectly to the point of view of another. For example, “my mother thinks I am a good student, but I’m not sure I am.” In such an instance, we can see the mother refracted semantically within the student. Yet, we must also be aware that at a semantic level the individual has a self-concept that will often exclude not only their enemies but also their friends. Returning to the example of the student, she would likely distinguish herself from her mother yet, these are *her* ideas about her mother (her mother might think differently). That is to say, people tend to see themselves as isolated and fail to see that the others with whom they interact and continue various dialogues with, are in fact, part of their own selfhood at a semantic level. The present chapter aims to explore in detail exactly how alterity, encountered through geographical movement, enters into and transforms the self.

### **Crossing Greek and Irish Borders**

In order to examine the relation between geographic and semantic movement empirically, we draw upon research from two studies. These projects share their focus on the encounters between people of different cultural worlds in one place as a result of geographic movement across borders. Our aim is not to introduce new data, but rather to integrate existing data from these two previously published studies in order to develop more generalizable theory.

The first corpus of data is from a project on immigrants living in Greece conducted by the second author of this chapter (Kadianaki, 2010a; Kadianaki, 2009). Immigrants who participated in the project came from a variety of countries, mainly South American and African. All participants were living in Athens, their residence in Greece spanning from 2 to 30 years. The data presented comes from individual in-depth interviews, group discussions and ethnographic observation in three immigrant communities from August 2007 to April 2008.

The second data corpus comes from research by the third author of this chapter with immigrants, asylum seekers, and Irish locals living in Ireland (O’Sullivan-Lago, 2009; O’Sullivan-Lago & Abreu, 2009, 2010). The immigrant participants were mainly from European countries. The asylum seekers were mainly from Africa and the Middle East. The participants had resided in Ireland for very varying lengths of time: from a matter of months to over 20 years. All of the participants, including the Irish locals, were residents in Cork in the South of Ireland. The data presented comes from in-depth individual interviews that were conducted between July 2007 and February 2008.

In both of these comparable empirical contexts, geographic movement put people with different languages, accents, physical characteristics, economic and symbolic power, beliefs, values, habits and so on, into contact. Both empirical contexts are thus instances in which alterity is encountered and identity transformation is likely. While the Irish locals may not have moved geographically, we will demonstrate that the movement of the other has an impact on their identity, as contact with migrants forces the recognition and evaluation of cultural identities.

Our analysis focuses upon discursive data in terms of the identity positions being sustained (i.e., local, immigrant, asylum seeker, cheater, contributor, and so on), and any movement within the

discourse between these identity positions. This analysis of movement at a semantic level led us to also analyze the ways in which movement in the representation of self and other can be both blocked and facilitated.

Throughout the presentation of the excerpts we use the following transcription conventions: square brackets ([ ]) are used to insert explanatory text, pauses ([pause]) and the removal of some utterances ([...]). Underlining indicates the presence of alterity, usually alternative representations, which is being encountered and negotiated in the excerpts.

### ***Geographic Movement: Semantic Consequences***

The representations of immigrant/local usually entail a rigid self/other opposition that are reinforced by such things as language barriers, skin color, and cultural practices. The distinction can also be reinforced by commonplace beliefs about competition for economic and social resources. Despite the rigidity of this self/other differentiation, it is geographic movement that has brought about the distinction: all immigrants were locals before they left. Although the movement from the geographic location where they were “local” to the geographic location where they are an “immigrant” might only take a few hours, the semantic movement into a self-representation as an immigrant usually takes much longer and is often resisted. Consider the following excerpt from Helén who moved from Spain to Ireland:

My mother used to say, she used to cry a lot, ‘why don’t you come home?’ always the same question, ‘why don’t you come home?’ And one time she mentioned the word immigrant and I thought, ‘but I’m not an immigrant’ because before, their generation, the generation before, they were immigrants in my view because they had to go abroad because of money, because of circumstances, being poor or whatever [pause] I didn’t consider myself an immigrant because I didn’t really have to leave my family and go because I needed a better life or money or anything like that, I just went because I wanted to [...] so I know very much that I’m not Irish and never will be, but I’m not an immigrant in that way.  
(Helén, 45 years old, Spanish, living in Ireland for 21 years)

Helén has been living in Ireland for 21 years and in a technical and legal sense, Helén is an immigrant. However, she does not consider herself to be one. The idea that she is an immigrant is an alternative

self-representation that she resists. The underlined text indicates the intrusion of the alternative self-representation (self as immigrant) into Helén’s discourse. The alternative self-representation, initially given voice to by Helén’s mother, is that Helén is an immigrant who has gone abroad out of a tragic financial necessity. Helén vehemently resists this being represented in that way, arguing that she is not an immigrant “in that way.” Each time the alternative self-image intrudes, she resists it, counter-arguing that she is different because she has moved out of choice and does not see the move as sad.

In this resistance, however, we can also see that the geographic movement to Ireland has repositioned Helén. She admits she is an immigrant in some ways: she does come from a different country, she has left her family behind and has a different culture, but she still resists the categorization. Thus we see that although the geographic move from Spain to Ireland is absolute, the semantic movement into the identity position of immigrant is not.

Moreover, the semantic movements occasioned by the geographic movement to Ireland do not end with a self-representation of being an immigrant. After a certain number of years, some immigrants feel, and want to be seen as locals. For how many years one has to live in a country to become “local” is contested, and often self-identifications come into conflict with the way in which they are identified by others. Consider the following from Antonia, a refugee from Romania:

People will ask me, even after 7 years, ‘where are you from?’ and I get so bothered, I’m becoming bothered and tired after seven years to say ‘oh I am originally from Romania’ and I will say sometimes to joke, ‘I’m Irish, I’m from Carrigaline’ and they say ‘ok, you are from Carrigaline but where are you from?’” All the time people will see me as being from another country. So that’s a little bit, you know, not such a good feeling. But I have to get used to this because this is it, what I am in the Irish eyes, I will never be one of the Irish even though I consider myself and I say, ‘come on, I’m an Irish citizen now.’

(Antonia, 41 years old, Romanian, living in Ireland for 7 years)

There is a disjunction between Antonia’s self-representation and how the Irish locals see her. The (underlined) alterity she encounters punctures her thoughts and discourse. Antonia wants to represent herself as Irish, but she is blocked by the views she encounters—her desired identity is

not recognized. Having moved 7 years earlier, she now asserts her Irish citizenship and belonging, but because her nationality and accent remain, the people she meets see her first and foremost as a foreigner. What is central to the semantic consequences of geographic movement is encountering alterity, other people and alternative representations: as with Helén, it is in the eyes of the other that the semantic consequences of geographic movement become salient.

Movement in the geographic environment does not lead straightforwardly to repositioning of identity at the semantic level of representation. There can be issues of lag, of coming to terms with a new identity position, and even acts of resistance and discrepancies between the identity positions that are claimed and the ways in which one is positioned. People are rarely free to choose their identity positions, and recognition from others is essential (Howarth, 2002). An overarching semantic consequence of geographic movement is a disjunction between how people see themselves and how they are seen. Geographic movement brings people into contact, and in that contact each discovers that they have a relevancy or surplus meaning (Gillespie, 2003) for the other that is somewhat at odds with the way in which they have previously represented themselves.

### Semantic Barriers: Resisting Alterity

It is not sufficient simply to be in the geographic presence of alterity to actually encounter alterity. Encountering alterity necessitates being open unto the other (Levinas, 1991), that is, representing the other as beyond self and representing self as potentially transformed by the other. However, because of threat of change, there is often a semantic effort to deny alterity and stabilize preexisting representations of self and other.

Moscovici (1974/2008) and Gillespie (2008) have begun to identify the semantic barriers used to resist alternative representations. Semantic barriers are ways of speaking and thinking that block transformative engagement with alterity. Semantic barriers, including creating rigid oppositions, negative associations, prohibitions, clear-cut separations, stigmatizing the other, undermining their motive, or presenting the other as having mere “beliefs” and “thoughts” about the world (rather than valid experiences), can all inhibit transformational interaction between ideas, representations, and perspectives. In the following analyses, we present

empirical examples of how these barriers work to block alternative representations.

In the encounter between immigrants and locals, there are many examples of semantic barriers being used to dismiss or block the alternatives presented. In the following excerpt Aidan, an Irish local, gives his rather blunt justification for not engaging with asylum seekers:

I just don't like to talk to most asylum seekers, like, especially you know that most of them are either on the run from the law in their own country and if they go back to their own country they'll get prosecuted for this or that, and our country doesn't wonder why they're so afraid to go back to their own country, 'oh they'll probably get killed' or something like that, you know they make up all these excuses. Why can't they request their criminal background from that country? This person could have been just saying this and this and this and like, 'I'll go back and I'll get killed' and this, but they never look past that and think they could have got in trouble with the law. The possibility of them being done for kiddy-fiddling, kidnapping, rape, anything—you could number a list of things that they'd be nervous about going back for because he doesn't want to go back to jail, so he makes up an excuse and how's our government supposed to check up on that?

(Aidan, 23 years old, Irish local)

In this explanation for his avoidance of asylum seekers, Aidan represents them as having an ulterior motivation for being in Ireland, namely, to escape legitimate punishment for grievous crimes. The alternative representation (underlined) is that the asylum seekers can't go back to their country of origin because “they'll probably get killed.” Even though this fear of persecution is the definition of what an asylum seeker is, it gains no traction with Aidan. He constructs a powerful semantic barrier to block the alternative representation of these individuals seeking asylum for genuine reasons. The extreme case formulation of his semantic construction (Pomerantz, 1986) leads him to distrust. Indeed, the vigor of their protestations could even be interpreted by Aidan as further evidence of their horrendous crimes and desire to escape punishment. The implication is that people who have committed grievous crimes will say anything to escape prosecution and thus nothing said can be believed. Dialogue with the other is accordingly presented as a waste of time for an honest person, which is why he doesn't “like to talk to most asylum seekers.” In

the absence of trust it is impossible to have open dialogical communication because what the other says and does loses value because of the possibility of an ulterior motive (Marková & Gillespie, 2007).

Another common alternative ulterior motive, voiced by the Irish locals, is that immigrants and asylum seekers are only in Ireland for generous social welfare payments. In both cases the representation creates a fundamental distrust of the other, which not only ossifies the self/other boundary but makes it very difficult for the other to challenge the distinction: their protestations, no matter how sensible, are not given any credence because of the block, boiling down to a suspicious, “they would say that, wouldn’t they?” This powerful semantic block halts further elaboration of the justification (Valsiner, 2002), because nothing said is trusted.

Openness to dialogical engagement entails perceptions of mutual trust and respect. It is difficult to be open unto the other if one perceives the other to be stigmatizing, distrustful, or dismissing. This is particularly evident among migrants who feel that their new community of residence is closed to them; this representation in turn, closes them to their new community of residence. Consider the following excerpt from Alike, who came to Ireland from Nigeria to seek asylum:

They think of us as pests, as bodies. That’s what they think of us. At times when I go to the post office to pick up my weekly payment I feel ashamed of myself because even if they are not looking at me, I feel their eyes on me saying, ‘Look at them, they are one of those people who come.’ So we are bodies to them. That is my belief. In as much as I know that not all of them think that of us, but we know it is a general thing that they feel. They feel that the asylum seekers are no good [...] that we are bodies who have come to use up their tax-payers’ money without contributing anything.

(Alike, 32 years old, Nigerian, 1 year in Ireland)

This quotation illustrates how stigmatization and overgeneralization (“that’s what they think of us”) inhibit dialogue with alternative points of view that might lead to a more nuanced conception. According to Alike, all Irish people see asylum seekers, including her, as “pests” and mere “bodies.” The alternative representation (underlined) of the Irish, that “not all of them think that of us,” makes a brief appearance, and if elaborated, it might have created points of commonality, but it is cut short by an overgeneralized feeling (Valsiner, 2002) reflected

in the utterance “but we know it is a general thing they feel.”

If one tendency in the face of alterity is to resist and stigmatize, as Aidan does, then it will be the case that in encountering alterity, one is likely to encounter stigma. While an easy response might be to counter with reciprocal resistance and stigmatization, such a response is a likely basis for escalating semiotic barriers. The alternative representations of self and other are threatening, and thus both parties tend toward protective stigmatization of the other, making the alternative representations of self and other more threatening, and so the cycle continues.

### *Nationality and the Representation of Difference*

In order to block out alterity, it is necessary to create a rigid opposition between self and other. Many strategies can be used to achieve this end, but particularly salient are representational resources that bring into play ideas of nationhood, belonging, and “essential” difference. These representations, which are fundamental to our culture, are “ready-made” templates for stabilizing self/other difference. In the following excerpt one can see how an Irish local uses multiple semantic barriers, and especially the idea of belonging, to block out the egalitarian point of view that “they’re just like us.”

Ireland is mostly just a place for foreigners. Everywhere you go you see a black person or a colored person or a Chinese or refugee or something. You see them everywhere you go. Inside in Dunnes, especially up in Lidl’s [supermarkets]. I was out there yesterday: it’s just all them. Too many of them are coming in, so it’ll be us leaving. And then our country will just be all colored, and no more Irish, we’ll all be gone. Too many of them are coming in and they’re all just leaving them come in. It’s not fair on us. It’s alright to be saying that they’re just like us, that’s alright, but they have their own country, they don’t belong here.

(Sinéad, 19 years old, Irish local).

Despite not relocating herself, the geographic movement of immigrants into Ireland has caused a change for Sinéad. Using an example of her recent visits to supermarkets as representative of societal changes (Bowen, 2008; O’Sullivan-Lago & Abreu, 2010), she relays her fears of being outnumbered (and therefore other) within her own country. Again we see that geographic movement can, at a semantic level, reverse seemingly rigid identity positions. Sinéad reacts to these changes by creating a

rigid opposition between “foreigners” and the Irish. Using words and phrases like “everywhere,” “all,” “just,” “too many,” and “no more Irish” to create a catastrophic representation of the situation. These extreme case formulations (Pomerantz, 1986) legitimize claims of complaint, accusation, justification and defense and can also be used in negotiating claims about identity and category labels (Verkuyten & de Wolf, 2002; Figgou & Condor, 2007).

Toward the end of the quotation, an alternative representation (underlined) makes an appearance: “they’re just like us.” As was the case with Alike, if this representation were expanded, it could lead to a collapse of the distinction between self and other, but it is quickly silenced and blocked by the stronger representation of nationalistic belonging. First, the alternative is bracketed: it is presented as something that people are “saying.” Opinion is not to be taken as fact. Second, the idea that everyone has a country to which they “belong” is used to establish a rigid opposition. Within the logic of such “banal nationalism” (Billig, 1995), an individual can only belong to one country and this belonging cannot change. Thus, it is argued, even if “they’re just like us” it does not matter because “they don’t belong” in Ireland. Nationhood, in Sinéad’s (and in Celia’s words below), is discursively represented as a natural category. National distinctions are talked about as essentially autonomous and unproblematic, reproduced through mundane phrases such as the use of “us” and “them” so that the speaker does not feel the need to explain (Billig, 1995).

### *Essentially Different*

The idea of nationhood and belonging to one’s place of birth is not only used by locals to differentiate immigrants, but it is also used by immigrants to differentiate themselves from locals. Consider the following quotation from Celia, a Colombian who immigrated to Greece, following her Greek husband. She relates a conversation she had with a Chilean immigrant in Greece:

I met this man from Chile and he said, ‘I am Greek but I was born in Chile...’ [pause] I told him, ‘You are either Chilean or Greek: you have to choose. If you like more Greece, you can say you are Greek, but let me tell you one thing—what’s your name?’ ‘Manuel.’ ‘Let me tell you one thing, Manuel: the person who denies his land denies his mother—so why? Chile might have this name of pickpockets, of this and that, but no, my friend: you have to love your land because this is where you were born.

Your land carried you, rose you up [...] You are not Greek.’ ‘Yes I am Greek.’ I told him, ‘I have the Greek nationality, but I was born in Colombia and I am Colombian until I die.’

(Celia, 54 years old, Colombian, 31 years in Greece).

In this excerpt, the (underlined) alternative representation is presented at the outset, namely the idea that one can be born in Chile and call oneself Greek. Celia is incensed by the idea. Powerful semantic barriers are used to block the alternative representation of either Manuel or Celia as Greek. According to Celia, the self cannot and should not give up the identity given by birth. Self and other are represented as “essentially” different by birth. Celia’s argument is so strong that we can sense a prohibition at work blocking certain thoughts: claims of being Greek are presented as an unthinkable betrayal to one’s nationality. A powerful metaphor of kinship is introduced here in order to seal the argument of national distinctions: the country is the mother who carries and raises her children. Celia has Greek citizenship in a legal sense, but this is overshadowed by her representation of nationhood and belonging.

In both excerpts above, there is a representation of nationality at work, which creates a self/other difference that is primary to any legal documentation, personal experience, or preference. In both excerpts we can see a similar representation of nationhood acting as a semantic barrier inhibiting any dissolution of the asserted self/other difference. This type of semantic barrier, what could be called a representation of essential differences, has been discussed by Raudsepp and Wagner (in press) in their study of the intergroup tensions between Estonians and Russians. If one considers the way in which the discourses of genetics, race, and culture are often deployed, it seems reasonable to assume that any representation which posits an essential or natural difference will serve to reinforce self/other distinctions. However, representations of essential difference coexist with representations that all people are “essentially” the same.

### **Counterpoint: Essential Sameness**

In the same way that representations of an “essential” difference between groups can act as a powerful enforcer of difference, it is equally the case that representations of “essential” sameness can promote identification and movement between self and other positions. The idea of “essential” sameness and how it is able to overcome the representation of

“belonging” to a nation is illustrated in the following exchange:

**O’Sullivan-Lago (ROS-L):** What does that mean to you? Being Irish?

**Aidan:** It means fuck all really—let’s be honest. I’m going to be truthful with you—it means fuck all. Jesus, if I was born in Spain I’d be Spanish, if I was born in Italy I’d be Italian, if I was born in America I’d be American, or if I was born in England I’d be English. All it is that it kind of gives you a place in the world. It’s that people are all ‘oh I’m from here’ and ‘oh what are you?’ Well, I’m from Corcaigh—so what? It’s not where you come from, it’s who you are—that’s what matters over all.

(Aidan, 23 years old, Irish local)

Aidan quotes other people as voicing an alternative representation (underlined) of nationalistic and cultural belonging: “I’m from here” and “what are you?” This representation, however, is blocked and dismissed by saying, “I’m from Corcaigh—so what? It’s not where you come from, it’s who you are.” Aidan’s basic idea is that nationality is happenstance and that people should focus on who people are as individuals. This is oppositional to the idea of nationality as an essential difference. It is also oppositional to his previous idea of the ulterior motivation of immigrants for being in Ireland (i.e., escaping severe crimes). Thus Aidan seems to move between quite different orientations, unaware of the potential contradictions.

Asylum seekers in Ireland also use the idea of essential sameness to resist the way in which some Irish locals perceive asylum seekers as different. Consider the following utterance from Janári who moved to Ireland from Albania:

I have been to friends’ houses, but I can’t bring them here [to the accommodation center for asylum seekers]. I can’t tell them where I live because I know I’m going to lose them. So that’s not good, that’s bad. Just I hope people understand that all the people are from one world, you know? So, all the people have one God. You might pray like that, I might pray like that, but all of us pray to God, you know?

(Janári, 31 years old, Albanian, 2 years in Ireland)

Janári is aware of essentializing representations that would posit him as essentially different if he were identified as an asylum seeker. Despite being familiar with these representations, he does not agree with them. Janári resists the differentiating representation that would mean being ostracized and the

loss of his friendships because of his “difference,” on the basis of an essential sameness—people are from the same world; despite religious and cultural differences, everyone still prays to God. The idea that all humans are essentially the same protects Janári from being more deeply affected by the stigma he perceives.

Both Janári and Aidan invoke the idea that the differences between people are inconsequential and humans are essentially the same. They present a contrast to the previous excerpts, which showed people talking about essential difference. That said, however, it does not follow that differentiating is in any way connected with being closed unto alterity, and “sameness” or identification implies being open to alterity. In the next section, we see how immigrants often invoke differentiations (albeit nonessentializing ones) in order to avoid stigma and thus remain open unto local communities.

### *Deflecting Stigma, Remaining Open*

In our discussion of the resistance people often enact when encountering alterity, we pointed out the potential for mutually escalating stigmatizing representations, as each side tries to protect themselves from the views they attribute to the other. In this section, we examine the ways in which the stigmatizing views attributed to the other can be blocked, or rather quarantined, so as to prevent an escalation. The basic strategy is to isolate the stigma either in a minority of the out-group or as an obvious misperception.

The following excerpt demonstrates how immigrants in Greece try to differentiate Greeks who are respectful from those who are stigmatizing and racist. This excerpt is from a conversation with Maria and Celia from Colombia and Elvira from Santo Domingo:

**Kadianaki (IK):** Many people now learn Spanish here in Greece and learn how to dance, how do you see this?

**Maria:** It is very nice!

**Elvira:** One feels as if... [pause]

**Maria:** I feel proud that they want to learn the language and the culture.

**Elvira:** Because I always, one has felt all this rejection of our traditions, of the tradition we have and now that they see it and it is pleasant and they like it and they say, ‘Look—Jennifer Lopez.’ I remember many times they have told me, ‘Oh, shit, look—Beyoncé! Did you see that?’ Well, so, these things they please

you, because they see you and they compare you with somebody, you see? With something, with a person who is something, important, they don't see you as trash, like they have always wanted to see you, like for the floor, like very low, like you are nobody. Like you came to this place and you are an unhappy, dying from hunger, and you came to eat. Like many have told me, 'you came to take our food.'

Maria: What happens is [pause] sorry for interrupting you [pause] what happens and I have seen it too [unclear] the Greeks, not all of them, [pause] but some are racists.

Elvira: Not everybody, yes.

Celia: There are racists everywhere.

(Maria, 52 years old, Colombian, 17 years in Greece; Elvira, 52 years old, Santo Dominican, 18 years in Greece; Celia, 54 years old, Colombian, 31 years in Greece).

The fact that some Greek locals learn to speak Spanish and learn Latin American dancing gives Maria, Elvira, and Celia confidence that they are respected by Greek people. Elvira comments on how proud she has felt when she was identified with Latin American superstars like Jenifer Lopez and Beyoncé. In explaining her enthusiasm, she raises the alternative representation (underlined) that the Greeks have “always” seen Latin Americans as “trash” and as “nobody.” The stigmatizing alternative representation gains traction for Maria, and she expands upon it saying that not all, but some Greeks “are racists” and Elvira agrees.

While Alike and Aidan, discussed above, homogenize their respective out-groups and refuse to make differentiations within the out-group, Maria and Elvira are able to engage with the idea that there is racism within Greece without it becoming overwhelming, which would lead them to take an identity position firmly opposed to Greeks. The way in which they achieve this is primarily through differentiating between the Greeks—“not all of them” are racist. Celia also achieves the same end by declaring that “there are racists everywhere”—the implication being that the women should not feel threatened by Greeks in general. By constructing racism as particular to a minority of Greeks on the one hand and commonplace on the other, these women manage to maintain a sense of pride and recognition in the eyes of the Greeks in general.

An additional means of silencing stigma is to understand the source of the discrimination, and to forgive it. By claiming to understand the source of the discrimination, the perceived discrimination

becomes neutralized and nonthreatening. This process is evident in the following excerpt, which is a part of a group discussion with women from a variety of African countries. Here, Lysette from Sierra Leone explains during a group discussion:

You know in Greece they have mythology, we were taught a lot in the school in my country, I learnt a lot of myths about Greece and I was thinking, how can they be like that?! [Everyone laughing] I was thinking of them as mythical beings, they had the twelve Gods, and all this made me see Greeks when I was there, like that, mythical, it is the same with those who believe that Africans are cannibals. We learnt about Hercules, about the twelve Gods, about Athena, it seemed like another world to us, you see what I mean? That is why I can't be concerned with people who believe that Africans are cannibals.

(Lysette, 43 years old, Sierra Leonean, 24 years in Greece)

Lysette gives voice to the idea that Africans are cannibals. What is interesting is that this alternative representation gains no ground; it is treated as ridiculous and is therefore laughed away and poses no threat. Being attributed to a minority of people neutralizes this potentially stigmatizing representation. Lysette raises herself above it through her construction of it as a phantasmagorical illusion. Indeed, the presentation of this particular alternative seems to reverse the trajectory of the stigma such as it falls back upon the stupidity of anyone who held such a view.

Encountering alterity can be threatening, and semantic barriers provide a means to dismiss alterity and maintain existing ideas about self and other. However, if discriminating representations are elaborated on both sides, then there is likely to be mutual escalation as the challenge posed by the other becomes exacerbated. This is not a necessary outcome, however, and in the present section we have shown how semantic barriers can also be used to silence discrimination, quarantine stigma, and thus diminish the challenge of alterity. In this way semantic barriers can be used to remain open to transformation by alterity.

### Unplanned Semantic Movements

Geographic movement is usually intentional and planned, but semantic movement is often unintentional and sometimes not even noticed. The adjustment of the representation of self and other to the changed geographic circumstance is a gradual process. Moreover, representations of self and other are

context-specific, and accordingly, insofar as people occupy multiple contexts, they participate in multiple representations (Wagner, Duveen, Themel, & Verma, 1999). Consequently, movements of migration can lead to semantic reverberations years later, when disjunctions can result in unplanned semantic voyages.

Consider the following excerpt from Carla, a Peruvian immigrant in Greece. She is talking about the places she has lived in Athens and particularly why she moved out of an area of predominantly immigrant inhabitants:

IK: How long have you been living here?

Carla: It's about 2 to 3 years, and [pause] I liked it, because I wanted my children to learn Greek from Greeks, because I was living in Aharnon [an area near the center of Athens] where there are many migrants. It is not that I discriminate, everybody, myself I am a immigrant too, but next to me there were some Albanians, and on the other side some Romanians, so my son, what was he going to listen to? It would be Greek that no [pause] so I didn't want a place like that.

(Carla, 40 years old, Peruvian, 10 years in Greece)

Carla says that she left an area where "there are many migrants" because she wanted her children to grow up among locals. As she speaks she becomes aware of a potential contradiction: not only might she be perceived to be discriminating against immigrants, but she herself is an immigrant. The contradiction is that while she is trying to sustain a difference between herself and immigrants, she still remains an immigrant herself. The distinction she is trying to sustain dissolves—indeed the immigrant category expands to include "everybody." Yet, the dissolution of the difference is only a temporary collapse (Gillespie, 2007a). Despite reversing self/other positions, she continues regardless. The difference is reconstructed on the basis of her neighbors being "Albanians" and "Romanians" and the fact that she wanted "something different" for her son.

Unplanned semantic movements are also evident amongst the Irish locals receiving immigrants. Ireland has a long history of emigration and thus there is a point of historical commonality between immigrants and the local Irish. In the following excerpt we see how Eoin, an Irish local, in the process of criticizing a subgroup of immigrants comes to see the Irish as the same. The collapse of the self/other boundary occurs because of the collective Irish history of economic migration to America and

the shared "immigrant" identity of self and other. The collapse is uncomfortable and Eoin rebuilds the differentiation in a new way:

So as I said, I know a few of them alright and they're getting along ok, and there are a few, the ones that come over and try to scam everyone and that just bugs the shit out of me. I don't know: it's like why come over and rip people off? You're coming over to have a better life and all you do is rip people off. But as I said, those that go away and get a job and do everything right, I've no problem with. It's just, you know, the ones that scam off everything and just try and try, you'll hear them, "Oh my brother went over and got this, that and the other thing, so I'm going to go over." Now, fair enough, the Irish do it all the time, we go over to America. A friend of mine went over to America [...] went over with a sleeping bag and got over, "right, where am I staying?" [...] They're over illegally as well, like, so they just go ship to ship, making their money. Now there are people over here doing the same thing, I've no problem with that, but if my friend went over to America and said, "Right, I can get a free house and free this, I can get free that." There's no, there's no, it's just sickening.

(Eoin, 24 years old, Irish local)

Initially, Eoin discusses some immigrants he knows who are "getting on ok" in Ireland, but also points out that there are many who are "scammers" that are "ripping people off." In short, as discussed in the previous section, he is differentiating the out-group. While he is very positively disposed toward immigrants who "get a job and do everything right," he is hostile to those who try to gain profit without contributing anything. He then gives voice to an imagined immigrant saying, "Oh, my brother went over [to Ireland] and got this, and the other thing, so I'm going to go over." This utterance comes close enough to the common collective Irish experience of emigrating to America so that the distinction between the Irish and the "scamming" immigrants collapses. As if responding to a voice pointing out that this is what the Irish have done, Eoin accepts, "Now, fair enough, the Irish do it all the time," and recounts the experience of a friend who went to America and worked there illegally. To maintain some distinction from the other, however, Eoin proceeds to qualify his complaint, restricting his identification to working immigrants and blocking the identification with immigrants who abuse the system and take what they can.

Geographic movement leads to semantic movement, both for those who move and for those who

receive, and often for many years later. The geographic movement of immigration creates huge semantic reverberations, as all the people affected by the movement reposition themselves in relation to that movement.

### **From Geographical Movement to Semiotic Regulation**

Encountering alterity cannot be reduced to contact in the sense of co-presence in the same geographical space. For a genuine encounter with alterity to occur, the perspective of the other has to permeate the self and to some extent, transform the self. In the empirical examples above, we explored how semantic barriers within the self are built and used to regulate this encounter, sometimes resisting and sometimes opening up to alterity. In the same way that living tissue expunges alien objects, semantic barriers operate within the semantic realm to expunge discomfiting ideas; just as the body regulates what enters it, the self regulates what enters the semiotic realm.

Semiotic regulation refers to the way in which meanings and actions regulate the thoughts and actions of self and other (Vygotsky & Luria, 1994). To regulate these meanings, as we have illustrated, the self can construct semantic barriers so that the content of ideas (the semantics) can block other ideas, specifically the perspectives of other people or groups. The focus of semantic barriers is not on strategies per se, but on the idea complexes, or social representations (Marková, this volume), which have a semantic logic that undermines the perspective of the other—such as beliefs about essential difference grounded in blood, genes, or culture. Ideas that the other is essentially different or fundamentally untrustworthy provide a basis for expunging their perspective from the semiotic system of the self. Equally, believing that all humans are essentially the same can potentially give the perspective of the other credibility within the semiotic system of the self.

Semiotic regulation, and its specific form in the work of semantic barriers, is forward oriented. Whether the use of signs is internal or external, there are always implications for the past, present, and future (Valsiner, 2001). Equally, semantic barriers exist in a temporal realm, and also have implications for the past and point toward the future. Why do Aidan, Alike, Sinéad, and Celia all work to circumvent the perspective of others? If the perspective of the other were entertained, it is likely that it would

have had uncomfortable future implications for the self. For example, if Aidan considered the idea that refugees might have legitimate reasons for seeking refuge, it would imply both that his previous claims were wrong and that he would need to change his behavior toward asylum seekers in the future.

Semiotic mediation is focused upon resolving practical and semiotic problems within a here-and-now context (Abbey & Valsiner, 2005) and the process is fundamentally open-ended. Thinkers and speakers can never be fully aware of where the trajectory of their semiotic regulation will lead (Valsiner, 2001). Equally, in the use of semantic barriers we have seen how both immigrants and locals tackle situated questions within an interview context, how they guard themselves from the implications of alternative points of view, and how the trajectory of their discourse can lead to unplanned outcomes. For example, Carla began by differentiating herself from immigrants, only to acknowledge that she too was an immigrant. And Eoin moved from differentiating immigrants in Ireland from the Irish, but ended up pointing out similarities.

Research on semiotic regulation has tended to focus upon the way in which thoughts and feelings are regulated, promoted, inhibited, or transformed. For example, Josephs and Valsiner (1998) analyzed the way in which people circumvented generalized beliefs that could not be easily ignored in such a way as to be able to act contrary to those beliefs without challenging the beliefs directly. In the present chapter we have been analyzing the way in which people can circumvent the perspective of the other. The appearance of alternatives that need to be dealt with by the individuals demonstrates that the perspective of the other can be difficult to ignore, especially in an interview context. However, using semantic barriers enables tarnishing the other as essentially different or untrustworthy and thus makes the act of dismissing their point of view much easier. As such, semantic barriers are a form of semiotic circumvention, where the object being circumvented is an alternative and somewhat discomfiting idea or perspective.

A key question is: how do the different perspectives of the various stakeholder groups get within the self? In each of the excerpts analyzed above, there is more than one perspective interacting. How do these different perspectives get within the discourse of one individual? Specifically, how is it that immigrants are able to see themselves from the perspective of the people they left behind in their

home country in one moment and in the next from the perspective of the host community? This is a variant of the long-standing problem of internalization. Namely, it is empirically evident that people's thoughts and discourse navigate alternative points of view, but it remains less clear how these alternative points of view become internalized by individuals. Geographic movement may provide one aspect of an answer to this.

Geographic movement provides a mechanism through which diverse perspectives can infiltrate the self. Simply put, before any individual leaves their country of origin, they are locals. As locals they encounter immigrants as "other" (i.e., the immigrants who come to their home country). Accordingly, immigrants-to-be already have the perspectives of locals toward both the people who leave and the people who arrive. Once the immigrants-to-be leave and become immigrants, these previous perspectives toward others can be reversed and turned upon the self. Thus, previous experience of others as immigrants becomes mapped onto self and the immigrants are, to some extent, able to see themselves from the perspective of nonimmigrants. One of the core problems of the development of self, according to Mead (1932), is how people can get outside of themselves and thus become self-aware. In geographical movement, people are, in a sense, stepping out of themselves and becoming other (Gillespie, 2006), and thus the previous exteriority they had in relation to others becomes exteriority they have in relation to themselves.

The excerpts analyzed in the present chapter illustrate the role of geographic movement in semiotic regulation. Helén, for example, first had the experience of other people leaving her home country of Spain, then when she moved to Ireland, she was, through the words of her mother, able to turn these previous experiences of others toward herself and, with some discomfort, see her self as other. Equally, Lysette takes her own experience of misunderstanding the Greeks, inhabiting a mythical realm, to forgive the Greeks who misunderstand her and her African heritage. In both of these cases we see how geographic movement enables a stepping out of the self, and thus self-reflection and self-regulation.

But what of the Irish who have not moved geographically? It is possible, although they have not migrated, that geographic movement does still have an important role to play, this time at the level of collective history. Aidan and Eoin, for example, had the imagined migration experience of the Irish

throughout history, and Eoin additionally had the imagined experience of his friend, to draw upon. Using this experience allowed them to semiotically regulate the alternative representations of migrants as essentially different or only migrating to "rip people off." Thus we see that people are able to regulate meanings about the self and self-reflect, not only from social positions actually occupied, but also from social positions inculcated and imagined, possibly with the aid of elaborate symbolic resources—such as Irish national narratives of migration.

### Future Directions

The overall aim of this chapter has been to follow the consequences of the geographic movement of immigration into the semantic movements that result. We have also shown the ways in which geographic movement leads to encounters with alterity, which can be threatening because of the alternative representations of self and other that are encountered. We have focused on the boundary between self and alterity, and tried to analyze the way in which the self either tries to expunge alterity or remain open to it. In this final section, we outline potentially fruitful lines for future research.

At a general level, we encourage research to focus upon movement: geographic movement, semantic movement, and above all, the relation between the geographic and semantic movement. By studying this relationship, we suggest, researchers can develop a genuinely social and material analysis of semantic and psychological processes. Within this orientation to future research we want to raise four specific lines of research.

First, which representations, or semantic content, enable people to dismiss or silence alterity? We identified ideas about nationality and belonging as being a basis for postulating a taken-for-granted essential difference (Billig, 1995). Are there additional representational complexes that can be used in this way? Do representations about genetics, mental illness, terrorism, specific religious or national groups, and so on, reveal similar properties? Can we understand the representations that colonialists used to have in relation to their colonies as serving similar functions (Said, 1978)? In any case, what are the key aspects of a representation that enable it to be dismissive of alterity?

Second, would the identified semantic barriers and essentializing representations be evident in face-to-face or mediated contact with alterity? Our analysis has not pertained to any actual contact zones,

but from intragroup discussions and interviews, and we have analyzed how participants engage with the voice of the other, which they themselves have given voice to. We have shown how the voice of the other is silenced, and equally, how stigmatizing views are blocked, but would either of these happen when the self is in actual contact with the other? There has been a lot of research on whether contact can overcome intergroup conflict and it would, we suggest, be profitable to analyze the interactional processes within such contact. Specifically, we ask, are semantic barriers and essentializing representations evident in actual interactions? And perhaps most interestingly, how would the other respond to encountering essentializing and silencing representations?

Third, why do some people at some points in time feel threatened by alterity and feel the need to dismiss it? How does the content of the alterity interact with their own semantic being to produce a threat to be resisted? Semantic barriers do not cause the silencing of a representation. Rather, they are the tools that are used to do so. In many cases, alternative tools could have been used. Why, for example, does Sinéad draw upon the idea that people naturally belong to different countries, while Aidan draws upon the idea that belonging is irrelevant? And perhaps, even more interestingly, what is that makes the same person shift between his/her use of semantic barriers blocking or enabling the same alternative? We saw how Aidan contradicted himself, once arguing about the ulterior motivation of immigrants and then enabling sameness between self and other. Future research can focus on the social conditions that make alterity threatening and on the ways that individuals psychologically negotiate and semantically move between these. This takes us to questions of motivation, and the overall, often overgeneralized, feelings that guide people (Valsiner, 1998).

Fourth, what are the conditions for more or less transformative dialogical engagement? Numerous theorists and researchers whose work originates with Mead, Vygotsky, and Piaget have shown how development hinges upon encounters with alterity, and sometimes even conflictual encounters (Psaltis & Duveen, 2007). Why then is it that people often resist alterity? And specifically, what are the conditions that lead at an individual level to a developmental encounter and, at a social level, to the production of more perspective-transcending knowledge? We have shown how semantic barriers can block the

elaboration of alternative representations; does it then follow that blocking the elaboration of alternatives closes down the potential for dialogical transformation? Or, might the converse be true—that the existence of semantic barriers and the resistance that motivates them is in fact evidence of a tension and thus the presence of change?

## Crossing Thresholds: Movement as a Means of Transformation

Zachary Beckstead

### Abstract

Any cultural practice in human life is accomplished by some kind of movement within the culturally organized environment. This includes movement in our everyday environments (e.g., home to school and work) and travel that extends beyond our home community. While going from our home to the grocery store entails some form of border crossing (e.g., private < > public), long-distance travel brings us into contact with unfamiliar lands, sights, smells, and people, and involves taking up a social role and position (e.g., soldier, tourist, immigrant, pilgrim). In an age when human mobility is increasing with an emphasis on speed and efficiency, pilgrimage remains a popular form of movement where many varieties of transformation is the goal. Thus, pilgrimage provides a concrete historical and cultural framework for human travel. Pilgrimages can be viewed socially and structurally (e.g., Victor Turner's ideas of *communitas* and the debates surrounding this), personally and culturally (through looking at material culture relevant for the persons on the move), and in terms of tourism as a version of secularized and commercialized pilgrimage. This paper builds an understanding of pilgrimage from a developmental, cultural, and psychological framework. Elaborating Turner's notion of *normative communitas*, I examine how pilgrims are guided and constrained toward episodic moments of deep affective value and how these experiences overgeneralize and feed-forward to the pilgrims' future encounters with the world.

**Keywords:** pilgrimage, social guidance, semiotic mediation, externalization and internalization process, sacred

Our modern world is filled with rapid movement and expanding mobility. Distances that people travel are increasing, while the time it takes to reach these far-away locations is decreasing. Flow of goods, ideas, and people circulate around the globe in large quantities and at dizzying speeds. It is little wonder that “travel” seems to have become the “image of the age” and that:

... porous borders, portable allegiances, virtual networks, and elastic identities now more than ever evoke the language of mobility, contingency, fluidity, provisionality, and process rather than that of stability, permanence and fixity.

(Euben, 2006, p. 1)

Boundary crossings are commonplace, and successful travel is largely measured by how fast people and information can be transported from place to place. However, travel has not always been commonplace and marked by efficiency. Indeed, the English word *travel* is derived from the French word *travail*, and so historically travel has been connected to hardship, effort, and suffering. Traveling to distant (and even not-so-distant) lands entailed large time commitments, physical exertion, crossing rigidly protected borders, entanglements between countries, collectivities and nations, the uncertainty of finding lodging and food, and a host of other dangers that existed in unknown lands and on the paths to these places. Travelers

across Europe for centuries encountered rutted roads that violently jostled carriages and the seas of course were a precarious place for anyone. Indeed, traveling was etymologically related to childbirth as it suggested labor, toil, and trouble (*Oxford English Dictionary*, 2011).

### **Different Forms of Movement**

Since humans emerged on the scene of Earth's history, we have been moving, migrating, and spreading out over the Earth, leaving behind our genetic and material traces. Like all organisms, human beings have frequently moved to follow food, find shelter, and temporarily escape harsh environmental conditions. As nomadic or semi-nomadic forms of movement gave way to a more sedentary lifestyle, human beings established more-or-less enduring centers or locations for their clans, villages, cities, and homes. Large-scale movement of human populations slowed without completely ceasing, as many diasporas illustrate. Yet large scale movements of migrations have always coexisted with more small-scale movements of people in their everyday, ordinary settings. In addition to the survival functions of movement, human beings move for social purposes. That is, we not only leave our homes to fetch water, but to also fetch a spouse. Social and cultural activities provide the impetus for much of our movement as we make small journeys to work or school, to visit family and friends and to return back home. Movement is thus interwoven in all of our experiences and flavors the texture of our lives as we travel between places in our local settings.

We can also move far from our local communities through various forms of border-crossing travel. While going from our home to the grocery store entails some form of border crossing (e.g., private < > public), long-distance travel brings us into contact with unfamiliar lands, sights, smells and people, and involves taking up a social role and position (e.g., soldier, tourist, immigrant, pilgrim). With each particular form of travel, ordinary people take up social roles and positions. That is, movement outside of our everyday settings entails that individuals become a soldier, explorer, tourist, pilgrim, business person, traveler, or anthropologist. From the perspective of those who encounter travelers, knowing if a person is a tourist or soldier has implications on whether or not the person offers money-making opportunities or potential death. For the person traveling, these social roles call forth different paths of action and ways of relating with the world. Obviously the

soldier performs different actions, wears a different uniform, engages socially with others differently than a pilgrim would. However, these social roles and identities are fluid and can blur together, as the case of the Crusades highlights (see below for the tourist becoming a pilgrim). Indeed, these roles *suggest* but *do not determine* how a person relates with the world (or how the world relates to the person).

Human exploration of unfamiliar lands is ancient and can be found in many varieties and for various purposes: trade, quests for knowledge, and conquest. On the one hand, travel has functioned to open groups and individuals to novelty in the form of goods and ideas (Euben, 2006; Turner & Turner, 1978). Through the work of merchants and traders, bridges were made between diverse countries and markets, as each was enriched materially and educationally from the other. Trade between countries and communities also led to the construction of roads and technological advancements in how people traveled. Extensive Roman roads and Great Silk Roads are but two examples of how early trade between countries and groups expanded travel for not just merchants and traders, but also for common people in search of the unknown, knowledge, pleasure, or their particular deity (Löschburg, 1979). Travel for the pursuit of knowledge can be found in *The Epic of Gilgamesh* (transcribed 1900 BCE) where “the attainment of wisdom was linked to direct experience of the radically unfamiliar” (Euben, 2006, p. 20–21). Interestingly, Plato argued for the importance of travel and firsthand experience for the benefit of political life and the development of *theōros* (Euben, 2006, p. 22).

Yet, travel has also been utilized as an act of conquest or subordination of the other. War has been a ubiquitous form of movement in which otherness is confronted and subjugated. Although conquests and the quest for knowledge and riches can be separated in function, they have often been intertwined. For instance, Alexander the Great's famous expeditions included philosophers and early naturalists such as Aristotle along with soldiers. Scientific knowledge expanded along with the reach of the Roman Empire. As noted above, the Crusades of the Middle Ages provide a stark example of when two different forms of travel (war and pilgrimage) have been blended. The Crusades were principally a military expedition, blessed by the Pope, and secondarily a pilgrimage to the Holy Land in which soldiers were granted indulgences. In spite of the obvious horrors of war, conflicts offer individuals

of poor economic standing the opportunity to visit new and unfamiliar lands.

In historical terms, traders have been called the first known travelers who “realized that outside their narrow circle there were other people, other goods and even treasures” (Löschburg, 1979, p. 9). Although certain forms of travel have become more salient throughout human history (e.g., pilgrimage in the Middle Ages and tourism in this era), the various forms of travel have been interlinked making a chronology of travel difficult, if not impossible. What is important to note is that the experience of traveling is influenced not only by the reasons for traveling (and the corresponding social roles), but also the means (e.g., cultural tools) people use to travel. Natural elements, animals, and human beings have each been used for transporting goods and people, and have also constrained and shaped where human beings can travel and how fast—or in other words, their experience as travelers. Except for certain periods in history—specifically during the Roman era and the construction of their road system (Löschburg, 1979), travel had been a slow, difficult, and arduous activity. Traveling and crossing boundaries posed many risks, and travelers encountered discomfort at almost every step. One unknown traveler lamented:

Oh, hard is travel and severe,  
It makes my belly ache.  
Lice bite on my bed of straw.  
I miss my soft white sheets,  
A fool I am to travel,  
Then, and why?, I ask.  
(cited in Löschburg, 1979, p. 31)

It is perhaps easy to forget the challenges, uncertainty, and threats facing travelers of the not-too-distant past. Indeed, this lament generally diverges from our modern experiences of travel that are marked by comfort, leisure, and speed.

In the midst of this period where speed and efficiency of movement are highly valued, travel for the sake of the experience created by the travel itself—historically known as pilgrimage—remain a popular and even increasing form of travel. This fact poses a paradox. On the one hand, pilgrimage is animated and supported by our modern mobility paradigm and technical advances, and on the other hand, it offers an alternative to the frenetic pace of life and overarching technological frameworks in which human beings are enmeshed. Although the business traveler tries to arrive at the destination as quickly as possible, the same person going on a pilgrimage

may elect to move toward the goal as slowly as possible. Pilgrimages provide opportunities for people then to go “offline” and explore the world at a decelerated speed (Slavin, 2003). Moreover, and in contrast to a business trip, pilgrimages are self-initiated journeys to places and objects of exceptional personal and social value where the form of movement is an essential. Hardships and difficulties of travel are not trivial annoyances to be avoided, but rather prepare the travelers for some form of personal or social transformation.

### ***The Pilgrimage: Cultural Psychology of Spirituality in Movement***

Pilgrimage is an ancient form of travel and therefore has common-sense as well as academic connotations. That is, we speak colloquially of going on a pilgrimage to see and stand where John Lennon was killed (Kruse, 2003) as readily as we describe our visits to Mecca or Jerusalem. Pilgrimages have also extended beyond typical religious traditions as people have made pilgrimages to battlefields (Gatewood & Cameron, 2004). Nevertheless, Islam, Hinduism, Buddhism, and Christianity have long-standing traditions of pilgrimage as part of their faith practices. For instance, Hindus travel to sacred places such as Varanasi where they bathe in the waters of the Ganges River and visit temples and shrines. Gesler and Peirce (2000, p. 225) note that the city of Varanasi derives its sacred character because it is considered by many to be the center of the universe and is associated with mythical events, is linked with the abodes of the gods, and is a microcosm of all other sacred places in India and therefore transcends (for many) all other places. The deceased (human) are transformed into ancestral spirits (nonhuman) along side the banks of the Ganges at Varanasi. Additionally, India also is the birthplace of Buddhism and thus the sites related to the major events of the Buddha’s life are central to Buddhist pilgrimage. However, as Buddhism spread and the possibility of adherents visiting India decreased, Buddhist practice supported the construction of proxy pilgrimage sites. That is, in order to offer adherents access to holy sites that were out of their reach, “copies” of many original pilgrimage sites were re-created in the new land. For instance, in Japan, pilgrimages to the Thirty Holy Places of Kannon in the Western Provinces, the Saikoku Pilgrimage at Seigantoji at Nachi on the coast south of Kyoto, and the Eighty-Eight shrines on the Island of Shikoku continue to draw many

pilgrims follow a circular course and circumambulate a series of temples and shrines and encounter sacred relics along the way (see MacWilliams, 2004; Foard, 1982).

#### WHAT IS A PILGRIMAGE OR WHAT DOES IT ENTAIL? (TURNER AND TURNER, 1978)

Finding a widely accepted definition of pilgrimage can be difficult as scholars and social institutions grapple with issues of religion/tourism, length of distance and time required to be considered a pilgrimage, and mode of transportation (e.g., whether a pilgrimage can be made by vehicle or needs to be on foot). Victor Turner described pilgrimage as mysticism externalized (and mysticism is pilgrimage internalized). Foard (1982, p. 232) describes pilgrimage as a “religious journey, both temporary and long, to a particular site or sites, which are invested with sanctity by tradition.” Similarly, Chélini and Branthomme (1982) conceptualize pilgrimages as marked by three interwoven components: the existence of a sacred place; spatial distance to be covered; and special ritual acts to be done by the individual or group prior to, during, and after the trip, and while at the sacred site. We can observe that Foard and Chélini and Branthomme offer a broad definition of pilgrimage that situates it as a spiritual or religious activity with long- and short-term travel. Both definitions seem to restrict pilgrimage to religious travel; however, Foard (1982) observes that historically pilgrimages and what we would now call tourism have been intertwined.

In order to go beyond emphasizing the structural elements of pilgrimage (i.e., the distance to travel, required ritual attitudes and prescriptions, etc.), I suggest that the complex phenomenon of pilgrimage should be understood along structural (form), functional (purpose), and experiential (e.g., as a spiritual experience) dimensions. Each type of pilgrimage has its own dynamic structure (e.g., rules, prescriptions, built-up environment, types of encouraged movement) and therefore exists only within social and historical contexts. Moreover, pilgrimage serves institutional and personal goals; it has been prescribed by religious and social institutions for their own goal orientations (e.g., to promote faith, or to encourage war as in the case of the Crusades), and people make pilgrimages out of devotion, curiosity, desire for healing, to increase their status or understanding and for other mutually overlapping reasons. Furthermore, pilgrimages are marked by episodic moments of deep relevance

that are experienced by the person as spiritual or somehow transcendent as they encounter religious and/or in some way sacred artifacts.

What is also of note is that pilgrimages entail movement directed at sites that are considered by communities and individuals to be sacred sites that are supported and sanctified by tradition. These places have been transformed by human and (asserted) supernatural intervention, and contain a form of *charisma* and power to the perspective of the pilgrim because of their association with divinity (i.e., theophany), sacrifice (i.e., battlefields), beauty, and/or with some other social virtue (e.g., creativity, honor, celebrity). As Victor Turner noted,

self-initiated journeys by individuals and groups to far-away places brings people into contact with places and objects that are “intimately associated with the deepest, most cherished, axiomatic values of the traveler . . .

(Turner & Turner, 1978, p. 241)

One characteristic unifying the manifold types of travel to distant places is the desire for transformation. People travel and make pilgrimages in order to effect change and to be moved in profound ways. The target of transformation is often the self. People make pilgrimages in hopes of forgiveness (modifying God-individual relationship), for physical healing, to gain merit for the next life, or for hoped-for-futures (e.g., success in business, health in childbearing). Humility, faith, and charity become a key virtues for many pilgrimages as individuals travel far from home to powerful places and must rely on the kindness of others and as they encounter sacred objects of their faith. Pilgrimages thus become the catalyst for reorganization of a person's value system (Beckstead, 2010; Beckstead, in press). The expectation and hope is that the return traveler is not the same as when he or she left and that there has been significant change in the personal realm because of the journey to a sacred or extraordinary and far-away location. The pilgrim should bring back not only stories, photos, souvenirs, and mementos, but also a less tangible yet significant insight or feeling that modifies their relationship with the world. As I expand below, this transformation of the self and the person-world relationship is related to the social suggestions in the immediate material environment. Pilgrims taking the Camino de Santiago encounter numerous signs such as sea shells, smaller shrines, and relics that point the way and prepare the pilgrim for their arrival and transformative experience.

Targets of transformation can also at times include social others and the environment. The Crusades had the intention to take back the Holy Land and rid it of Muslims. Sax notes how transformation through pilgrimage in Hinduism includes and extends beyond the individual:

By journeying to these powerful places and performing certain actions there, pilgrims achieve some kind of transformation, either in themselves or in their circumstances. Pilgrims may be bodily transformed or cured of disease, or the deity itself may be transformed. . . . A pilgrim's relatives may be transformed. . . , or his prospects—of prosperity, fertility, liberation. Pilgrimage places can themselves be created or transformed by the actions of pilgrims.

(Morinis 1984, p. 279)

In all religious faiths, the actions of pilgrims modify the places visited in terms of the built landscape and for those living at or near the pilgrimage place (Eade & Sallnow, 1991). Pilgrims leave behind their “footprints” as they join together in ritual activity, inscribe their name at critical places, make cairns on the side of the road (see Fig. 33.1), and spend money contributing to the economic development of the pilgrimage site and surrounding areas. Thus, places that pilgrims visit are transformed in both mundane and sacred ways.

There also exist “mini-pilgrimages” in the social secular worlds. Children are sent on field trips to city halls, temples, shrines, and a host of other locations of great social value with the desire and expectation that they will return home affected in some way. Self-initiated journeys are likewise made so that systemic changes occur in intrapersonal and interpersonal realms, and between the person and their environment. Foard notes the similarity between pilgrimages and *shūgaku ryokō*, the school trips senior high-school students make in Japan to the temples, shrines, and national historic sights (Foard, 1982, p. 248):

The initiatory overtones of these trips are obvious, down to their antistructural rambunctiousness. These students are not, of course, being brought to revere Buddhas, bodhisattvas, and kami, but to make the Japanese tradition their own.

These ubiquitous “field trips” serve to promote institutional goals and provide opportunities for children to internalize the social suggestions, or to “make the Japanese [or any other] tradition their own” (Ibid). Through these mini-pilgrimages young people are socialized and affectively guided toward reconstructing the values and traditions suggested by the goals-oriented social institutions that organize and frame these journeys. Of course these mini-pilgrimages are not only for children; every age

**Figure 33.1** Cairns (indexical signs) constructed at the side of a pilgrimage path to the Peace Pagoda in western Massachusetts.

group visits museums, battlefields, and other more culturally organized secular sites. As with religious pilgrimages, secular pilgrimages draw on “guides” to assist the individuals on their journeys (Bharati, 1963; Foard, 1982).

What are the conditions that lead to these changes? How does the pilgrimage experience facilitate social and personal development?

### **PILGRIMAGE AS CULTIVATION: THE LENS OF GEORG SIMMEL**

Travel to distant places is intertwined with change and is a process that fits what Georg Simmel described as *cultivation*, an analogy used for the development of natural organisms applied to human beings. This notion provided the basis for his conceptualization of *culture*. Cultivation implies that something changes from one state to another, and more specifically for Simmel, it entails the unfolding development of a thing beyond its “previous developmental possibilities” (Simmel, 1971, p. 228). Simmel uses the example of a pear tree to illustrate how a gardener only takes the latent “natural” potential of the wild pear tree and “brings it to the most complete unfolding of its own nature” and transforms it into a tree that bears edible fruit (p. 228). Cultivation then is not only development of an organism, but development in accordance with inner core or deepest dispositions. Cultivation entails some form of intervention that guides the organism toward its potential, and this applies to things found in nature and to human beings. However, in discussing cultivation in the realm of human beings he makes the critical point that,

... culture exists for only if man draws into his development *something that is external to him*. Cultivation is certainly a state of the soul, but one that is reached only by means of the use of purposefully created *objects*.  
(p. 229, emphasis in original)

For Simmel, then, cultivation occurs when human beings and institutions draw upon “purposefully created objects” for their development or to arrive at a “heightened existence” (Simmel, 1971, p. 233). *Objective culture* refers to things in a state of embellishment and growth that guides or points the psyche to its fulfillment or path to be taken in order to achieve an elevated existence. Semiotic devices—language, rituals, cultural images and artifacts, and practices—can be considered elements of objective culture that are set up to guide human feeling and

thinking (Valsiner, 2000, 2007). *Subjective culture*, Simmel describes, is the process of drawing on objective cultural objects and “its measure is the extent to which the psychic life-processes makes use of those objective goods and accomplishments” (p. 234). Subjective culture and objective culture do not exist independently since subjective culture can only be accomplished through the use of objective culture. Simmel’s insights point to the mutuality between person and culture, and as Fuhrer (2004, p. 73) argues,

... the general insight underlining the concept of cultivation as a reciprocal feedback process refers to Simmel’s conviction of the human being’s unique capacity to complete his/her personality by internalizing influences external to his/her personal sphere. That is, Simmelian cultivation means the elaborative change of inherent opportunities that the developing individual cannot reach out to on his/her own without socio-cultural ‘structures’—i.e., in my terms the external mind—external to him or her. What this also means is that establishing, expressing and transforming a person’s subjective culture—i.e., in my terms internal mind—through external, material things is a process that continues throughout the life-span.

Person and culture are intertwined and mutually related, each transforming the other. Pilgrimage is one exemplar of a cultural practice that is supposed to lead people toward a “heightened existence” as people journey to the places imbued with social and religious relevance.

### **Cultural Psychology of Pilgrimage: Building a Theoretical Account**

Before exploring how pilgrimage experiences become a source for transformation, let me briefly clarify the theoretical framework I am adopting in this chapter. Contemporary socio-cultural psychology is filled with theoretical claims—usually based on empirical work—that lack clear grounding in the wider methodology cycle (Branco & Valsiner, 1997). The axioms I take as the basis of this theoretical exposition come from basic developmental science and social psychology of the constructionist kind.

#### **THE AXIOMATIC BASES**

Firstly, I take as axiomatic that human development and meaning-making processes unfold in irreversible time (Bergson, 1913, 1944). This notion posits that time flows from an infinite past to an

infinite future and no event ever repeats itself; hence, the future is inherently uncertain and unpredictable. This is an inevitable given in all biological systems, or open systems. As defined by von Bertalanffy (1968), an open system is characterized by the interactions of its components with the environment and the nonlinearity of those interactions. Open systems—in contrast to closed systems—engage in exchange relations with their environment. Novelty is only possible in open systems.

Secondly, because of the openness and general unpredictability of the future, human beings and institutions develop signs to overcome this uncertainty and ambivalence to make what is fluid more stable (Shweder, 1995, pp. 41–42; Josephs, Valsiner, & Surган, 1999). Cultural tools like roads and paths as wells as meanings or signs (e.g., the notion that “travel is exciting”) promotes movement and increases human exploration of unfamiliar realms that is necessary in any form of travel. Of course paths and roads are also evocative of feelings and ideas of uncertainty. Thus, signs or meanings mediate between the past and future and provide stability in an inherently ambiguous world.

Thirdly, there exist perceptual and cognitive limits upon relating with environment. We can only follow the length of the road or path with their visual system up to the horizon, but there is knowledge that something exists beyond. Like all other organisms, humans can use roads and paths as a way to go from A to B because of the perceptual cues the path affords and our particular bodily configuration. However, given our species-specific ways of relating to the environment (our *umwelt*), a path or road may have a meaning that goes beyond what it affords (i.e., the meaning of movement or *transportation*; see Chang, 2009 for a discussion of *umwelt*). Paths connect and bridge known and unknown far-away places. Victor Turner (1969/2009) has noted that Ndembu hunters would “blaze a trail” by leaving a series of marks on trees in order to find their way back home from unknown territory (p. 15). Indeed, ritual practice bore the meaning of connecting the unknown and known realms for the Ndembu and of bridging the sensorily perceptible realm of the living with the invisible realm of the dead (p. 15). Similarly, pilgrimages offer sensorily perceptible markers and ritual practices that not only connect living and dead/deity, but also orient people toward their uncertain futures.

Fourthly, I draw on the notion that our experiences within the world leave traces in us. We speak

to our neighbor about the weather, play with our children, or visit a museum, and these interactions lead to reconstruction of new signs intrapersonally and feed forward into our future encounters with the world. Our experience and action can also leave behind traces and signs in the environment. These signs can be apprehended and experienced by others and can take the form of utterances or perhaps embodied in the built-up environment or made available in some other material form. In various ways the signs of the world become “translated into internal signs (or internalization), and inner signs find an expression in shared signs (externalization)” (Zittoun, 2010, p. 174). This translation and sign-exchange process can be conceived as a semiotic process and builds on Simmel’s notion of culture-as-cultivation (Fuhrer, 2004).

Fifthly, human development and semiotic processes occur in specific settings, which are organized to guide and enrich the semiotic processes (Innis, 2011; Murakami, 2011). These settings can be schools, the workplace, home, church, or a myriad of other places in our everyday world or they can be memorials, temples, shrines, and other sacred or quasi-sacred settings. Human beings are wholes (e.g., open systems) and embedded in the environment, and actions only make sense against the wider social milieu. Thus I draw on the socio-genetic viewpoint that considers personalized meaning-making activities as unfolding and always guided by others (Lawrence & Valsiner, 2003). Social institutions guide and constrain human development in socially desired directions by setting up affective boundaries (i.e., “how one should feel here”) through the activities and material cultural objects that make up these settings (González-Ruibal, 2011; Beckstead et al., 2011). Pilgrimage sites and the pilgrimage route offer rich settings that are organized through discursive and non-discursive strategies and elements to immerse and guide people toward encounters with *sacred* places and objects. However, people actively interpret (constructively internalize) these social messages and suggestions and can resist (or ignore), modify, and offer alternative interpretations and understandings. This builds on the notion of *inclusive separation* of human beings and the environment where both are parts of a larger whole (Valsiner, 2000). Both the external environment and person co-develop in relation to each other.

This chapter, then, offers a cultural psychological perspective of pilgrimage rooted in semiotics. People

move through the environment encountering people, buildings, and other artifacts that—material and symbolic traces of human living—of which they make sense and internalize. Culture is thus the process that relates people to the world through signs or semiotic mediation and guides individuals' experience and sense making (Valsiner, 2007). Through the construction and use of signs (both intrapsychological and in the environment), here-and-now settings are transformed for human beings. Human relating to the world through culture thus “entails simultaneous closeness to, and distance from, the actual situation the person is in” (Valsiner, 2007, p. 72).

#### FINDING THE WAY ALONG THE PILGRIMAGE PATH

The notion of the path provides a rich metaphor of the journey of life—as we move from birth to death. The path or road was seen in Japanese society as an important element of the development and realization of the self (Tobin, 1992, p. 24). Traveling away from home and one's family allowed the person to gain important experience by meeting social and concrete “others.” The path in many diverse religions indicates the way—providing people with potential answers to fundamental questions and longings. The routes, paths, and trails taken by the traveler can be viewed as an exceedingly important aspect of the pilgrimage. Pilgrimage is a form of path taking and path making, as pilgrims leave behind their traces in the roads they take, objects they leave behind, and narratives they share afterward. Path making then is a semiotic device of culture, and as Christopher Tilley (1994) notes,

... a journey along a path can be claimed to be a paradigmatic cultural act, since it is following in the steps inscribed by others whose steps have worn a conduit for movement which becomes the correct or ‘best way to go.’  
(p. 31)

The path is a cultural transformation of the natural environment that, in the case of pilgrims, tourists, and other sojourners, enables them to seek answers to fundamental questions (e.g., why live?) and makes sense out of religious and spiritual values. In this sense, paths and symbolic movement of pilgrimages provide social guidance through the traces of others and orient pilgrims toward the future (this point is developed below). Paths are therefore a quintessential aspect of *objective culture*

that societies and individual people draw upon to guide them in their development and can be considered liminal structures that are between and betwixt past and future, familiar and unfamiliar, and ordinary and extraordinary. Not surprisingly then, the metaphor of paths and concrete paths, roads, and routes have been conceived as important in fostering social and personal development.

#### Liminality and *Communitas*: Freedom and Constraint

Understanding how pilgrimages may lead social communities and individuals to a “heightened existence” has largely been predicated on the notions of *liminality* and *communitas*. Victor Turner expanded Arnold Van Gennep's (1960/2004) work on rites of passages and his provocative notion of liminality. Van Gennep posited that any rite of passage (or rite of transition) was marked by three separate but interrelated phases—separation, liminality, and aggregation. With the first phase, the individual physically and symbolically is separated from the social community. The liminal or marginal phase finds the individual or community in an ambiguous realm or state where previous social conditions (e.g., status) no longer exist (or are temporarily suspended) and the new social state is not known or is at least uncertain. In the third and final phase, the individual or group returns with a new social status to the stable and mundane life conditions where they are expected to reintegrate into the society and follow the norms of the community that accompany their new status. In other words, the individual moves from a stable state to a highly fluctuating transitional period before physically and symbolically returning to the social order in a new social state. Van Gennep developed his framework while working in “primitive” societies and argued that rites of passage were obligatory.

Victor Turner (1978) took van Gennep's notion of liminality and developed its meaning to entail more than a transitional period but also a transformative phase. He argued that “liminality is not only a transition but also a potentiality, both what is ‘going to be’ and more importantly also ‘what may be’” (Turner & Turner, 1978, p. 3). Separation from one's society has a liberating effect as one moves from the center to the social and spatial periphery. What differentiates the rituals Turner explored from that of Van Gennep was that they were marked by a high degree of voluntariness. Hence he made the distinction between *liminal* (obligatory) and

*liminoid* (voluntary) phenomena. As religious life had become increasingly intertwined with the secular and mundane aspects of daily living (even in monastic life), Turner argued that pilgrimages were prime examples of a liminoid and transformative phenomena since the pilgrim set out voluntarily from their place of residence and the structured social orders, crossing into new lands and ambiguous states and statuses. The physical separation from one's home community and journey to a new place provided a rich metaphor for transformation from one social status to another, and the possible becoming realized. Alex Gillespie (2006) notes that the pilgrim and tourist become "nobody" since they lose their familiar social positions, roles, history, and expectations. They are free to play with their identity and how they present themselves since they move beyond their home community and the social expectations (Gillespie, 2006, pp. 62–63). On the social level, liminality has been associated with anti-structure and seen as an important condition for fostering group cohesion and *communitas*.

### ***Examining Social Transformations in Pilgrimage***

Pilgrimage as a cultural activity that intervenes and guides people toward a "higher existence" is expressed in Turner's concept of *communitas*. Indebted to Durkheim, Turner (1969) saw pilgrimages as a process ideally overcoming group division and leading to social unification. For him, pilgrimage leads to a "relatively undifferentiated *communitas*, community or even communion of equal individuals" and echoes Martin Buber's *I-Thou* relationship when he describes it as a "direct, immediate and total confrontation of human identities" (pp. 96, 132). Pilgrimage is a socially regenerative ritual because it operates partially outside of social structure and everyday settings of interaction marked by social stratification and obligation. That is, outside of everyday social structures and social roles that often shape our human interactions, pilgrimage's liminal phase space allows for fellow pilgrims to (often temporarily) spontaneously and generously relate to each other as they approach and interact at the pilgrimage center. Pilgrimage in this light can be seen as a ritual activity oriented toward overcoming divisions and cleavages in the social fabric of a group that inevitably occur in the day-to-day interaction of group members. Leaving behind one's home community, according to Turner, engenders freedom from social obligations and entrenched patterns of

interaction, thus allowing individuals to relate to each other out of a sense of love and fellowship. As the pilgrim travels away from their particular communities, they encounter symbolic markers and engage in ritual activities that convey more universal meaning (e.g., "we are all one"). Status differentiation is symbolically erased as pilgrims put on the similar clothing and unity is amplified because of the temporal and spatial distance from everyday life. These symbolic markers, joint travel, and social distance are then seen as leading to a "community of feeling" that is not bound to blood or particular locations, but rather toward more abstract notions of humankind (Turner & Turner, 1978, p. 201).

The pilgrimage path as marginal space played a significant role in breaking down structure, combining the sacred and profane, and revealing dangers and freedom of travel. Pilgrims of all segments of society shared the same route and interacted together outside under unusual circumstances. Patterns of typical social interaction could be reconfigured in this context. Much like birth and death, travel in the form of pilgrimage could be considered a great equalizer (Foard, 1982, p. 239). Thus liminality opens up possibilities for challenging and questioning dominant structures in one's social environment.

Turner's conceptualization of *communitas*, marked by freedom, unity, and community, however, has been widely challenged as utopic and essentialist (Eade & Sallnow, 1991). Critiques have pointed out that non-Christian pilgrimages do not fit the model of *communitas* and so it has little generalized value outside of the Christian context. Other pilgrimages are marked by status distinctions instead of social homogenization and unity (Eade, 1991). Graham St. John (2001) articulates a common criticism that is leveled at Turner's notion of *communitas* when he states that within events such as pilgrimages, "performative homogeneity is delineated at the expense of open-ended political maneuvering and contestation" (p. 49). That is, critics argue that instead of faithfully promoting unity or similarity of experience, pilgrimages often contain contested viewpoints and meanings, and exist in a highly political zone of conflicting interests. Instead of seeing pilgrimage as a vehicle that transforms difference into similarity, these scholars emphasize the competing voices, interests, and groups that engage each other.

However, *communitas* is predominately treated as an either/or prospect, as if unity and difference could not coexist synchronously or diachronically. There are examples in the literature for both

pilgrimages that lead the (temporary) abandonment of social hierarchies and social cohesion as well as the maintenance and instantiation of social hierarchies and division between social groups (Coleman, 2002). Moreover, as Coleman (2002) argues, both *communitas* and *contestation* should not be seen as antagonistic, but rather as in many ways complementary and sharing common ground.

Although scholarship on pilgrimages has generated a plethora of research and writing on Turner's model of *communitas*, focusing on the validity of this model has certain drawbacks. First, *communitas* is either assumed or negated *a priori* and thus the very mechanisms that are employed to foster cohesion and socially sanctioned messages, as well as the strategies used to challenge and resist them, are neglected. Second, the emphasis on treatment of *communitas* often fails to distinguish between *existential communitas* and *normative communitas*. Many accounts of *communitas* read Turner as eschewing structure and social guidance and therefore fail to keep his distinctions between different forms of *communitas* in mind. The latter notion can highlight the ways that social control and guidance is part of the pilgrimage process and a constitutive aspect of the pilgrimage experience. As I examine below, social guidance plays a significant role in orienting pilgrims' sense making and fostering moments of deep affective value. Third, and in a related vein, emphasizing the model of *communitas* has perhaps obscured Turner's phenomenological analysis of the unfolding process of pilgrimage from the standpoint of the pilgrim, particularly as they approach their destination. Nevertheless, critiques of the *communitas* model are indeed valuable in arguing that pilgrimage experience is interwoven with an intricate and dynamic socio-cultural setting.

### **Cultural Psychological Perspective on Pilgrimage**

How do abstract social values and messages that pilgrims glean become "internalized" and powerfully felt meanings? In other words, how do pilgrimages lead to a "heightened existence" for the individual pilgrim? I do not mean to assert that pilgrimages have only been investigated as a social phenomenon as opposed to a personal or individual phenomenon. Neither do I wish to explore the personal instead of social aspects of pilgrimage. Rather, my intent is to examine how social and personal worlds constrain each other in the context of pilgrimage. In order to accomplish this task, I consider how pilgrimage

is a personal and social process and draw on and elaborate Turner's notions of normative *communitas* and the approach of the pilgrim to the holy site.

### ***Pilgrimage as an Unfolding Social and Individual Process***

Pilgrimage is a communal activity in which people move about and eat together, engage in conversations, and participate in ritual acts of devotion with their fellow believers. Even if pilgrims begin their journey alone, they soon encounter fellow travelers and strangers along the path, especially as they draw near to the pilgrimage center. Pilgrimages are dramatic rituals that occur in public settings, and pilgrims encounter living social others and the traces of those who have passed before (and perhaps passed away). However, these journeys are "individualistic" in the sense that they are voluntary and "each is a personal act, following a personal decision, and resulting in a wide range of personal experience" (B. Lewis, cited in Turner, 1974, p. 175). Pilgrims on the same path and going toward the same destination may have similar though not the same goals, experiences, and hopes and expectations. Pilgrimage is a general process and undertaking people make for particular reasons and aims (even if these aims are similar and shared with others), and therefore each pilgrim's journey has a unique developmental trajectory.

We can also understand the unique and personal aspects of pilgrimages if we reexamine the notion that human development and meaning making take place in irreversible time (Bergson, 1913, 1944; Abbey, 2007). Recall that this axiom states that time flows from an infinite past to an infinite future and no event ever repeats itself; hence, the future is inherently uncertain and unpredictable. This suggests that the conditions of environments are constantly changing, requiring organisms to preadapt to possible and never given situations (Josephs et al., 1999). Existential uncertainty requires that human beings create signs and strategies to anticipate the tentative futures and regulate their relationship with the environment (Valsiner, 1998; Shweder, 1995). Pilgrimages thus allow people to adapt and orient themselves to uncertain futures. Because of this preadaptation function and the distancing function of leaving one's everyday environment, pilgrimages provide individuals (and groups) the critical distance from their ordinary life settings and encounters with socially and personally important artifacts that guide and suggest how individuals should relate to their

environment (e.g., concrete others, deceased loved one's, institutions, and themselves) and to the development of their personal ways of being and value systems (Beckstead, in press).

#### HOW PERSONAL TRANSFORMATION WORKS

Reorganization and modification of one's value system through pilgrimage is exemplified in Malcolm X's *Autobiography* (Malcom X, 1966). The pilgrimage to Mecca is a religious obligation for every orthodox believer and must be made at least once, if health and circumstances permit. Thus, Malcom X undertook this journey, hesitantly, and after his sister financed his trip (Malcom X, 1964/1999, pp. 325–326). After reaching Mecca and worshipping with a diverse group of believers, he writes that:

You may be shocked by these words coming from me. But on this pilgrimage, what I have seen and experienced has forced me to re-arrange much of my thought-patterns previously held and to *toss aside* some of my previous conclusions. . . . During the past eleven days here in the Muslim world, I have eaten from the same plate, drunk from the same glass, and slept in the same bed (or on the same rug)—while praying *to the same God*—with fellow Muslims, whose eyes were the bluest of blue, whose hair was the blondest of blond, and whose skin was the whitest of white. And in the words and actions and in the deeds of the 'white' Muslims, I felt the same sincerity that I had felt among the black African Muslims of Nigeria, Sudan, and Ghana.  
(p. 347)

Malcolm X's experience "re-arranged" his value system and re-framed how he saw and related with others in the interpersonal domain. The "white" person no longer meant to him "power" and "corruption" after worshipping together and praying to the same God, and as those familiar with the life of Malcolm X, his worldview and relating with others shifted in dramatic fashion. Malcom X's transformation of worldviews was based on a communal experience rooted in rituals (*both ordinary and sacred*) and shared by a variety of people of different races. Of course race and racial issues played a major role in Malcom X's life prior to his Hajj to Mecca. However, for the purpose of this chapter, the point I wish to convey is that what often is transformed in a person's value system may be a by-product of their journey and not what was initially intended: the "outcome" of Malcom X's Hajj to Mecca was not

inevitable or anticipated by Malcom X (and indeed it was "shocking" at least for others).

In spite of the different circumstances under which pilgrims make their journey, there are always personal reasons and hopes that motivate and frame their experience. Of course Malcom X's experience demonstrates only one path (trajectory) of transformation. That is, pilgrimages allow individuals to come to terms with their illnesses and inevitable death, gain strength to deal with and flee from abusive relationships (Jansen & Kühl, 2008), seek redemption (Murakami, 2011), and decide about possible future job opportunities (Hoshino, 2007) among other things. Indeed, as with the case of Malcom X, even those with major illnesses often return with a new perspective on their illness instead of a cure. Asking what the causal agent is for these transformations would be misleading from the theoretical perspective I outlined above. Since human beings are open-system and actively construct meaning, actions and meanings therefore are not caused in a mechanical fashion. In other words, pilgrimage experiences orient people toward uncertain futures, allow them to anticipate possible fates, and reconfigure their relationship with their world.

Pilgrimage is rooted personal desires, questions, longings, and needs. However, pilgrimages do not occur in a context-free zone, free of constraints where people can explore, evaluate, and reorganize value and meaning systems, and anticipate the future. Pilgrimages transpire and unfold in particular organized settings. The next section examines how pilgrimages—especially paths pilgrims take—constrain and enrich the semiotic processes of pilgrims and contribute to the transformation and development of the person–world relationship.

#### *Social Organization and Guidance of Pilgrims*

Although freedom from social obligations, roles, and mundane concerns is often a desired and realized aspect of pilgrimages, Turner refutes the notion that pilgrimage is a completely open and uninhibited zone for social and personal development. Turner posited that pilgrimages typically begin as unorganized and relatively unstructured movement toward a holy site and then "under the influence of time, the need to mobilize and organize resources to keep the members of a group alive and thriving, and the necessity of social control among the members in pursuance of these and other collective goals, the original existential

communitas is organized into a perduring social system . . ." (Turner & Turner, 1978, p. 169).

Rules, codes, and norms and material structures (e.g., way-stations, hospices, vendors, churches, etc.) become established for pilgrims at the pilgrimage center. Turner calls this form of pilgrimage normative communitas since it is an attempt by social institutions to guide pilgrims toward collective goals (and to offer safety), and subsequently order and organization is introduced to reach this end. For Turner, then, social guidance and control plays a significant role in the pilgrimages. Social guidance comes from collective systems and institutions that run pilgrimages, and from other groups—for instance local parishes and churches (Eade, 1991) and tourist companies that develop over the course of time to support and assist pilgrims.

We can observe how social guidance begins prior to pilgrims' physical journeys as they become oriented to both the everyday and symbolic dimensions of their journey and surroundings through the use of symbolic resources. Pilgrims hear and read accounts of previous pilgrims, look at photographs, and become more familiar with the settings, local customs, and history of where they will be visiting. Guidebooks, maps, pilgrimage accounts, pilgrimage accounts, and other symbolic resources function in similar ways: to prepare pilgrims for the everyday and mundane necessities of life (e.g., where to eat and sleep); orientation toward interacting with foreign people; history and meanings of the holy site; and normative ways of acting at the pilgrimage center. On the journey pilgrims encounter a plethora of signs that can offer literal direction (e.g., shells found along the Camino to Santiago de Compostela, letting pilgrims know they are going in the right direction), in both the literal and metaphorical sense.

#### APPROACHING THE GOAL

Turner focused on the socially regenerative nature of pilgrimages, but also examined pilgrimage from the perspective of the individual pilgrim within the social context. Nowhere is the perspective of the pilgrim more apparent for Turner than in his brief discussion of the pilgrim's approach to the pilgrimage center or holy site. He noted that as the pilgrim draws nearer, he or she is increasingly hemmed in by sacred relics and through the vividness and trials of the long journey becomes more vulnerable to the religious and social messages (Turner & Turner, p. 10). The purpose of the approach, Turner argued, was to build up a "considerable load of reverent

feeling, so that the final ingress to the holiest shrine of all will be for each pilgrim a momentous matter" (pp. 22–23). What is particularly noteworthy in this account is: (a) that Turner treats the pilgrimage as an unfolding process across time and space, and (b) he treats "sacredness" (here discussed as "reverent feeling") as a dynamic phenomenon that emerges in the subjective realm through the pilgrim's movement and encounters with objects in the environment. In some sense, we can observe constraint systems becoming more operative—since they are never entirely absent—as the pilgrim draws nearer after encountering traces or external signs of previous pilgrims (cairns and other inscriptions) and from collective meaning systems (e.g., religious artifacts). Pilgrims are thus immersed in the pilgrimage field, canalized toward understanding and relating with the objects as sacred objects (instead of ordinary objects). Key to this guidance is the complex spatiality and material cultural objects that constitute the pilgrimage environment (González-Ruibal, 2011; Beckstead et al., 2011; Beckstead, in press).

From the perspective of the pilgrim, then, there is movement (physical and in the subjective experience) from the ordinary/everyday environment, to the unfamiliar, and to the sacred realm (*see* Fig. 33.2). This is not to say that the sacred is not to be found in everyday environments, but rather to argue that the sacred (or extraordinary) is differentiated from the ordinary or mundane in the process of pilgrimage as the pilgrim moves toward his or her destination (or destinations as in the case of many forms of pilgrimage) and as they approach the sacred site. What is *cultivated* in the pilgrim is a sense of "sacred"—as a more- or less-developed and articulated sign—that modifies how pilgrims relate to the holistic field. As I noted above, Turner argues this movement toward the sacred site is intended to increase the "load of reverent feeling" in order to make the final ingress a "momentous matter" (Turner & Turner, 1978, pp. 22–23). Moving from the ordinary to the sacred, the pilgrim crosses a threshold—a boundary—which is itself an evocative experience.

Christopher Tilley makes a similar point regarding how monuments are approached. Referring to Günther Schlee's (1992) research on Kenyan-Ethiopian camel herders' journeys to their lineage origin sites, Tilley states that "the shortest route to a ritual mountain from any point on the plain is not taken but rather a prescribed walk in which it can be approached and seen from the propitious

**Figure 33.2** Ascending the hill toward the Peace Pagoda.

direction” (Tilley, 1997, p. 28). Tilley emphasizes the importance of the way that humans encounter monuments in movement and states, “there is an art of moving in the landscape, a right way (socially constrained) to move around in it and approach places and monuments. Part of the sense of place is the action of approaching it from the right (socially prescribed) direction” (Tilley, 1994, p. 28).

Turner might add that social guidance mechanisms used to draw in and immerse pilgrims in the field function to constrain the flow of feeling for the pilgrim and prepare them to internalize the more abstract messages that a collective system wants to emphasize (e.g., sacrifice, love, peace) (Turner & Turner, 1978).

The approach of a pilgrim is captured in Hoshino’s (2007) account of a pilgrim on the Shikoku pilgrimage route in southern Japan. This pilgrimage is comprised of 88 temples that are traditionally associated with Kobo Daishi. Wherever the pilgrims started from, they made a circuit route visiting each temple. Pilgrims pass through the four provinces of Shikoku (Awa, Tosa, Iyo, and Sanuki) and travel nearly 1,400 kilometers. The following comments were made by a pilgrim as he approached the final temple:

[Early morning arrival at temple] . . . Today I was alone, so I could chant slowly and loudly. Within

one or two minutes I got the feeling of completely sinking into a different world. The chirping of the cicadas in the trees around me is more intense. I feel as though I was the only one existing in the world. I feel as though I am at the centre of the universe.

I have gained the knowledge that ‘I am not *living*, but rather that I am *being allowed to live*.’ . . . As soon as I was certain that the eighty-eighth temple, Okuboji, was getting closer, my eyes overflowed with tears, and there was nothing I could do to stop them. I walked along without thinking, repeating ‘thank you, thank you’ over and over, waving clenched fists with huge tears running down my cheeks.

(Hoshino, 2007, p. 70; emphasis included in original)

Hoshino notes that this pilgrim did not consider himself religious or even very spiritual, though he did feel reverence for Buddha. He had taken this journey to cleanse his mind and body from the impurities of the world (Ibid, p. 68). Yet his experience led to feeling communion and a deep intimacy with his immediate surroundings and humanity. There is an almost willful passivity orientation that evoked or was evoked as the pilgrim approached. Indeed, it was even prior to reaching the final temple that this pilgrim began to experience overwhelming (positive) emotions. This deeply emotional experience had a corresponding

relation on the meaning system through the insight that he was “not *living*, but rather . . . *being allowed to live*” and so his relationship (at least temporarily) with the world (and himself) had been reorganized. What is important to emphasize is that the very abstract notion of “I am not *living*, but rather I am *being allowed to live*” is more than an abstract utterance, but rather is deeply felt. Perhaps this pilgrim has heard the idea of “being allowed to live” before, but here it becomes internalized and linked with deep affective value. We could interpret his approach—his chanting, movement, and prior experiences along the route and at other temples—as preparing him to be open to and to internalize this message.

Pilgrims are situated in this spatially and temporally bounded field with sensuous and symbolic dimensions that function in the intrapersonal realm. Although the pilgrim’s development is intertwined with the here-and-now setting, they also have the uniquely human capacity to go beyond the setting to imagine other worlds of “what has been” and “what could be” (Abbey, 2007; Josephs, Valsiner, & Sorgan, 1999). Pilgrims then can be closely connected to the environment and at other times enter into abstract reflection that distances them from the here-and-now context. These offer two different modes of engagement—one intimate and connected and the other distanced. In the context of pilgrimage, it is not too difficult to imagine how these processes might be recursively related; the pilgrim upon entering the grotto where Christ was reportedly interred might reflect on what it was like thousands of years ago (distance) and feel more connected to the place because of this reflection. Abstraction and reflection can either distance one from the field or bring one into more intimate connection with it.

#### **THE CONTINUITIES OF THE PATH: HOW PILGRIMAGE HAS LONGEVITY**

Although social guidance is operative prior to and during pilgrimages, it often continues after a pilgrim returns home. Pilgrimages encompass more than the period that the pilgrim is on the path and at the holy site. Each pilgrimage includes prior preparation and individuals share their experiences and insights with their family and friends. Occasionally pilgrims are invited to speak to larger groups about their journey, which then may then resonate with others listening, even in the distant future (Watson, 2006). Almost always pilgrims return with mementos,

souvenirs, photos, journals, or some other material artifact that functions as a mnemonic device and is suffused with meaning by the person. These objects afford discussion about the pilgrim’s experience with others and with the pilgrim him or herself. In addition to the relics a pilgrim brings home, his or her status may be transformed, as is well-known in the case of the pilgrimage to Mecca or Hajj. In very concrete and symbolic ways, the pilgrimage experience has longevity.

Furthermore, pilgrims often are socially guided to share their experiences, go to church, and participate more fully in the activities of their religious organization. For instance, pilgrims visiting Lourdes are encouraged to return to their churches and share their experiences with each other after making their journey. Likewise, I have observed religious services dedicated to the experiences of Mormon pilgrims returning from their youth-oriented pilgrimage (what is colloquially called *trek*). Often these include young people and adults who attended the pilgrimage standing before the congregation and talking about the trails, blessings, and lessons learned from their experience. I have never heard a “testimony” that has been negative, and many follow a pattern in which young people talk about their initial apprehension about being away from family, friends, and technology and finding happiness, fellowship, and the “spirit of God.” Many people seem deeply moved in retelling their experiences and insights. We could posit that the intended audience of these testimonies are twofold; the other members of the congregation and the self (i.e., person sharing their testimony). These instances of talking to others are also form of an auto-dialogue in which individuals can reconstruct and reframe their understandings and experiences in the social arena while talking to themselves. Social others encourage—though do not enforce—this activity, promoting talk as a way of continued internalization/externalization (see Valsiner, 2007, pp. 112–116) after the pilgrim has returned home.

If we consider pilgrimage as a fluid phenomena transpiring in irreversible time, then orientation and guidance can be found at two levels: first, pilgrims are oriented toward addressing mundane concerns and relating to the immediate and particular environment; and second, pilgrims search for and are guided toward more general meanings and futures that extend beyond the pilgrimage setting. Extending and modifying Turner’s notion of normative *communitas*, which focuses on the legalistic

aspects of pilgrimages, we could postulate that social guidance functions to:

1. facilitate the everyday basic needs and concerns of pilgrims,
2. constrain and orient pilgrims toward noticing the “holy” or otherwise salient features of the landscape,
3. prepare pilgrims for moments of heightened emotional responses and internalizing abstract social values,
4. integrate pilgrims’ generalized insights and changes upon returning home.

Social guidance, therefore, has immediate and more long-term consequences for pilgrims and guides the semiotic process of pilgrims in the *here-and-now* environment of the pilgrimage field and orients them toward *then-and-there* contexts after their journey is complete. Pilgrimage experiences that become internalized then are extended to new situations. Yet we still can examine how pilgrims are guided toward “momentous moments” or episodic moments of deep affective value. This occurs through the movement of pilgrims from extraordinary to sacred settings and is related to the discursive and nondiscursive signs and devices that differentiate the sacred from the ordinary (Beckstead, 2010). The sacred < > nonsacred (or ordinary < > extraordinary ordinary) sign complex (see Josephs et al., 1999 for a discussion of sign complexes) is a powerful social regulator and facilitator of personal transformation.

### **The Secular Transformation: Pilgrimage and Tourism**

Pilgrimage has typically been conceived as a “religious journey” and linked with spiritual goals, attitudes, and activities. However, different forms of travel such as tourism have proliferated and beg the question of how openly should pilgrimage be defined and understood. Are pilgrimages only religious journeys? How are pilgrimage and tourism related or distinguished? Often there is a line drawn between the tourist and pilgrim that distinguish the tourist as a pleasure seeker on a leisure quest and the pilgrim as devotee on a spiritual quest. At first blush, there are certainly differences between the pilgrim and tourist. Many modern representations portray the tourist as searching for exotic and novel locations and sites and constantly with camera ready to pounce on the best photographic opportunity. The

pilgrim, on the other hand, has struggled and traveled (and travailed) much to reach their symbolic destination and have acted out of a deep belief of the healing or saving powers of the place imbued with a sacred presence. Thus the reasons for pilgrimages and tourist travels are often seen as opposed; the pilgrim is motivated by faith, hope, redemption, or any other religious sentiment and a tourist is propelled by hopes of pleasure, self-education, and a desire for encounters with exotic cultures.

However, this distinction and dichotomization—while offering an economic typology—has been criticized as entirely too reductionistic (Foard, 1982). For instance, pilgrimages also include activities that would traditionally be labeled tourist acts (e.g., sightseeing, consumerism, pleasure seeking). Pilgrimages have historically involved actions oriented toward devotion *and* pleasure. Almost since its inception, the Ise pilgrimage included entertainment, the enjoyment of special foods, and even trips to pleasure quarters (Foard, 1982, p. 238). Discussing Christian pilgrims in the Middle Ages visiting Italy before continuing their journey, Löschburg (1979) notes that:

Agents and ship chandlers kept office in the open, offering among other things, excursions and sightseeing trips of several weeks into the surrounding countryside. They also contracted longer passages. Contracts were made for the return journey, including berth, two daily meals, fresh drinking water and the cost of sightseeing, safe-conduct and rent of a donkey. Everybody profited from the pilgrims’ travel, Venice, other ports of call on the way, the Turks who had to be paid for safe-conduct, the authorities in Jerusalem who charged entrance fees everywhere . . . It was a well thought-out business not unlike modern tourism. Pilgrimages were organized just like the packaged tours of our day. (p. 36)

Commercial and religious activities have long been intertwined as economic structures emerge in relation to spiritual centers (Dahlberg, 1991; Turner & Turner, 1978). Elements of pleasure have been associated with pilgrimages, but the reverse is also true: spiritual experiences also accompany tourism (see Fig. 33.3) (Gatewood & Cameron, 2004; Foard, 1982). Taking time and the constructive nature of meaning making into account, we might recognize that people at various points may participate in activities and feel like a pilgrim or tourist. This is not to say that there is no

**Figure 33.3** Trail leading to Ginkakuji Temple (Kyoto) where people pass by stores before arriving at the Temple.

meaningful difference between tourism and pilgrimage. Certainly the destination and meanings ascribed to the symbolic settings will necessarily vary for the pilgrim and tourist, but both are searching to reach a “heightened existence” (Simmel, 1971, p. 233) via spatially distant encounters with meaningful locations. The tourist and pilgrim are both on a quest and the symbolic settings become “divine go-betweens” in the pilgrim’s attempt for salvation (Mullins, 1974, p. 1) or self-reconstruction. Pilgrims and tourists travel to effect change and giving a fixed boundary between the two could lead us to overlook the experiences of *pilgrims becoming tourists* and *tourists becoming pilgrims*.

### Tourists Becoming Pilgrims

My preceding argument is that the lines between tourism and pilgrimage are not sharply defined, in part, since historically sightseeing, pleasure seeking, and purchasing of local goods have been intertwined with pilgrimages. Moreover, the trajectory can be reversed in that “tourists” have spiritual experiences that are more associated with pilgrimages (Hoshino, 2007). That is to say that tourists can *become* pilgrims even when their initial activities and reasons for travel are not understood

(by themselves) as falling within the domain of pilgrimage. Yet their experiences and meanings constructed from these experiences reconfigure their intentions and create moments of elevated feeling that feed into their relating to the immediate environment and overgeneralize to texture their lifeworld. This tourist *to* pilgrim transformation can be illustrated in the following account. My friend and colleague from Turkey recounted her visit to the House of the Virgin Mary in Ephesus, Turkey, which I later asked her to write down. Long having been considered the last residence of the Virgin Mary in the Christian tradition, this site is today venerated by Christians and Muslims alike. Pilgrims have traveled to the Ephesus since an invalid German nun reported having detailed visions of a house where the Virgin lived. Years later a French clergyman searched for the House of the Virgin Mary and found a house matching the nun’s description. Pilgrims visit in large part for the healing waters that are associated with the spring that runs under the house. Tangible markers of healing are left behind (e.g., crutches, walkers) by those who have reportedly been healed by the sacred waters.

My colleague, Cedy, had visited the house when she was younger and wishes she had made had come true after visiting and taking some of the water. She connected her fulfilled wishes to the water and Mary, and had promised to return to pay respect and offer her gratitude. Cedy was raised as a Muslim though she did not “wholeheartedly practice it.” At this point in her life course, she considered herself to be agnostic. Yet she looked forward to returning to fulfill her promise. On the day she visited the House of the Virgin she visited touristic places around Izmir (near Ephesus) with a group of friends:

Having seen the antique city of Ephesus a few minutes ago, I was in a mode of a happy and a little bit *tired tourist*. I was not quite in my religious mode but I was also excited having come to accomplish a promise that I failed to keep for years. Having come to the House of Virgin Mary was more like accomplishing a dry task for me. (emphasis added)

Cedy had considered the House of the Virgin to be similar to other touristic places she had visited and it is evident that she considered herself a (tired) tourist and not a pilgrim. At this point her visit had little spiritual significance for her and instead was more of checking something off of a to-do list. This

experience of being a tired tourist shifted dramatically as she entered the House of the Virgin:

However, as we walked into the garden of the House, my mind was filled with a sudden peace of mind which was far different than a relaxation that would come up from an accomplishment of a task. Also, I felt like I was surrounded by a very serene atmosphere. All of my anxieties and psychological burdens which usually make up my very default existence were away from me. I remember that I accepted this mode quite naturally, enjoyed the serenity and thought that I could stay there forever. I do not quite remember people around me or anything that impressed me to step into such a state of mind. I rather found myself in such a tranquil mode. I felt like I really appreciated the *Holiness* of the place.

(emphasis added)

Moving through the entrance triggered a sudden and surprising shift in the feeling-tone of Cedyā. As I argued above, approaching symbolic places is especially evocative and thresholds are usually marked by ornaments that function to guide the person's affective relating to the field. Not surprisingly Cedyā could not remember what evocated this elevated "state of mind" though for her there was an unmistakable modification in her affective feeling field. What was a touristic experience and place became to her marked by the hypergeneralized feeling field (Valsiner, 2007) that was later described in terms of holiness, peace, and serenity. This elevated affective response and meaning then fed-forward and regulated how she related with her immediate environment and impacted her future expectations.

I prayed in the church there. I drank the holy water and made new wishes. And I said 'I will come back here and I will visit here as much as I can.' Of course I made wishes that I really would like them to come true; and if they come true I was supposed to visit the House.

Cedyā recalled that her experience at the House of the Virgin was so unexpected because her experience there was so incongruent with her earlier experiences visiting sites around Izmir. She had not gone there expecting to have a moving and spiritual experience.

Later, I remembered it and told about it to my friends a few times. Some friends told me about the Jerusalem syndrome. I do not feel like my experience fits into something like Jerusalem syndrome, because

even people with me did not notice that I was experiencing something special, neither did I tell them anything about it.

Cedyā came to the House of the Virgin with similar belief and value system (nonreligious, Muslim background) to her friends and, yet with a unique history and relationship to the place. Her friends attributed her experience to the Jerusalem Syndrome, which Cedyā refuted since, as she told them, she kept her experience private. This statement is interesting because it demonstrates how the trajectory an individual is experiencing can branch off from the joint activity and supposed consensual experience and activity of the group. Cedyā's lived experience and meaning construction diverged from her friends' and was to a large extent hidden from them.

#### **HUMAN BEINGS: CAUGHT BETWEEN THE MUNDANE AND THE SPIRITUAL**

People make "sacred journeys" thereby crossing boundaries from the ordinary to the extraordinary. Yet utilizing a simple dichotomy of sacred/profane would suggest that sacred is what is out there, unfamiliar, and wholly other. In this sense, the sacred is something one would not encounter in a local environment since our local life settings are familiar. Does this imply that one would have to leave our normal settings to have elevated spiritual feelings? Of course the sacred/profane structure is untenable for many reasons. One weakness is that sacred objects are constantly circulating, especially as pilgrims return with holy water and dirt (or sand) and other artifacts of devotion. Sacred objects do not simply remain in a single place; rather they circulate and cross boundaries from far away to near. Shrines and relics become part of ordinary life settings inside or near the home (Mazumdar & Mazumdar, 2003). Museums are one secular place that operates between the boundary of mundane < > spiritual that does not always require long-distance travel and yet affords settings for moments of deep affective value.

Pilgrimage and similar travel is purposeful movement toward something that is highly valued. Yet sacred ornaments saturate our settings that people pass by and typically only catch in their peripheral vision (Valsiner, 2008). Churches, small roadside shrines, and other architectural structures can be the focus of movement (e.g., church attendance), but in our everyday routines they are bypassed. What functions do they serve in the intrapersonal domain? What communicative messages do they

convey? For instance, roadside shrines marking the death of someone are commonplace in the United States. Why does someone construct this object? What does it communicate? For whom? Under certain conditions it seems that they can provoke episodic escalation of feeling in spiritual directions. In other words, material objects in our everyday settings can episodically trigger shifts in a person's affective field (see Fig. 33.4). This brings to focus that, as González-Ruibal (2011) posits,

There lies the power of things: they keep us remembering us other things, people, places and events to which they are associated, whether we want it or not. (p. 154)

Many of the material artifacts that we encounter in our everyday life settings can become the catalyst for “hyper-abstract and overgeneralized higher-level total feelings” (Valsiner, 2007, p. 312).

### Conclusion: Guided Exploration of Liminal Worlds

Pilgrimage is a transitory phenomenon constituted by movements of people from various points of departure to sacred centers. Geographic movement has consequences for the movement of meaning and reverberations in the psyche of the traveler (Gillespie et al., 2011). Any travel in which borders are crossed has the potential to become a destabilizing experience. Victor Turner's notion of liminality emphasized the possibility of “what might be.” Pilgrims leave their ordinary environments and gain a critical distance from their everyday world as they move toward and

encounter artifacts of great significance. Grounded in everyday realities while reaching toward the numinous, pilgrimages join together the elevated and ordinary, sacred and profane, structure and antistructure. This is apparent as the pilgrim is faced with the mundane aspects of securing lodging, finding places to eat and relieve themselves, boredom, and fatigue. These everyday concerns and objects occur and exist in close spatial and temporal proximity to the encounters with holy and sacred objects. Additionally, the *telos* of any pilgrim is rooted in addressing basic life circumstances such as physical pain, spiritual or psychological suffering, boredom, loss of job and more, as well as with a desire to take part in a world set apart from the ordinary and initiate some form of transformation—personal, social, and/or physical.

The efficacy of self-transformation, insight, and increased faith for the pilgrim is bound up with their encounters with material and symbolic objects, other people, and far-away places, which could be called the *pilgrimage field*. Material cultural artifacts and sacred viewings of these objects are emotionally charged. However, for pilgrims these objects do not stand alone since they are embedded in rich, liminal environments. Although the final holy site might be the goal, pilgrims arrive after hardship, encountering other significant objects and places, ritual acts, and conversations with fellow travelers. The holistic organization of these settings and the semiotic guidance of pilgrims *crossing the boundary from ordinary to sacred* places are crucial conditions to fostering emotionally salient and transformative experiences.

**FIGURE 33.4** Jizo statues found on the roadside and at large temples and shrines. They are ubiquitous in Japan, especially Kyoto.

## Future Directions

1. Understanding pilgrimage as a process that extends beyond the path and pilgrimage center opens up possibilities for future study. What are the developmental implications of pilgrimages as people face futures that are always under construction? How do their pilgrimage experiences and signs derived from their pilgrimage encounters feed-forward and continue to reverberate and shape their value systems, identities, and self–other understandings? In other words, how do changes that take place during and in the field of pilgrimage generalize and texture the lifeworld of pilgrims long after their journey? How do their experiences act in their self and other dialogues, if at all?

This issue tackles the complex interrelationship of microgenesis and ontogenesis and brings us back into contact with Karl Buhler's notion of abstractive generalization (1990). How could this phenomenon be studied in research on pilgrimage?

2. As the case of Cedyra above suggests, we can examine travels to pilgrimage places at varying levels of organization. That is, we can look at the individual or the group (i.e., the immediate group that the person is journeying with or the more abstract community of fellow pilgrims). Eade and Sallnow (1991) and others have argued that the experience is multivocal in apparent contradiction to Turner's notion of *communitas*. One possible way of going beyond this false dichotomy would be to the collective or joint experience and meaning making and the trajectories of individual meaning making as they converge and diverge in real time. Studying this process suggests that group activities and individual meaning making would need to be captured and examined in relation to each other. How could Sato's Trajectory Equifinality Model (Sato et al., 2011) be utilized to accomplish this understanding?

3. Pilgrimages and similar visits to places of symbolic and social value are quite complex. Explanatory approaches that grapple with personal and social transformation must move beyond reductionistic frameworks that offer deterministic and linear accounts of change. The notion of catalysts broadly defined as the study of conditions under which something happens—offers a systematic causal framework that unites the richness of empirical phenomena with the generalizing value of science (Beckstead, Cabell, & Valsiner, 2009; Cabell, 2010; Beckstead, 2010). This could help flesh out the possible trajectories of visitors' experiences

to symbolically evocative places. What other theoretical approaches can be constructed to overcome the main paradigms of *communitas* and contestation, and the tension between universality and particularity reflected in this dichotomy (Coleman, 2002)?

4. What are the implications of increasing commercialization of pilgrimage places? How do sign complexes such as authentic < > unauthentic inhibit or block the spiritual qualities of pilgrimage? Are shopping malls a place of modern pilgrimage? Should travel for cosmetic surgery be considered a form of pilgrimage? How does the secular social world borrow from pilgrimage traditions?

## Note

1. This symbol indicates a boundary that relates at least two concepts that have often been conceptualized as opposites. In this sense, the symbol implies the notion of unified opposites.

## Never “at-Home”?: Migrants between Societies

Mariann Märtsin and Hala W. Mahmoud

### Abstract

This chapter explores the dialectic meaning of “home,” and movement away from home. Movement away from home—or migration—is characterized as a dynamic, dialectic, and developmental experience. We emphasize the *sense of being at-home* and the intertwined *sense of identity* as interlinked and mutually defining anchors of our existence that become inevitably shaken and ruptured in the experience of migration. But when looking at how this rupture is experienced and managed, we highlight the inherently complex and dialectic nature of migration, instead of seeing it as a unidirectional sequence from rupture to shock, to coping and finally to new stable being. We discuss the complexities of migration experiences as entailing dialectics of home and non-home, rupture and continuity, novelty and everydayness, changing and remaining. The *sense of being at-home* is simultaneously enabling and constraining, helping us to build self-continuity in a new environment, yet also holding us back and distancing us from novelty. Similarly, migration is a threat, yet also a promise; it is a painful, yet possibly exhilarating experience that makes us lose our center of security and familiarity, yet also opens up opportunities for transformation and reinvention.

**Keywords:** home, migration, identity, rupture, dialectics, development, ambivalence, repatriation

The phenomenon of *home* is one of the most fundamental aspects of being human. Its significance pervades our everyday language in the form of metaphors and proverbs we use to communicate feelings of comfort, security, belonging, ease, familiarity, and roots. For example, the proverb “there is no place like home” captures the essential value of home in our lives. Phrases like “I feel at-home” or “make yourself at-home” reflect feelings of familiarity, easiness, and comfort. Similarly, we refer to home as a place that offers security and protection (Charleston, 2009), as the well-known English proverb “an Englishman’s home is his castle” and its Estonian counterpart “minu kodu on minu kindlus” indicate. But what is home? Is it the house, neighborhood or country where we were born or raised? Is it the place where our loved ones live or have lived? Is it a single place or a multitude of localities?

Or is it “where the heart is”? And how does migration affect the value and meaning of home in our existence?

Indeed, the difficulty in answering such questions stems from the existential pervasiveness of the meaning and value of home in our everyday lives, society, culture, and history (Moore, 2000). Home cannot be defined; it can only be *experienced* and characterized. As such, our objective here is to address the above questions by investigating the characteristics of home and how migration affects the personal, identity-related, experiential meaning of home in our lives.

In this chapter, we adopt a dialectic view of home and migration. Migration is seen as a complex phenomenon that entails dialectics of home and non-home, rupture and continuity, novelty and everydayness, changing and remaining. We see the

*sense of being at-home* as simultaneously enabling and constraining, helping us to build self-continuity in a new environment, yet also holding us back and distancing us from novelty. Similarly, we look at migration as a painful, yet possibly exhilarating experience that makes us lose our center of security and familiarity, yet also opens up opportunities for transformation and reinvention. Although the new country of residence is a place full of novelty and foreignness, it is also filled with possibilities for re-establishing familiar patterns of everyday life. Therefore, the processes of being at home, being away from home, and being “never at home” are complex, dialectical and ever-changing. This reflects the dynamic, relational, mutually defining relationship between individuals and their environments, echoed in the majority of chapters in this volume (see for example Boesch, 2011; Marková, 2011; Rasmussen, 2011; Zittoun, 2011).

Throughout this chapter, we address issues of being at home, away from home, and never at home, in relation to migrants in general. Our aim is to unpack some of these complexities and show that both home and migration are not stable or unidirectional phenomena. The movement away from home is not necessarily characterized first by disruption, loss, pain, and later by coping, reconstruction, and new stability. Instead, we aim to explore it as being a fundamentally ambiguous experience of loss in relation to finding, change against the backdrop of everydayness, and disruption within continuity. This dialectic approach is followed throughout the chapter, where we start by characterizing the complex meaning of home in our lives, then move on to the rupturing experience of migration and what it does to our sense of identity and sense of being at-home. Next, we explore how migrants attempt to re-establish the sense of being at-home when away from home, and finally, we discuss the possibility and impossibility of feeling at-home again.

### **Meanings of Home**

From the vast research into the meaning and experience of home, several common categories emerge. Home is seen as a “nucleus of culture” (Boesch, 1991), a field that organizes and provides a reference point for our actions; it is a point of departure and return, a haven where one returns after a journey or at the end of one’s life (Moore, 2000). Through home we perceive and experience the world (Hayward, 1975; Case, 1996).

According to Sixsmith (1986), our modes of experience in relation to and within home yield a tripartite division. Firstly, home is a physical location, a dwelling surrounded by physical boundaries, divided into territories and supplied by different services. As a physical structure, home separates the private space of individuals and their families from the public space, functioning therefore as a means of regulating privacy (Altman, 1976; Märtsin & Niit, 2005).

Secondly, home has a social meaning. It is a milieu of a person’s everyday interactions with others (Hayward, 1975), a meaningful and emotionally based relationship between people and their environment that becomes embodied and anchored through ordered structures of space, time, and socio-cultural worlds (Dovey, 1985). As a “node in networks of social relations” (Easthope, 2004, p. 137), home is defined by relationships with others from this and previous generations (Parkin, 1999), functioning as a bridge between past, present and future, thus giving the person continuity in time and space (Twigger-Ross & Uzzell, 1996; Manzo, 2005).

Finally, home is a personally relevant and significant place. It is an extension of the self, which starts to represent the self through the person’s investment into the place. It functions as a nucleus through which one defines oneself (Hayward, 1975; Proshansky et al., 1983; Sarbin, 1983; Dovey, 1985; Twigger-Ross & Uzzell, 1996; Fried, 2000). In his description of his home office, Boesch (2007a), for example, illustrates how the objects that surround him are laden with personal meaning, evoke personally significant memories and reflect his identity. Home has thus something to do with our identity. To be “home” involves knowing where and who you are, being oriented in space and inhabiting a secure center (Dovey, 1985). This identity-giving quality of home, then, is our focus in this chapter.

From this perspective, home is a subjective, experiential, identity-related phenomenon. Along those lines, Manzo (2005) reminds us that places gain their meaning through our lived experiences. Home, then, may not refer to one physical location (a dwelling, neighborhood, city, or homeland), but rather to a bricolage of various experiences within and in relation to a variety of home-places involving several significant others. This experiential sense of being at home involves bodily, spatial, kinesthetic, sensual, emotional, rational, and interpersonal qualities that combine speakable and unspeakable,

explicit and tacit, reflective and prereflective ways of experiencing. It is this broad experiential *sense of being at-home* (Case, 1996) that concerns us in this chapter.

### *Antinomies of Home*

But what does this sense of being at-home entail? And how do we experience home? As Dovey (1985) correctly argues, the sense of being at-home is only experienced through dialectics that entail interdependent, mutually defining antinomies in tension (Billig, 1996; Marková, 2003). Home is animated by the tension between home and journeying, security in an insecure world, inside and outside, the feeling of being at-home as opposed to yearning for home, self in relation to other, and private in relation to public (Dovey, 1985; Manzo, 2005). It involves a powerful combination of the tangible with the intangible, concrete and ethereal, physical and imaginary, inflexible and flexible (Papadopoulos, 2002). Although home is often represented by comfort, it can also be a place full of obligations (Moore, 2000). It can be a private place free from the gaze of the other, while being also a place of isolation for those who cannot leave it (Fried, 2000; Rowles, 1983). Home is the primary locus where those dialectics are experienced, negotiated, and rendered meaningful (Papadopoulos, 2002). According to Dovey (1985), to experience the meaning of home is to experience such dialectics: “There is no sense of home unless there is also journeying. [...] Without a public realm there is no privacy. And in a sense, without homelessness, we would not be concerned with what home means” (p. 48).

The experiential, emotional, and dialectic qualities of home make it at once very flexible yet conservative (Dovey, 1985), enabling yet constraining (Boesch, 1991). It is flexible because it is embodied in the patterning of experience, behavior, and emotions. However, home is also conservative because the qualities of familiarity, comfort, identity, security in their all-pervasiveness become easily taken for granted (Dovey, 1985). As such, the meaning and value of home are awakened in their absence (Dovey, 1985; Case, 1996; Papadopoulos, 2002; Diriwächter, 2009). As a secure center through which we become oriented in time and space, absence of home makes us lose this sense of rootedness (Tuan, 1980; Easthope, 2004; Chow & Healey, 2009) and thus creates a basis for self-exploration. Here is where the simultaneous enabling and constraining nature of home becomes crucial for our

discussion. That is, we are interested in exploring the absence of home—migration—as simultaneously painful and exhilarating, as promising yet threatening, as a need and also a possibility for self-exploration, transformation, and reinvention.

### *Home and Identity*

The *sense of being at-home* is intertwined with a *sense of identity*. In conceptualizing identity, we draw on the work of Holland and her colleagues (Holland, Lachicotte, Skinner, & Cain, 2001; Holland & Lachicotte, 2007), who suggest that:

Identities are social and cultural products through which a person identifies the self-in-activity and learns, through the mediation of cultural resources, to manage and organize himself or herself to act in the name of an identity. Identities are personally significant, actively internalized, self meanings, but first and foremost [...] they are formed in relation to collectively produced social identities.

(Holland & Lachicotte, 2007, p. 114)

Identity is therefore a meaningful way of being in the world that has emerged through our continuous and repeated engagement with others in various activity contexts (Märtsin, 2010). Our identities are shaped by our interactions with others, while our sense of who we are shapes the way we act and interact in the world. Yet, identity is more than just a self-understanding constructed through internalization and accommodation of others' perceptions of us. Instead, as a way of being, it also goes beyond those internalized meta-perspectives to include bodily, sensual, reflective/rational and prereflective/affective ways of experiencing who one is. Thus, to signify this generalized sense of what it means to be me, we herein use the notion *sense of identity*. Importantly, self-continuity and sense of sameness are central to our conceptualization of identity. Falmagne's (2004) words capture this idea eloquently: “In some content-related sense I am constructed differently at [...] different moments. However, I remain myself, not you” (p. 835). Sense of identity, then, gives us a *meaningful* sense of who we are, where we come from and where we are heading; it bridges the past through the present to the unknown yet anticipated future. It refers to a sense of seeing oneself as continuous and more or less the same across various, even contradictory experiences in the world.

Our sense of identity is partly constructed through our engagement with others in places and

spaces that we consider to be our home. Through our engagement with home-places we feel rooted in a certain space and time context and we feel we belong to the groups we engage with in those contexts. Sense of identity and sense of being at-home are mutually defining; we derive our sense of identity, our sense of sameness, continuity, and rootedness from the experiences of being at-home, while home becomes a significant place precisely because of these meaningful experiences. Put differently, we are who we are because we come from a certain locale in space and time, and we call this locale our home because we derive our sense of identity from the experiences within and in relation to it.

As already indicated, this sense of identity is not necessarily a reflective and conscious self-definition, but rather a tacit sense of knowing how things are and what to expect. Familiarity and taken-for-grantedness are the primary features of this way of being (Heller, 1995), which involves sensual elements such as familiar smells, sounds, colors, shapes and language, as well as everyday routines, such as eating certain foods at certain times or sleeping in our own bed with our own pillow and duvet (Case, 1996). It also involves our embeddedness in social relations and our belonging to certain groups. As Shotter and Lannamann (2002) suggest: "Our being and belonging arise from the condition of being embedded in an ongoing flow of spontaneous, reciprocally responsive, living activity, occurring between us and the other in the group" (p. 597). Through our belonging to different groups and engagement with different activities we also internalize values, cultural practices, and roles related to these. All these elements come together to form an intertwined and not easily disentangled whole of being in space and time, rooted in a subjective conception of "home," and including idiosyncratic ethnic, national, religious, and other self-definitions. Therefore, our sense of identity in relation to home forms a part of the holistic, taken-for-granted existence, guiding our functioning in the world in a powerful, yet often unreflective manner.

### Migration as Rupture

Migration is a rupturing experience that introduces a break into a person's normal and taken-for-granted flow of being (Becker, 1997; Zittoun, 2007a, 2007b), and produces a diversity of ever-changing outcomes ranging from pain and trauma to feelings of exhilaration, excitement, relief and self-discovery. Migration could be a disquieting

experience "that hurts our *expectances*, prodding the subject cognitively as well as affectively to feel, think, and act" (Simão, 2003, p. 450). Because of the rupture, the patterns that sustained life before are no longer functional, and the taken-for-granted is questioned (Stein, 1986; Zittoun, Duveen, Gillespie, Ivinson, & Psaltis, 2003; Zittoun, 2004, 2006). In the words of Josephs (2002): "The formerly taken-for-granted (and thus backgrounded) life-world suddenly becomes foregrounded and 'visible'" (p. 171). In discussing first experiences in a new context, we thus move away from the concept of *culture shock* that has been widely employed to describe the disorienting and disturbing nature of meeting a new context (Ward, Bochner, & Furnham, 2001), and toward the dialectic and multifaceted experience of breaking up the taken-for-granted, living in between cultures, and renegotiating identities (Bhatia & Ram, 2001b).

By bringing to awareness the taken-for-granted, the rupture of migration concurrently provokes questions about one's sense of identity as it was intertwined with the sense of being at-home. Experiencing a rupture in one's sense of identity resulting from migration is an all-encompassing feeling that one's normal way of being no longer "flows" in the new context. That is, although migration introduces a disruption in physical environment, self-understandings, values, practices, social relations, etc., all these elements as an intertwined whole become broken as we encounter the strangeness of the new physical and social environment. Meintel (1973) correctly argues that feelings of alienation and isolation resulting from cultural strangeness, unfamiliarity, and unpredictability may well start to diminish once the migrant becomes familiar with the new environment. In this sense, such culture shock represents the less significant and less enduring aspects of being a stranger, while the more significant and serious shocks resulting from being a stranger are indeed those of self-discovery, where the migrant's previously established values and beliefs about the world and oneself are challenged, and by implication, the social world that endorsed them. Those sudden, unforeseen revelations about the world they had taken for granted are much more significant and of a longer lasting effect than the shocks of the new environment *per se* (Meintel, 1973). Zittoun (2007a) similarly states: "The first criteria to consider an event as a significant rupture, is that it is subjectively, consciously or unconsciously, perceived by a person as questioning

her sense of self and sense of continuity” (p. 190). Importantly however, a rupture in one’s sense of identity in relation to home may take various forms.

To begin with, rupture to one’s sense of identity in relation to home may have taken place even prior to migration. As Graham & Khosravi (1997) note, most of the research on home has been written by those who left it, but it should not be assumed that those who have not moved are in a secure state, feeling “at-home.” Research on political refugees, for example, shows that they leave their countries precisely because they do not “feel at-home.” Zarzosa (1998), a Chilean refugee describing her experiences of the 1973 coup, explains that: “One can become an exile while remaining on one’s soil [...] Chile was my country of origin, but ceased to be my home” (pp. 189–190). This experience of “internal exile” (Abu-Lughod, 1988) while remaining in one’s soil can be caused by different reasons, such as a radical political change, which ideologically divides people of the same country, or belonging to an ethnic population that is not officially recognized by the country, or feeling and acting differently from what is socially accepted. Lawrence, Benedikt, and Valsiner (1992), for example, discuss this latter kind of “homeless in the mind” in the case of a young woman living in and eventually breaking free from an ultra-orthodox Jewish community.

Similarly, people may feel uncomfortably restricted in their home community because of their inability to fulfill their life plans and aspirations. For example, Märtsin’s (2009a) semi-longitudinal multiple-case study, which explored how young Estonians studying in the United Kingdom made sense of themselves in relation to their experiences in a new environment, touched on this issue. Many of the participants indicated that they left Estonia because it was too small and offered too few opportunities for them and for their anticipated future ways of being. For these “internal exiles,” then, leaving home may be in agreement with their life projects (Giddens, 1994). In fact, and especially in the case of temporary migrants such as international students, leaving home may actually be perceived as an attempt at actualizing one’s life project by seeking educational, career, or financial opportunities believed to enrich one’s life. In this sense, there is a degree of choice in leaving home, which is based on feelings of discomfort or restriction, whether or not the person in question intends on returning home in the future. As Bühler and Massarik (1968)

and more recently Boesch (1991) suggest, humans are guided by their goals and imagined futures and therefore questions about anticipations and motivations largely shape the way in which migration as a rupture is experienced.

Boesch’s (1991, 2007b) work is important to the current discussion also in another way. He suggests that all human functioning and meaning making is characterized by the tension between *Heimweh* and *Fernweh*, between known home (or more generally “I”) and unknown faraway (more generally “non-I”). That is, while being within the familiarity of home, humans long for the strange, foreign, and unknown. They are attracted by the promise of the other that is undiscovered. Yet moving away from home makes them *Unheimlich*—unhomely or homesick; it makes them long for their intimate, hidden, secure, and safe haven in the world. Home is intimate and safe, but also known and unexciting. Faraway can be a promise, but also a threat. Understanding this double-bind, this tension between “home” and away and the dialectics within both realms is, in our view, crucial for understanding the experience of migration. These contradictory feelings are discussed next.

### *Encountering the New Physical Environment*

Encountering the foreign environment may not initially result in alienation or nostalgia but may indeed involve a great deal of exhilaration (Meintel, 1973). This is because humans are not only oriented toward what is familiar, but are also attracted to what escapes immediate understanding (Van Leeuwen, 2008; Boesch, 1991). The experience of Elina<sup>1</sup>, a young Estonian woman arriving to London, illustrates this excitement about the new and unknown (Märtsin, 2009a, pp. 140):

**Elina<sup>2</sup>:** For example, when the metro train pulled into the station, my stomach was turning. It was something new for me. Wow! Everything is so interesting! Yes. Like a child. Double-decker buses...

The initial excitement and fascination may be replaced or complemented by other feelings, such as nostalgia and homesickness, caused by the loss of subtle elements of one’s past life—familiar smells, sounds, tastes, and bodily experiences of being in certain spaces and places. In many cases, the migrant experiences both ends of the continuum, or can go through various stages throughout their time in the new environment. Van Leeuwen (2008) argues that

cultural strangeness or contact with a new culture can give rise to “affective ambivalence”, i.e., coexistence of positive and negative feelings toward home and non-home. On the one hand, cultural strangeness can cause “existential unease” simply because it puts our taken-for-granted common sense into question. On the other hand, contact with a new culture may give rise to positive feelings of wonderment and fascination (Van Leeuwen, 2008).

The example of Elina above illustrates a positive rupture in encountering the new physical environment. But in contrast, the new physical environment may introduce an uneasy rupture. Consider the experience of Zein, a Sudanese refugee in Cairo, who was interviewed as part of a qualitative study investigating the culture, identity, and coping pathways of Sudanese refugees in Cairo (Mahmoud, 2010)<sup>3</sup>:

**Hala:** What do you miss from life [in Sudan]?

**Zein:** By God, a lot [...] the nature, the rain, the fields, the houses [...] I mean, we had big houses [in Sudan], all on the ground floor [...] here [in Cairo], sometimes the weather is very cold for us [...]. Sudanese meals are also different from what's available here [in Cairo].

Many other Sudanese refugees in Cairo mention that they miss the “earth” or “soil” of Sudan. This represents a subtle type of loss that nevertheless highlights the pervasive and general loss of the sense of being at-home and its associated sense of identity.

### *Encountering New and Old Social Others*

Moving away from home entails both coming into contact with new social others, as well as a qualitatively renewed kind of contact with old social others in the homeland. As the work of Mead (1934) and its recent development (Gillespie, 2007), as well as growing research into migrant identity suggests (*inter alia* Aveling & Gillespie, 2008; Bhatia & Ram, 2001a; Hermans, 2001; Kadianaki, 2009; O’Sullivan-Lago & de Abreu, 2010), our identities are constructed and constantly renegotiated through encounters with others. Thus, encountering new and old social others may introduce additional threats and ruptures to a migrant’s sense of identity. Coming into contact with new social others may shake our preestablished sense of identity because we no longer get the recognition and acknowledgement we used to get from others in the homeland (Van Leeuwen, 2008). Therefore,

rupture may arise from an experience of personal isolation, where the person feels that the environment is unfamiliar and instead of recognizing the person, it rejects and excludes them (Van Leeuwen, 2008). This seems to be the case with Såde, a young Estonian woman studying in England (Märtsin, 2009a, pp. 197):

**Såde:** It truly bothers me how they ignore these dots [in my name] [...] I can’t stand it. I’ve been polite and everything, calmly reminded them, but I constantly get smacked in the face, up to the point that I’m already worried that they will not use them on my diploma [...] They know how things should be. It’s like some sort of disturbing privilege that you are demanding your stupid dots [...] Perhaps I’m so touchy about this because my name has always been so central for me.

Såde’s feeling of “getting smacked in the face” emerges out of her perception of others’ perception of her. She thinks that her university considers her needs to be trivial, unimportant, sees them as “disturbing privilege.” This feeling of not getting recognition and acknowledgement about something that is important for her, and instead being considered as an alien because of her strange needs, thus heightens Såde’s sense of being disconnected with her old way of being. In contrast, there are many examples of migrants who were never recognized in their homelands, but become appreciated and acknowledged in the new environment. This is the case for poets and artists who realize their potential away from their homeland.

Encounters with new social others, identifying and being identified by them is central in the process of renegotiating one’s sense of identity, and re-establishing familiarity after migration. Migrants strive to understand who these new social others are (e.g., What are their values, their customs?) and they also get a sense of who they are through these encounters (e.g., How do these people see me? Who do they think I am?). At the same time, their sense of identity is still very much tied to the social environment of their homeland. Visits to the homeland or visitors from the homeland and even indirect ways of learning about their home communities (e.g., media, correspondence) can contribute to a changed way that migrants both perceive and are perceived by their home community. Consider for example the experience of Andres, a young man studying in England. When talking about his visits to Estonia, Andres says (Märtsin, 2009a, pp. 131):

**Andres:** Some sort of freedom that you have here in London. You are over 30, but you don't feel this total social pressure that we have in Estonia. In that age you have to have achieved something and if you are just [...] doing your research or something, you are just a nonsense bloke. You are just wasting your time, prolonging your childhood. This is precisely what I've been told in Estonia. That [pause] in Estonia, if you are away for a bit longer, you immediately feel [pause]. Others who have returned from abroad have said this too. Someone I know who lives in Paris, says that he comes to Estonia, is there for a week and already feels that he should get a mortgage and buy a flat. This is the way you do things.

Unlike Sæde's example above, Andres thinks that others *at home* do not acknowledge his chosen way of being. Instead, he is considered as a "nonsense bloke," who is "prolonging his childhood." Not being recognized by his old home community makes him turn his gaze toward other groups, toward other "in-betweeners" who seem more similar and therefore more attractive to Andres.

Thus, both home and resident communities, as well as other groups beyond these, are crucial in the redefinition of one's sense of identity in relation to home. Because of the rupture of migration, the migrant's position in relation to both home community and resident community becomes questioned and needs to be reconstructed from a position of being in between.

### *Liminal Space between Home and Non-Home*

Thus far, the discussion has focused on the multifaceted, complex repercussions of moving away from the homeland. A central thread of argument that appears both implicitly and explicitly is that the experience of moving away from home activates the dialectic of home and non-home, as these become simultaneously present and absent in our way of being in the new context. On the one hand, we are physically away from home, cut out from those routine and familiar callings from others that we respond to spontaneously (Shotter, 2003, 2008). Yet through that absence, by realizing what it meant to be at-home, the sense of home becomes very much present in the new context. Hence, it becomes a powerful reference point, a lens through which we evaluate the new encounters with others and otherness. On the other hand, in the new and physically present socio-cultural context we

are experiencing the flow of others' callings, which are unfamiliar and to which we do not yet have spontaneous responses (Shotter & Lannamann, 2002). That is, we are engaged with others in activity contexts that do not seem familiar and mundane and in which we do not necessarily know yet how to respond and interact. The otherness is thus very actively present, demanding a response from us. Nonetheless, it is not part of our being and as unknown and unfamiliar, remains absent. Thus the sense of being in between, in transition, not anymore there, but also not yet here emerges (Bhatia & Ram, 2001b), and is characterized by feelings of liminality, ambiguity, and ambivalence (Turner, 1967; Harrell-Bond & Voutira, 1992; Becker, 1997; Coker, 2004).

Turner (1967), in his classic work on liminality, considers society to be a "structure of positions." *Interstructural* human beings are those "transitional beings" or "liminal *personae*" who are at once "no longer classified and not yet classified" (p. 96). They are neither one nor another; they are betwixt and between all the recognized positions in space and time. In other words, they are "at a threshold outside the boundaries of society" (Becker, 1997, p. 119). From this perspective, migrants can be considered transitional, interstructural, or liminal beings who are at once no longer at-home, neither in relation to their homelands nor in relation to their new habitat.

The inherent ambiguity in any liminal position is associated with feelings of ambivalence. As Valsiner (2006) contends, ambiguity of existence leads to ambivalence in human feeling, acting, and thinking. Although ambiguity and ambivalence are present in every human psychological act (*see* Abbey & Valsiner, 2005; Valsiner, 2006; Valsiner & Abbey, 2006), they become exaggerated in the case of migrants. Therefore, besides the intrinsic ambiguity in any liminal position, there is also a marked degree of ambivalence—i.e., stressful uncertainty, being simultaneously drawn in opposite directions, and having mixed feelings toward people, objects, values, meanings, and so forth. Being a stranger in a foreign culture, where common sense no longer serves its function (Leeuwen, 2008) increases ambiguity and ambivalence. Not having a clear social position can make different possibilities equally desirable, repulsive, or confusing for the person (Mahmoud, 2010).

This state of being in between is vivid in the case of Ruth, a young Estonian woman studying in England (Märtsin, 2009a, 2009b). Talking about

the possibilities of living in England after having stayed several months in Estonia, she says (Märtsin, 2009b, pp. 207):

**Ruth:** I don't know, my mood changes all the time. [...] I started to think with horror that what if I'll come to the point when I actually don't need to return to England anymore [...] To be honest I don't want to think about it now. At the same time I really liked it in Estonia in the summer. I don't know, probably I'll have to stay being amphibious.

Importantly, the ambivalence between home and non-home can extend beyond comparisons of the new environment with the old one. Instead, ambivalence can well exist within one's relation to home itself, where home becomes the source of extreme ambivalence. For example, for many Sudanese refugees in Cairo, Sudan at once symbolizes both their home *and* the unwanted (Mahmoud, 2005). Sudan represents their home, their sense of identity, their loved ones, their productive roles, their memories. On the other hand, it represents war, rejection, genocide, torture, abuse, fear, and death. As a result, those refugees tend to have a sharply ambivalent relationship toward their homeland. *Heimweh/Fernweh* tension (Boesch, 1991) thus becomes awakened and renegotiated, as both home and the faraway appear simultaneously strange and hostile, while also being known and safe.

Yet the refugees' experience thus described surfaces another aspect of liminality. The space of in-betweenness, opened up by migration is, metaphorically speaking, a space where everything is possible and where one can experiment with different ways of being. However, although the transformation and development is intrinsic in the rupture → repair cycle, the possibility of perceiving liminality as promise and not as threat is linked to the safety net around the liminal space. In other words, migrants who have others' advice or their own aspirations and life goals that allow them to transition to the other side through the ambiguity are more likely to see it as possibility for change and growth, while it remains a threatening and hostile territory for those who do not have such social or symbolic support at their hand.

It is also clear that safety nets are not always offered to migrants. Instead they need to be discovered and created. The (re)establishment of a sense of home away from home—that is, creation of support systems that allow coping with liminality—is the topic we turn to now.

## Home away from Home

Thus far we have been concerned with migration as change. Our focus has been on the novelty of the physical and social environment that disrupts the taken-for-granted flow of everydayness. However, everyday life continues also beyond the rupture of migration. That is, migrants' lives are not lived only in the registers of catastrophe, drama, and change, but also in mundane and ordinary registers. Furthermore, novelty changes too; with time and through repeated encounters, the unordinary becomes ordinary. Thus migration is not only about changing, but also about remaining and maintaining. In other words, because our sense of being at-home and its associated sense of identity are dependent upon the qualities of familiarity, comfort, and continuity, one way of dealing with the rupture of migration is by re-establishing those qualities. Yet underlying our discussion about establishing continuity is the idea that maintenance, just as alteration, is an active and transformative process (Valsiner, 2007). In what follows we thus talk about “progressive, new adaptations between the person and her environment” (Zittoun, 2011) that are characteristic to transition periods triggered by the rupture of migration.

### *Pathways of Re-Establishing Continuity*

Rupture of migration exists in relation to continuity, and change happens only against the backdrop of sameness. In the words of Hall, Coffey, and Lashua (2009), “change is experienced and accommodated through mundane, everyday registers” (p. 551). Migrants attempt to keep certain everyday activities untouched in the new context, even if the ways of conducting these activities become altered. The Sudanese refugees may miss the smells and tastes of their traditional cooking in their new life in Cairo, but the pattern of eating at certain times of the day together with certain social others may remain, and is brought forward to the new context, where it continues to build up migrants' personal history. The everyday practices that we need to attend to thus function as kind of safety nets in the space of in-betweenness. This dialectic of change and continuity, novelty and sameness in understanding oneself and the world, is thus central to our understanding of migration.

In order to move beyond the break in one's way of being and re-establish sense of continuity and sameness, in order to turn threat into promise, and respond to new challenges, individuals' experience

and knowledge stores that build upon available cultural resources can be mobilized (Zittoun, 2006, 2007a). Sense of sameness and continuity can entail different things for different people (Becker, 1997). For some, it involves linking with loved ones, for others it involves sustaining daily routines or activities that were part of the familiar and taken-for-granted flow of being. For others still, it means using resources (Zittoun, 2007b; Zittoun et al., 2003; Zittoun, 2011), such as institutions, music, literature, or dance to make sense of their current situation and do the psychological work that is needed for reaching new stabilities. These and other elements of the sense of being at-home constitute familiar spaces in which the migrants' past ways of being were appreciated and rendered meaningful. Retaining those activities, bringing them to the present as an old basis for new creations, therefore means retaining one's sense of continuity, and in a way, creating an experiential "home" in the new environment (Mahmoud, 2010). In what follows we elaborate some common pathways for re-establishing continuity through strengthening the ties with the past home.

Maintaining *routines of everyday life* can be a powerful pathway for re-establishing continuity and recreating home in the new environment (Becker, 1997; Desjarlais et al., 1995). Many migrants care to cook their own food, burn incense, and perform their ordinary activities, habits, and hobbies from home. When possible, traditional dress is worn (Mahmoud, 2010):

**Hala:** So when you feel that you miss your family in Sudan, or anything else from Sudan, what do you do?

**Zein:** I try to [pause] for example, if it's family, I bring out the photos, if it's food, I try to cook it, if it's something social, I try to gather with the Sudanese here [...] everything I miss from Sudan, I try to do here.

Sense of continuity also involves *complying with traditional familiar cultural values* that ensured self worth at home. For example, the Sudanese refugees in Cairo consider the domain of *fertility and procreation* an important protector of their previously established sense of identity. In many parts of Sudan, one of the primary roles for a man or woman is to have children. In Cairo, married Sudanese refugees continue to embrace the value of childbearing very highly. This is a value that reinforces their manhood and womanhood, as they were defined in their past. It is also their only opportunity to continue their lost life projects,

since many of them project their own unfulfilled ambitions and dreams onto their children. Although procreation is an important protector of their identities, it imposes increased difficulties for them and their entire family. How to protect and safeguard their children? How to give them the needed education? How to maintain their connection with the (parents') homeland? Despite these dilemmas, some refugees continue to want to have more children, because procreation is a core value that sustains their personhood in the midst of inevitable change (Mahmoud, 2008, 2010). Consider the case of Michael, an unemployed Sudanese refugee in Cairo who has seven children and struggles to provide the food of the day for them (Mahmoud, 2010):

**Hala:** Tell me more about your life here. You said that you came here temporarily in order to travel?

**Michael:** One always seeks improvement. And I was thinking that from Sudan to Egypt, there will be improvement, and then we could move somewhere better from Egypt so that my children could get educated. This was my ambition. I want my children to have a good education. If they do not have an education, they will be lost. They could become criminals. I wish my children could get a good education. I want my children to say, 'Baba, you worked hard for us.' This is all I want from this world.

Michael, like many other refugees and migrants, is confronted with a catch-22 situation. By having many children he is challenged in his identity as a father providing for them and securing their future. At the same time, having many children is essential for preserving his identity as a man and husband and for carrying his legacy.

*Linking with family and friends back home* is another way of recreating continuity and coming closer to home, since "home" involves connectedness through meaningful relationships with friends and family (Dovey, 1995). For example, many young Estonians studying in England reported that their relations with their parents had improved significantly after their departure to England (Märtsin, 2009a). They claimed to have long and deep discussions about their experiences in the new environment and about their families' lives back home over phone and internet—an experience they hardly had when living at home. Again we can see the Boeschian *Heimweh/Fernweh* dialectic at work here—that which is out of reach and absent is dear and longed for.

Lastly, *cultural retention* is a powerful means for ensuring continuity and activating the sense of being at-home. Some refugees or migrants, especially those who belong to a social network of people from their own tribe or background, will try to recreate their social gatherings and celebrate national holidays or special occasions in the new environment, in order to revive their culture (Mahmoud, 2010):

**Hala:** Are there people from your tribe here?

**Taheyya:** Yes, there are many. Many of my relatives are here. Also, we go every fortnight [to] the Nuba Mountains nursery to revive our culture. We speak *Rotana* [tribal language] all day, and we perform our dances. [This is] something that brings us together, because life and work increase the gap between us.

Although fostering bonds with home may help to sustain and recreate everydayness, it also serves in intensifying feelings of nostalgia and homelessness (Mahmoud, 2010), as well as increasing the gap between the migrant and the local communities. Likewise, linking with family can remind the person of what they are missing. This makes the migrants' attempts of re-establishing continuity through the strengthening of home ties an inherently ambivalent endeavour, since it reinforces the mode of liminality. For example, Sadek, a 27-year-old Sudanese refugee man in Cairo mentions that he is comforted when talking about his family, yet at the same time the thoughts are painful and add to his suffering (Mahmoud, 2010):

**Hala:** Is there anything that you like to talk about and which makes you feel better?

**Sadek:** Well, when I talk about my family, it gives me *ra'ha nafseyya* [psychological peace] but at the same time suffering. You feel that you have not done anything for them. You feel that you haven't fulfilled your duties. All of this is poured on you. It is both happiness and sadness. You are happy that you are remembering them, but at the same time [sad].

Boesch (1991) too emphasizes this ambivalence. He recognizes that the absence of home can deprive a person of its supportive elements, putting at stake a sense of familiarity and stability. At the same time, these supportive elements can also be constraining, exactly because of their taken-for-grantedness and stability. Using Robinson Crusoe's cave explosion as an example, he argues that the explosion functioned as a trigger and basis for Crusoe's self-transformation, which was regulated by his memories of his self prior to the explosion. For migrants

then, the absence of familiar and homely, while depriving them of support, can enable transformation and innovation, while the relatedness of this novelty to what is absent also allows preserving a sense of continuity.

### *Migration as Process of Becoming (An)Other*

As already indicated, migration is ultimately a transformative and developmental experience. It is a process of becoming (an)other. The rupture may become repaired through the maintenance of old ways of being. Yet through this repair the maintained old way of being becomes transformed. The old everyday practices become recreated and renewed. Although they may look the same on the surface, the process of rendering them the same has brought along change and transformation.

Thus, it is not only the re-establishment of the familiarity of the old home that can function as a bridge to the new way of being in a new environment. The event of migration itself can be seen as a necessary link in one's life project that meaningfully connects the past with the present and anticipated future. Continuation of one's life project, a meaningful way of changing and developing as a person that emerges from the experience of migration, can thus also provide the needed sense of sameness and continuity. Moreover, the redefinition of the self through actualizing new empowering identities in the new context may also foster feelings of comfort, recognition, and self-worth which are necessary for establishing the sense of being at-home, and its associated sense of identity (Mahmoud, 2010).

For example, some Sudanese refugees in Cairo have coped with their ruptured preestablished ways of being by gaining empowerment through acting as representatives of the refugee community; they have proudly redefined themselves as activists and helpers of fellow refugees (Mahmoud, 2010). Likewise, consider the case of Andres, who reinvents himself as a European person in order to make sense of the liminality of being between Britain and Estonia (Märtsin, 2009a, pp. 130):

**Andres:** I have probably developed, I don't know if it is European identity. [...] Being European means differentiating oneself from the rest of the world. It is not in the sense of differentiating, but in the sense of thinking and acting freely. I feel natural in this environment [in Britain/Europe]; it doesn't feel like going abroad. Or like, I go abroad from Estonia,

I go to Europe. It's not that, it's my environment. And I definitely want it to stay this way. And I am afraid that if I go there [to Estonia], perhaps I'll get stuck there, and all this will somehow remain closed.

For Andres then, seeing himself as European allows going beyond the distinction between Estonia and Britain. This higher-level self-definition brings the two environments together in a meaningful manner and allows Andres to rebuild his sense of continuity while simultaneously responding to his new experiences.

Migration is thus an inherently ambiguous experience, ripe with discontinuity in the midst of incredible sameness, filled with excitement and pain of finding and losing. The experience of migration not only makes us reconstruct our patterns of everyday life, but it also changes our perceptions of our original home, and our self-understandings, acting sometimes as a powerful trigger for redefining ourselves and becoming (an)other. Through contact with unfamiliar worlds, we gain knowledge and experience, and we change. This change takes place as we make the initially unfamiliar world our own, and push the foregrounded experiences of strangeness to the background as ordinary and known. Although this re-established normal flow of being becomes functional in a new context, it may become dysfunctional for other contexts, including the previously known and familiar home. This raises the question: how do migrants fit in when they go back home?

### Never At-Home?

And when they return to the place they were born, they will be, more than likely, in a different space and therefore remain, in a sense, in exile.

(Constable, 1999, p. 225)

Perhaps the best-known repatriation story in the Western world is that of *Odyssey*, who upon returning home, not only fails to recognize his land, but nobody recognizes him either (Papadopoulos, 2002). As we have indicated, migration inevitably brings with it change and reinvention, even if it entails recreating the familiar patterns of everyday life and retaining continuity and sameness beyond disruption. Furthermore, people and places change with or without migration. As Fried (2000) has argued: "If we grow and age in place, the environments in which we are born and reach adolescence are no longer the same as the places in which we

become adults." There is a deep and pervasive meaning to Thomas Wolff's title: "You Can't Go Home Again. Home is, indeed, never again!" (p. 198).

The difficulties related to repatriation thus stem from the inevitable change in the home environment as well as in the migrant's own way of being and sense of identity that have changed through the migration experience. This process of self-discovery and knowledge accumulation, including the renegotiated sense of being at-home and the reconstruction of the taken-for-granted everydayness may not be fully realized until an actual return home (Meintel, 1973). Homecoming is not only about the arrival in the physical environment, but more importantly about the re-establishment of all the meaningful connections with the environment, people, and with one's own way of being (Constable, 1999; Papadopoulos, 2002). Although the (maybe idealized) image of home sustains migrants during exile, it can collapse abruptly upon return (Maletta et al., 1989; Zarzosa, 1998; Habib, 1996; Ghanem, 2003). Repatriation is thus another migration, another uprooting entailing a separation from the physical location of the country of residence and its social networks.

The experience of Helena, a young woman from Estonia, who returned home after having lived half a year in England as an exchange student, illustrates the difficulties that homecomers may experience (Märtsin, 2009a, pp. 153):

**Helena:** During the last month I've been trying to [...] cope with being in Estonia. Somehow I still feel that this isn't my life or that I'm not able to live it anymore the way I used to (before leaving). I still feel that I moved on with my life while living in England. And coming back and staying here is like a step back in my life. A very difficult step. [...] I feel that I've changed so much and I don't want to go back where I started. [...] Sometimes I even feel as if I have returned to hell. I don't feel as if I'm at home. I miss the people and the things we used to do, and the life we used to live. [...] I've understood that there is nothing keeping me here. And after graduation I'd like to go and live somewhere else. [...] When you go to live in a new place, then you are kind of a blank page [...] You can create a picture of yourself and you like that new picture. And then you go back and you have to be who you were before. And it's so difficult to stay who you have become, because all the people are different and they see you the way you used to be. [...] It's difficult to explain, but this is

the way I felt. I moved on and then I had to move back to be able to be here [in Estonia].

Helena's description indicates how one's sense of identity is intertwined and emerges out of her joint activities with others in specific time and space contexts. When this background of taken-for-granted connections is not there anymore to support her way of being, she feels lost. The reinvented way of being seems thus not to be functional in the old/new environment and she needs to go through another cycle of reinvention to re-establish the meaningful sense of identity and sense of being at-home.

The connections with old and new social others and the views we think they hold about us—the meta-perspectives—can be simultaneously upsetting and pleasant, because of the feelings of nonbelonging that they evoke, as well as the admiration they may carry. The work of Graham and Khosravi (1997) for example indicates that political refugees, who return to their homeland after the end of a period of political turbulence or war, feel or are made to feel by their home communities that they abandoned the country at times of difficulty and therefore have no place in it upon their return, as in the case of Iranian political refugees in Sweden. And although the home communities see them as reminders of a painful past, returnees are hurt by the collective silence that they think characterizes the home communities regarding the events that made them flee (Maletta et al., 1989; Habib, 1996; Zarzosa, 1998). The situation for refugees can be even more devastating. Besides the fact that millions of refugees in the world never return home, the ones who repatriate find themselves in a war-devastated homeland that may not resemble the home they had in mind. This can certainly cause them tremendous confusion, ambiguity, and ambivalence. On the other hand, the refugees who spend years seeking asylum start painting a pleasant image of their future homes in the resettlement countries (Mahmoud, 2010). Many refugees come to the new host country with high expectations (Stein, 1981), only to arrive (if ever) in countries so foreign to them that they start experiencing the difficulties of being away from home all over again (see Holtzman, 2000).

Furthermore, some returnees come home having achieved a somewhat higher position in the social and economical ladder, of which they are proud. Bhatia (2007), for example, discusses how Indians living in the United States, are admired by their

home communities, for they “have made it.” Yet, while evoking pride, the changed socio-economic status may also evoke feelings of being an outsider in the general atmosphere of poverty and deprivation. Similarly, those migrants who have become acquainted with different gender roles in the new environment, for instance, return home to face the traditional gender roles that have now become alien to them (Striffler, 2007; Zarzosa, 1998). Migrants who have received years of education abroad may return to their home villages feeling disenchanting with the traditional worldviews they may find there (Salih, 1969/2002).

Constable's (1999) interesting study of Filipina domestic workers in Hong Kong shows how returning home has become an increasingly ambivalent thought for the women. On the one hand, home is where their families and personal histories are. On the other hand, the experience of working and living in Hong Kong, despite their low social status, has brought them a sense of independence, empowerment, and liberation. When they go home briefly, they often experience a honeymoon period after which their homecoming goes downhill. They start the confrontation with problems at home, with traditional gender roles and constraints. This makes their feelings about possibly returning for good largely ambivalent.

Repatriation then is another cycle of migration, accompanied by mixed feelings of alienation, disillusionment, estrangement, unfamiliarity, and sometimes guilt. As Hall (1987) put it, “Migration is a one-way trip. There is no ‘home’ to go back to” (p. 44). However, like migration, homecoming is an ambivalent experience full of feelings of pride and guilt, joy and shame, of wanting to belong, but also wanting to remain distinct. And again, there is the everydayness that unfolds under and beyond that ambivalence, which shakes one's security and comfort, functioning as an anchor in the process of recreating one's ordinary ways of being and turning change into the mundane.

### **Conclusion: Migration as a Dynamic, Dialectic, and Developmental Experience**

In this chapter, we attempted to explore the meanings of home and how these are affected by the experience of migration. Home has been characterized as a complex, dynamic, dialectic, and *experiential* phenomenon. We emphasized the *sense of being at-home* and the intertwined *sense of identity* as interlinked and mutually defining anchors of our existence

that become inevitably shaken and ruptured in the experience of migration. But when looking at how this rupture is experienced and managed, we have emphasized the inherently *dynamic, dialectic, and developmental* nature of migration, instead of seeing it as a unidirectional sequence from rupture to shock to coping and achieving a new stable being. Migration is accompanied by complex, contradictory, ambivalent feelings and attempts to cope with novelty against the backdrop of sameness, change in relation to continuity, and reinvention against the backdrop of the mundane. Similarly, we have tried to move away from the representation of home and resident societies as “hermetically sealed or mutually exclusive spaces” (Bhatia & Ram, 2001b, p. 3), but rather have seen them emerging as mutually defining aspects of our being through our lived experiences in and between them.

Another implication of the discussion in this chapter is the irreversible effect of movement on one’s sense of identity, giving rise to a mix of feelings in relation to one’s homeland and one’s sense of identity. The return home turns out to be significantly complex and dynamic, to the extent that it sometimes is experienced as yet another cycle of migration. Emphasizing this intertwined and mutually defining character of societies and dialectics of moving between them has thus taken us away from either/or, entity-like definitions, lists, and terminologies. And this is an important contribution that socio-culturally informed studies, including these reported in this chapter, have made to migration research.

Before closing, we should, once more, stress the idiosyncratic and highly personal nature of home, moving away from home, and returning home. Such experiences are not shaped by the *circumstances* of migration per se, but more so by the individual person in question. The diversity of circumstances surrounding the experience of home and movement, and all the complexities and tensions involved, may seem threatening to our comfortable way of seeing the world. Nevertheless, it is also liberating to know that migration can be an exhilarating experience, opening up new horizons for the person, and animating communications between and within cultures.

### Future Directions

But where does this conceptualization of migration as inherently dynamic, dialectic, and developmental experience leave us with our research efforts?

The research into cultural change and migration has in recent years moved away from seeing cultures as mutually exclusive entities and toward a more process-oriented approach, which seeks to understand how multiple cultural ways of being are held simultaneously in a constant dialogue by individuals who move between cultures. Thus our conceptualization of migration as a dynamic and dialectic process that entails simultaneous renegotiation of bonds with and meanings of home and new environment is becoming increasingly present in contemporary migration research. However, the third aspect we have emphasized in this chapter—the inherently developmental nature of migration—has been less central in this area of research. Therefore, we would welcome studies that take a fundamentally developmental approach to migration, seeing it as leading to change and growth alongside the maintenance of homeliness, and explicitly explore the double-binding experience of promise and threat of migration.

In our discussion we have already hinted at another possible alley of research—that of exploring the experiences of internal exiles. Migration research has traditionally been concerned with those groups of individuals who move between cultures or whose family has in the past moved between cultures. Yet in our multicultural, achievement-oriented class societies, the experience of social exclusion is not common only for migrants, but for many locals too. Exploring how people come to be foreigners in their own country, how they carve out spaces for themselves on the margins of the popular subcultures in their home society, and how they come to consider migration as a way of dealing with this feeling of being an internal outsider, are thus questions which are worth exploring further. Our conceptualization of migration as a dynamic, dialectic, and developmental experience that may begin far before the actual event of migration may be especially suitable for these kinds of studies.

Finally, in this chapter we have been concerned with the individuals’ experiences of migration. Yet the individuals carve out spaces for themselves in the context of societal and institutional structures, such as education, employment or health care, which is simultaneously enabling and constraining. Although this intertwining of migrants and institutions has not been our focus here, we would welcome studies that turn away from looking at migrants as humans whose being is rendered problematic by their belonging to a liminal space between cultures and societies, and toward exploring

institutional structures that constrain migrants in their efforts to cope with liminality. We would thus hope to see future studies that examine how societal structures and institutions enable and constrain migrants in imagining themselves forward in the new context. This type of analysis seems to be especially important in the case of refugees, yet can be equally useful for understanding the experiences of other migrants too.

## Acknowledgments

We are sincerely grateful to Irimi Kadianaki for her valuable feedback on the ideas presented in this chapter, many of which, we believe, have become clearer and more grounded thanks to her contribution.

## Notes

1. All personal names have been changed to preserve the confidentiality of participants.
2. The interviews in Märtsin's (2009a) study were conducted in Estonian, transcribed verbatim and later translated to English by her.
3. All the interviews in Mahmoud's (2010) study were conducted in Arabic, then translated and transcribed verbatim in English.

# Values and Socio-Cultural Practices: Pathways to Moral Development

Angela Uchoa Branco

## Abstract

The major claim I make in this chapter is that psychology must overcome the traditional tendency of considering the topic of moral development as an almost exclusive domain of cognitive-oriented constructivists. When we consult the literature about subjects concerning moral development, we easily find a vast amount of references that draw on constructivist assumptions, where Piaget's and Kohlberg's ideas still prevail. However, some authors are already pursuing explanations for moral development elsewhere, namely, taking a different, less reductionist, epistemological scientific approach. This alternative approach relies on a cultural and systemic paradigm that makes it possible to take into account the complexities of human development. As I analyze the issue from a cultural psychological perspective, I first refer to the conceptual origins of the constructs pertaining to the area, their roots spreading from philosophy and sociology. Then I highlight some of the main contributions of a few key philosophers, social scientists, and psychologists to the theme, however far from presenting an actual review of their interesting ideas. Last, but not least, I present to the reader my own contemporary elaborations on the topic, drawing on the resourceful contributions of theorists such as Shweder, Rogoff, Tappan, and Valsiner to come up with a perspective that I like to designate as a socio-cultural constructivist approach to moral development. From such perspective, culture, affect, cognition, and motivation (values) all come to the forefront of the analytic picture in order to investigate the ontogenesis and the cultural co-construction of moral development. The cognitive bias is therefore overcome, and the intertwined quality of affect plus cognition now plays a fundamental role in the emergence of specific moral motivations found in social practices and individuals' actions.

**Keywords:** moral development, values, moral motivation, cultural psychology, morality, ethics

*One of the most important consequences of separating the individual from the social world, and cognitive processes from affect, in moral psychology theories, has been a deep impoverishment in the treatment of morality as a fundamental, pervasive aspect of human functioning. Morality refers not to the abstract world of reasoning but to the world of actions and choices, having, at least potentially, deep social and interpersonal implications and involving both intrapsychic cognitive and affective mechanisms.*

—P. Paolichi, 2007

*L'egoisme est la racine de tous les vices; l'orgueil en est une  
branche. Lorsque l'orgueil grandit, il arrive un moment où  
l'individu deviant stupide.*  
—A. N. Philippe, 1902

Why did it take so long for psychology to actually address morality development issues at both motivational and interaction domains? Except for cognitive psychologists such as Piaget, Kohlberg, Blasi, and similarly oriented theorists, very few scientists in developmental psychology carried out scientific studies to make sense of how moral and ethical values develop along human ontogenesis. This has always surprised me as a researcher of human social interactions and relationships, since I started to investigate the roots of aggression and the promotion of prosocial development (Branco, 1989, 2003, 2009; Branco & Mettel, 1995). After all, ethics and morality are a major concern to human life and experience. Together and embraced with economy and politics, ethics and morality provide the rules and principles for social organization and human interactions that may, or may not, create possibilities for mutual respect and therefore the construction of democratic societies.

Consisting of omnipresent concepts applied to both personal, subjective, and collective social realms, morality and ethics are the two sides of a same coin, which consists of human daily life interactions and relationships, constructed and reconstructed at multiple different levels, from family to international domains. From a systemic perspective (Bronfenbrenner, 1989; Ford & Lerner, 1992; Thelen & Smith, 1998), moral concepts, beliefs, and socio-cultural practices mutually and continuously construct each other at all levels (from micro to macro to global), and they have fundamental effects on our everyday lives. The way moral values (or their absence) guide our actions and judgments in powerful ways can never be overestimated. This chapter is a contribution to the topic, and refers to some of the main thinkers that can help psychology to take a more proactive role in the investigation—and better understanding—of the development of ethics, moral values, and social practices that lie at the core of a just and democratic society.

### **Psychology and the Development of Moral Values and Interactions**

Although *morality* and *ethics* have always been of central relevance to philosophers and sociologists,

psychology tried to maintain the issue outside its boundaries, at a distance, for a long time. In general, psychologists' incursions on the topic were timid and outstandingly primitive or simplistic. When we think about Freud's limited ideas about guilt and identification processes during Oedipus unconscious experiences, and behaviorist reductionism sweeping away any idea of human intentionality and reflexivity—as it claimed for simplistic, mechanistic behavior conditionings—we wonder why the topic remained for so long as a matter seriously taken into account almost exclusively by philosophy and sociology.

Piaget's reaction to this unforgivable lack of interest, which prevailed in the twentieth century, offered a significant contribution to the study of moral judgment development in children. When he published his 1932 book on children's moral development, the prevalent idea held by most psychologists and by some important sociologists was that human beings *were not* responsible for the moral consequences of their actions. For psychoanalysts, irrationality triumphed over intentional reflexivity, and for behaviorists, as well as for Marx-aligned sociologists, one should mostly blame, respectively, the mother (Freud), the family (person's conditioning history), and poverty (Marx), which resulted from capitalist oppression. Miserable life conditions and experiences of criminals, and other moral offenders, left no room for intentional thought, reflexivity, or any sort of personal choice or decision whatsoever. This, however, sounded overwhelmingly absurd even for laypeople, and later on, new approaches to the issue—from constructivism to cultural psychology—proved that even though what happens to us has strong impact over our development, we are as well responsible, although in different degrees, for our own actions.

Although sociology, behaviorism, and psychoanalysis downplayed individual responsibility, Piaget and Kohlberg, inspired by Kant's philosophy, put a special emphasis on individual activity, autonomy, and responsibility. That opened a new era for approaching the issue of moral responsibility, but, as we will see, their contributions were constrained to a person's discourse and judgment regarding moral

dilemmas about what is right or wrong in complex social situations. Hence, this chapter aims at bringing the topic of moral development to discussion from a critical approach of mainstream psychology while assuming a socio-cultural constructivist psychological perspective that highlights the role of culture and constructive individuals. Some selected interdisciplinary contributions to the topic are discussed, aiming at a better understanding of human beliefs, values, and interaction patterns development along ontogenesis. I will particularly emphasize how values and interactions develop within complex situations where dilemmas concerning right or wrong become of particular relevance within contexts of everyday life experiences with peers, family, strangers, all the way to national and international affairs.

### **Ethics and Morality: Conceptual Issues**

Despite the confusion resulting from the etymology of the words derived from their Latin and Greek origins—both *ethos* (Greek) and *moris* (Latin) refer to “customs”—according to Hegel (1999) *morality* refers to the *personal* principles that guide an individual’s conduct, while *ethics* refers to the *collective* norms within society domains. In fact, this differentiation was also acknowledged by ancient Greek philosophers and thinkers, and Sofocles’ play *Antigona* reveals the major dilemma faced by the protagonist when she has to decide between abiding by personal, family cultural principles versus by collective (*urbes*), public, social norms. As she disobeys the last, she suffers a death sentence that was no easy task to the king, Cleonte, to pronounce. Ghosts whispering the faults of both choices haunted the characters all along the play. The masterpiece illustrates how people often need to make a choice between terribly conflicting moral rules concerning right versus wrong, and makes us wonder how such incompatible moral principles develop. Moreover, we need to understand how individuals abide by one or other principle, and actually choose among them depending on multiple and complex conditions and subjective interpretations. In fact, both personal and collective cultures (Valsiner, 1987, 2007) are too plural, contradictory and complex, and we should not be surprised to realize how complicated it is to be able to predict people’s choices and to determine underlying motives and moral principles.

What makes a value or an action moral or ethical (its social counterpart)? The answer lies in evaluations and actual behaviors regarding rightness, fairness, and justice in opposition to wrongness,

unfairness, and injustice, the antinomy relating to one’s own and others’ behavior concerning matters of justice, loyalty, and human welfare. Morality (going forward I will use the term “morality” to encompass its sociological complement, “ethics”) is directed linked to the historically constructed notion of human dignity and the value of human existence. The value and dignity assigned to human existence have their Western roots in Greek philosophy, flourished during Enlightenment and more recently became the core of humanistic philosophy. The major accomplishment of such values was the internationally approved Declaration of Human Rights in 1948 by the United Nations. At an abstract level, few nations and people disapprove the Declaration’s terms. However, as cultural psychologists would insist, problems arise when those general assertions need to be translated into real life judgments, decisions, and actual behaviors. In everyday life, state laws may conflict with cultural norms that may also conflict with subjective moral principles, giving rise to endless battles and controversies that very often are extremely difficult to negotiate or solve. This is the foremost reason why the topic demands a trans- and multidisciplinary approach. For example, social norms and rules mostly pertain to sociology; axiology and transcendence, universalism versus contextualism are matters of philosophical reasoning; and subjectivity, the development of social motivation and personal actions are certainly topics that demand efforts by psychology in order to shed some light onto the complexity of moral phenomena.

### ***Philosophical Roots and Contributions***

Evil or good, right or wrong? Humanity has long struggled with these issues. Plato and Aristotle, among Greek philosophers, while dedicating their insightful thoughts searching for the truth, also suggested, respectively, that truthful reason and happiness were the major goals in life. Virtues consisted of, particularly to Aristotle, a very important characteristic to be cultivated and promoted by humans.

The French philosopher Rousseau considered kindness as a human *natural propensity*, only corrupted by society with its norms, unfair relations, and the distortion of natural values of goodness and virtue. Rousseau emphasized the importance of a pedagogy oriented to promote good and prevent society’s negative influence over the developing child. *Émile*, his most famous book, does an eulogy to human inbuilt kindness, and promotes his ideas

about how the morality of goodness should impregnate everyday life, and bring about justice and fair politics. In his own words, “deep in our souls, there is an innate principle of justice and virtue with which, despite our own beliefs, we judge our and other’s actions as good or evil, and it is this principle that I name as conscience” (Rousseau, 1966).

Although Rousseau underlined innate, biological predispositions toward goodness, Kant relied almost exclusively on *reason* to establish the parameters for moral judgment and actions. His most well-known contribution to the discussion of morality was a maxim that he designated as the “categorical imperative.” Along his numerous philosophical writings this principle was stated in different ways, but could be shortly summarized as “you should act as though the principle governing your will and action may simultaneously serve as a principle orienting a general law” (Kant, 1994). Kant emphatically claimed for the supremacy of reason over any other argument. For the German philosopher, no ends justify immoral means, and human dignity prevails over any utilitarian goal. The utmost finality of human values and actions is the promotion of human worth and goodness, no matter how social utilitarianism defends the notion that social benefits overrule human individuals’ rights and transcendent condition.

Hegel (1999), however, did not agree with such ideas on what he considered to be a too abstract conceptualization of reason as the only guide for morality. Hegel considered that a dialectical balance was needed to contemplate both individuals and society. His proposal of a dialectical materialism creates a tension between the individual and society, and this overcomes the excessive idealism of his mentor. Morality—in his word *moralitat*—is now related to the subject, while the concept of ethics—*sittlichkeit*—refers to collectivities such as institutions, society, and the state itself. The dialectical tension created by the individual-society polarity, though, needs to be comprehended assuming that individual morality is always socially mediated, and social ethics is permanently enriched by people who live within the social group or community. There is no person without society and no society without persons. His dialectical ideas, hence, will further contribute to the dialogical and inclusive approach of contemporary cultural psychology, which cannot conceive morality and ethics as different, exclusive categories but, *au contraire*, they are conceptualized as distinct but subject to “inclusive separation”

(Valsiner & Cairns, 1992). In lay words, the two sides of a same coin, except for these sides are profoundly interconnected although distinct from each other. Taking into account that Hegel’s tendency was toward the social side, for him morality issues are sort of absorbed by *sittlichkeit*, or ethics.

Marx does not particularly address the subject of morality or ethics. His powerful emphasis on historical materialism highlights history and economy to make sense of politics and sociology. In sharp contrast to Kant, Marx justifies the means when the goals are considered as good, just, or socially desirable. Weber criticizes this positioning, and reconsiders the importance of also taking into account the means, for human dignity must be preserved, even when radical changes are socially necessary to provide for justice within society. On the other hand, Durkheim (1973) takes an extremely positive and, I would say, even naïve perspective. As he sees society like the only legitimate parameter for morality, he reduces this fundamental dimension of subjective and social experience to a simple function of the social system. Everyone should then submit to the system and learn the desirable moral behaviors that society expects them to learn. Later on, they have to act toward each other according to the mechanisms of what he designated as “organic solidarity” (Durkheim, 1973).

Last but not least, I would like to refer to Habermas’ bright ideas concerning discursive ethics (Habermas, 1990, 1991). The concept of a *discursive ethics* is significantly meaningful, particularly from contemporary scientific and philosophical perspectives. This concept, intrinsically linked to his Theory of Communicative Action, allows Habermas to substitute Kant’s epistemic and moral subject by a heuristically productive category of discursive *intersubjectivity*. Now, the intellectual effort to make sense of what truth is—or may be—is not taken by a singular rational individual but, instead, it is taken by the participants of a fairly negotiated discourse, constructed through intensive and democratic communication. He argues for the restoration of spontaneity, sociability, solidarity, and cooperation as the necessary ground for communicative action, which he thinks is more important than instrumental action (Freitag, 1997). Although Habermas’ arguments sound much more in tune with the new, semiotics- and complexity-oriented paradigm, they suffer from a significant weakness resulting from the naiveté of their own assumptions. Society, and consequently social practices, are characterized by

cultural historical power games that are a fundamental, central aspect of negotiations. The actual possibilities for anything like spontaneity or fair negotiations are not substantial. In other words, discursive ethics resulting from intersubjective communication must always take into account those power games, and the co-construction of morality needs to be considered as a permanent process of negotiation and change that weighs up the role of unequal communication conditions.

### **The Appropriation of Moral Development by Cognitive Reductionism**

Piaget's and Kohlberg's interest on the psychological study of moral development allowed for knowledge construction on a specific dimension of moral development, namely, moral judgment or moral reasoning. Even though their ideas and work advanced our knowledge when they used the categories of heteronomy and autonomy to describe the general mindset of developing children—with heteronomy preceding autonomy in ontogenesis—the notion of universal stages, so well-appropriated by Kohlberg, is hard to sustain, even if we constrain our analysis just to cognition. The role of language, so brilliantly emphasized by Vygotsky (1978), is however excessive in the establishment of Kohlberg's six stages of moral development— progressively arranged along ontogeny in two levels categorized as preconventional, two as conventional, and two as postconventional levels of moral development. Kohlberg, though, was not bothered about how language games could determine some of the nuances between stages, and he did not take that into account. It turned out that more advanced stages à la Kohlberg are usually inferred from mostly linguistic, discursive degrees of sophistication. In fact, we can say that Kohlberg reassured the Platonic faith in the power of the rational good later assumed by Kant (Kohlberg, 1970, 1984), namely, when a person knows what is right, s/he will necessarily struggle to act accordingly, for reason prevails over any other human characteristics. Kohlberg goes even further in his strong beliefs linking rationality and morality. For him, only actions resulting from rational choice—cognition plus intention—could deserve the label of a moral action. Bergman (2004) reminds us that “in Kohlberg's view only a judgment that an action is right or obligatory makes that action moral” (p. 25). In short, Kohlberg's extreme rationalism led him to conclude that moral actions are almost an inevitable expression of high moral

judgments. The amount of counter-evidence against positive correlations between superior cognition and/or language skills, and moral actions, though, is definitely undeniable (Kurtines & Gewirtz, 1991). Nuremberg court reports very well show the independence between cognition and morality in astounding ways (Arendt, 2000).

Ratner (2002), a ferocious critic of idealism and cognitivism, argues that:

Kohlberg's abstract stages disregard and obscure concrete moral values and reasoning. They collapse vastly different values in common categories that promote the false appearance of similarity. They are impoverished, incomplete descriptions of people's real moral values and reasoning [ . . . ]. Subsuming [ . . . ] responses in any of Kohlberg's stages or categories [ . . . ] expunges them of interesting, important, concrete views of life and fosters the erroneous impression that they are 'basically' similar. In fact, the specific values and views that constitute the subjects' moral reasoning are far more interesting, important, and real than notions such as postconventional reasoning.  
(pp. 191–192)

Notwithstanding, the amount of influence and research generated by Piaget and Kohlberg cannot be overestimated. Even today the great majority of research and theoretical literature in psychology about moral development is based on or directly related to their work. Books and research reports related to their cognitive-constructivist perspective continue to proliferate and do represent the vast majority of literature in psychology concerning the theme (Daniel, Lapsey, & Narvaez, 2004; Kurtines & Gewirtz, 1991). As this chapter does not intend to do a review on the subject (easily found elsewhere, see Damon & Lerner, 2006; Killen & Hart, 1995), I will particularly speak to a couple of recent theorists that still address the complex issue of moral development from a cognitive-constructivist theoretical framework.

### ***The Persistence of Cognitive Reductionism: Contemporary Psychologists on the “Moral Self”***

One of the most well-known theorists related to a constructive, cognitivist framework is Augusto Blasi (1983, 1990, 1999), although he does advance the study of moral development beyond the usually narrowed investigations of narrative judgments typical of Kohlberg's tradition. However, Blasi is still

too faithful to Kant's legacy. The innovation introduced by him and other similarly oriented psychologists (as we will see below) is the role of personality and self in relation to morality. They also refer to the notion of identity, not with a social psychology connotation, but as a concept that sounds closer to the clinical psychology vocabulary.

For Blasi (1999, 2004), we agentially structure our motives and desires, namely, we structure our will, and then begin to establish our identity. The action is therefore *chosen* by the subject according to his/her freedom of will. Hence, each person has a free choice that determines, in significant ways, the shaping of his/her own identity. The bet on rational choices, however, are too unrealistic, as contemporary psychology progressively demonstrates, for instance, by acknowledging the role of affect, emotions, nonverbal and unintentional motives as legitimate and important factors contributing to the constitution of the individual's motivational system. But Blasi does not go that far. He states that morality results from a successful integration of personality, and it is granted by the need for self-consistency underlying moral choices. According to him, if I am a moral person, a rational logic syllogism will oblige me to act morally in order to reduce dissonances. Therefore, even if there are different motives at work on a certain situation, the moral self, consisting of a deep motivational structure, will prevail and lead the person toward moral actions. After all, betraying oneself is something unthinkable, according to the author.

For Blasi, moral understanding needs to precede moral identity, and the logic sequence requires that moral understanding leads to moral identity that leads to moral action, because of the necessity of identity integration of one's personality (1990). In addition, "self-consistency [is] as a central tendency in personality organization" (Blasi, 1983, p. 201).

Nucci (2004) criticizes Blasi, arguing that his model pretty much suggests the existence of a kind of "homunculus" who freely decides to be consistent. Affect, Nucci says, is as important for morality as reason and identity are, but this issue is not quite elaborated by the author. Even though he attacks Blasi's reductionism, evoking the complexity of human personality, he still believes and overemphasizes self-consistency and the idea that a moral self needs to be nurtured since childhood. Without disagreeing that a moral self cultivated from early childhood has a substantial chance to deeply internalize moral values, I insist, from a developmental

perspective, that a moral self may emerge later through meaningful experiences (Branco, Branco, & Madureira, 2008).

Damon (1984; Damon & Lerner, 2006) asserts that morality and self are separate conceptual systems, which are only later integrated in ontogeny. He argues that stages of moral development, as proposed and studied by Kohlberg and followers, are not related to moral action. Damon suggests that true personological dynamics need to be taken into account, and again refers to morality as being a central aspect in a person's identity that can provide for consistent moral actions.

Colby and Damon (1993) studied 84 individuals—called as exemplars—whose self was deeply impregnated with morality principles. The authors were able to demonstrate that self and morality can lead to "spontaneous actions," and therefore they concluded for their unity, namely, moral selves will behave morally. It seems to me that claiming for "unity" is perhaps too much, because we all know that such a perfect consistency—moral selves will always behave morally—cannot be true. In case they mean moral selves *tend* to behave morally, then it is too simplistic and obvious. Subsequently, the authors leave out of the equation the major role of contexts (with their numerous variables and conditions) and competence (i.e., the ability to act in effective ways). Bergman (2004), for instance, refers to the complexity of human motivation, affirming that even activists who work hard for common good are also motivated by ambition, pride, anger, need to please others, or even fear. Moreover, Colby and Damon (1993) do not examine their exemplars' specific motivations, and by attributing their actions just to blind obedience to abstract moral principles, the authors provide us with a perfect example of reductionism. Another shortcoming of their position resides in the fact that their model only describes the existence of significant integrations between self and morality, but it does not shed any light on how such integration does develop along ontogeny.

Although researchers as Wren (1991) propose simplistic linear schemes such as moral thinking generating moral motive, which in turn generates moral action, Lapsley and Narvaez (2004) present a much more sophisticated model. Although cognitively biased, their model suggests the inclusion of the *aretaic* dimension, that is, the dimension where virtues and values are taken into account. They affirm, among other ideas, that more recently we can

observe a growing interest in the relations between moral rationality and selfhood, moral cognition and personological processes. They criticize Piaget's biological and structuralist bias (as in morphological maturation plus the concept of stages), and underline the fact that both Piaget and Kohlberg showed no interest in the self, moral motivation, or identity. As Piaget and Kohlberg said nothing about virtues, they put aside a whole important dimension of moral development. Lapsley and Narvaez (2004) then go a step ahead, but still have difficulties to explain the evidence against consistency in moral behavior presented by the so-called moral individuals. Data allow us to confirm the existence of some coherence when self characteristics are kept in mind; nevertheless, cross-situational variability concerning moral actions is certainly undeniable.

Lapsley and Narvaez (2004) refer to the two major variances of morality: justice and care. But again the voice of justice prevails, since they, too, claim for a social-cognitive theory that demands the examination of the "moral personality in order to understand moral functioning". Most of the constructs they use in their arguments are cognitive constructs like scripts, schemes, strategies, competencies and so on. They agree with their colleagues that personality is "organized into coherent, integrated systems that impose constraints on the range of possible configurations" (p. 196). They go on stressing self-coherence while claiming that goal systems "structure the organization of the cognitive-affective system and influence the perception, selection, and interpretation of various contextual settings" (p. 196). However, contradictions can be found when they say that "schemes filters perception" and that "there is now mounting evidence that much of our lives is governed by cognitive processes that are tacit, implicit, and automatic ..." (p. 197). Now I ask: Where did the previously mentioned construct of "affect" by the authors go? Again, we observe that the affective dimension disappears when they assert that a "social-cognitive approach emphasizes the central importance of self-processes, personal goals, and life tasks that give meaning to one's motivated behavior and purposive striving" (p. 197).

Unlike cognitivists, contemporary psychology is increasingly pointing out at the blending of affect and cognition (Ford & Lerner, 1992; Rosa, 2007; Valsiner, 2007). If affect guides selective memory retrieval, filters perceptions and sensations, as well as channels the person's attention for reflective

appraisal and response, it does play a major role in human psychological functioning, not just regarding the development of morality. Affect and cognition are in fact interwoven into a single process of unification, and their distinction for analytical purposes contemplates the principle of inclusive separation earlier mentioned in this chapter. In general, though, to most theorists studying moral development the reference to affect comes easily, but it is better spoken out than actually meant.

To conclude, cognitive-constructivist perspectives end up bringing forth a network of ill-defined constructs such as moral motives, moral understanding, moral identity, moral self, moral action, self-reflection, etc., as though all were different things, but quite often one translating into others, all claiming for intentionality, reflexivity, integration, and unity. *Such unity and integration, though, is impossible* from a systemic perspective, for it demands a *dialogical* framework from which development and change can actually occur, and innovations can substantially emerge as a result of multi-causality, plurality, and interdependence.

Turiel (2002) has also elaborated on the topic of morality, including dimensions such as care and welfare in addition to justice and human rights. Hoffman (2000), on his turn, has emphasized the role of empathy together with cognition, but his stages for empathy development typically follow a cognitivist tendency. But neither takes into account the existence of culture as a powerful canalizing force driving moral thinking and actions in specific contexts.

In short, why does the study of moral development need to free itself from cognitivism? First, there is no universal developmental pathway for moral development as cognitivists want (Cole, 1998). And second, Staub (1992, 1993, 2003), with his bright work on the roots of anti- and prosocial behavior, provides us with plenty of evidence that demonstrates that *extreme violence is often perpetrated by individuals with very sophisticated cognition* (I recommend his book on the origins of genocide, Staub, 1989).

### **The Turning Point: Integrating Historical-Cultural and Constructivist Assumptions from a Systemic Framework**

*... to develop is not to become more rational. Instead, [the individual] enters a new frame of mind about self-other relationships.*

(Paolichi, 2007, p. 570)

As many theorists dedicated to the scientific study of human psychological phenomena have pointed out, human development cannot be addressed by linear, reductionist, or simplistic approaches anymore. *Au contraire*, the adoption of a systemic perspective is a *must* to make sense of the complex, dynamic, and processual nature of human development. Psychological phenomena can only be understood from an inclusive framework that considers multi-causality and interdependence as the epistemological ground for theoretical elaborations, the phenomena being characterized by permanent dialectical tensions between process-and-structure and individual-and-culture tensions, among other “inclusive” dualities (Ford & Lerner, 1992; Morin & Prigogine, 2000; Schnitman, 1996; Thelen & Smith, 1998; Valsiner, 2007). Contemporary all-encompassing systemic approaches have definitely overcome functionalist interpretations of reality, and cleverly take a process perspective to study human phenomena according to its multifaceted, complex nature. Systemic perspectives also emphasize the interwoven flow of time dimensions along change and stability processes, which consist of the main characteristics of open, multiple, interactive, developing living systems. Living systems are dynamic but also hierarchically organized in web-like networks, which overlap and intermingle with each other along irreversible time. Hence, systems exist at different though interrelated levels, and one level—the person—cannot be fully understood without the analysis of other levels as well—organized contexts for human and societal development constructed over a history of interdependent cultural contexts.

When psychology finally realized that its object of study was complex, but still analyzable in terms of general laws and regularities, it started to investigate human *experiences* in order to identify and analyze meaning-construction processes (Bruner, 1997), for those lie at the core of psychological phenomena occurring along social interactions within culturally oriented contexts (Valsiner & Rosa, 2007). The same applies to moral experiences concerning right and wrong regarding our relations with others, ourselves, and the world. From such a viewpoint, it is not difficult to understand why morality and ethics are phenomena simultaneously characterized by both convergences—related to our singular ecological status in the animal kingdom—and divergences, resulting from our unique cultural

and sociopolitical histories within particular environments.

Meaning-making processes are absolutely central in determining the quality of our interactions and relationships, and in studying the moral dimension of our collective and individual experiences. However, meaning-making processes are not just constrained to language and cognition as most semiotics experts end up suggesting in one way or another (Leeds-Hurwitz, 1995; Pearce, 1967; Saussure, 1966). The roles of emotions, body, and affect are increasingly acknowledged and taken into account by contemporary theorists (Lewis, & Haviland-Jones, 2004; Rosa, 2007; Valsiner, 2007). Hence, the scientific investigation of moral experiences and development requires multi-causality approaches that certainly challenge those who find it easier to emphasize this or that aspect, such as cognition, intention or behavior, in order to explain the moral dimension of human beings.

Processes involved in meaning construction, viewed from a socio-cultural *and* a constructivist perspective, are numerous and relate to each other in extremely complex ways. Such processes take place within and throughout different levels of open-ended systems—i.e., individual *and* social organizations (e.g., Branco, 2001, 2003; Valsiner, 2005, 2007). Aspects such as cultural-historical frameworks, specific culturally structured contexts and social interactions, situational characteristics, communication and metacommunication dynamics, individuals’ subjectivities and goal orientations, all play a fundamental role in the co-construction of *meanings emerging within particular social activities*; consequently, all play a central role in the emergence of particular *experiences*.

The encompassing view of semiotics (Rosa, 2007; Valsiner, 2007) brings together language, affect, and body as essential parts of meaning-making processes. Consequently, this perspective prevents the naïveté of one-dimensional, biased approaches to issues of morality, ethics, and their development, for now the subject can be addressed from a broader and system-like perspective compatible to its complex nature.

One important controversy on moral issues is the pseudo-dichotomy: universalism versus contextualism (Lourenço, 1998). Why is it a false dichotomy? To start with, our status among biological species constrains our options *and* demands a couple of general principles to grant our own survival as a social species. Even though general principles

are still object of endless negotiations, some wide-ranging laws—such as reciprocity, mutual respect, and certain degrees of tolerance toward diversity—are a definitive “must” for global survival; otherwise we may end up blowing ourselves up in the near future. On the other hand, because of *diverse* reality conditions, we developed within very distinctive geographical and cultural-historical contexts, characterized by different sets of norms and rules that emerged and developed to grant each group’s survival. The result is diversity, namely, multiple ethnic, social, and individual singularities.

Globalization has acted upon cultural histories and human diversity according to an agenda toward hegemony. But such agenda is a dangerous one, because it presupposes the existence of an actual balance between democratic nations, and this is a huge pitfall from a capitalist perspective. It is very difficult to envision societies and people sharing the same degree of power and quality of life—a tricky culture-dependent category! Even though desirable, people need to be alert concerning the possibilities for just and fair international sociopolitical contracts. New trends are always possible but great efforts will be needed to promote changes toward a progressively better planetary balance among different cultures and societies.

The important aspect we have to consider from a scientific viewpoint (Wilson, 2007) is that *diversity is an essential source of innovation and development*, and therefore needs to be preserved. Thus we conclude that contextualism indeed makes sense. This is certainly true, but human survival with dignity also demands the existence of some basic general principles of mutual respect, and respect for the intensively negotiated conditions for preserving human rights and worthiness. The universal declaration of human rights here plays a vital role. The acceptance of a broad ethic/moral spectrum can allow individuals and societies to abide by negotiated laws of justice and efforts for mutual understanding. Therefore, it is possible, although not easy, to rely on constant negotiations over the dialectical tensions resulting from universalism *and* contextualism, in order to establish ethical principles and norms for social regulations among humans. In other words, biology and culture do *not* necessarily oppose each other, and may jointly operate toward continuous negotiations allowing for both convergence and divergence—i.e., both shared basic moral values *and* multiple expressions of moral diversity.

## Cultural Approaches to the Study of Moral Development

Building on Vygotsky’s legacy concerning the cultural-historical roots of human development and the role of language and contexts to explain complex psychological phenomena, many theorists have elaborated models to understand human development in relation to meaning-construction process. As Bruner (1997) brilliantly puts the subject, meaning-construction processes are indeed the major topic to be investigated by psychology. Among those who have studied the moral dimension of development, I should mention some authors whose contributions are of particular interest. Shweder deserves a special place for his insightful ideas concerning the cultural construction of morality along everyday life experiences (Shweder, 2001; Shweder & Much, 1987). His most interesting work (Shweder & Much, 1987) nicely demonstrates the inaccuracy of Kohlberg’s research on moral development based on his six stages theory.

### *A Case against Ethnocentrism*

Analyzing their interview with a Hindu man called Babaji, Shweder and Much (1987) show the impossibility to follow Kohlberg’s orientation regarding the interviewee’s classification. Where a cognitive-constructivist approach would suggest classifying Babaji into a lower moral judgment category—conventional stage—Shweder and Much disagree, and denounce Kohlberg’s ethnocentric classificatory system as consisting of a pitfall. Why? The answer is that in Hindu culture, acts such as robbery are condemned not only from a social-contractual perspective (conventional reasoning), but from a much broader, universal, spiritual, and existential framework related to the meaning of life (postconventional reasoning). Their analyses bring forth the major role played by *culture* on topics like morality and ethics, and such deconstruction of the cognitivist teleology expands our knowledge beyond the ethnocentric boundaries that previously claimed for universal patterns and standards for moral development and evaluation.

Shweder and Much (1987) consider everyday life interactions as the relevant site to study moral development. They also claim for the “objective” possibility to assess and analyze meanings when the researcher can conjecture and distinguish between valid and invalid inferences based on prior knowledge of culture, context, relationships, and practices. The acknowledgment of divinity dimensions led Shweder, Much, Mahapatra, and Park (1997)

to identify three different types of ethics, which are not mutually exclusive but have different priorities depending on culture and history: autonomy, community, and divinity. The distinction of different types of morality is also stressed by Gilligan (1982; Brown, Debold, Tappan, & Gilligan, 1991). She criticizes most authors, particularly Kant's affiliates, for the exclusive consideration of reason and justice in detriment of care and loyalty. Even though her first evidence that women and men were different—caused by general dispositions to prioritize justice over care (men) or care over justice (women)—was later questioned (Lourenço, 1998), her work reveals the complexity of morality, and the existence of principles other than justice, which participate in the dilemmas over right and wrong regarding human experience.

### **Radical Culturalism**

A typical representative of a radical cultural positioning is Carl Ratner. Ratner's cultural perspective (2002) is strongly based on Activity Theory, therefore being consistent with the views of Leontiev's ideas, also shared by some contemporary fundamentalists. Ratner compares the American and Chinese senses of love and value, and finds that the way each culture promote one's responsibility for each other is always based on the quality of cultural activities mostly observed in specific cultures. He invites researchers on the topic of morality to investigate the cultural activities and concepts that mediate and organize morality in specific contexts. Ratner (2002) provides and analyzes various examples such as abortion (i.e., whether the embryo has a status of person), premarital sex, gender roles, etc. According to him, "cultural concepts stipulate which social relationships between individuals deserve to receive help as well as the kind of help that is morally appropriate" (p. 187). He argues that prostitution can be considered as moral in some cultures because it is a voluntary contract between individuals, with mutual agreement, and does not involve dishonesty. Therefore, it is a commodity exchange from a capitalist perspective, based on the buy-and-sell logic of free markets. This may sound preposterous or weird for some people, but the same dilemma emerges when students buy the authorship of manuscripts or dissertations from someone willing to sell them. Would consensual contracts and free-market rules still apply?

Other problematic or dilemmatic issues arise: some people think pornography is innocuous for

children. Also the case of slavery is worth analyzing: today it is condemned, but for centuries it was seen as perfectly moral and acceptable by most civilized nations! Ratner thus has a very good point when he convincingly shows how history and culture in fact determine what is, or is not, classified as moral or immoral along sociohistorical time.

In addition to denounce the biased, too abstract, and noncontextualized cognitive-constructivist theories of moral development, Ratner also criticizes Gilligan (1982) for not analyzing actual cultural aspects of morality, even though she investigates gender, situations, and feelings. Other narrativists, as Tappan (1992), also do not escape from Ratner's sharp critiques. According to Ratner (2002), just referring to and investigating people's narratives for "recurrent words," "shifts in narrative," and "emotional resonances, inconsistencies in styles, the use of first, second or third person voice, turn taking etc [all end up to] obfuscate the cultural content of moral belief" (p. 192). He goes on criticizing the "reiteration compulsion" of discursive psychologists like Edwards (1999), and also Gee (1999), when he states that "most work in discourse analysis, for example, focuses on linguistic (semiotic) properties of statements and ignores cultural concepts and activities that are embodied in the statement's content" (Ratner, 2002, p. 128). He alleges that most discursive psychologists do not add anything to the mere words pronounced by research participants, consequently their studies well illustrate an individualistic approach, instead of an actual cultural approach to complex psychological phenomena. To further emphasize this aspect, Ratner quotes Sobel's appraisal of society's excessive individualism when he states that:

... at the outset of the 18<sup>th</sup> century most people seemed to regard themselves as having porous boundaries and as part of wider or 'we-self.' [ ... ] By the close of this period, the ideal white male was individuated, self-concerned, and determined to succeed in a rapacious market economy."  
(2000, p. 4, in Ratner, 2002)

In a few words, Ratner is a very convincing advocate for a cultural approach for the study of morality. The major problem with Ratner, as I see it, is that based on such extreme denial of individualism he also denies individuality as well as the stance of self and personal agency, showing an explicit contempt toward individuals.

Even targeted by Ratner, Tappan (1992, 1997, 1998) can be pointed out as an author who

represents, under the umbrella of cultural psychology, a narrative approach to the study of moral development. In his investigations, he stresses the significance of language for meaning-creation and attribution processes that pave the ground for moral judgment and action. No wonder he also presents and actually finds a broad range of variability and diversity while studying persons belonging to different cultures, particularly members of different social classes.

According to Ratner (2002), many qualitative researches are too abstract and do not objectively (concretely) refer to specific values or beliefs, namely, they just count frequencies of certain words, therefore the results are too general to add any innovation to scientific knowledge about psychological phenomena. In defense for a cultural approach that makes qualitative studies of psychological phenomena meaningful, Ratner (2002) states:

A cultural psychological analysis transcends the subject's knowledge. The subject is aware of details of her psychological functions: however, she is not aware of how these details reflect cultural activities and concepts. [ . . . ] We may say that a cultural psychological analysis goes beyond describing manifest psychological themes that individuals are aware of and delves into latent cultural themes that pervade individuals' psychological phenomena but remains outside the individuals' awareness. (pp. 178–179)

Therefore, the task of cultural psychology is “to remain faithful to what the subjects say, yet transcend the literal words to apprehend the cultural meanings embedded in the words [ . . . ]” (Ratner, 2002, p. 179). Shweder, very likely, would not disagree, since that is also his approach to moral investigations. However, Ratner's good ideas do not necessarily imply that he utilizes a flawless research design. The project he proposes to investigate children's moral beliefs (Ratner, 2002) presents many methodological problems because of excessively inductive instruments for obtaining children's narratives, for example.

### ***Social Practices and Meaning Constructions***

Another theorist who provides an insightful contribution to the topic, although she does not use the concept of morality, is Barbara Rogoff (2003). She analyzes phenomena related to the diversity of social norms, practices and beliefs in different

cultures, and her definition of human development emphasizes progressive degrees of individuals' participation in cultural practices. She draws on results of many anthropological studies and she herself develops interesting investigations on socialization, among other issues. Rogoff presents and thoroughly discusses the concept of social participation (Rogoff, 1990, 2003) to explain human development in specific cultural contexts. In her examples, she informs how some cultures, for instance, morally value discreetness and humbleness while others value bragging and arrogance; also, how some treasure autonomy while others stress interdependence. In a similar vein with the work of Margaret Mead (1937), Rogoff draws attention to huge contrasts existing between cultures that morally value sharing and cooperation, in opposition to others that proudly promote individualism and competition. In short, she provides substantial evidence for culturalism and contextualism regarding the construction of dependence versus autonomy, individualism and collectivism, and many other apparently antagonist practices and values, some of them qualifying to participate of the domains of morality and ethics.

Paolichi's (2007) socio-cultural viewpoint calls our attention to the other side of the dialogical relation between culture and individual. He underlines the *agenciality* of the self (i.e., human beings need to be seen as reflexive agents). He stresses the action of intentional selves in intentional worlds. Narratives should, then, be analyzed to find meaningful, plausible, and convincing evidences (as Bruner suggests, 1997) for moral motivation. Paolichi (2007) concludes for the inexistence of hierarchically fixed system of principles, and argues for the possibilities of different interpretive frameworks. He elaborates on affect and motivation but he neither expands his analysis on these topics, nor highlights the role of power relations and the existence of different values systems within a same society (Bronfenbrenner, 1989).

### **Moral Development from a Cultural Constructivist Perspective**

From a cultural constructivist framework, the foundation stone for the ontogenesis of moral values, practices, and actions consists of a true amalgam of culture, motivation, and affect. This means that the actual ground for the development of ethics and morality lies in the historically contextualized blend of culture, affect, cognition, and motivation, which gives rise to a permanent and *mutual co-construction*

*of values and human actions within social practices.* This perspective does not privilege either the domain of semiotics—or meaning-construction processes, or the domain of social activities and practices. It conceives culture as the result of a historical mutual constitution between human social practices and values, and also overcomes the dichotomy between culture and individual. Social practices canalize values that promote social practices and so on and on. Culture canalizes individuals' trajectories; and active, constructive individuals promote cultural changes. This happens even though not according to a deterministic approach, for indeterminacy also plays a fundamental role in the development of open systems, hence, personal and social developments (Lyra, Fogel, & Valsiner, 1997).

Because of the centrality of meaning co-constructive processes, and the conceptualization of hierarchically organized—though dynamic—networks of meanings, the study of everyday communication and metacommunication processes is necessary to make sense of how ethics and morality evolve in determined contexts. Values, beliefs, and goals consist of the core of human motivational system, which develop according to experiences along microgenesis and ontogenesis. Values are conceptualized as those particularly affect-laden beliefs (Valsiner, Branco, & Dantas, 1997), which offer more resistance to change because of their major function in providing a sense of continuity to human self-development (Branco & Madureira, 2008; Branco, Branco, & Madureira, 2008; Branco & Valsiner, in press). However difficult, though, even values can eventually change, since the whole system is open and therefore deeply meaningful experiences may radically transform developmental trajectories (Soares da Silva, 2003).

Scientific knowledge construction has mostly relied on *episteme* (related to Plato's notion of truth), but a growing number of theorists claim that *phronesis* (related to Aristotle's ideas on wisdom) should occupy an equal status concerning knowledge construction. Human experience transcends and goes beyond cognitive theories. For too long, developmental psychology constrained itself, as mentioned before, to the study of language and cognition. When contemporary studies show how affect and motivation are central for meaning-construction processes then a new venue is open for actual consideration of all of human dimensions as parts of a wholesome development (Branco, 2009). Paolichi (2007) argues for the centrality of an interpretation

framework populated with semiotic processes to understand morality, and alerts about the existence of conflicting, ambiguous messages and values that call for a detailed and profound analysis.

According to Barth (1993), contemporary authors have little to offer about values, in contrast with those of the 1950s and 1960s, and this is why we need to bring a constructive and dynamic conceptualization of values to the forefront of theoretical psychology (Branco, 2006; Valsiner, Branco, & Dantas, 1997). The inference of values and their role in moral development, though, can only occur after complex analysis and interpretations of observable actions, cues, and strategies mostly found in communication and metacommunication phenomena (Branco, Pessina, Flores, & Salomão, 2004; Fatigante, Fasulo, & Pontecorvo, 2004; Fogel & Branco, 1997; Lavelli, Pantoja, Hsu, Messinger, & Fogel, 2005).

Last but not least, it is worthwhile to discuss the issue of moral intentionality as a “must-be” characteristic of moral action. The stress put on moral intentionality may be fallacious, and it derives from the excessive emphasis on morality as cognition. No doubt intentionality is a fundamental ingredient for moral action; however, such intentionality does not need to be explained in terms of morality. The point here is that many people can behave in “moral” ways without being capable of presenting a nice discourse on the “moral” quality of their own behavior. As moral values and actions are differently internalized by different people, such awareness is definitely not necessary to qualify the person's action as moral. To keep this in mind helps us to free morality for good from cognitive and linguistic abilities found in discourses about sophisticated reasons for one's own actions. In short, less-educated people can indeed be exceptionally moral.

### ***Virtues as Values***

In relation to moral values, there is a topic rarely mentioned by psychology but very promising to be investigated: virtues as values, namely, the arataic dimension of moral development (Camps, 2005; Galán, Águila, Blanco, Camps, et al., 2005; Lourenço, 1998).

Virtue is a psychological category that refers to the notion of excellence in respect to moral standards (Rosa, 2007). According to Camps (2005), it is not right to affirm that in order to bring virtue to the forefront we need to go back to small communities where a belonging feeling is easier to develop,

and where easier identification among individuals makes possible their mutual recognition. The author criticizes the myths related to the notion of virtue, and proclaims that it is not necessary that people share a same language, religion, nor ethnic background to be able to understand that solidarity, mutual respect, tolerance, and responsibility are virtues that all individuals, no matter their social position, must strive to accomplish and develop. She goes on, saying that:

... the ethics of principles or pure duty is not enough, [...] the procedural ethics is insufficient: it is necessary to complement it with an ethics of virtues. Otherwise, we forget or ignore that democracy literally means 'people's government,' *demos*' government. The construction of *demos* must be one of the objectives of the ethics of our time. (Camps, 2005, p. 28)

Camps wonders what sort of virtues our democratic societies actually need, and concludes that human dignity, independently of time or place, will always require individuals and society to pay allegiance to virtues (or values) related to universal duties and rights. Without acknowledging the existence of basic human duties and rights, directly linked to corresponding virtues, no freedom, justice, mutual tolerance, and diversity acceptance will prevail over oppression, prejudice, and injustice. Moreover, as citizens, we shall actively engage in the promotion of such virtues or values with the aim of constructing democracy.

Vargas-Machuca (2005) asserts that the virtue of solidarity must be the imperative for democratic justice. He claims that:

... moral solidarity is not conditioned to mutual identification, nor to a sense of belonging, nor even to reciprocity, for its foundation resides in the recognition, respect and consideration due to other people, and this constitutes the primordial moral argument, which demands the person to imagine him/herself in a similar situation as that of other people. (p. 319)

The author highlights the role of motivation, therefore goals, beliefs and values, when he further elaborates:

In fact, in order to grant the blooming of virtues within political domains, motivation and powerful incentives for individuals' actions are necessary,

and both need to be congruent with the reasons that determine the precious quality of community's norms, which will allow for the achievement of a level of excellence in the community's practices.

(Vargas-Machuca, 2005, p. 322)

Consequently, solidary motivation and action are fundamental to provide for moral development at all levels, from institutional to personal interactions. As Vargas-Machuca (2005) well puts it, "... as a general hypothesis, I sustain that structures of solidarity and solidary motivation/attitudes are engaged in feedforward processes: the first stimulates the appearance of the second, and the second [improves] the quality of the first" (p. 328).

### ***Research Perspectives: The Mutual Constitution of Moral Discourse and Moral Practices***

Many are the possibilities to investigate moral development from a socio-cultural constructivist perspective. The work of most cultural psychologists (some already mentioned in the previous section) do correspond to a theoretical-methodological approach in tune with the premises presented here. Our research team has also investigated the issue using adapted ethnographic approaches, interviews, as well as microgenetic analysis of both naturalistic observations and filmed interactions during structured sessions (e.g., Barrios & Branco, 2010; Freitas, 1999; Martins, 2000; Palmieri, 2003). As a brief illustration, Barrios and Branco (2009) made use of all of the above mentioned methods. Our aim was to investigate, within the context of an early child educational institution, the kind of everyday activities and the dynamics of teacher-students interactions in relation to a possible incentive—or inhibition—of moral development among children. After direct observations of some groups, and two filmed sessions of an activity selected by the teacher herself to "promote" moral development, we proceeded to interview the teachers, the coordinator, and the principal in order to investigate how they conceptualized moral development and its promotion among children.

The groups of children studied included kids between 5 and 6 years old. Results showed a general absence of conceptual knowledge about moral development, which was defined by all interviewees as behavioral control, discipline, and obedience; social skills and good manners were also occasionally mentioned (Barrios, 2009). The activity selected

by the teacher to encourage moral development was particularly expressive concerning such conceptualizations. First, she selected a book meant to be used with 3- to 4-year-old children. Second, the content of the book consisted of a few assertions, illustrated with pictures, about what a young child could or could not do, especially concerning its abilities and difficulties (“I can draw,” “I can play with my friends,” etc. versus “I cannot take medicines by myself,” “I cannot hurt the cat,” etc.). During the activity, the teacher read the sentences and showed the pictures to the kids, asked nonsense questions—like “What does ‘to draw’ mean?”—to one child at the time, and did not allow them to talk whatsoever. Next, she asked them to draw and do some mimics about the “story.” In sum, no talking, no discussion, only obedience was required. The microgenetic analysis of everyday social interactions plus the interactions that happened during the session clearly revealed a pattern where discipline, inhibition and elimination of child-child interactions prevailed.

Data found in other studies with similar goals carried out by our team within school contexts have consistently shown teachers’ ignorance concerning not only moral development, but related concepts such as cooperation and prosocial behavior (e.g., Branco, 1989, 2003, 2009; Palmieri & Branco, 2008; Oliveira, 1999; Salomão, 2001). The conclusions we draw from such results are quite worrisome and suggest that little—if any—attention is paid to the social objectives of school education. Even worse, with the exception of Kohlberg’s traditional projects, most schools allow hidden curricula to take care of the development of ethics and morality, often stating explicitly that such issues are solely a matter of families’ responsibility (Branco, 2009).

### ***Practical Perspectives: The Promotion of Ethics and Moral Development***

The socio-cultural constructive theoretical approach—constantly elaborated within a systemic framework—opens a vast field of practical perspectives concerning the promotion of ethics and moral development. From genetics, we learn about the existence of predispositions for both aggression and competition, on one hand, and for prosocial behaviors and cooperation, on the other. The obvious conclusion is that *culture therefore makes the difference*, and the encouragement of ethics and morality does not go against any innate predisposition for sheer selfishness. In addition, studies about empathy show that its emergence is indeed innate, and its

development can be highly influenced by the quality of relationships and educative techniques employed by caregivers—i.e., empathy development depends on cultural values, rules and practices. Another important branch of biological sciences, ecology, today poses a dramatic challenge to human societies, meaning the need to share a planetary environment characterized by an interconnected world. So biology as well joins human and social sciences in demanding for a world with basic ethical and moral negotiated principles, to allow for the successful survival of diverse cultures and societies.

The major challenge for psychologists, in particular, comprises knowledge construction about how internalization of values occurs. Realizing that certain cultural practices canalize certain values is not enough, so the key for moral development will demand investigative actions at all levels of individual and social lives. Besides the necessary construction of a more just society, characterized by ever-improving economic and political institutions, everyday life interactions need to be impregnated with a sense of justice, care, and empathy that transpires in most human interactions. Microsystems such as family, school, and other relevant community sites have to be continuously co-constructed in order to entail positive social interactions among participating individuals.

Imitation and affectivity, together with inductive techniques, which facilitate the development of empathy, and the utilization of consistent rules constructed on the grounds of genuine dialogues even when people hold divergent positions, have shown to be substantially effective (Damon & Lerner, 2006; Fleer, Hedegaard & Tudge, 2009; Valsiner & Connolly, 2003;). Cultural psychology, though, will particularly remind us to provide for the actual engagement of individuals in cooperative social practices, where moral values are concretely translated into autonomous, respectful, and caring interactions among participants. The power of cultural canalization, then, cannot ever be overestimated (Branco, 2009; Rogoff, 2003; Valsiner, 1989, 2007).

### **Conclusions and Future Directions**

*The question of morality [then] would not be the problem of one person, one party or one society, and nor would it be an exclusive matter of philosophy or a particular science. The question of morality concerns all of us, everyone. It is the central issue of social life, and cannot be dissociated from a democratic, just and*

*rational project for humanity along its historical time,  
both at present as well as in future times.*

(Freitag, 1997)

Psychology needs to approach social sciences in general, particularly anthropology, sociology, history, and political sciences as already suggested. Here I claim for the need that science further dare to examine and carry out the difficult task of unraveling the complexities of human experience. Of similar importance is to highlight the need for the encouragement of reflexivity, autonomy, and responsibility at the levels of social institutions and individuals. I also stress the relevance of the topic of moral development in contemporary globalized world, for moral neutrality simply does not exist. What may exist is an attempt to divert our attention from the topic or to comply, intentionally or not, with the prevalent unawareness regarding the issue.

Along phylogeny and historical time, human groups have found different ways to live together, intermingling competition, cooperation, and individualism in many distinct versions. Periods of war and peace characterized our history ever since. Political and religious leaders as well as intellectual personalities contributed in multiple ways to guide people and civilizations along history. Although many paved the road for the construction of prosocial values and practices, some stood out claiming for intolerance, inequality, and prejudice (e.g., Hitler), and many created a kind of moral void—among them Freud, Nietzsche, and Marx—as they overemphasized the supremacy of either individuals or collectivities. This sort of trap—radical individualism or collectivism—we can no longer endorse. As Lash (1987) puts it, we cannot give our support to societies that actively encourage extreme individualism, narcissism, and the nurturance of a minimal self. Competition and individualism, which facilitate aggressivity, are counter-productive for teamwork, and teamwork requires cooperative efforts that have proved much more effective than tough rivalry among individuals. Competition and individualism, or the annihilation of individuality, all create a lot of ambiguity and personal frustration, for even within the context of global capitalism, collaborative efforts are exceptionally needed at most levels, including socio-affective support and friendly actions. As a result of this lack of moral reflexivity and action, most people complain today about the excesses of violence, hostility, social indifference, very low levels of empathy, as well as

the absence of respect, justice, and solidarity. In other words, today's world is plagued by competition and individualism that leave little to no room for moral and prosocial actions among people. Therefore, we have to face the necessity to investigate the complex development of subjective and collective goals, values, actions, and interactions to actively construct a better future for mankind, rooted in mutual respect, diversity acceptance, and the commitment to promote equality, freedom and solidarity in everyday life.

Globalization certainly turned all societies, nations, and cultures, no matter their specificities, into members of a planetary interdependent network. Like a huge visible and invisible system, technology, economy, and cultural practices lead people from all over the world to surrender to the power of the irresistible hegemony created by the media, the Internet, and capitalism. As globalization culturally canalizes whole generations of people everywhere, human beings need to confront a historical turning point, namely, how to collaboratively develop shared ethics and moral guidelines to make social relations viable, from everyday interactions to international negotiations. Thus, there is an unavoidable need to engage in meaningful interpersonal and international dialogues. As ethics and moral issues are a fundamental aspect of our coexistence, the topic will necessarily become a must-investigate-discuss-and-negotiate agenda, which will permanently develop—hopefully—into promising peaceful and productive social relations at all possible levels.

Within the realms of psychology, a lot can be done in order to contribute to the achievement of an increasingly peaceful and better world. Developmental contexts such as family, school, entertaining, and leisure sites should be carefully studied to unveil the actual everyday processes that continuously create and promote practices and values too often incompatible with ethics and morality. Awareness of activities' structures and communication and metacommunication mechanisms and strategies—which create subtle beliefs related to prejudice and injustice—will certainly consist of a first step. The role of the media, the internet, videogames—i.e., the industry of cultural standards and individualistic values demands serious investigation. Scientific psychological knowledge will then help parents, teachers, and policy makers to find more efficient ways to foster moral development. New institutional proposals, the implementation of novel practices, and eventual interventions

will also be necessary to encourage moral development according to the principles of democracy and freedom with responsibility. Kohlberg's welcome contributions concerning dialogue and group communication should be extended, and new perspectives for educational and cultural change can emerge and be put into practice.

Evidently, scientific transdisciplinary investigation will be needed, as well as permanent discussions about alternative approaches to make sense of, and to promote ethics, morality, and moral development within society. Consequently psychology, together with other social sciences, will face the challenge to develop theoretical perspectives that take into account the systemic, complex, and dynamic nature of the topic. These efforts will help explain the mutual constitution of cultural practices (activities) and cultural meanings (semiotic domain), as well as the development of moral individuals (subjectivities) and societies (collectivities). This challenge, though, has to be taken not just by psychological and social sciences, but also by all diverse fields of knowledge and human activities so we can jointly find out and encourage developmental changes toward justice and happiness.

# The Intergenerational Continuity of Values

A. Bame Nsamenang

## Abstract

Intergenerational values generate from cultural scripts and family exchange systems, which induce family solidarity that sustains intergenerational transmission and continuity of values. Intergenerational values vary by culture, family form, and individuation into individualistic or interdependent norms, among other values. Across history, family values have changed and are changing in response to micro-familial and macro-societal factors, technological transformations, and globalizing forces. In consequence, family profiles are changing, exemplified by an accentuating visibility of multiple generations of grandchildren and grandparents in households in variable degrees across Minority- and Majority-World countries. Regrettably, intergenerational research hitherto has privileged the Euro-American nuclear family form in a world of diverse family forms. Equity and objectivity in science oblige attention to the intergenerativity of family forms in its global diversity. A learning research position could lead to the discovery of the changing intergenerational phenomena of the Majority World's extended families in context to enrich and extend theory and the knowledge base of intergenerativity. This disposition can prime theoretic innovation and methodological creativity to respect the diversity that exists to be discovered. Since intergenerational phenomena traverse several disciplinary boundaries, it seems plausible to adopt a multidisciplinary research framework.

**Keywords:** family forms, multigenerational families, social-exchange norms, family solidarity, intergenerational values transmission, intergenerational continuity of values, intergenerational discontinuity of values, multidisciplinary research approach

Whether human origins are viewed as creationism or evolutionism, the human being cannot be disjoined from nature. Biologists position evolution as the process by which populations of species, including humans, acquire and transmit their traits across generations (Baig, 2002). Evolutionary theory explains the survival and transmission of human genes and other traits by way of natural selection (Wood, 2011; All About Science.org, 2011). Biological evolution entails the changes in the genetic material of a population of species over time. The modern theory of evolution posits that individuals best suited to their environment of adaptability perpetuate the

species by transmitting their genes and traits to their offspring.

This chapter is a discursive triangulation of my work, selective archival research, and my ongoing participant observation since 1993 as an instructor in a yearly hands-on, faith-based course on HIV/AIDS lay-counselor training (Nsamenang & Loomis, 2003) in which trainees have been multigenerational, mixed-sex cohorts. The discourse sidelines the obscure debate over evolution as “fact and theory,” “fact not theory,” and “only a theory, not a fact” (Moran, 1993; Muller, 1959; Religious Tolerance.org., 2011) to refer tacitly to evolution simply as changes in any trait or gene frequency in

a population of organisms from one generation to the next. In this sense, *evolution* (e.g., Smocovitis, 1996) includes: (1) differences in trait composition between isolated populations over many generations that may result in the origin of new species in both biological and social senses, and (2) all living organisms alive today are theorized to have descended from a common ancestor (or ancestral gene pool), therein precluding the idea of creationism.

Ambitiously, the chapter is framed to incite a shift of discourse and research focus on intergenerational transmission of values from privileging Euro-American nuclear family orientations to researching family values in the context of the world's cultures. My primary mission is to point to how different enculturation regimes and social exchange systems shape intergenerational learning and how different family forms endeavor to sustain continuity of attitudes and values through varied cultural tools and processes. I believe different family forms and interdependent versus individualistic exchange norms are responsible, at least in part, for the global diversity of intergenerational values. Although Western cultures privilege adults with child care, African cultures separate child-care skills from the life period of parenthood and situate child-care training as a familial commitment for children to learn (Nsamenang, 2008) as part of their shared management, caregiving, and socially distributed support of the family (Weisner, 1997). Accordingly, African family values socialize children into social exchange norms that commit them to sibling and elder care (Nsamenang, 2010a).

During development, boys and girls build up a "parental identity" (Goodnow, 1988, p. 289) within the cultural contexts in which they are parented; sibling caregiving primes them gradually into the parental role. The "... *process and the experience of childhood does not end with childhood itself. It remains within all of us as a live and informative experience that influences our current and future relationships and activities*" (Neven, 1996, p. 13). In some cultures, children are cared for by their parents or grandparents with the understanding that children will take care of parents and grandparents in their old age. In the Caribbean, child care may not be provided only by the extended family, but may also involve dependable adults in the community (Dudley-Grant, 2001). Understanding the structure and function of different family forms can therefore enrich and extend intergenerativity discourse and research.

Social evolution speaks to "a past that is culturally present as tradition" and that has been "encoded in customs rather than in genes and transmitted socially rather than biologically" (LeVine, 1974, p. 227). Culture, as social heritage and cultural tools, nudges human values in the direction of a given community's cultural meaning systems. As Maquet (1972) asserts, the universal humanity in the human genome shapes into diverse specific individualities in different contexts, hence the variety of intergenerational continuity of values across the globe.

Visualization of human nature and social evolution occur within the meaning systems of the diverse cultural communities worldwide, albeit not with the same lenses and epistemology of scientists. Thus, cultural worldviews or frames of reference to the universe exude mindsets, human motives, and intergenerational values as well as mediate their transmission channels. Soyinka (1990, p. 37) posited "an ethnocultural reality, a humane quality which uniquely informs human artifacts, music, poetry, and philosophy", and obviously family solidarity and support networks, as a "crucial factor of human existence." Intergenerational continuity of values connotes evolution in the sense of both biological and social transmission across generations. This fact highlights the evolutionary basis of grandparents to family security (Silverstein, 2009). Worldwide, parents and grandparents seek to pass on their values and the exchange norms of their families to their next generations, hoping to ensure not merely the survival of their offspring, but that of their culture as well (Reagan, 1996). In fact, long-lived and supportive grandparents who served as surrogate parents (in cases of parental death, environmental threats, or parental absence resulting from migration, imprisonment, or other causes) enhanced the survival chances of their grandchildren (e.g., Dudley-Grant, 2001).

The impetus for this essay is the fact that the continuity of intergenerational interconnectedness in family systems is increasingly being threatened and shattered by a flux of unrestrained social schisms and innovations in information and communication technologies. Of course, there are obvious policy implications for intergenerativity research to understand how to sustain cultural identity as enshrined in the United Nations' (UN) *Convention of the Rights of the Child* (1989).

Indeed, intergenerational research ought to figure out how to promote cultural identity and

simultaneously equip the next generations, particularly in Africa, with the right techno-cognitive values and contextually suitable skills to cope with and make progress in a competitive, knowledge-driven global community. This is important in the face of the aversive attitudes to immigrants reported around the globe. So, how would research contribute to “cultivating” mindsets and value systems inclusive of and tolerant of the growing presence of immigrants and refugees in both Minority and Majority World countries? If ethnocultural reality is a universal but varying feature of cultures, then, we must problematize scientific narratives and programmatic research that have regarded or interpreted the expression or assertion of some ethnocultural realities as positive and useful but considered others as negative and detrimental from instinctual inclinations and not from research evidence.

The intergenerational stake hypothesis (Bengtson & Kuypers, 1971) holds that children and parents diverge on family solidarity measures because they manifest different expectations and understandings of filial relationship status. Intergenerational differences in value perceptions result from changes in the timing of life-course events for parents and children (Hareven, 1994). Instead of timing events in concert with the family’s collective needs and solidarity, children display a more individualized timing wedged on peer norms, for example. Although parents are concerned with the continuity and intergenerational transmission of values they have found useful and important in life, children focus mainly on the differences in the two generations’ value systems in an attempt to establish independence from their parents. When children notice confusions and ambiguities in their interactions with adults, they endeavor to transform them into familiar routines of their peer culture (Carsaro, 1990). But children are not mere accommodators of adult norms and values; they are also creative social producers of their own worlds (Nsamenang & Lamb, 1995).

The next section presents forms of family around the globe but without a judgmental eye.

### **Family Forms around the World**

A variety of family forms rather than a universal, single family form is found around the world. In a nutshell, the principal family structures and household patterns are nuclear, extended, and blended, albeit with several other variants. The *nuclear household* contains two generations, parents and children. *Extended families* are multigenerational and

include a wide circle of kin and servants. In Senegal and much of Africa, the concept of family is fluid (Vandewiele, 1981); it sometimes includes a polygamous man and his wives and children, spousal kin, and friends. In *blended families*—the result of divorce or the death of a spouse followed by remarriage and a new generation of children—mothers and fathers can be both biological parents and step-parents simultaneously, along with stepsiblings.

*Communal families* also exist in many parts of the world. These families are usually extended families living in one household, including father, children, brothers, sisters, aunts, uncles, cousins, elders or grandparents. Sometimes such societies are *matriarchal*, with everyone living under roof being related through a grandmother, mother, or aunt; some societies are *patriarchal*, with everyone being related through a grandfather, father, or uncle. Everyone within this community has his or her own share of responsibilities and often every home within the community helps with child care, elder care, and the destitute.

The growing number of immigrant families in different countries and their acculturative values increases and complicates family values. It is critical to remark that throughout the world, family patterns vary greatly between urban and rural settings and reflect such differences as ethnicity, class structure, and religion, among others. Differences in family forms and demographic behaviors are more striking for migrants to Europe and North America from developing countries. The immigrants bring into their recipient communities the demographic profiles and more traditional exchange values of their natal cultures and agrarian economies. However, intergenerational values research continues to be draped in conventional theories and methods of the dominant culture, therein losing sight of the rich diversity of intergenerational values that coexist. In this sense, North American counseling perspectives tend to gloss over the intergenerational values of most African refugee and immigrant families.

Across times, family structure took a variety of forms throughout the world and increasingly adjusted to continuously changing family circumstances. Such diverse data sources as history, ethnography, sociology, demography, and law, among others, reveal the human family as an institution and not a biological fact founded on the natural bond of consanguinity. That is, intergenerational exchange values need not be family-based or biological.

Early scholars of family history applied Darwin's biological theory of evolution in their theory of family systems, therein reinforcing the idea of social and cultural evolution. This theory was quite popular until it was challenged in the 1980s by sociological theories, most notably structural functionalism. Research was framed by and reported mainly within the kinship terminologies of the Western family. The family types of pre-industrial Europe belonged into two basic groups, the *simple household system*, i.e., the nuclear family, and the *joint family household*, i.e., the extended family (Kertzer & Barbagli, 2002). In the joint family household system, early marriages allowed for multigenerational families to form. The organization of the pre-industrial family is now believed to be similar to modern types of family (Geller, 1994). Many sociologists used to believe that the nuclear family was the product of industrialization, but Colón and Colón (2001) cite evidence proposed by Peter Laslett suggesting that the causality is reversed, and that industrialization was so effective in Northwestern Europe specifically because the preexistence of the nuclear family fostered its development. The extended kinship is very strong in non-Western cultures and any event in the individual's life is, in principle, a group concern. Family relations and dynamics were characterized by patriarchal relations and gendered roles, early marriage, low divorce rate, and low age at first birth (Cliquet, 2003). In Nigeria, for instance, the eldest male is the patriarch and is the head of not just the immediate, but the entire extended family. In that role, he is the adjudicator of family disputes—from the personal to those about division of the family's wealth. He's also the spiritual leader of the family (Nossier, 2003). There was also childbearing into higher ages, as well as high fertility and larger household size.

### **Cultural Blinders: The Oedipal Model of Family**

Although some families stress the importance and authority of the father (patriarchy), others give primacy to that of the mother (matriarchy). Other families are *endogamous* in character, which permits marriage within a specific group or they may have an extreme *exogamous* emphasis, which taboos marriage within closely related kin. Most Western societies employ kinship terminology based on conjugal or nuclear families, which they regard as having a degree of relative mobility. They seem to hold the idea that there is only one type of family, a

consanguineous triangle of husband-wife-children, relatively isolated from other social connections. This has been called the *oedipal model of the family*, and it is a form of patriarchal family.

Such systems generally assume that the mother's husband also serves as the biological father but in many societies around the world, *social fathers* take care of children without regard to whose paternity is involved. For example, "African grandfathers, uncles, stepfathers, foster-fathers, older brothers, cousins, family friends, and other men who take responsibility to care for non-biological children do play and have played" the paternal role (Nsamenang, 2010b, p. 388). Emphasis on the nuclear family has lured some researchers and interveners into thinking about and working on the nuclear family as the "right" kind of family. This belief is an incredibly misinformed one as across the globe at any point in human social history there have been all sorts of views on what families are and how they are composed.

In some families, a woman may have children with more than one man or a man may have children with more than one woman. For collateral relatives, more classificatory terms come into play, terms that do not reflect nor build on the terms used within the nuclear family. The nuclear family, at least in the research literature, appears to be the most researched family form and the one form that international advocacy and the donor community, including UN agencies, promote as best-suited for family welfare policies and child-rights programs. This policy positioning is deeply regrettable, as it pays attention mainly to a minority of family realities and the English-language literature, largely bypassing other family forms and literature in non-English languages. This bias may be attributed to the capturing impact of Western-Christian civilizing crusades and the Euro-American hegemonic control of the world. In large measure the paragraphs that follow draw content from the website: Theophanes(2010).AroundtheWorldinSearchofDifferentFormsof"Family". Retrieved on October 9, 2010.

### **Other Family Forms**

*Polyamory* translates quite literally as "multiple loves" (Weitzman, 1999). It is the practice that consenting adults decide to create marriage-like bonds with more than one individual at a time (Barker, 2005). It is distinct from polygamy and polyandry in the fact that it is usually composed of multiple persons of either sex and if it ends up in a harem-type

system this is generally coincidental, not intentional. Everyone within the group does not necessarily have to share sexual bonds but in these networks emotional bonds are always of overriding importance. Pockets of polyamorous groupings around the world are not open about their choice because of the strong prejudice cultures have regarding it (see Allan & Harrison, 2002). *Polyandry* is probably the rarest form of family ever practiced by humanity at any point in history. It is speculated that with the combined statistics of modern and ancient cultures, polyandry only makes up less than 2% of the world population (Levine, 1988). It is a practice in which one wife will marry several husbands who are usually brothers. This is matriarchal society at its extreme. The wife will bear children and the husbands will share duties within and outside the home. This practice is sometimes used when one husband is rarely home (e.g., a sailor, hunter, migrant worker, merchant, etc.) so another may stay to care for the wife and children. It can be used as a form of population control, as one woman can only have so many children in her lifetime but men can potentially sire dozens, if not more.

*Polygyny* or polygamy is a relationship in which one husband has at least two wives. Unlike polyandry the wives are usually unrelated (Ridley, 1995). Polygyny is practiced in some Middle Eastern regions as well as in various places in Africa and Latin America, but it is not a universal practice. *Sororal polygyny* is a type of marriage in which two or more sisters share a husband, but this is specifically prohibited in Islam (see al-Lahaydan, 2011). Polygyny is illegal in the United States and Canada, but it is an aspect of fundamental Mormonism that is practiced in parts of the United States. The principle most often associated with Mormon fundamentalism is plural marriage, a form of polygyny (Bradley, 2002). In Christian Filipinas the family is *monogamous but* multiple wives are allowed in Muslim Filipino families (Herrington, 2010). Nsamenang (1992) recorded polygyny among the Nso Muslim of Cameroon as 17.5% but it is not universal among Nso Muslim. In the Kisumu, Siaya, and South Nyanza districts of Kenya, women in polygynous unions represented 38%, 47%, and 41%, respectively (Kenya, 1986).

### **Intergenerational Values Transmission: What Do We Know?**

Literature on intergenerational values transmission is vast but lopsided in geographical reference

in favor of Western societies. Programmatic research in non-Western societies such as Africa is noticeable by its scarcity and what little research has been done has largely been in comparison with European and American datasets. As such, it has been reported within the conceptual and family systems of Eurocentric epistemes and normative systems. Compared to Western societies, non-Western communities have been little-researched in their own terms; hence we know little about the contextual situativity of their intergenerational solidarity and values transmission, except for few studies captured in socio-cultural surveys (e.g., Colón & Colón, 2001). Scientific discourse and research reports tend to place fateful values on the so-called “researched” societies, implying non-Caucasian peoples, with concepts whose meanings are variable and inconsistent in the literature. For example, the African-Caribbean family has been presented as exhibiting unique mating and childrearing patterns and the emotional availability and social ties of their men to children are unclear (Sharpe 1996). With this state of the field, it seems plausible, in this section, to present only a synopsis and broad overview of the sparse intergenerativity literature available to the author and to devote more space to examining what the pluralism of intergenerational values that exist in the world’s varied family forms portend. It also endeavors to prompt inclusive discourse about and research into intergenerational solidarity and conflict of values in their global diversity. The desire is to extend the field by priming innovative research methodologies into hitherto unexplored intergenerational phenomena with the objective of rousing the discovery of the intergenerational transmission-of-values stories that exist in all cultures.

Intergenerational continuity of solidarity values, as documented in a number of studies, suggests that the family plays a key role in the socialization and transmission of values. The family has a universal and basic role (Hareven, 1991). For the majority of people the most influential aspect of the immediate social context is the family, which is increasingly becoming a multigenerational unit across the world. Indian-Caribbean families, like those in Africa, tend to share their limited resources and have mutual obligations to each other. It is not unusual to see several generations of African and Caribbean family members living in the same house or in houses built close to each other, even after marriage (Seegobin, 1999). African “kinship is the nucleus from which social networks ramify, moral behavior

is initiated and prosocial values, productive skills and the mother tongue are learned" (Nsamenang et al., 2008, pp. 55–56).

The notion of continuity is central to intergenerational values transmission research. How family members perceive continuity is directly related to their particular cultural ethos and family exchange norms. Family members interact in two ways, outward and inward. The outward interaction reflects how members respond and openly interact with one another. The inner interaction has more to do with each member's perception of or inner feelings about interacting. Perceptions can carry more influence than the reality of the act or interaction. Both sides of family interaction affect the dynamics of the family and the self-image of individual members. The two sides to family interaction make family dynamics and values transmission much more complex and account for family members harboring different feelings, perceptions, and action tendencies related to the same event. Furthermore, family forms provide the primary setting through which culture is defined and interpreted (Luborsky & Rubinstein, 1987). As a conduit of culture, the family represents continuity. The family is key to most phenomena that represent cultural continuity, such as family solidarity, social organization, religion, and ritual; it is the repository of specific cultural beliefs and practices and a primary site for cultural meaning for grandchildren and grandparents (Hareven, 1978). In fact, the notion of continuity of solidarity should be central to gerontological theories of aging and elder care. Throughout much of gerontology's history, theories of continuity have been grounded in a model of life-course development that emphasizes "normative" behavior in individuals rather than in the family unit. Jingxiong (2009) recently studied the single-child policy in three-generation families in urban China and pleaded for genuine knowledge on factors that influence children's lifestyles in multigenerational families. Family dislocations regardless of cause exert dire consequences on intergenerativity.

Continuity theory (Atchley, 1989) has largely focused on the individual rather than the family and has been informed by a normative perspective. Increasingly, families in many parts of the world share a household with both their parents and grandparents, especially in three-generation families. There has been a shift away from constructs that model normativity to concepts that problematize phenomena and examine them in their fragmented and

contingent nature (Becker, 1997). This explains why some views of continuity have deconstructed the notion of continuity; in doing so, they have emphasized disruption (Becker, 1993, 1997) and life reorganization (Becker & Kaufman, 1995). The family is shaped by continuities and discontinuities in cultural history, and by disruptions to the ongoing fabric of everyday life, such as those caused by slavery, colonialism, war, civil unrest, chronic poverty, and migration (Becker, 1997; Becker & Beyene, 1999; Elder, Rudkin, & Conger, 1995). These and other events have directly threatened family cohesion and generational continuity in the present and future.

The "United States is far from unique in representing a confluence of voluntary immigrants, involuntary immigrants, and conquered indigenous peoples" (Greenfield, 1994, p. x). In Africa (e.g., Nsamenang, 2002), the continuities and discontinuities in family structures and functions partly reflect the extent to which multigenerational family members are coping with the coexistence of traditionalism, the "modernism" of Islamic-Arabic heritage, Western-Christian colonialism, and globalizing acculturation in the face of Africanity (indigenous African realities). The contemporary African family is thus best seen "as an intergenerational, multilocal, psychosocial community linked to local, national and global economies and polities" (Bradley & Weisner, 1997, p. xxvi). For most communities and families these forces are useful but at several points they crash, causing a deepening loss of personal and collective identity and an intensifying sense of alienation.

Early intergenerational values transmission research on acculturation reported significant intergenerational differences in three generations of Japanese Canadians in their retention of traditional values of familism (Maykovich, 1980). Maykovich's conclusions supported the theoretical proposition that acculturation is a multiphase process, whether it is measured by the retention of traditional familism or the adoption of "New World" (i.e., American) values (Akiyama, Antonucci, & Campbell, 1997). Similarly, Sugiman and Nishio's (1983) study of socialization and cultural duality among aging Japanese Canadians concluded that, in contrast to the traditional age-related norms of the first generation, middle-aged second-generation parents demonstrated a decreased dependence on their children for support in later life. Ujimoto (1987) attributed this change in support expectations to generational differences in the retention

of traditional first-generation values. Among the Nso of Cameroon, Nsamenang and Lamb (1995) reported substantial similarity in generations of parents living in quite diverse circumstances as well as significant variation of parenting values by sex, parental generation, rural-urban residence, religion, and level of education. This study, along with Africa's historical traumas and social schisms, inform us that African family adaptation, like those of African Americans, has been an ongoing struggle to create a meaningful, sustainable, and coherent pattern of everyday life. Regrettably, African and African American generational transmission patterns have been studied primarily in comparison to norms derived from data obtained from urban Caucasian families (Cantor, 1979; Shimkin, Shimkin, & Frate, 1978).

Intergenerational transmission research has focused largely on family generations but with little evidence of attention on such value spaces as the so-called demographic transitions and the transmission of values, skills, and proficiencies in family formation, the workplace, and peer generation, particularly in cultures in which age grading is normative. This author (Nsamenang, 1992) has explained the bonds and deference in African peer groups and the caring responsibilities of older siblings as a product of family socialization and parental education with emphasis on the notions of locus of authority, seniority, and filial service; core elements of African social solidarity systems. In this regard, we can extend continuity theory by exploring disruptions (Becker, 1993, 1997) in the life courses of peer generations in societies where age grading is common. Exploring the ways in which people seek to ameliorate disruptions to cohesion and solidarity in their families and life journeys, striving to regain a sense of continuity and personal integrity have direct relevance for the study of aging. Even when continuity appears to be present in daily life and people take their sense of continuity for granted, they strive to maintain it, especially in old age (Becker, 1997). Older parents may enhance family solidarity and continuity for all generations (Bengtson et al., 1996). As custodians of family history and autobiographical memories, elders have the greatest stakes in their group's roots and repairing historic disruptions, as well as with the maintenance of tradition and the continuity of the generations (Keesing, 1992). As such, elders would be expected to resist social change, combating change through traditional roles and statuses and working overtime to

maintain intergenerational connectivity. Although some research has reported that African American men have fewer supports than African American women and are less integrated into social networks (Barker, Morrow, & Mitteness, 1998), other studies found that although African American men's networks were sometimes less extensive; they were nevertheless complex.

An apparently ignored area of intergenerational research is the impact on autobiographical memory when shifting the elderly into elderly homes. That is, how is an elderly person's intergenerativity affected by placement in an old-people's home? This invokes the sense of *place attachment*. In Abraham Maslow's hierarchy of needs, belongingness is about human bonding; most accounts of identity formation discuss self-definition vis-à-vis others, not in vacuums but in physical and social settings with some significant others. Place attachment, then, is as central to adult attachment and identity as it is to intergenerational connectedness and values transmission. Most adults, having consolidated their identity formation that involved systematic differentiation of the self from the nonself, break down these processes and barriers in adult life, particularly in old age, such that places and their social networks become invested with personal memories and connotations. Places and neighborhoods become extensions of the self, so to speak, culminating in *autobiographical insideness* that is held with sensitive reminiscences, as when almost everyone resists hospitalization and some elderly resist abandoning their residences to enter elderly homes. Another neglected area of intergenerational research is the accentuating wave of interethnic and interracial marriages and the multicultural intergenerativity such families engender.

In addition, research on intergenerational transmission is only beginning to study grandparent-grandchild relationships, which may have a greater potential for the transfer of intergeneration-distinct information. The role of grandparents and grandchildren in caregiving in both developed and developing societies has received increased albeit lopsided research attention over the last decades. In part, this trend reflects the aging of societies, the greater availability of grandparents in families across the globe, the emergence of alternative family forms, and differing government policies on Social welfare services (Silverstein, 2009). Family caregiving demographics presuppose that providing care to one's aging parents, even in elderly people's homes, is a normative Euro-Western task and family responsibility. However,

providing care to a grandparent by children, adolescents, and young adults tends to be considered a non-normative life task; even cursory observation would reveal this as a normative task in the Majority World, particularly in Africa. Whereas the reigning Western developmental theories position the care of children as a specialized task of adulthood, African life-span theories separate the learning of childhood skills from the life stage of parenthood (Nsamenang, 2008) and situate sibling caregiving into children's "shared management, caretaking, and socially distributed support" of the family (Weisner, 1997). Thus, different cultural orientations fan out differing generational transmission values and profiles.

The *International Society for Behavioural Development (ISSBD) Bulletin* has reported a set of research on grandparenting from a range of cultural backgrounds and theoretical and methodological traditions (Weichold, 2009). Nishiyama and Yamada (2009) focused on female three-generational relationships over time in Japan and highlighted the issue of mutual support and role reversal between generations. Oburu (2009) explored support and caregiving, sometimes to a burdensome degree, provided by grandparents of sub-Saharan African orphaned children. The "burden" is perhaps being imputed from the interpretative visions of scholars but may not be an experienced reality of Africa's grandparents, given their cultural exchange values. Bullock (2009) departs from the tradition of focusing grandparenting research on grandmothers to understand parenting among grandfathers who raised children along with grandmothers. This approach is necessary in the sense that "to consider the status of either sex without reference to the other is to distort the reality we are trying to understand" (Fortes, 1950, p. 363). Two more papers within the special issue dealt, first, with grandchildren as caregivers who provide support and help to their grandparents (Fruhauf & Orel, 2009), and second, the behaviors of grandparents in three-generation Chinese families that may induce a more negative developmental pathway for grandchildren (Jingxiong, 2009). The special section also includes field reports of sociological research on grandparenting by research teams in Brazil (Kosminsky, 2009), the UK (Smith, 2009), and the Philippines (Antonio, 2009). Taken together, these studies reveal consistency of support and help to generations in the different contexts and family traditions in which the research was done.

### *Changing Dynamics in Intergenerational Values*

Micro- and macro-social, political, and economic factors provide the parameters for understanding changes in family structure and values. The African family, for instance, persists as a unit of production, consumption, reproduction, and accumulation that has been intensely battered by the economic downturns that have transformed the settings in which families make their decisions and socialize children. Worldwide, opportunities have arisen from considerable socio-economic changes that continue to alter the structure of the family away from traditional patterns toward new ones generated by the expansion of education, health care, technologies, employment, and migration. For example, in the Oriental Gulf states, contemporary means of communication have increased the knowledge of young people and given them specific alternatives that put them in touch with peers all over the world, and especially in the West. That contact influences the values, traditions and practices of Gulf youth and complicates socialization by their families (El-Haddad, 2003). Similar forces open new opportunities as well as produce multiple constraints. A telling case is that of African families affected by intrafamilial schisms and engrossed in longstanding fragile economies, chronic poverty, poor governance, and civil conflicts (Bigombe & Khadiagala, 2003).

African parents are always exasperated about their children's unwed parenthood, which is now alarming in many countries. Traditionally, there usually is little aversion toward such children, even the so-called illegitimate ones. Illegitimacy does not exist in the Western sense in that every child is always the "child" of someone, of an individual or of the family of origin (Nsamenang, 1992). This is because in most African communities, children of unwed mothers belong to their families of origin. In Western societies single-parent families are often seen as nuclear families that for one reason or another have been divided. This can be the case, but is not always. It is true that single parents can result from divorce or widowhood but it is also becoming more common for individuals to purposefully opt to be a single parent, although in some cases hedonistic attitudes and career or economic considerations underpin options for childlessness. With artificial insemination, tolerant attitudes to single parenthood, and the option of adoption, these families are growing in number.

Single-parent homes are not really accepted in African family traditions. They do have some benefits, however, but are not without dire consequences on next generations. A single parent has the sole responsibility and rights to care for the child or children, meaning they will not have to struggle with differences in maternal and paternal values and parenting methods (Richter & Morrell, 2006). However, in Western societies the single-parent family has been growing more accepted and has begun to truly make an impact on political culture and the social welfare system. The majority of single-parent families are more commonly single-mother families than single-father. These families face many difficult issues besides the fact that they have to raise their children on their own, but also have to deal with issues related to low income, “hostile” social welfare systems in some countries, and generational issues if procreative partners are not revealed to the children. Many single parents struggle with low incomes and find it hard to cope with other issues that they face, including connectedness to extended-kin networks, especially if there are societal snares to the single-parent status.

### ***Forces Supporting Intergenerational Continuity of Values***

Continuity is a human need and a universal expectation (Harris, 1989) although in family values, the concept has a culture-specific character (Becker, 1997). One way to interpret the variety of the continuity of values is to shift away from ongoing universalization of Western family forms to design and interpret research on the shape that the different socio-cultural tools and artifacts that mediate family values take in different cultural contexts. A second framework is the cultural structuring of family forms and the organization of life courses within family systems, given familism as a primary value in most cultures (Cuellar, 1990). In Cambodia, for example, families are the social platform from which cultural moralities generate to individuals, reinforcing family connectedness to reveal evidence of good-face/bad-face in behavioral intentions (Smith-Hefner, 1999). Similarly, in Cameroon, the conjugal unit is the hub of family formation from which social networks ramify, moral behavior is initiated, and prosocial values, productive skills, and other cultural learnings occur (Nsamenang et al, 2008). Universally, the parent-child generational relationship is an important and complex one, but

more of its unidirectional nature has been studied than its reciprocal complexity.

Social and emotional interdependence are the norm through which family members view each other and the family unit. Social norms of the Filipino family, for instance, dictate close family relationships, emotional ties, loyalties, and economic exchanges (Williams & Domingo, 1993). Therefore, family continuity is best studied in the nature and direction of responsibilities and obligations within families as well as solidarity and mutual support across the life spans of several generations. In Africa, such mutuality exists in child care and elder care. The unexpected projection that 22 to 28% of unpaid caregivers to family and friends in the United States are young people age 18 to 40 years (Center on Elderly People Living Alone, 1995) points to the direction in which uncritical intergenerativity research may lead the field.

Social exchange can be viewed not only as a means by which those who are old maintain power but as a major vehicle for perpetuating continuity across the generations. When family exchange breaks down, elders suffer from loss of power as expressed through role loss. To retain power, elders must have a negotiable commodity to exchange as well as the flexibility to adjust to changes in the extended family. For many elderly persons around the world, caregiving and guiding grandchildren is their “negotiable commodity.” But in African intergenerational relations, the parent, especially the father, is increasingly becoming the net loser, as his once undisputed authority is declining as children and their mothers are becoming economically viable and finding their way in the world without necessarily relying on men’s protection and guidance (Nsamenang, 2000). Mutual reciprocity or intergenerational transfer research over the life course, especially in Majority-World families, should not only focus on ongoing exchanges but should explore anticipation of elder care in the growing generation of the elderly. In Cameroon, where publicly organized social security schemes are remarkable for their dearth or inefficiency, both the young and old rely on intrafamilial schemes that comprise parental lifelong investment in childrearing in anticipation of filial service as an old-age social security net (Nsamenang, 2002). In this light, Kenyans perceive old age as “a reaping for the elderly whose rewards for successful childrearing were expected to be unconditional support from adult children” (Oburu, 2009, p. 7).

Having a big extended family is highly valued in Africa and other Majority-World societies as a source of emotional sustenance and mutual support. Accordingly, mutual assistance is one reflection of a broader cultural ethos about family relationships to which people in a given group subscribe and learn values and skills. Portraits of social interdependence and preparation of future generations should map out how family continuity is perpetuated in culturally specific ways as well as what nuclear and extended families are doing to fit children and grandchildren into a changing world. Mutual assistance and concerns about the goodness-of-fit of children in future years are deeply embedded in the cultural context of family life of most societies. This is, and related issues, a critical element in intergenerational continuity in terms of familism and its change from various causes that should be tracked in their contextual situation and variation.

The cross-transfer of currencies is evidence of continuity and discontinuity of mutual support and ongoing involvement with families, even when dislodged from family units. Of course, differences between families and groups in overall approaches to social connectedness and induction of skills, the factors to which families assign the greatest salience, and the degree of “loss-of-face” or disaffection expressed over family relations are expected to differ across families and cultures. We suspect that the varied approaches to mutual assistance and competency preparations have been shaped by cultural traditions, family norms, and role expectations, as well as by threats of their disruption. Competing demands on everyone’s time, energy, and resources are important, but are changing the shape of intergenerational expectations and actual values that are expressed.

### ***Sources of Changing Family Patterns and the Toll of Family Discontinuities***

Intergenerational research has been shaped by the “spirit” of the early European settlers and pioneers in the New World who claimed mobility as their birthright. The original colonies were not long-established before expansion began on the East Coast for more farming land inland. The frontier was the next piece of unexplored land to the west, and successive generations of Caucasian Americans worked their way from the Atlantic coast across the continent to the Pacific coast. After the American Civil War, many freed slaves migrated to spread African American family patterns across the

United States. Despite lower birth rates and women delaying childbirth, increased longevity has resulted in people from four or five generations being alive at the same time and at times in the same household (see Jingxiong, 2009). We need to more keenly address issues that result from multiple generations and multiracial families coexisting not only in society but also in the workplace, and the same household in all societies.

As social mobility and migration has become more racially and ethnically diverse, dating, cohabiting, and marrying a person of another race or ethnic origin has become more tolerable, at least among liberal men and women and their sometimes frustrated but helpless kin. Worldwide, the number of interracial or interethnic families is increasing, but we know little yet about the intergenerational phenomena they engender and create. In recent times, same-sex couples have also cracked the family door to gain recognition, but this is an acutely contested family form in most countries.

It is now obvious that the family is both a custodian of tradition and an agent of change. However, a widespread assumption hints that family continuity through the generations will override individual discontinuities (Becker, 2000), yet the contemporary family is beset by internal and external disruptions that threaten family continuity. Among persons who have migrated from other societies, threats to continuity lie in food items and feeding habits, cultural and language differences between generations, long-standing separations from loved ones, and changes in younger generations’ views of the family. Furthermore, job loss, divorce, illness, and death are among the many disruptions that force families to regroup or detach. The late twentieth century also ushered in new household structures, particularly with Euro-Americans, with unwed parents, gay parents, and remarried parents who brought with them a series of step-kin. Divorce, premarital childbearing, and single parenthood are losing some social stigma almost everywhere, albeit at different rates. Children in divorced families generally experience independence at an earlier age; some develop close relationships with more than one adult, and they develop new relationships with each parent. However, children’s sense of stability cannot help but be disrupted by the breakup of their family units, as parents date other people, and in some cases new families come into existence as a result of these new relationships. These not-so-blended families require tremendous emotional, if not, social and

financial adjustment and are expected to be confused about which values to perpetuate. Children with same-sex parents also face complex social and emotional issues, including building perspective on gender roles as well as dealing with social aversion of this nontraditional family structure.

### Policy Considerations

Although the UN *Convention on the Rights of the Child* (1989) has been critiqued as an overly Euro-Western document (Reid, 2006), it nevertheless supports everyone's right to a cultural identity. In order to uphold cultural identity, an intergenerational research agenda should take the Convention into explicit consideration. Research is largely matricentric, reflecting lack of focus on parenting as a shared duty between father and mother. Researchers and policy planners need to do more to understand and take into account what states and families should do to give every child that right. The tendency in research to observe and measure people in lieu of listening to and working with them somehow breaches this right. The image of African family systems and intergenerational values in print used to guide policy development and programming by otherwise well-intentioned donors and international advocates has been offered mainly by itinerant foreign researchers and does not only "embody the different perspectives which such expatriates bring to Africa" (Wober, 1975 p. ix) but also largely excludes what the recipients know and the apprehension they have about the services.

In the light of Wober's (1975, pp. ix–x) wisdom, intergenerational research might "turn a corner" if it increasingly comes into the hands of Africans "with their own outlooks, needs, and directions of enquiry." Smith (2004, p. 222) made a related point by noting how Nigerians who were bearing children did "not conceptualize what they are doing in the language or formulas of demography." Although development cooperation agents experience difficulty understanding African ways of thinking and acting, many African-born policy makers and scholars often make many of the same mistakes as expatriates (Creekmore, 1986). Whose interest and perspective should be the focus of research?

A related concern is whether rights considerations come to the fore when research reports create or conjure stigmatizing allusions of research participants. What does it mean if researchers, even African scholars, must figure what to see or hear and how to report it not for their own people—Africans

(Tangwa, 1996)—but for the Western audience, as most editors of most of my manuscripts have sought clarifications for the American audience? That is, African scholars tend to research and report in a manner to satisfy Western markets rather than to promote understanding of their intergenerational values or other realities. As such, intergenerational research in Africa has largely lost sight of the soil out of which the contemporary family structures have grown and the exchange values they have produced (Kishani, 2001).

An important issue is the extent to which various forces that should be tracked have modified "traditional" family forms and values to create generation gaps and what state parties have in place to sustain family solidarity and tackle intergenerational crises. The mixture of cultures within nation-states is a fact that is gaining increasing recognition and importance in both national and international affairs (Greenfield, 1994). What does it portend for theory, research methods, and policy, for example, if "new immigrants from Asia and Latin America have added a large measure of cultural and phenotypic diversity to the American population in recent decades" (Perez, 2009)? Intergenerativity in the Majority World is driven more by socially distributed norms and less by economic fortunes, per se. In the majority of families, worldwide economic considerations are not as salient or central to exchange values for child care and elder care as are emotional investment and the spirituality of child-bearing (Sam, 2007).

### Recapulative Reflections

The family is a universal institution, the hub of intergenerational values. It has varied and will continue to differ in form, function, and generation of continuity values across time and lived family circumstances. Social exchange is central to the continuity of family values; reciprocity and equity are core values in all social exchange systems. However, intergenerational inequitable thinking is perceptible in political motives when individuals and interest groups that would have been expected to support early-childhood services and elder care oppose Social Security benefits to these cohorts of citizens.

We live in a world that deserves intergenerational research inclusive of family values in the context and diversity of the world's cultures. Regrettably, the extant corpus of intergenerativity knowledge is Euro-American in main thrust and value content. It has mainly been strewn from middle-class

European and American families and largely reflects the conceptual lenses and practical issues that shape their visions of the world and individualistic social exchange norms. As such, intergenerational transmission research has been cast in the epistemes and kinship realities of the Euro-American nuclear family for projection onto the intergenerativity and policy prescriptions for the rest of humanity. Any intergenerational research that obtained data from non-Western samples was designed within comparative paradigms with little, if any, explicit goal of understanding the intergenerativity within societies in their own right. Furthermore, the methodologies and norms developed from research on Western nuclear families have been and continue to be used as referential grids for research worldwide.

So, intergenerational research has largely undermined or bypassed the family values inherent in the family systems and socially distributive norms of the vast majority of the world's families, particularly those in Africa. If the knowledge base from research on intergenerational values or any other behavioral phenomenon is overwhelmed by one culture, and it does not matter which culture (Ardila, 1982), it plainly ignores or excludes the situativity of the researched phenomenon in other cultures. Such research transgresses global era values and only at best depicts a partial and obviously misguided picture of the reality or the full spectrum of the phenomenon it objectively claims to understand.

Scientific objectivity thus obliges and justifies any and all efforts to shift the paradigm to broaden the scope and subject content of intergenerational research. In the next and final section of this chapter, I endeavor to articulate my preliminary views on how to move forward with intergenerational research within African cultural settings.

### **Future Directions**

In a globalized world of plural cultures, the future of intergenerational research that speaks to intergenerativity in its entire diversity will depend on steadfast commitment to the belief that "all cultures can contribute scientific knowledge of universal value" (UNESCO, 1999). The production and sharing of knowledge and perspectives from intergenerational research will occur under changing conditions incidental to the micro-familial, macro-societal, and globalizing forces that will continue to profoundly impact family values and their transmission channels. Various key factors have indeed transformed, and will continue to alter the relationships between

scientific disciplines and interactions among scientists, intergenerational phenomena, and the scope and cultural inclusivity of intergenerational research agendas.

In Africa's agrarian societies, production is family-based, mostly unspecialized, and accredits children as significant contributors. Until the recent past, successive generations of Africa's children were socialized into similar livelihoods, typically farming and local crafts. With rapid globalizing shifts of production and career prospects to workplace processes and the knowledge economy, career fortunes are more dependent on an inherent division of labor and competitive specialization than on intergenerational transmission of family work ethic and vocational aptitudes. Increasingly, individualism in global labor markets is diffusing into other spheres of life, including individual identity, solidarity values, mutual exchange systems, and the legal system, among several others. Intergenerativity research will happen within changing social and economic opportunities accentuated by the necessity for youth to move away from home in search of employment and better life prospects. This trend has already resulted in declines in the availability of multigenerational family members in African households and neighborhoods. With growing urbanization, rural African parents and communities are losing children and youth increasingly to sprawling city slums and, through illegal migration, into precarious conditions abroad (Nsamenang, 2011). These phenomena are disrupting African family structure and complicating values transmission. When social exchange breaks down, elders suffer from loss of power and the disaffection of being forgotten by their families; they are disappointed in their children who failed, in the light of psychosocial theory (Erikson, 1968) to ensure their old-age welfare.

In spite of the Euro-American parochialism of research databases, we cannot afford to dismiss the extant knowledge base on intergenerational values. We must be keen and ready, nevertheless, not to acquiesce to a state of a scientific field that lopsidedly reports research on Anglo-American intergenerativity as if it represented largely uncharted African intergenerational profiles. We must plan and design research from a resourceful apprehension that the "most creative theories are often imaginative visions imposed upon facts; the source of imagination is also strongly cultural" (Gould, 1981, p. 22). In accepting science as part of culture, we must acknowledge that by its nature science "influences what scientists

see and how they see it and, more critically, what scientists report, ignore, or fail to notice, as when serendipitous research findings are not reported (Nsamenang, 2010b, p. 389). Therefore, we must go beyond questioning the current state of the science in order to ingeniously correct an inadvertent bias in intergenerational research.

Accordingly, the central mission of Africa-centric research should be to discover the situativity of intergenerational phenomena and their changing trends in Africa. In so doing, we must work from an understanding of Africa's triple heritage (Mazrui, 1986) of historically earlier Islamic-Arabic family patterns and later Western-Christian nuclear family ethos superimposing a toll on deep-seated African family values. African family values are said to be deep-seated in the sense that, thus far, scientific evidence reveals Africa as the origin of modern humans (Johanson, 2008). As such, Africa should be researched as home of the earliest and longest-standing versions of family forms and intergenerational transmission of values. Research within this hybrid context will require plausible theoretical as well as methodological innovations because no existing theory suitably explains Africa's triple-strand braid of family values.

Faith in science and the work of intergenerativity researchers permits proposal of alternative theories and methods. I invoke Bertold-Brecht's wisdom as a guide: "The aim of science is not to open the door to infinite wisdom, but to put a limit to infinite error" (Cited in Laccarino, 2003). The handiest strategy is the scientific method, an established set of rules that should be applied to all phenomena regardless of context. In the search, we must recognize that Africa possesses its own conceptual grids and knowledge bases, which may explain, at least in part, why scholars who have applied Western models and epistemes to African phenomena discovered that they did not exactly fit (MacGaffey, 1981; Ojiaku, 1974).

Scientific understanding is one knowledge system among many others (Nakashima, 2000). Cultures from all regions of the world have developed complex views of nature, rooted in their philosophy, which has led to their understanding and explanation of the natural world. The indigenous knowledge of non-European cultures is the expression of specific ways of living in the world, of a specific relationship between society and culture, and of a specific approach to the acquisition and construction of knowledge (Laccarino, 2003). These insights

and knowledge systems build up from local culture and the people's worldviews. Mazrui and Ajayi (1998) claimed that science and technology in Africa were once quite advanced, comparable to European levels of the time, in the fields of human and veterinary medicine, agriculture, food conservation, fermentation, metallurgy, and the preparation of soap and cosmetics. Slowly, the importance and influence of indigenous knowledge diminished because of the success of Western science and technology and the economic and political power that accompanies that success, but also because of deliberate denigration and treatment of Africa's knowledge and techniques as antiprogressive.

For these and other reasons, the knowledge systems of other cultures are reported and understood in reference to Western systems, a disrespect of diversity and great harm to humanity. By its design, Western science is reductionistic, mechanistic, and attached to quantitative measurement. On the other hand, traditional science relies on naturalistic observation from an inclusive point of view. Scientists limit or "reduce" their explanations of phenomena to unique observations; this reductionistic approach tends to ignore some facts that may be key factors in some situations (Laccarino, 2003). The traditional knowledge of non-Western cultures puts empirical observations into a larger context. Thus, in all cultures, we can notice efforts to harmonize empirical observations in order to represent phenomena and to be able to interpret and predict them. Such holistic knowledge provides much of Africa with frames of reference to individuate a sense of belonging to networks of social others that support satisfaction of basic needs.

Laccarino (2003) refers to Szent-Gyorgyi as having identified the problems of modern science as the inability to integrate results and concepts that come from different approaches and levels of analysis. African scholars tend to experience difficulty connecting or translating their academic or professional knowledge and research skills to the appalling state of their continent and ethnic communities. The extent to which African scholars are knowledgeable of the social capital of their communities is at best tenuous. The tacit juxtaposition of primitive versus civilized values in scientific literature exacerbates their difficulty.

Africa's exchange values open up opportunities to learn about elder care within the family and to approach analysis of phenomena with holistic, integrative lenses. Such opportunities prime an

innovative disposition to theory and method in order to address a phenomenon not as a defined concept but as it is implanted in context. Ingenious application of integrative thinking can thus instigate contextually sensitive research into the complex intersubjectivity inherent in the transmission of family values across diverse family forms and cultural contexts. The scientific community should be ready to re-evaluate what the out-of-Africa-origins of modern-humans theory (Johanson, 2008) portends and Africa's potential contributions to intergenerational values research, as the Renaissance scientists did with the ancient knowledge of the Greek and Arab scholars (Laccarino, 2003).

Intergenerational relationships and exchanges are sites of reaction to wider social change or key sources of change (Jamieson, 2006). That is, intergenerational exchange values need not be traditional or biological. Older adults and younger peers can validate and help each other. Intergenerational mentoring, for instance, can make a significant difference in a child's or elder's life. Some of the modes in which intergenerational values are generated and spread are culture-specific; but they have been changing in all cultures and will continue to adjust to prevailing conditions. If research reveals that the benefits of intergenerational interactions accrue to both the younger and the older generations, are they universal and inert or do they vary by family forms and social exchange systems? What policy insights could be lost if research continues to privilege economic exchange if some culture-specific factors are more salient in Africa? Population profiles are changing, as the number of elderly and multigenerational families of all countries is increasing, more rapidly in some countries than others, posing an unprecedented challenge to current and future generations. Most of these factors, and the fact that intergenerativity values cross disciplinary boundaries, necessitate interdisciplinarity and triangulation.

# The Making of Magic: Cultural Constructions of the Mundane Supernatural

Meike Watzlawik and Jaan Valsiner

## Abstract

Construction of magical thinking has been central for human cognitive adaptation to uncertainty of living. In this chapter, we present a rare comparison of how such thinking is culturally constructed across two different countries (Germany and the United States) and historical periods (1920s and 2000s). We demonstrate how reanalysis of empirical data from other historical periods can be a productive epistemological step in comparison with current historical phenomena. Heinz Werner's and Martha Muchow's work on magical thought in the 1920s continues to be of importance in the twenty-first century.

**Keywords:** cultural tools, magical beliefs, Heinz Werner, Martha Muchow

Kultur entsteht aus dem Bestreben des Menschen,  
Chaos zu vermeiden und Glück zu gestalten.

*[Cultures emerges from the human ambition  
to avoid chaos and to create luck.]*

—Boesch, 2000, p. 12

Magical thinking is all around us. In Germany, a black cat—coming from the right disappearing to the left—crosses the path of a man on his way to work. The man is startled for a moment and then cites the following lines internally:

Schwarze Katze von links nach rechts,  
*[Black cat from left to right],*  
bringt Schlecht's,  
*[brings bad things,]*  
schwarze Katze von rechts nach links,  
*[black cat from right to left,]*  
Glück bringt's.  
*[brings luck.].*

Relieved, he continues to walk his way. In South Korea, a white butterfly flutters past a boy in the park. It is the first one he sees that year. He is devastated, because the butterfly is a bad omen: A family member will die soon. He calls a friend to tell her about it. In Mexico, an older woman almost set her purse on the ground next to her while sitting in a café ready to order tea. In the last second, she stops herself and puts the purse on the chair next to her. She decides not to challenge luck and be safe since putting down the purse on the ground would have meant to lose all the money that is in it. The *Dieri*, an indigenous Australian group from the South Australian desert, would call upon the spirits of

their ancestors to grant them power to make a heavy rainfall during dry seasons (Leuba, 1912).

The themes of the incidents described above are luck, bad luck, unforeseen personal tragedies, and natural forces (e.g., rain, wind). What do these themes have in common? All of them cannot willingly be controlled or unerringly predicted by the involved or affected individuals. Of course, here it is assumed that one believes in (bad) luck. Of course, there are individuals who do not, who base their interpretations of the world on different belief systems and, thus, would use other concepts to predict/anticipate what will happen in the future.

Interesting here is the differentiation between *Spiel* (game) and *Glücksspiel* (gamble/game of luck or chance). In the case of the game (e.g., chess), the players learn or agree on certain rules. The question of why a game took a certain turn or led to a certain outcome can be explained by the players (B was a result of A, which allows for conclusions like: next time, I do A to arrive at B). In the case of the gamble, the players have less control. Of course, gambling also follows certain rules, but the outcome is uncertain/unpredictable. Luck is assumed to determine whether, for example, the roulette ball falls into a black or red slot. For the notion that all games are “games of chance,” see Neveux (1966).

The examples above show that—no matter which cultural setting (*culture* as condition for action; see Boesch, 2011; Eckensberger, 2011)—an individual may still try to predict or influence the unpredictable/uncontrollable by interpreting objects (signs) in a specific manner or by engaging in specific actions (*culture* as a result of action). While doing so, differences in culture are reflected by differences in the meaning-making processes involved.

### Trying to Control the Uncontrollable World

Uncontrollability and unpredictability imply that the causes for a certain and favored outcome are unknown. Depending on the perspective, this leaves the individual with none (*I do not know what to do, so I do nothing*) or endless ways (*I do not know what to do, so anything might help*) to act so that the probability of an outcome, which the individual regards as positive, increases. These two conclusions can be interpreted as the opposite ends of the possibility spectrum—both can leave the individual either helpless or overwhelmed, but not in control. The feeling of helplessness only emerges if the individual actually has an interest in predicting future events

(see Boesch, 2000, for his definition of *valence*). If the individual is indifferent to this matter, being unable to predict it will not have an impact.

Ways to (re)gain control over the situation are thus necessary (see for example, Lefcourt, 1973)—yet not possible—since the situation constantly changes ahead of the control efforts. It is that uncertainty that makes the need for the emergence of culture—*semiotic mediation*—both possible and necessary (Boesch, 2011; Valsiner, 2007). Of course the lay-person needs to survive, and there are some options for that. One option is to still admit that one cannot do anything, but to believe in a (higher) power that can (e.g., a deity), or to invent an action that will, by definition, have a positive impact on the outcome (see Belzen, 2011). The emerging routines (e.g., luck making, fate determining) that are based on magical beliefs can either be created by individuals, groups, or even societies. The invention of deities takes the form of *circularity of control*—a person invents a supernatural figure for the purposes of controlling him- or herself (Valsiner, 1999). In case of human willful efforts to control the situation, the agent of such control becomes indeterminate.

### The Foundational Role of Magic

Leuba describes one characteristic feature of *magic* as follows:

The term magic I would restrict to those practices intended to secure some definite gain by coercive action in essential disregard [ . . . ] of the quantitative relations implied in the ordinary and in the scientific dealings with the physical world [ . . . ].  
(1912, p. 350)

Leuba bases this definition on observations made in “primitive” cultures and children—a comparison not uncommon at the time (cp. Frazer, 1920; Tylor, 1871; see Lévy-Bruhl, 1921, for critique). Also, Werner (1927) assumed that only the people close to nature in traditional societies—at that time labeled “primitive man”—and children/adolescents (are able to) believe in magic. For Werner, the counterpart of the *magical adolescent* was a nonmagical, adult, civilized man. The former would be convinced that objects are ultimately not moved by natural causes, but that individuals and the surrounding objects are secretly interrelated, that they influence each other in a magical and nonnatural way. Piaget—following the lead of Lévy-Bruhl—explained this causality of the child’s thinking with the “Law of Participation.” He considered participation to be “the result of simple

transduction, of the syncretistic fusion of particular observations” (Piaget, 2001, p. 33). Participation is, thus, the

... relation which primitive thought believes to exist between two beings or two phenomena which it regards either as partially identical or as having a direct influence on one another, although there is no spatial contact or intelligible causal connection between them.

(Piaget, 1969, p. 132)

Piaget explained this way of thinking by an egocentric logic (“constant assimilation of external processes to schemas arising from internal experience,” 1969, p. 132) that is overcome when the child discovers that others do not think like it does, when it is disillusioned, so that it has to “bow to the exigencies of control and verification which are implied by discussion and argument” (Piaget, 2001, p. 302). Eventually, according to Piaget, the child will thus replace the egocentric logic with “true” logic (see Piaget, 2001).

Where does magic play a role in this? Piaget assumes that the egocentric logic corresponds with a primitive psychological causality, “probably in a form that implies magic proper” (2001, p. 303), since children believe that their desires can influence objects. They believe in the obedience of external things. It is important to note that “magic,” as described here, is summarizing cognitive processes based on the *Law of Participation*. Other authors have used it in the same, but others also in different ways. Sully (1897), for example, uses the term “magic” to describe imaginativeness of children, thus, referring to fantasy. Following these observations, Piaget uses the term *magic* “for the use the individual believes he can make of the [above defined] participation to modify reality” (1969, p.132). In correspondence

to Leuba, Piaget stresses that magic has something to do with wanting to influence the external world in favor of one’s own wishes/desires (in different ways, see Box 37.1 for classifications). In other words: For the child, it is one way of *controlling* or, at least, *wishing to control* the outside world because convincing alternative explanations (arguments) are not available. This becomes possible because the boundaries between the self (thought) and the external world (things) are less rigid than they are in adults (Piaget, 1969).

### ***Who Believes in Magic?***

The question is, whether it is true that *only* children, adolescents, and the “primitive” believe in magic and perform magical practices. The examples given at the beginning of this chapter would suggest otherwise.

If magical practices/rituals like the ones described above are observed in adults, some sort of “disturbance” is often assumed. Piaget (1969) points out that Freud would take *narcissism* as an explanation for the magical practices some of his adult patients performed. The assumption here is that adults, who are in love with themselves, consider their desires and wishes of special value and thus believe in their efficacy—which Piaget distinguishes strictly from the child’s developmental phase of narcissism (*absolute egocentricity*). Piaget himself assumes that magical practices and beliefs in adults can be explained by a temporary weakening of the boundaries between the self and the external world. The examples he gives are *involuntary imitation* (e.g., someone has a stuffed nose, the observer feels like blowing his nose to improve the situation of the other), *anxiety*, and *monoïdeic desire*. Piaget says that when adults experience *anxiety*, processes that usually only occur in children (feelings of participation) can be observed. The

#### **Box 37.1 Classifying Magical Practices by Structure (Piaget, 1969)**

- *Magic by participation between actions and things*: The child performs an action (including mental operations like, e.g., counting) to influence an event that he or she either desires or fears.
- *Magic by participation between thought (only internally or articulated aloud) and things*: The child thinks of something to modify reality (e.g., wishing for somebody to visit in order to increase the likelihood of this event).
- *Magic by participation between objects*: The child uses (or particularly does not use) an object to influence another object (e.g., wearing a certain pair of socks when competing in sports because they make you a better athlete).
- *Magic by participation of purpose*: The child regards objects as living and purposive (*animism*). The object thus has a will, which can be influenced by the child’s will, displaying participation between the object’s and the child’s will (e.g., telling the clouds to go away).

example he gives is the desire to “observe even the most insignificant details of the ordinary routine so that the balance of things shall not be upset” (Piaget, 1969, p.164). Rituals thus help adults to maintain a feeling of control, which can only be explained by the above-mentioned feeling of participation (=magic). In the case of the *desire*, participation goes hand in hand with animist ideas.

The study of these shows that it is generally sufficient ardently to desire something outside of our control [...] in order to have the impression of a sort of hostile power seeking to mock us. The desire thus becomes hypostatized in the things and by projection personifies fate and events. This realist tendency is sufficient to cause any number of magical tendencies. (Piaget, 1969, p.164)

Piaget illustrated this description with the story of a man who is reluctant to take off his raincoat after it stopped raining to prevent rain from starting again—an example for which Risen and Gilovich (2008) later show that many adult individuals actually believe that the likelihood of the event “no rain” actually decreased because of “them not taking off the raincoat” even though they recognize rationally that the events are not correlated. This can be observed in different cultures—“primitive” or not:

People in different cultures, regardless of their explicit beliefs, do not much differ in the tendency for negative outcomes to jump to mind and in the use of accessibility as a cue for judging likelihood. Instead, cultures are more likely to differ in their access to and reliance on abstract rules that override such automatic associations and assessments [...]. Thus, members of some cultures fully believe that it is bad luck to tempt fate. Members of other cultures intuitively believe it (and often behave accordingly) but simultaneously know that the belief is not rational. (Risen & Gilovich, 2008, p. 305)

The difference between adults and children seems to be that, for the child, magic (=participation) is a way of thinking to which there is, for at least some time, no alternative. Phelps and Woolley state that children rely on magic when “they encounter events that both violate their expectations and elude adequate physical explanation” (1994, p. 385). Adults, however, know—if the environment has provided them with this knowledge—about the scientific, fact-based background of different phenomena. They know, for example, that rain cannot be influenced by not taking off a raincoat since the rain is influenced by other

factors (e.g., temperature, evaporation). This observation leads Meehl to define magic as a

... belief, quasi-belief, or semi-serious entertainment of the possibility that events which, according to the causal concepts of this [or other] culture[s], cannot have a causal relation with each other, might somehow nevertheless do so.

(1964, as cited in Berenbaum, Boden, & Baker, 2009, p.54)

Meehl’s definition of magic, as presented here, is a rather broad one. Others prefer a narrower approach to, for example, be able to differentiate between magical thinking and peculiar beliefs. Here, both are considered to be one and the same (see Berenbaum, Boden, & Baker, 2009, for further readings on this topic). Even though being taken from the *Manual for Use with Checklist of Schizotypic Signs*, the definition seems to describe a possible behavior among adults that are not in need of any treatment (see Belzen, 2011). Berenbaum et al. (2009) actually draw a picture of a continuum: On one end would be those individuals who do not believe in magic or apply magical practices, on the other end, patients with psychopathological symptoms—suffering from delusions (=extreme versions of magical thinking)—would be found. In the middle, nonpathological cases that (partially) believe in magic and maybe even apply magical practices would complete the continuum.

This assumption is supported by studies that focus on ritualized behavior in clinical obsessive-compulsive disorder (OCD) and nonclinical cases. Here, rituals are believed to be necessary to ensure a positive outcome of some, often apparently unrelated event. Consistent with Piaget (1969), Franzblau (1997) showed—for the nonclinical cases—that engaging in rituals is perceived as reducing feelings of *anxiety*, fear, and discomfort, while at the same time increasing feelings of *control* and security. Reuven-Magril, Dar, and Liberman (2008) show similar mechanisms in OCD patients: They describe rituals as means for achieving an illusory sense of control to cope with stressful life events—just with a different intensity. By drawing a picture of a continuum between the pathological and the nonpathological, we address a topic that others have already discussed in the past. Kretschmer (1921), for example, thought that thin individuals tended to be introverted and timid, which was seen as a milder form of the negative symptoms exhibited by withdrawn schizophrenics. Even though Kretschmer’s constitutional approach, linking body

shape to personality, does not influence today's personality theory anymore, the description of a continuum between the normal and pathological is still up to date.

### **What is Real Logic?**

Berenbaum et al. connect magical thinking with "errors" in thinking. According to them, these errors lead to "judgments, decisions, and beliefs that are not entirely rational and logical" (2009, p.198). "Real" logic or nonmagical thinking would thus be based on rationality and would be "error-free." Nevertheless, not only children, but also adults often are irrational—one reason being emotional processes that interfere with rationality (cp. Pham, 2007). Many examples for this irrationality can be found in Dan Ariely's book (2008) *Predictably Irrational: The Hidden Forces that Shape Our Decisions*.

Josephs and Valsiner (1999) prefer the term *inconsistencies* over errors in thinking, and map the associated meaning-making processes with which humans try to make sense of themselves and the world. Using microgenetic developmental analysis, they show that, in fact, the belief in miracles (magical thinking) utilizes the same meaning-making processes that are used in everyday life, which leads them to the argument that these processes are essential and mature rather than primitive—in contrast to what Leuba, Werner, Piaget, and others have suggested. Josephs' and Valsiner's interviewees most of the time argued not in the extremes of "miracles happen or do not happen," but rather allowed for the possibility that they "might or might not" happen. This reminds us of Meehl's definition of magic in which—despite knowing better—individuals would still consider causal relations between apparently unrelated events as possible explanations; even though they might start off with a preference for either "might" or "might not." Using Josephs' and Valsiner's (1999) terminology, this apparent contradiction can be solved by applying circumvention strategies. *Circumvention* is a meaning-making process that temporarily neutralizes generalized semiotic macro-organizers that represent convictions, worldviews, rules, etc. An example for *circumvention of meaning by focusing on harmonious coexistence of meaning complexes* is the following (Josephs & Valsiner, 1999, p. 111):

- Rationally, the biblical miracles cannot happen. (1)
- I am a rational man. (2)

- I believe in them anyway. I know this sounds crazy, but it is as it is. (3)

The person in this example is rational *and* believes in miracles at the same time. This contradiction does neither confuse him, nor does it mean he is crazy. Circumvention allows him to balance incompatible domains of belief: Everyday knowledge and religious reasoning, showing that it sometimes is not an either/or question when it comes to being rational or not.

What is missing from Josephs' and Valsiner's example is the reason for *why* the man decides to—despite his accentuated rationality—believe in miracles. Is it because he would question his parents' upbringing and their beliefs if he questioned biblical miracles, which he does not dare doing? Or is the argumentation closer to the one used in Pascal's Wager (cp. Hacking, 1972) that makes the man believe in miracles? Or is the reasoning a completely different one? Cathcart and Klein (2008) describe Pascal's Wager very informally, but to the point as follows:

[Pascal] argued that deciding whether or not to believe in God is essentially engaging in a wager. If we choose to behave as if there is a God and we get to the end and it turns out there isn't, it's not such a big deal. Well, maybe we've lost the ability to thoroughly enjoy the Seven Deadly Sins, but that's small potatoes compared to the alternative. If we bet there isn't a God, and get to the end only to find out there is a God, we've lost the Big Enchilada, eternal bliss. Therefore, according to Pascal, it is a better strategy to live as if there is a God.  
(p. 100)

A deeper microgenetic analysis would be necessary to answer this question—if answering it is possible at all, since some of the underlying reasons might not be directly accessible for the individual. If they are, for example, part of the sub- or unconscious, they might only lead to a vague feeling of *anxiety* (see for example, Mayer & Merckelbach, 1999).

### **Voices from the Past**

A step toward answering the questions above is the analysis of already existing data. In 1928, Heinz Werner and Martha Muchow—working at Hamburg University in close collaboration with William Stern and Ernst Cassirer—developed a questionnaire to examine (magical) personal customs, which was

published in the *Journal for Educational Psychology* in Germany (Muchow, 1928). Precedent interviews with adolescents and adults at Hamburg's Psychological Laboratory had shown the relevance of these magical customs with which adolescents as well as adults tried, for example, to secure the positive outcome of future actions or to influence decisions that depended on chance in favor of their wishes. It is assumed that about 600 completed questionnaires must have existed at the time, but that most of them were lost at the beginning of World War II (Faulstich-Wieland, 2007). Fortunately, a few of these questionnaires still made their way to Clark University in Worcester, Massachusetts, together with other academic belongings of Heinz Werner, which allowed us to reexamine the then-collected data. In addition, we translated Muchow's questionnaire and had it filled out by current undergraduate students of the Psychology Department at Clark University, so that we can compare the answers given 80 years ago with the answers provided today. A brief description of both samples can be found in Table 37.1.

### Comparing the Use of Magic Then and Now

Although Werner (1927) argued that only children and the primitive believe in magic, his and Muchow's data provides evidence that also adults believe in magic and engage in magical rituals—as already discussed above. In the following sections, we will introduce an excerpt of the questions asked in both studies and the results for both samples. This will allow us to see if magical rituals have changed in content and use, or whether the underlying functions of rituals have stayed the same over time.

**Question 1:** Did you [as an adolescent] sometimes need so-called oracles or interrogations of your

destiny when you had to make important decisions or perform in a certain way or when you thought that the outcome was mainly a question of chance?

This question also included an explanation of what *oracles*—as one example of magical practices—are, which was taken from Muchow's (1928) questionnaire. The explanation was the following:

By oracle we mean the following:

a. Oracles for which you had to do something that had (almost) nothing to do with the expected or feared (e.g.; balancing on a low balustrade, foot racing a car or bus to a certain point, gathering a certain number of hats, coins, etc.).

b. Oracles for which you remain rather passive (e.g.; two bus lines drive past your house, seeing one of the two on your way home brings "good luck," seeing the other brings "bad luck;" counting the trees that grow alongside a certain street, if the final number is even, it is considered "good," if it is uneven "bad," etc.).

Of Werner's and Muchow's interviewees, 18.6% (N=8, with 2 missing) said that they did *not* use oracles at all when they were younger, and 25% (N=10) of ours said they did not. All others had consulted oracles of some sort with varying frequency, showing that it was and is a quite common phenomenon among adolescents.

**Question 2:** Do you still use the oracles described above [or other magical practices]?

Of the ones that consulted oracles as adolescents, 84.9% (N=28) of Werner's and Muchow's interviewees and 83.3% (N=25) of ours still use(d) oracles (occasionally) today. In both cases, it is striking that many claim to know that oracles or other magical practices are irrational (e.g., with statements like "They are interesting but of course not reliable"

**Table 37.1** Sample description

[WV-ID 9]), but that they would still perform them, if:

(a) a very important decision has to be made (e.g., “Yes, rarely, only for important decisions” [WV-ID 24]);

(b) the decision to make is very insignificant (e.g., “I still perform them often today, but never before big decisions, it appears to be playful and wrong” [“Ich übe sie heute noch des öfteren, aber nie vor großen Entscheidungen, es erscheint mir spielerisch und unrecht”] [MW-ID 3]); or

(c) the situation is extremely stressful (e.g., “In times of strong mental efforts, when overstimulation of the nerves occurs, rituals of this kind re-emerge” [“In Zeiten von starker geistiger Anstrengung, bei Überreizung der Nerven treten solche Bräuche wieder auf”] [MW-ID 456], or “unless I have absolutely no idea about what to do” [WV-ID 12]).

The argumentations found in both samples are very similar and can be phrased in terms of Josephs’ and Valsiner’s (1999) concept of circumvention of meaning. As in the example introduced above, we would start off with the statement:

- Believing in magical rituals is irrational. (1)

Then the self-evaluation follows:

- I am a rational person. (2)

To still be able to apply magical rituals, circumvention is necessary, which can be achieved by different paths of meaning making:

- But in this situation, it still might help me find the right solution. (3a)
- But I do not use them for important things anyway. (3b)
- But it makes me feel better at the moment. (3c)

In each case, the contradiction between being a rational person and applying or believing in magical practices is solved and allows for a balanced evaluation of the situation. Of course, this is only necessary if a contradiction exists. In both samples, few interviewees seemed to simply accept their beliefs in magical practices and did not evaluate this as “irrational.” Some even stated the following: “It [consulting oracles] seems logical” [WV-ID 18]. Circumvention is then not necessary.

The answers to Question 2 showed, that no matter if we look at the data collected in 1928 or in 2009, many *adults* still apply magical rituals (oracles) in different situations. Of course, it can be argued that the 2009 sample does not consist of

adults, but *emerging* adults (Arnett, 2004) that are still in an exploratory state and are, thus, prone to using practices that allow them to feel in control of their lives. Nevertheless are they aware of the magical practices’ irrationality, so that applying magic does (a) not equal participation beliefs as found in children, and (b) is also not pathological since it helps the individual to cope with current insecurities. At this developmental stage, magical rituals can therefore be a possible coping strategy (cp. Keinan, 1994). It is thus questionable, if it is only a developmental stage or even disturbance. It seems more likely that these practices fulfill certain functions: facilitating decisions, providing a feeling of control, or regulating emotions. The answers to the following questions will provide further insight in this matter.

**Question 3:** Can you remember how you came up with these rituals; specifically, can you tell us something about the inner and outer causes that would help us understand how these rituals developed?

Of Werner’s and Muchow’s interviewees, 28 provided an explanation for why they came up with these magical rituals, as did 29 of our interviewees. We categorized the answers to give an overview of the different explanations. In Table 37.2 the different categories, sample answers, and frequencies can be found.

The most frequent answer in both samples is that magical rituals were or are used, because they were introduced by others or were observed in others. The answer that magical rituals are a cultural thing goes in the same direction. These rituals are thus suggested or shown by different sources that, for example, Bronfenbrenner (1979) divided into different, but cross-linked systems. Attitudes and ideologies that characterize cultural groups would be subsumed under the *macrosystems*, whereas the family, peers, and others form different *microsystems*. From both, as well as in-between systems, magical rituals can be suggested (see Figure 37.1).

Whether an individual adopts the rituals depends, on the one hand, on the intensity with which they are reinforced, on the other, individual characteristics—such as anxiety, emotional salience/awareness, etc.—also play an important role (cp. Berenbaum et al., 2009). Another *individual mechanism* is described by the participants from 1928. They mention the parallel occurrence of events as one possible cause for the emergence of magical rituals. In fact, Pronin,

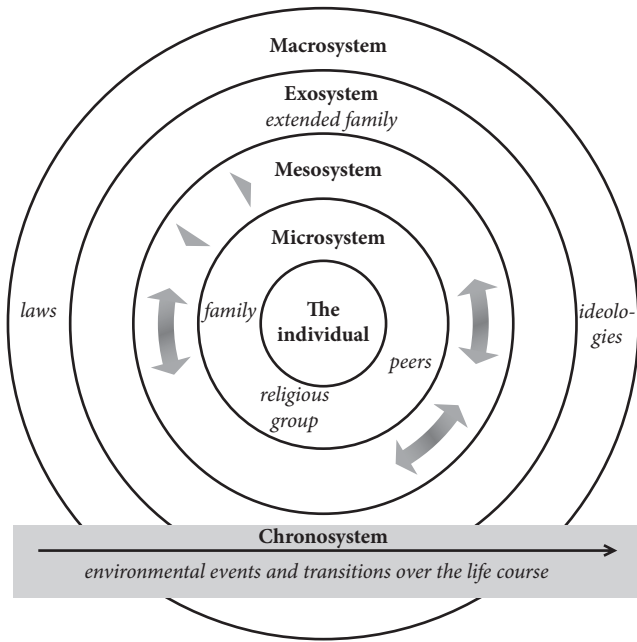

**Table 37.2 Categories, sample answers, and frequencies of the different explanations for why magical practices emerged (multiple answers possible)**

Category	Sample answers	1928	2009
Learned rituals through or from others	<ul style="list-style-type: none"> <li>• Mostly through the influences of friends. I saw them doing it and would try for myself.</li> <li>• My mother came from Lusatia, which is full of superstitions. The whole upbringing was interspersed with it.</li> </ul>	13	15
Rituals are considered to be part of the culture	<ul style="list-style-type: none"> <li>• I guess using a coin was something that was part of the culture I was growing up with.</li> </ul>	–	2
Rituals were just “made up” (on the spot), emerged from sudden ideas/impulses	<ul style="list-style-type: none"> <li>• Made them up, they dealt with chance. For example, ‘If I make this shot in basketball I’ll get an A on my test.’</li> <li>• Quickly, I said to myself: ‘If you reach the door at the same time as the man (to make me go faster), you will find something nice, a letter, a lunch.’ I promised myself a reward, but I knew that it might become true even without the promise to me; I did not want to promise anything completely absurd. But I knew that it could also not occur, but I admitted that to myself only after I performed what I had promised something for. I used those rituals thus to incite myself.</li> </ul>	6	4
Rituals were triggered by unpleasant/traumatic experiences	<ul style="list-style-type: none"> <li>• They started when I started driving and I often would count cars passing, and one day after the eighth car, there was an accident. I do not know why it affected me.</li> <li>• In my opinion, they emerged after unpleasant experiences that needed an explanation. One is rarely inclined to see oneself as the determining causal factor of the unfavorable events.</li> </ul>	5	2
Rituals emerged by the coincidental parallel occurrence of events	<ul style="list-style-type: none"> <li>• The cause of this ritual is, in my opinion, that I walked that way maybe coincidentally and then, especially that day, the lessons would—contrary to expectations—be good.</li> </ul>	6	–
Others	<ul style="list-style-type: none"> <li>• A certain anxiousness [ . . . ] was over-compensated by a strong religiosity, that caused a fast faith in wonders. The rituals might have been an outlet of this faith; they were their field of activity. When the thought of causality slowly interfered, religiosity served to outcompete it (God can do anything, even act against laws).</li> </ul>	5	4

Wegner, McCarthy, and Rodriguez (2006) showed in several studies—with which they examined whether having thoughts related to an event before it occurs leads people to infer that they caused the event (*magical causation*)—that this quite often is the case, even when the thought-about outcome was unwanted by the research participants (also cp. Rothbart & Snyder, 1970). In 2009, this parallel occurrence is only referred to by the interviewees with the examples given for the traumatic events that preceded magical

rituals. The *chronosystem* (see Figure 37.1) stresses the importance of the situation when we examine the emergence of magical rituals. An individual might be more receivable for the adoption of magical rituals in stressful than nonstressful situations (e.g., after traumatic or stressful events, Keinan, 1994; also De Rios, 1997, presented how cultural superheroes [*magical realism*] can be used as an intervention for traumatized children). Another important factor of “time” or the *chronosystem* is the *Zeitgeist* being reflected

**Figure 37.1** Different environments with potential influence on magical rituals (cp. Bronfenbrenner, 1979).

in the content of different rituals. Even though the function of rituals seems to be fairly stable over time (based on the observations presented above), the content is not. Werner's and Muchow's participants state, for example, that they would count a specific type of horse ("Schimmel"=gray horse) which was, at their time, still an important matter of transportation. With horses being replaced by cars, they are not mentioned anymore by today's participants. Overall, we can say that magical rituals are not caused by a single factor, but emerge out of the interplay of personal, social, and cultural factors (cp. Risen & Gilovich, 2008). Closely related to the question about what causes magical rituals is the question of what they are good for: Why do individuals engage in magical practices? Some answers to this question are already implied in the categories described in Table 37.2. The rituals that were made up on the spot, for example, serve the function of *self-motivation*. This is explicitly mentioned by the interviewees: "Because I tend to procrastinate often these help me stay on task" (WV-ID 11), or "to make me go faster" (MW-ID 472). They are applied to serve a specific purpose at a certain moment (only). They are very much controlled by the individual to challenge oneself, escape boredom, or—as one of Muchow's and Werner's interviewees phrased it—"to counterbalance the too much reinforced intellectualism in school" (MW-ID 485). Rituals of this kind seem to be not as

"powerful"—meaning the effect *on* the person, not the effect they had *for* the person—as other rituals that almost seem to dictate the actions of an individual and are perceived as not willingly controllable ("I suffered from such mental compulsion and they bothered me" MW-ID 480). The latter would lead us to rituals described in connection with OCD and would therefore serve a different function: *reducing feelings of anxiety, fear, and discomfort*, and *increasing feelings of control and security*. For the first, additional evidence is provided by the answers to Question 4 (see below).

Again, we observe a continuum of ritual controllability: from willingly and purposely inventing and applying rituals that are based on the *Law of Participation* to being dictated by such rituals that cannot be willingly controlled. The cases in which individuals state that rituals help, but that they do not have to perform them necessarily, would lie in between the above-described extremes. It is very likely that the relief (emotional component) an individual feels after applying a certain ritual determines the frequency with which it is used, but we cannot prove this assumption with the data collected. Further research is needed in this case.

We stated above that children rely on magic when they encounter events that both violate their expectations and elude adequate physical explanation. Is this also true for adults? Two of our participants

actually describe events that would fall into this category, one being: “I thought if I was skating particularly good one day—and not the others, and I was doing everything the same, there must be some mysterious force that was improving my ability or that I was just getting lucky that day” (MW-ID 5). Experimental studies with adults also confirm that adults also tend to assume relations between events, where—rationally speaking—there cannot be any (cp. Risen & Gilovich, 2008; Pronin et al., 2006). Thus, magic is indeed considered when we are *lacking alternative, rational explanations*—but not only then.

**Question 4:** Do you think that these rituals that you performed during adolescence developed because you were afraid of important decisions or maybe even afraid of life in general?

Of our interviewees, 29 answered this question, as did 30 of Muchow’s and Werner’s interviewees. The interviewees in both groups differentiated between the different things they were afraid of—if they were afraid—so that we decided to do the same when summarizing their answers (see Table 37.3).

Overall, the samples do not differ much in their answers confirming that anxiety was and is an important trigger for magical rituals.

**Question 5:** What happened if you were meant to do something to influence an outcome and then you didn’t succeed? [American sample only]

For the American interviewees, we added the above question to find out how fragile/stable the belief in these rituals was. The answers were again categorized and are displayed in Table 37.4.

The different reactions to the failure of a ritual may be influenced by the importance the particular ritual has for that person. Some of our interviewees were just able to “shrug it off” (low importance), other simply denied the failure and looked for alternative explanations (high importance)—the most popular one being blaming oneself instead of the ritual.

Although Werner and Muchow did not ask specifically what we asked, some participants still described situations in which rituals lost their importance or were abandoned altogether. The following case shows that the importance of what one wishes for also is an important factor:

**Table 37.3 Summary of the answers to Question 4 (multiple answers possible)**

Category	Sample answers	1928	2009
No		11	9
Yes (without further explanations)		5	6
Maybe (without further explanations)		–	5
Afraid of life in general	<ul style="list-style-type: none"> <li>Probably more because of being afraid of life in general.</li> </ul>	5	–
Afraid of important decisions	<ul style="list-style-type: none"> <li>They did not that much emerge because of being afraid of life, but because of being afraid of important decisions.</li> </ul>	5	–
Afraid that something bad will happen (failure)	<ul style="list-style-type: none"> <li>Probably, I’ve always been afraid of losing a family member.</li> <li>Maybe because I was scared that if I didn’t have these rituals it would be hard for me to get motivated any other way.</li> <li>I think I was afraid of not being perfect.</li> </ul>	5	7
Afraid of solely being responsible for one’s actions	<ul style="list-style-type: none"> <li>Because I don’t want to be solely in charge/responsible for my actions.</li> </ul>	2	2
Afraid of authorities	<ul style="list-style-type: none"> <li>Being afraid of the mother and school.</li> </ul>	2	–

**Table 37.4 Categories, sample answers, and frequencies for the answers to what would happen if a ritual was not successful (American sample only) (N = 23)**

Category	Sample answers	2009
Blame myself, instead of ritual	<ul style="list-style-type: none"> <li>• I would blame myself most likely (for poor preparation, etc.) rather than blame the rituals, although I may consider what the outcome would have been if I had followed them.</li> </ul>	6
Shrug it off/ignore it	<ul style="list-style-type: none"> <li>• I'd just ignore the oracle and do what I wanted anyway.</li> <li>• Shrug it off.</li> </ul>	4
Feel bad/awful	<ul style="list-style-type: none"> <li>• I would feel awful.</li> </ul>	3
Try again (later)	<ul style="list-style-type: none"> <li>• I would make sure to do it next time; it was almost like a superstition.</li> <li>• Then I would try again and hope it worked better.</li> </ul>	3
Re-interpreted situation	<ul style="list-style-type: none"> <li>• Talk myself into believing that it actually worked, just in a modified version.</li> </ul>	2
Change ritual (was flawed)	<ul style="list-style-type: none"> <li>• Perhaps the ritual was flawed; I would need to modify it.</li> </ul>	1
Deny it, but keep believing in it	<ul style="list-style-type: none"> <li>• I start denying it, but still believing in it next time it occurs.</li> </ul>	1
Would be disappointed, but kept believing in them	<ul style="list-style-type: none"> <li>• Disappointed but didn't diminish my belief in them.</li> </ul>	1
Lost some faith in them	<ul style="list-style-type: none"> <li>• I lost some faith in the rituals.</li> </ul>	1
Think about it	<ul style="list-style-type: none"> <li>• I would walk away and think about what happened.</li> </ul>	1

When my parents were in hospital, badly injured because of a car accident, I desperately tried different things to influence their fate. Being very religious from early on, I prayed to God. I also jumped over a fence in the yard that was 1.3 m high and believed that things would turn out well because of my success. When my mother died shortly after, things changed: I now hated religion and with that all rituals that I once cherished and that now seemed useless to me. I swore to myself never to believe in any rituals like that again, or to suppress them should they occur nevertheless, (MW-ID 476)

**Question 6:** Did you keep those rituals a secret or did you talk to others about them? Who did you tell? If you didn't tell anyone, what were the reasons? [German sample only]

A question that only the German sample answered was the one above asking whether rituals were kept secret or not. The vast majority says that they did not speak to anyone about their magical practices

(N=26; 78.8%). Only one person said that he *did* speak to others about these things. Unfortunately, he did not comment any further on this statement. Six people (18.2%) replied that they selected the people they talked to very carefully: They did talk to some and did not talk to others. What were the reasons for not talking to anyone or to carefully select the appropriate confidants? Most of the participants that gave reasons said that they were afraid others would laugh at them, they were embarrassed or feared embarrassment (N=18). Other reasons were that discussing a ritual might have affected its success (N=1), the ritual was not a conscious thing (N=1), one did not want to bother others with subjects they were not interested in (N=1), the ritual was too important (N=1), or too insignificant (N=1), or—last but not least—the ritual was not the business of anyone else (N=1).

These answers show that magical rituals usually are a very private matter. Applying magic often means to act against one's better knowledge ("I know this is not rational, but ..."), which cannot

easily be justified when being confronted with it. The functions discussed above show, nevertheless, that magical rituals make “personal” sense and can fulfill different, important purposes (*see* Question 3)—even though knowledge would suggest otherwise. Furthermore, the magical rituals created by the person oneself are parts of personal culture—hence not necessarily shareable with others.

### **Conclusion: The Unbearable Pleasures of Magic**

If we think that a society has left magical thinking behind, because of the technological and economic orientations, think twice. The phenomena of fascination with Harry Potter and the lures of getting rich by luck on a stock market bring us to new magics of the video screens and consumer cults. Contemporary societies abound in ever-new magical rituals in public life and on TV screens. Hence, magical rituals:

... are not merely the product of people who have failed to reach formal operational thought; rather, they reflect the felt limits of science and technology for answering questions about meaning, value, and being. These issues are significant, not only in their own right, but also for the insight they provide into the wider importance of existential concerns in human development.

(Vandenberg, 1991, p.1284)

Instead, magical thinking is part of any forward-oriented productive thinking. Human minds weave their semiotic webs of organization of the meaning so as to face the future. This is mostly accomplished by thinking in complexes—rather than in concepts. Lev Vygotsky emphasized that:

... the complex, like the concept, is a generalization and unifier of concrete varied objects. However, the tie with which this generalization is built, can be of most different type. Any kind of link can lead to the inclusion of a given object in a complex, if it only practically exists—and the characteristic feature of the complex is exactly that. When linkages of unified type—logically equivalent to one another—are at the foundation of the concept, very varied factual linkages that often have nothing in common with one another, are the bases of a complex. In the concept, objects are generalized by one characteristic, in a complex—by most varied practical bases. That is why in the concept the relevant, unifying link and relationship between objects finds its reflection, while in a

complex—practical, occasional, concrete [relations are reflected].

(Vygotsky, 1931, p. 250)

The process of differentiation and hierarchical integration in the process of moving from complexes to concepts was viewed by Vygotsky to entail an important transitional form—that of *pseudo-concept*. This is a form of reasoning that at the outside looks like *concept* (i.e., seems organized by an abstract, unitary relation between objects), but in reality remains a *complex* (i.e., entails multitude of relations between objects). Among those relationships, the beliefs in rationality of the necessarily irrational world are widespread.

The invention of the supernatural is particularly rampant in critical life situations. In the civil war in Uganda in the late 1980s, it was the war activities that were cast in the power of supernatural forces (Behrend, 1999). Such inventions are possible thanks to the capacity of the mind to create semiotic hierarchies that can include high-level field-like signs (Valsiner, 2007). The crucial nature of the supernatural forces a person could believe in is their nebulosity—they are considered to be responsible for very concrete acts, yet they are not in any place. They are believed to be everywhere.

### **Future Directions**

Contemporary cultural psychology needs to take a fresh look at newly emerging examples of magical thinking. Looking at these phenomena at the intersection of society and individuals can reveal the connections of intrinsic motivational forces and social guidance of human minds. More specifically, it would be important to study:

- What kinds of social representations (“luck,” “devil,” “success,” etc.) support the emergence and use of new personal magical rituals;
- How a person creates one’s new “lucky charm” in one’s personal life? How would magical moments enter into any mundane area of living? The invention of a ritual of luck in competitive settings, or of a new belief in the power of a new electronic gadget in bringing happiness into private lives;
- How social institutions promote the use of magic thinking in social situations—in peace and war settings.

### Abstract

Evidence for relativistic theories of rights and duties is overturned by an analysis of supererogatory acts in Afghan, Asian, and Spanish-speaking cultures. The authors present a cultural evolutionary account of the development of rights and duties to explain the appearance of certain universals in the domain of justice. An order of evolution is proposed: from functional origin in primitive social relations, to informal labeling as “rights” and “duties,” to formalization in black-letter law. The authors recommend two future directions of research: an investigation of the cycle of rights and duties as understood in different political and cultural contexts, and a closer analysis of universal duties, beyond human rights alone.

**Keywords:** rights and duties, supererogation, cultural evolution, primitive social relations, universals, family rights and duties, religious systems, normative justice, cycle of rights and duties, Afghan culture, Latino and Spanish cultures, Asian cultures

Do you refuse me, Antigônê? I want to die with you:  
I too have a duty that I must discharge

These words are spoken by Ismene, sister to Antigônê, in a play by the same name, written by Sophocles (442 B.C./1977, p. 207) at a time when Athenian democracy was at its height. The democracy of Athens was centered on *duties*, demands placed by others on the persons who owe them. Every Athenian male citizen not only served in the military, but also had judicial, legislative, and executive duties:

Even many of the highest offices in the land were filled by allotment and so could fall on any citizen; almost all offices could be held only for a single year. In this way maximum participation was achieved, and every man was a public servant.  
(Lang, 2004, p. 7)

This sense of duty was shared by women: Antigônê buries her brother Polyneicês, a rebel

against the king, even though she knows she will be killed for this act. Her sister Ismene also requests to die with Antigônê, in order to discharge her duty. This duty, says Antigônê, is for laws that:

... are not merely now: they were, and shall be,  
Operative for ever, beyond man utterly  
(Sophocles, 442 B.C./1977, p. 203)

The centrality of duties in ancient Athens seems far removed from the culture of twenty-first-century Western societies. Indeed, the march of technological, scientific, economic, and political progress in Western societies has been accompanied by a trumpeting of *rights*, what we are owed by others, from the struggles of the suffragettes to win voting rights for women, to desegregation and the civil rights movement that eventually allowed an African-American to be elected as America’s president in 2008, to gay rights, disabled person’s rights, senior rights, children’s rights, patients’ rights, animal rights, and

so on. But this has not been a universal trend; the “progress of rights” has not moved forward much in practice, if at all, in some countries. For example, though rights such as freedom of expression and freedom of assembly are taken for granted in Western societies, these remain severely restricted in many parts of the world, such as China, Iran, and Russia. Indeed, despite the 30 articles set out in the *United Nations Universal Declaration of Human Rights*, and “agreed to” by nearly all nations as signatories, there are obvious violations of rights in many countries. These sometimes include Western countries as well; critics point to the U.S.-led invasion of Iraq in 2003, torture of Iraqis at Abu Ghraib prison by U.S. military personnel, and other such “incidents” to support the claim that Western societies also violate human rights.

It seems, indeed, that there is “. . . no universally honored conception of rights and duties” (Louis & Taylor, 2005, p. 105), and that rights and duties are normative and can be socially constructed and justified in many different ways, particularly by those who enjoy greater power. For example, in some societies powerful groups serve their own interests by highlighting duties (e.g., in Iran the duty to obey the “Supreme Leader” is highlighted), whereas in other societies, power groups prioritize certain rights (e.g., the right of the super-rich to spend hundreds of millions of dollars to influence election results in the United States, justified under the “right to freedom of expression”). This *relativistic* viewpoint runs against the idea, as suggested by Antigoné, that there are duties (and rights) that are “not merely now,” but “forever” and “beyond man” in the sense that they are found in all human cultures.

The question of whether there are universal rights and duties is one of a number that psychological science has explored, as reflected in the volume *The Psychology of Rights and Duties* that brought together an international group of leading scholars in this field (Finkel & Moghaddam, 2004). We begin this discussion by describing a hierarchy of rights and duties and clarifying our position on five questions that are central and must be addressed in any psychological account of duties and rights, including the question of possible universals. Next, we describe a cultural evolutionary account of the development of duties and rights. This evolutionary perspective suggests that certain functional behaviors evolved early in our history, and at a later stage in human evolution these were labeled “duties and rights” as part of informal everyday life. Still

later, selected duties and rights became transformed and formalized in *black-letter law*. A psychological understanding of duties and rights thus considers the development of these informal rights and duties, which evolved prior to formal, black-letter law.

This overall process will be explored using examples of *supererogatory duties*, behaviors that a person is not obligated to perform, but is applauded for carrying out, and *supererogatory rights*, or what a person is owed by others, but is willing to forgo for the sake of the greater good (Moghaddam, 2008, p. 56). We use cross-cultural examples from case studies in Afghani, East Asian, and Spanish-origin cultures to showcase the power of social norms in shaping formal and informal rights and duties. Evidence for relativistic theories of rights and duties, we argue, is overturned by a cultural evolutionary account of social behavior in the domain of justice. We propose that although there are large variations in duties and rights across cultures and across time, this variation has masked certain universals, small in number but of great importance.

Our argument in support of universals is “top-down” and is rooted in our “cultural evolutionary” conceptual framework. On the other hand, we work “bottom-up” to show variations across cultures in rights and duties. Given the foundational influence of religious systems on conceptions of rights and duties in the contemporary world, we begin by exploring rights and duties in religious systems.

## Religious Systems and the Hierarchy of Contemporary Rights and Duties

The next day he took out two denarii, gave them to the innkeeper, and said, “Take care of him; and when I come back, I will repay you whatever more you spend.”

(Luke 10:35 (NRSV))

Today the concept of supererogatory action is generally used in a secular context, though its origins lie in religious ethics. The term appears in the Christian ethical debates in the late Middle Ages in reference to voluntary works that are besides, over and above God’s commandments. In the biblical parable of the Good Samaritan, a man from the southern region of Samaria in Israel finds a stranger on the roadside who had been beaten by robbers. The Samaritan takes the stranger to an inn, bandages his wounds, pays for his lodging, then promises to go above and beyond: “I will repay you whatever more you spend.”

In Latin, “super-erogare” means to over-expend, or pay in addition. In the Roman Catholic tradition, supererogatory acts constitute not simply the performance of good works, but good works beyond sacramental requirement. Roman Catholic officials held that such acts, often performed by saints, could create a “store of merit which the Church can dispense to others to make up for deficiencies” (OED, 1989). This framework has been applied to other acts such as sexual abstinence in place of marriage and procreation (Mellema, 1991). In the early sixteenth century, controversy erupted around the Catholic Church’s interpretation of supererogatory acts in exchange for indulgences paid to the church. These were cited perhaps most famously in the Ninety-Five Theses against the church by Martin Luther. Today, the Church of England still requires all clergy to declare allegiance to thirty-five articles of faith including one (Article 14) stating that “the performance of supererogatory acts cannot be taught without arrogance and impiety” (“Opera quae Supererogationis appellat non pussunt sine arrogantia et impietate preaedificari”) (Book of Common Prayer, 1662/1999).

Importantly, the concept of supererogation is not unique to Christianity. In Jewish law the Talmudic concept of “beyond the letter of the law” (*lifnim mishurat ha din*) applies to self-sacrificial acts of fairness and charity that go above the bare minimum prescribed by law (Shilo, 1978). In Islam, the concept of *Isaal-e-Sawaab* refers to performing a good deed and granting the heavenly reward for that act to another person, a practice not entirely unlike the Roman Catholic conception of stored merit, as well as the Church of Latter Day Saints’ doctrine surrounding the afterlife and “saving ordinances” for deceased relatives. To perform *nafl* prayers in Islam, prayers beyond the general minimum of five times each day, is supererogatory. So too are extra fasting, the giving of voluntary charity (*sadaqa*) beyond obligatory alms (*zakat*).

In secular ethics, divine command is substituted for formalized laws and rights. British philosopher J. O. Urmson (1958) argued that saintly and heroic acts should constitute a fourth category in secular ethics, beyond categories of mandatory, permitted, and forbidden. A soldier who throws himself on a grenade to save the life of his comrades, according to Urmson, is committing a supererogatory act. It is neither required, nor morally neutral, nor forbidden by law. The standard view, generally held by philosophers Urmson (1958), Sheldon Peterfreund

(1978), and Robin Attfield (1979), is that an act becomes supererogatory when it meets three criteria: (1) it is beyond the call of duty, (2) it is meritorious or praiseworthy, and (3) omission of the act is not blameworthy. Secular acts of supererogation have been argued to include legal pardon and clemency by kings and presidents, volunteering and community service, acts of qualified self-sacrifice such as election to be an organ or blood donor, and acts of forgiveness, conscientious tolerance, and forbearance (Heyd, 1982; Benbaji & Heyd, 2001; Portmore, 2003).

To be clear, little has been written about supererogatory rights and duties, but some debate around the criteria for supererogatory acts continues in the disciplines of philosophy and ethics. One group argues that supererogatory actions must be self-sacrificial and other-regarding: the act should be “completely gratuitous” (e.g., Heyd, 1982), it should bring “much good for the other person,” and should be performed “at considerable cost or risk to the agent” (Rawls, 1971, p. 11), and should be “more onerous for ourselves” than for others (Hale, 1991). Others disagree, arguing that supererogatory acts can be self-regarding (Kawall, 2009) and without benefit or even intended benefit for others (Mellema, 1991). Susan Hale (1991) argues that there are no truly supererogatory actions, only apparently supererogatory actions motivated by duty or principle. This is reminiscent of debates in social psychology about whether or not there really is *altruism*, behavior intended to help another, without regard for benefit to oneself. Among the major theories of altruism, the empathy-altruism model of Batson (1995) is closest to assuming there is true altruism—all of the others dismiss this assumption (Moghaddam, 1998, Chapter 9). In this discussion we are not interested in the question of whether or not either supererogatory acts or altruism actually exist according to some objective criteria, but in the question of how, by labeling a behavior as “supererogatory,” society influences behavior. In the next section, we further clarify our conceptual orientation.

## Five Basic Questions

At the outset it is useful to clarify our position on five foundational questions concerning duties and rights: source, function, relationship to supererogatory rights, free will, and replaceability. First, what is the source of duties and rights, particularly as set out in formal or black-letter law? Second, what is the functional nature of black-letter law? Third,

what is the relationship between black-letter law and supererogatory duties and rights? Fourth, should we assume that humans have some measure of free will (in the domain of rights and duties, at least)? Fifth, are rights and duties replaceable?

With respect to the source, there are two major positions: *natural law*, whereby duties and rights are assumed to have derived from natural and divine sources, and to have been discovered by humans; and *positive law*, where duties and rights are human constructions and can vary over time and across societies. The account we develop strongly supports a positive law interpretation, based on cultural evidence. We argue that duties and rights arise out of cultural evolution that is to some degree shared between humans and other animals, but we do not see it as necessary to assume an inherent universal “moral grammar” (Hauser, 2006). Rather, we adopt a functional interpretation whereby certain behaviors, later interpreted as duties and rights, prove to be adaptive and continue to manifest themselves in the behavior of animals and humans.

Second, we adopt a minimalist interpretation with respect to the functional nature of black-letter law. That is, black-letter law answers the question: what is the minimal or lowest standard of acceptable behavior? This “minimal” takes shape, we believe, with respect to the functional needs of society. Black-letter law reflects the baseline conditions for the survival of a particular form of society, given its various characteristics, and especially its group-based inequalities and power relationships. From this perspective, then, law is a set of rules, enforced by institutions, that sets the minimal acceptable standard of behavior, to sustain a particular type of sociopolitical order.

Third, black-letter law and supererogatory duties and rights together define the boundaries of obligations, since we argue that supererogatory duties and rights establish the “upper level” for standards of behavior in a given society, just as black-letter law establishes a minimal or “lower level” standard of behavior. For example, imagine if Sam is standing on a bridge, looking down at the boats passing in the river below. A father and child are standing near Sam. Black-letter law sets the minimal “lowest” standard for Sam’s behavior: Sam must not push the

child into the river, since doing so would be a criminal offense. On the other hand, if the child accidentally falls into the river, black-letter law does not stipulate that Sam must dive into the river to save the child. If the child falls into the river and drowns, Sam will not be sent to jail for failing to be courageous enough to dive into the river to save the child. However, if Sam does dive into the river and saves the child, she will be enthusiastically applauded and she might even receive a medal: a supererogatory duty fulfilled (see Figure 38.1)

Although informal social and cultural norms influence parenting practices, and in turn, the formation of rights and duties, formal black-letter law also influences family contexts and informal norms. The relationship is reflexive. For example, black-letter law formally defines certain parental duties according to definitions of abuse and neglect. However, numerous instances illustrate the mismatch that can occur between parenting practices and the law, particularly among immigrant groups; parenting practices that are common in one culture may be legally construed as neglect and a failure to fulfill parenting duties in another. The practice of *cupping*, a traditional medical technique performed in some cultures, is interpreted as child abuse in some contexts. In regions of Africa, a mother who fails to circumcise her female child is chastised by other women in the community, whereas female circumcision in the United States is punishable by prison and the child may even be removed to government child custody. Similarly, Hmong parents who view epilepsy as a form of spiritual rapture have often been charged with neglect for not seeking treatment for their children (Coleman, 2007).

Also, black-letter law reifies the informal rights and duties in the family. Imagine a woman named Helen, a retired English banker living in Paris, who decides to make a will that leaves almost all of her considerable fortune to charity. This is accepted by her first husband and their two children, who are English and live in England. Indeed, after the initial shock of learning about the contents of the will, most of Helen’s English family applauds her action as an example of a supererogatory duty. However, the situation is very different with Helen’s second husband, a Frenchman, and their three French

**Figure 38.1** The continuum of “minimal standard” (black-letter law) to exemplary (supererogatory rights and duties) behavior.

children, who all live in Paris and adhere to French law. From the perspective of Helen's French family, her will is not only illegal, but immoral. Indeed, in 26 out of 27 member countries of the European Union (EU), Helen's will would be regarded as illegal, because in most of these countries about half of the estate is automatically inherited by surviving children (unless they have committed parent killing or the like). In most of the European Union, Helen would not be legally allowed to leave her estate to charity.

The situation in England and Wales is very different because the individual enjoys almost complete freedom to decide who will inherit the estate, and thus there is room for Helen to carry out a supererogatory duty by allocating her estate to charity. This Anglo-Saxon tradition of individual choice is also present in the United States. Now consider the influence of black-letter inheritance law for a recent immigrant family to the United States. If the family immigrated from one of those 26 EU nations in which Helen's action was illegal, informal family perceptions of inheritance rights and duties will likely give way to formal law, over successive generations. In essence, black-letter law sets the boundaries of supererogatory duties and rights.

Fourth, in religious systems as well as in secular ethics, a supererogatory act assumes at least a minimal level of free will and conscious choice, so that merit can be rewarded on the basis of the assumption that the meritorious person freely chose to do good rather than evil. It is assumed, for example, that saints and heroes are not forced to do good works; they act as individual agents. But in traditional experimental psychology, it is assumed that independent variables (such as environmental factors external to the person, or cognitive mechanisms within the person) serve as causes, and bring about changes in dependent variables. In this cause-effect relationship, there is no room for free will. An argument has been made that while some behaviors are causally determined, other behaviors, including behavior in the realm of duties and rights, are better explained through a normative account, which does allow for free will (Moghaddam, 2002).

A *normative account* of behavior assumes that much of human thought and action is regulated by norms, rules, and other features of the normative system. Most of the time, most people behave according to the rules for correct behavior in a given context. However, people can choose to behave in non-normative ways; second, certain behaviors are

causally determined rather than normatively regulated. For example, when her optician asks Susan, "Can you read the last line?" This has to do with Susan's visual performance being causally determined by factors such as aging (what Moghaddam, 2002, has termed *performance capacity*). Susan could read the last line when she was 20 years old, but can no longer read it now that she is 50 years old. But if Susan's optician asks, "What do you think that symbol means?" This question has to do with the meaning we ascribe to things, or what Moghaddam (2002) has termed *performance style* (for example, "Oh yes, that symbol represents a mysterious love potion on this tropical island!" versus, "That symbol is just a gimmick used by the local tourist board to attract more visitors to this island!").

The fifth question concerns the replaceability and interchangeability of duties and rights: can a duty always be reinterpreted as a right, and a right as a duty? We can identify two main conceptual positions on this issue (*see* Dembour, 2006 *for an example of a more detailed classification*). First is the natural law position, which holds that at least some duties and rights are fixed. For example, the duty to abide by certain moral imperatives, such as "thou shalt not steal," "thou shalt not kill," and so on are purely duties; a duty to abide by the command "not to steal," "not to kill," and so on, cannot be changed to a "right not to steal," a "right not to kill," and so on. Similarly, a "right to freely choose a God" cannot be replaced by a "duty to freely choose a God."

The other view, which we find more compelling, takes positive law as a point of departure, where duties and rights can be interpreted as replaceable in almost all cases. This is suggested by various examples across societies in areas such as inheritance of estates and voting in elections.

### ***The Power of Context and Replaceability of Rights and Duties***

Our final two suppositions—the power of social context to influence choices and free will, and the replaceability of rights and duties—merit special attention as keystones in our argument. For the first, consider Gregory Mellema's (1991) prisoner example. A man is held prisoner by political terrorists, and he is commanded to swear allegiance to the leader of the terrorists—and to renounce allegiance to his own government. The prisoner knows that a refusal to cooperate will result only in bad consequences. He will be beaten, and the angered terrorists will only stiffen their resolve to

eradicate all opposition to their cause. Moreover, no one but the terrorists will ever know if he refuses. Nevertheless, the man is willing to endure these bad consequences. As a man of high principle, he is simply unwilling to renounce allegiance to his own government. Mellema considers the prisoner's decision supererogatory because he acts out of a concern for morality or principle. It would appear that the prisoner chooses this freely, without force or coercion—indeed, against coercion.

Now suppose the prisoner had been a member of the Taliban government in 2001, and his capturer had been an American military officer. Would it make a difference on whether the act can be called supererogatory? Then, would it make a difference if the prisoner were John Walker Lindh, an American citizen who fought on the side of the Taliban? In the first case, we must ask: whose morality and whose consequences make the act supererogatory? In the second example, group affiliation and expectations of citizenship matter: John Walker Lindh is an American citizen, but affiliated with the Taliban. For Lindh, a decision not to renounce allegiance to the Taliban would be supererogatory within the norms of Taliban group identity, and forbidden within the norms of American group identity. In fact, Lindh did not report his American citizenship to his captors, despite the fact that it might have provided him better treatment. What becomes apparent is that assumptions of praise are relative to perspective: Who blames? Who praises? In both cases, the moral logic is rooted in group identity.

Free will, for an individual, therefore presumes certain group constraints. However, a social psychological perspective also considers collective and communal acts, beyond individual choices. Duties and rights are fundamentally normative expressions, and norms are shaped by groups and cultures more than individuals. Consider a collective agreement by a military group not to pillage an enemy village captured in war, or to show clemency when it is neither required nor forbidden. If supererogatory acts may be collective expressions, it follows that supererogatory rights and duties can be expressed through groups and networks: family networks, tribal networks, nation-states, and networks of nation-states such as the United Nations. Indeed, international declarations of human rights and duties may be argued as supererogatory acts themselves, as meritorious expressions by diverse communities responding to global forces.

Importantly, as we will observe through animal and cross-cultural human examples in the next section, the fact that supererogatory duties and rights are manufactured by culture does not make them arbitrary. In practice, duties and rights embody internal logic and serve adaptive purposes for survival. Our argument assumes a social intuitionist model, where morality, like language, is an evolutionary adaptation for intensely social life; moral intuitions are both innate and enculturated and can best be understood in an evolutionary context (Bekoff, 2005; Haidt, 2001).

To some extent, attention to cultural context makes it obvious that rights and duties are replaceable. Replaceability can simply be a matter of group perspective. Suppose there is an English woman of some wealth named Lady Slattery, and Lady Slattery writes a will leaving the bulk of her estate to her gardener. One group of villagers claim that Lady Slattery “Did not have a right to do this!” while another group claims, “She did her duty, because the gardener was completely devoted to her.” Because Lady Slattery lives in England, black-letter law allows her to fulfill this right/duty. But as seen in an earlier example, had she lived in France she would be obligated (by French law as it stands in 2010) to leave at least half of her estate to her children—and her choice would have been limited at the outset.

Similarly, in the domain of elections, the act of voting can be interpreted as a right or a duty, depending on context. According to black-letter law, voting is treated as a right in some countries (such as the United States) but a duty in some others (such as Australia, Belgium, and Switzerland). Even in countries where voting is treated as a right, the attitude of (at least some) citizens is that citizens have a duty to vote. For example, among some groups of “patriots” it would be unpatriotic for a citizen not to vote in national elections. On the other hand, among other groups, who might also see themselves as patriotic, it is a duty not to vote, because voting in national elections would strengthen the central government and thus work against their libertarian vision of what the nation should be in the ideal (i.e., a country of free individuals unencumbered by a strong central government).

A clearer variation across countries concerns the participation of prison inmates in elections. In the United States, inmates are banned from voting in most states, and even former inmates are banned in some states. In the European Union, seven of the 27 European Union member states (including the

United Kingdom) do not permit inmates to vote in elections. In these countries, inmates do not have the opportunity to carry out voting as a supererogatory duty, because they do not have it as a legal right. In other countries where inmates have the right to vote in elections, voting can become a supererogatory duty.

The proposition that duties and rights are replaceable is also supported by a number of empirical studies (Moghaddam & Riley, 2005), particularly in the family context. For example, in studies of families with young children, researchers found that parents tried solving sibling conflicts through “care” orientations emphasizing duties (“You should share your toys with your sister because she loves you”) while young children prioritized “justice” orientations emphasizing rights (“It’s not fair—these are my toys!”) (Lollis, Ross, & Leroux, 1996; Lollis, Van Engen, Burns, Nowak, & Ross, 1999). The same transaction, sharing a toy with a sibling, led different actors to invoke either rights or duties in accordance with their perspective. As the authority figures in the family system, parents appealed to duties; in contrast, children challenged parental authority by invoking their rights (Moghaddam & Riley, 2005).

### **Primitive Social Relations and the Evolution of Duties and Rights**

Having explored a few ways that duties and rights are bound by group context and social positioning, we now turn to illustrations that help describe duties and rights as functional adaptations that evolve over time. A *cultural evolution* explanation assumes two major stages in the development of duties and rights: first, the emergence of certain styles of behavior, termed *primitive social relations* (Moghaddam, 2002, p. 40), that are adaptive and enable some people to compete better for scarce resources and to improve survival chances; second, at a later stage the labeling of such adaptive behaviors as a duty or a right, depending on cultural conditions. The timing and sequence of the second stage, labeling and interpreting primitive social relations in terms of duties and rights, is unclear. It might evolve tens of thousands of years after the emergence of a particular primitive social relation, or shortly after. In this theory, primitive social relations arise out of the common challenges confronted by humans. These challenges are partly based on human physical characteristics and the physical environment. Commonalities here—bodily and environmental

constraints—result in certain universal styles of behavior adopted by humans, the roots of which lie in our evolutionary past.

### ***Primitive Social Behaviors among Animals***

The evolutionary account we provide suggests that the roots of “fairness” should be found in animal behavior and, indeed, there is some evidence to support this idea. Rudimentary behaviors that later developed to be labeled as duties and rights are reflected in cooperation and empathy among animals (Bekoff, 2005). Elephants help injured or ill members of their group, as do whales and dolphins. During play, high-ranking wolves are known to “handicap” themselves by engaging in role reversal with lower-ranking wolves, even allowing the low-ranking wolves to bite. If the low-ranking wolves bite too hard, it will initiate a “play bow” of submission before the play resumes. Coyotes who bite too hard during play can be ostracized by the rest of the group (Bekoff & Allen, 1997). Ant colonies are highly cooperative; often individual ants will sacrifice themselves to increase survival chances of the group (Wilson, 1975). Monkeys react negatively when they witness other monkeys receiving more favorable rewards for the same effort, or for less effort (Brosnan & de Waal, 2003). Mice reacted in ways that could be interpreted as empathic when they observed cagemates, but not strangers, suffering pain (Langford et al., 2006). Although insects and animals do not make sacrifices, act empathic, or feel unfairly treated out of political ideology or principle, their behavior has been interpreted as reflecting “wild justice” (Bekoff, 2005) and demonstrating a level of behavioral continuity between animals and humans. Humans were able to move to increasingly complex interpretations of justice through the evolution of their sophisticated social lives.

### ***Human Settlements, Duties, and Rights***

The evolution of duties and rights in human societies took a dramatic turn after the transition, around 12,000 years ago, from hunter-gatherer to settlement societies. Development of agriculture and the domestication of animals allowed for the growth of a reliable surplus, which was used by power elites to develop institutions for governance and control. Through the monopoly and control of the surplus, power elites supported security and military forces, as well as administrations for collecting taxes and redistributing wealth to benefit their supporters.

These developments led to the growth of larger and more complex urban centers, with an established elite enjoying “high culture.” For example, the Minoan civilization that flourished on the island of Crete lasted about 1,500 years, from 2,600 to 1,100 B.C., and centered around luxurious palaces with over 1,000 rooms each. The Minoans were one of a number of civilizations that flourished in the Mediterranean region from around 5,000 years ago and laid the foundation for the Greek city-states, culminating in the golden age of Athenian democracy. The foundation for these developments was trade between stable and secure urban centers.

The development of large urban centers and the flourishing of interstate and intrastate trade and commerce had foundational implications for social relations, because now a normative system was needed to regulate frequent and necessary interactions between strangers, rather than just kin. Until this time, and for almost all of our evolutionary history, we lived in small, nomadic groups. Evidence suggests that during the many thousands of years of our existence as hunter-gatherers, we lived in groups numbering a few hundred in size (*e.g.*, Dunbar, 1993). This long evolutionary past has led some researchers to argue that the optimal size for human groups continues to be 150 to 200 members (*see* Moghaddam, 2008, p. 34). Certainly, this “optimal group size” seems to exert influence on the way even high-income twenty-first-century societies are organized, particularly in terms of the organization of local or “everyday-level” small groups. For example, although many people now work in organizations with hundreds of thousands of employees and live in cities with millions of inhabitants, they actually function in small work units (*e.g.*, the office or university department) and neighborhoods that allow some level of intimacy and face-to-face interaction with other group members (Moghaddam, 2008, pp. 77–79). However, whereas during our hunter-gatherer era our small groups consisted mainly of others who were our kin, in twenty-first-century Western societies our work, neighborhood, and even social groups tend to consist of nonkin.

Out of interactions between nonkin individuals and groups has evolved practices such as turn-taking, which appears across multiple cultures (Moghaddam, 2000), as well as other practices that help mitigate competition over resources and encourage collective fairness. These normative practices continue to influence behavior in modern societies, so that for the most part order is maintained

without “calling in the law” (Ellickson, 1991). Here duties and rights appear as functional adaptations, with cultural variations reflecting local conditions, a topic we turn to next.

## **Culture and Supererogatory Acts**

Whereas our argument for universals in rights and duties was top-down and began with discussions of primitive social relations and evolutionary processes at a high level of abstraction, we now turn to a bottom-up analysis to highlight variations in rights and duties across cultures. Our specific focus is on supererogatory rights and duties in Afghan, Asian (especially Korean), and Latino- and Spanish-culture family contexts. Family units are primary sites for the development and transmission of supererogatory rights and duties. Certainly, the family is only one of many social systems into which a developing child is socialized, but all societies have developed one or another form of family structure (Segall, Dasen, Berry, & Poortinga, 1999). In family contexts we can observe how culture defines certain behaviors as either duties or rights, obligatory or supererogatory. However, in highlighting variations across cultures, we do not lose sight of possible universals and in the concluding discussion we argue that the highlighting of cultural variations ultimately serves the purpose of pointing to a small number of commonalities across cultures.

## ***Socialization of Rights and Duties in Families***

Human beings do not develop in isolation, but rather in a unique physical and social context influenced by culture. Culture and child-rearing is therefore intimately linked: children must learn to survive and grow in their given context, and parents must prepare the next generation for integration into the existing culture (Bornstein, 2010). Cultural values therefore influence not only the form of families, but schools, neighborhoods, and other social structures. The shape that these social structures take has great implications for rights and duties, as we will see later.

Within families, duties can be delegated to parents, children, or members of the extended family. In most cultures, however, actors with the greatest face-to-face interactions with children—for example, parents, teachers, and babysitters in Western contexts—are most directly responsible for providing the bare necessities of development. In many contexts now, failure to fulfill these duties can be

formally prosecuted as child abuse or neglect. Nevertheless, it is important to remember the origins of these behaviors as informal duties establishing a minimum requirement for behavior.

In countries such as the United States, for example, parents are almost solely responsible for feeding, protecting, and nurturing their child. In other more collectivistic cultural environments, the child's regular face-to-face interactions include members of the extended family, neighbors, and family friends. By extension, the minimal duties assigned to parents in the United States are now assigned to aunts, uncles, grandparents, and the like. Among the Nso in Cameroon, for example, a child "belongs" to the community as a whole. Educating the child according to social norms and enforcing discipline is an obligation shared by all adults, not merely parents (see Nsamenang in this volume for a discussion of social exchanges in non-Western family contexts.) The exercise of such duties is not seen as encroaching on a parent's responsibilities because the parents are not solely accountable for the child—and perhaps not even principally responsible for the child's development (Rabain, 1979).

Beyond these minimalist obligations, characterizing behaviors as supererogatory duties becomes difficult because what is laudable (though not required) in one context may be expected in another. There are informal pressures at play, which complicate assumptions about what is "required." For example, payment by an uncle for his nephew's school tuition may be supererogatory in Western contexts though required in others. In the United States, an uncle would not be the boy's legal guardian, so he has no minimum legal responsibility. In the absence of social norms that pressure him into supporting a child that is not his, the uncle's contribution is supererogatory by virtue of meeting all conditions established by theorists: the act is beyond the call of duty, meritorious, and its omission is not blameworthy (Peterfreund, 1978). However, if the uncle lives in a context where there are informal social pressures to support his nephew—e.g., an assumption that males must be caretakers of extended kin, as often the case in tribal societies—paying for the nephew's education fails the first condition of a supererogatory act and becomes an ordinary duty.

Then there may be substantive varieties, a division of labor in supererogatory duties, as it were. For example, kin support among African-American families usually takes the form of practical support (child care, help with transportation, household

work, and so on), whereas European-American kin support is characterized by the extended family providing economic resources or emotional support to parents (Sarkisian & Gerstel, 2004). In both cases, members of the extended family are not expected to provide resources to the same degree as parents. Nevertheless, they are commended for their actions on behalf of children for which they are not directly responsible.

#### RIGHTS AND DUTIES IN ASIAN FAMILIES

Culture dictates more than who is responsible for what within the family; the family is also "nested" in a context of larger social and religious values. For example, among the Javanese, Indonesia's largest ethnic group, a patriarchal social structure and the heavy influence of Hinduism means that individuals' opportunities, duties and rights are determined by their gender as well as their caste. Boys—particularly eldest sons—have greater responsibilities than their siblings, but they also enjoy more attention from their families and have greater rights than their sisters. Similarly, individuals from the *Brahmana* (spiritual leaders) caste enjoy greater rights than those in the *Ksatrya* (warriors), *Waisya* (traders), and *Syudra* (low class society) (Shwalb et al., 2010).

Perhaps one of the best-known examples can be found in East Asians' parenting practices; a review of this literature shows that socialization goals of Asian and Asian-American mothers emphasize children's duties to bring honor to the family in a way that is consistent with the interdependent and collectivistic Asian culture (Kim & Wong, 2002). Many attribute this phenomenon to East Asia's cultural roots in Chinese *Confucianism*, a comprehensive philosophical system encompassing ethics, interpersonal relations, and governance. This philosophy is the basis for *filial piety* (*Xiao*), one of the most important and distinctive concepts of Asian families. In Korea, for example, the devotion of children to parents involves a number of duties that can be classified into five broad categories: obeying (e.g., *Myong-Shin-Bo-Kam*, children must immediately answer when called), attending (e.g., *Kuk-mong-yo-keul*, when parents are ill, children must give priority to attending to their illness), supporting (e.g., *Don-Mon-Seun-Sup*, children must ensure parents are comfortably housed and fed), comforting (e.g., *Yi-ki*, children must be careful not to expose themselves to danger and cause their parents distress), and honoring (e.g., *So-hak*, children must restrain themselves from dietary and sexual

pleasure for 3 years after their parents' death) (Kim & Choi, 1994). Filial piety rooted in Confucian ideals is widespread throughout other countries as well, including Vietnam and Japan. Surveys reveal that the importance of children's duties in Vietnam is on par with Korea: more than 90% of adolescents agreed with the statement that no matter what the circumstances, they would support their parents in their old age (Le, 2000). However, some research suggests that filial piety has weakened in postmodern societies (Shwalb et al., 2010).

In addition to these filial duties, parents in Asian families also have duties to their children. In order for children to reach maturity and exercise these obligations, parents must first raise, care for, and educate their children. Indeed, in Korea, Vietnam and other Asian societies, the concept of "womb education" (*thai giao* in Vietnamese) stipulates particular duties for a woman to her unborn child (Shwalb et al., 2010; Kim & Choi, 1994). Although basic parental duties of raising children may be fairly uniform—feeding, protecting, socializing to cultural norms—the nuances and meanings of these duties vary by cultural context. For example, one ethnographic study revealed cultural differences in attitude toward motherhood among Korean and Canadian women (Kim & Choi, 1994). Whereas Canadian mothers emphasize personal (career) development and maternal caregiving equally, Korean mothers place greater weight on their role as caregivers, and see little conflict in sacrificing their careers for their children. This reflects the Korean culture's deep-rooted consciousness of parent and child unified in "body and soul" (*ilshim dongche*; Choi, 2000; Shwalb et al., 2010). Parents' continual support for their children is also seen in their greater willingness to support their adult children financially. In a cross-national survey of European, North American, and Asian countries, Korean parents were most willing to pay off their children's debt, contribute to college education, and pay for wedding celebrations (Gallup, 1983 as cited in Kim & Choi, 1994). This intense child-centeredness reflects many parents' beliefs about their role in the lives of their children: it is the parents' duty—and a critical part of their existence—to continually sacrifice for their children (Shwalb et al., 2010).

#### **RIGHTS AND DUTIES IN SPANISH-ORIGIN FAMILIES**

Respect for parents and hierarchical family structures, however, are not unique to East Asian

contexts. Much like Koreans, Latino- or Spanish-origin families are also characterized by an interdependent orientation (Oyserman, Coon, & Kimmelmeir, 2002). A review of literature indicates that three cultural values rooted in this orientation—familism (*familismo*), respect (*respeto*), and moral education (*educación*)—are held by Latinos of all national origins and underlie many parenting decisions, including the assignment of rights and duties (Halgunseth, Ispa, & Rudy, 2006). Of these, *respeto* and *educación* are most relevant for our discussion of rights and duties, since they bear on the duties of children and parents, respectively.

In an ethnographic study of Mexican-American immigrant families, researchers described that by the age of 4 years, children are taught verbal and nonverbal rules of demonstrating respect, such as politely greeting elders, not challenging elders' views, and not interrupting adults' conversations (Valdes, 1996). Thus, behaviors parallel some of the filial duties apparent in East Asian cultures. However, the meaning of *respeto* is more comprehensive in that it includes respecting the role of each member of the family, not just parents. For example, sisters did not act affectionately toward their husbands or boyfriends in front of their brothers because to do so would be interpreted as a *falta de respeto*, an affront to the brothers' sense of dignity and their roles as brothers (Valdes, 1996).

*Respeto* is also an important motivator in the grief responses of children and other survivors when a loved one dies. In an account of the funeral ceremonies of Mexican-Americans in Texas during the 1930s through 1950s, Williams recounts family obligations surrounding the funeral rites. Wakes were held in the home over the course of an entire night, and talking and laughing were strictly prohibited during the viewing. At no point was the body left unattended, since doing so would be a sign of disrespect. At that time, widows were also expected to wear black for the remainder of their lives, a concrete symbol of their enduring duty and loyalty to the deceased (Williams, 1990).

If *respeto* is the value most central to children's duties in this culture, *educación* is the most important value for understanding adults' duties to their children. *Educación* extends beyond the English word "education" in that it also refers to the training in responsibility, morality, and interpersonal relations. A close comparison is the concept of *bildung* (education) active in German taxonomy since the sixteenth century: broadly, *bildung* refers to not

only a transfer of literacy or a body of knowledge, but also to a process of personal and cultural maturation (Schmidt, 1996). Ethnographic accounts of Mexican immigrant mothers indicate that mothers often mention *la educación de los niños* (the moral education of their children) as an important parental responsibility. Further studies also indicate the importance of this duty: in a study on child-rearing practices of U.S.-born and foreign-born parents of European, Mexican, Cambodian, and Vietnamese descent, Mexican parents reported that social skills and motivation were as or more important for children's school readiness than cognitive skills (Okagaki & Sternberg, 1993). Similarly, a second study found that Latinos gave higher importance ratings to children's socio-emotional characteristics than Euro-American or Asian-American parents (Okagaki & Frensch, 1998).

Just as respeto motivates the duties surrounding funeral ceremonies, educación plays an important role in the birth and baptism ceremony, another important traditional life-cycle ritual. Most important here is the *compadrazgo* (literally co-parent-hood), the practice of expectant parents selecting a married couple from among their friends to be the child's sponsors at a baptismal ceremony. On the day of the ceremony, the *compadres*, which the child will eventually refer to as *madrina* and *padrino*, are responsible for purchasing the white christening outfit. This functions as a symbol of the *padrinos'* duty: to take care of the child's physical and spiritual needs in the event of the parents' absence (Williams, 1990)

#### RIGHTS AND DUTIES IN FLUX

Although the previous case studies have focused primarily on duties—whether of parents, children, friends, or extended family—it is nevertheless important to address the issue of rights as well. Earlier we argued that rights and duties are in the vast majority of cases replaceable, and that children will give preference to autonomy while adults will emphasize obligations. We also illustrated the influence of culture and group context on the formation of rights and duties. But what happens when families move from one cultural context to another? How are diverse perspectives and identities negotiated, and what does this mean for rights and duties?

In immigrant families, conflict over diverse perspectives and identities is marked by generational differences. For successive generations of Mexican and Central American families in the United States,

adolescents in one study were increasingly likely to believe that disagreeing with parents was acceptable and that autonomy was desirable (Fuligni, 1998). This seemed to indicate a shift from duties (obedience to parents) to rights (freedom to make personal decisions). Another example concerns changing expectations around the marriage decisions of sons and daughters. Spanish-heritage families often experience conflict in these areas, since parents emphasize children's duty to accept a "good match" while sons and daughters stress their right to choose a mate (Baptiste, 1987).

#### *Between Laws and Norms: The Case of Afghan Rights and Duties*

We have seen how black-letter law and informal perspectives influence each other, but what if enforcement of black-letter law appears weak or absent? Such is the case in Afghanistan. In Western literature, Afghanistan is often depicted as a "lawless" and tribal society where drug lords gather private armies and build mansions with illegally acquired gains. Despite a new constitution and strengthened national police force for enforcement, Afghan laws regarding safety, prohibition of alcohol and gambling, or compliance with intellectual property rights are rarely enforced. The Afghan-Pakistan border has remained highly porous; credentials of Pashtun tribal identity are often a more important "passport" than actual citizenship for travel across the Durand Line envisioned by the British (Barfield, 2010). At the same time, Afghanistan is remarkably rule-bound. Daily life is regulated by a mix of "renegade" freedoms and strict cultural, moral, and religious codes—most orally, informally, and locally transmitted through family and village networks. During Taliban rule and still today, an Afghan man could own and operate a gun, drive a motorcycle, and set up his own dentist's office without a government-issued license. However, during Taliban rule the same man would be expected to grow a beard to a fist's length, and perform *namaz* (Arabic, *salah*) prayers five times a day—or face imprisonment and beating. Even today, Afghans still accept harsh legal interpretations that most Western cultures would not tolerate. Under conservative interpretations of *Sharia* (Islamic) law, specifically for the *hudud*, adultery is punishable by death from public stoning. Religious conversion from Islam to any other faith tradition explicitly warrants the death sentence, though can be appealed under conditions of "insanity." In January 2008, an Afghan

court sentenced a 23-year-old journalism student to death for asking questions about women's rights under Islam (Sengupta, 2008).

Where these apparent paradoxes of lawlessness and strict rules intersect, a picture of cultural rights and duties emerges. Like any complex society, Afghans divide and order themselves along a multitude of different social categories, each with formal and informal rule structures. These categories may contradict each other, or apply simultaneously, depending upon the circumstances. Certain rights afforded by local interpretations of Sharia law may be encouraged or discouraged by local custom, and further negotiated at kinship levels. For example, an urban man who takes a second wife by choice, as allowed formally by law, will be ostracized and scorned by the first wife's family network, if conducted without their permission. Although the letter of the law, for moderate Islamic interpretations, requires women's hair to be covered in public, most late-teenage and adult Afghan women still dress in full-body *burqas*.

Not only is law bound, adapted, and sometimes extended by cultural customs, but also the enforcement of law and customs are negotiated at the level of kinship networks. Consider that in 2004, the Afghan *Loyal Jirga*, or Grand Assembly, agreed upon a constitution that provides that both genders "have equal rights and duties before the law" (Constitution of Afghanistan, Article 22:2). Culturally, women are generally not allowed to pedal bikes, drive cars, travel alone, or serve as primary household head in the presence of a male alternate. Women who run for political office, attend co-educational schools, or travel alone often face serious threats; many women have been killed or mutilated for taking these actions, even after the fall of the Taliban in 2001. Yet many Afghan families still urge their daughters to attend local schools, and restrictions on women's mobility and dress varies considerably across kinship networks and nuclear families. This heterogeneity is not arbitrary. In many cases, conditions of poverty at the village level trump conservative religious customs; women will work in fields without burqas and assume otherwise traditional patrilineal roles for survival. In the 2005 parliamentary elections, the world witnessed Afghan women running for parliamentary office, often campaigning through extended family networks of support. In 2005, Afghanistan nominated its first and only female governor, Habiba Sarobi, to assume control of the more liberal and

predominantly Shi'a region of the central highlands, Bamian province.

As these examples illustrate, what constitutes a duty or right—and therefore also what goes beyond the "minimum" behavior required—is negotiated on multiple levels. In tribal societies, lineage members generally have mutual obligations to assist each other—as well as mutual liabilities, in terms of honor and often finances. Anthropologist Bernt Glatzer (1996) observed that among Durrani Pashtun nomads in the western part of the country, patrilineally related kin provide social security and political support. But relations between them can become strained when competing for authority in the kin group and for inheritance. Property is passed patrilineally, as are feuds about previous inheritance. Within maternal kin, however, which lack this resource competition, relations tend to be marked by "cordiality and helpfulness" (Dupree & Gouttierre, 1997, p. 116).

A people, an ethnic group, and a tribe are called *qawm* in Pashto and Dari, and most other languages of Afghanistan. The term reveals that ethnic groups and tribes are structured by genealogical ties. Subtribe or clan is *khel* in Pashto often extending to the level of a neighborhood or village. Kin groups are normally expansive, stretching from the nuclear family unit and the *khel*, to the tribe, to the larger ethnic group. Last in line is the nation-state, which can be fluid where nation-state boundaries and *khel* or *qawm* boundaries contradict—such as along the border between Afghanistan and Pakistan. Local segmentations between tribes are sometimes described by the Arab proverb, "I against my brother. My brother and I against my cousin. My cousin, my brother, and I against the world." The potential for tension with kin is expressed in a common Afghan saying, "Do you have an enemy? I have a cousin." Beneath and between the formal law and vernacular practices governing social behavior are unwritten supererogatory rights and duties. An individual can be applauded for giving up an "unwritten" right, or expected to give up a particular right to preserve social harmony. When facing a shared enemy or threat, the importance of preserving harmony within these kinship bonds increases. An heir to an inheritance may volunteer to share portions of the inheritance with other kin, or demonstrate forbearance or tolerance over a past grievance, where that preserves kinship collaboration.

Another example of supererogatory duties and rights appears in the Pashtunwali code of

hospitality toward guests and travelers. A guest in someone's home has the supererogatory right to ask the host for tea and food. These are customarily offered by the host, with varying degrees of expectation that the guest should accept the offer. The guest has the unwritten right to accept these offers, but sometimes preserves social harmony by not doing so. Taken to an extreme, a guest may demand from the host extraordinary items beyond what is offered, including bedding, clothes, and even money. If the guest demands to be served meat, a luxury food for most Afghan families, the host family would be expected by custom to do so. A failure to serve the guest would be considered shameful. However, exercising these rights may provoke resentment from the host. Similarly, in the Christian parable of the Good Samaritan, the Samaritan offers the innkeeper money for the guest, and then promises to pay for anything more that the guest might need. Offering the option to the guest is supererogatory; it is granting a right, perhaps gratuitously, that simultaneously goes beyond the law and preserves honor within a kinship and cultural context.

Supererogatory duties and rights for guests apply even during wartime. Jason Eliot (1999) recalls a story of Ahmad Shah Massoud, leader of the Northern Alliance, who, while inspecting the front lines against the Taliban in the late 1990s, accidentally took a wrong turn, lost the route, and drove unarmed into the heart of a Taliban stronghold. Massoud, who was instantly recognized and facing almost certain death, demanded confidently to see their leader. So baffled were his hosts at the sudden appearance of their arch-enemy, they obliged, and a cordial exchange was reported between the rival leaders. Their meeting was just long enough not to offend custom, but short enough to prevent the Taliban from realizing that Massoud's appearance in their midst was nothing more than a one-in-a-million mistake (p. 76).

Whether this legend is exactly true or not, it conveys the reality of the Afghan duty of hospitality toward guests. In this case, it saved Massoud's life, but his protection was only afforded when he presented himself as a guest, rather than a fighter. The shift in positioning meant a shift in social codes for what constitutes fair behavior. Certainly, the very same shift in positioning would not work in a Western culture: a member of the Taliban wandering into an American military camp would be served something quite different than tea!

## Common Goals, Different Expressions

As part of cultural evolution, rights and duties across cultures can best be understood as evolved ways of resolving dilemmas; solutions instead of black-letter law (Ellickson, 1991). As we have seen, these are best understood using an evolutionary-ecological approach. Dilemmas may arise from specific physical, environmental, cultural, and historical facts and are resolved by structured tribal and group affiliations where adaptive duties and rights can be enforced (Ferguson & Whitehead, 1992). For example, in Sherry Ortner's (1989) study of the Sherpan Buddhist community of Darjeeling, Nepal, supererogatory acts were found to resolve contradictions in the social hegemony and strengthen low-class social identity. In particular, voluntary construction of Buddhist temples by low-class Sherpan workers in the nineteenth and early twentieth centuries served an adaptive function: on the one hand, these were acts of charity or religious devotion, but on the other, they were an expression of working-class empowerment. Constructing a temple was a "denial that having fewer material resources defined them as 'small,' and of no social consequence" (p. 151). The act carried indirect benefits, such as self-expression and expression of group identity, and resistance of culturally defined hegemony. Ortner explains that "many small [low-status] people who participated in the monastery foundings were like the returning heroes of the schema, newly empowered and expressing or claiming 'bigness'" (p. 153). Supererogatory acts maintained group harmony and collaboration. An informal system of meritorious acts made the working class powerful, and in turn, kept the powerful class in check: priests and power figures were praised for "making statements of smallness, of (political) concern for the people and of (religious) egolessness." Arguably, this expression is no different from the submissive "play-bow" among wolves or other cooperative, evolved animal behaviors.

Within family units, child-parent dilemmas of status, inheritance, and identity were resolved by sending the children to a monastery. Low-income parents unable to provide inheritance for children through property and arranged marriages, could otherwise elevate their family's status through religious participation. Many children pressured their parents to send them to be monks or nuns, where monasticism conveyed high status and exit from low-class obligation (p. 180). Sending a child to join was considered a super-meritorious act, and both parents and children were praised.

Not entirely dissimilar is the American tradition among teenagers from primarily low- and middle-income families to join the military, gaining access to higher status and income. The act of voluntarily joining the military is generally considered meritorious, an opportunity to sacrifice for the benefit of one's country. When the risk of bodily self-sacrifice increases, such as during active combat, the degree of merit increases. In theory, veterans of war are given special respect and valor by their government and countrymen. Super-meritorious and supererogatory acts in combat are rewarded with purple hearts, silver stars, and other medallions. Failure to exemplify special bravery in combat is not punished or blameworthy, but in the case of mandatory military service, failure to serve in combat can be punished.

### ***The Soldier's Sacrifice***

Can there be a "universal ethic" of service in a soldier's sacrifice? Possibly so, but from a functional perspective, supererogatory acts are informal methods of resolving dilemmas. They promote social harmony and survival, rather than a set of universal values per se. Supererogatory acts are best understood therefore not in categories but rather in functional shades and degrees. These degrees vary based on the pressures exerted by the social conditions and relevant spheres of cultural influence. Age, gender, and status, for example, may change the expectations beyond formal duty, as well as calculations of the sacrifice and intentions involved in a supererogatory act. Consider, for example, the case of the American Pat Tillman. Among the thousands of American soldiers who sacrificed their lives in Afghanistan and Iraq, the American press and the United States government gave special attention and praise to Tillman, stating the significance of his sacrifice. Tillman was an American football player who, after the events of September 11, 2001, turned down a multi-million dollar professional sports contract in May 2002, to enlist in the United States Rangers (Krakauer, 2009). Tillman's decision to join the military was considered supererogatory in large part because of the apparent sacrifice involved. A soldier from a low-status background with less access to resources than Tillman would not normally be given the same public praise for the deontological considerations of his supererogatory choice. Given so many financial and personal reasons not to join the military, Tillman is assumed to have acted out of principle rather than social or cultural pressures. It is our position, however, that supererogatory acts

are best understood with reference to principles that function within cultural and functional contexts, rather than separate from them.

### **Minority-Majority Cycle of Rights and Duties: An Example of Universals?**

The identification of cultural variation in rights and duties can be useful, in part to demonstrate the enormous plasticity and range of possibilities in human social life. But we must also return to the question of universals: are there universals in rights and duties in the family context? If so, do they have wider implications outside the family context? Based on the functional analysis we have been using, one possible universal in this context is the *minority-majority cycle of rights and duties* (Moghaddam, 2004), elaborated below.

In all human societies, infants come into this world completely helpless and dependent on others. This means that the young have less power than their caretakers; it is the caretakers who (initially at least) set the rules for behavior and assign rights and duties to the young. Irrespective of whether the child is in a Spanish, Korean, Afghan, or any other culture, it is adults who assign duties in particular. In the caretaker-child relationship, caretakers tend to focus on the duties of children, whereas children assert their rights. This tendency is most extreme in Western societies, where youth rebellion has become a "tradition." Our contention is that the same tendency for caretakers to emphasize duties ("You have to do your homework," "You must tend to the sheep.") and for the growing child to emphasize rights ("I want to go play with my friends.") is found across cultures (Moghaddam & Riley, 2004).

Although the child, a power minority, emphasizes rights, and the caretaker, a power majority, emphasizes duties, the child shifts position when she or he becomes an adult. The child who 20 years ago was rebelling against her parents ("I don't want to do that!") shifts position and emphasizes duties when she has her own child ("I am telling you, you have to do that!"). This "cycle" of rights and duties has wider implications outside the family context.

The study of minority-group behavior reveals that in their relationships with majority groups, minorities tend to give priority to rights—this is reflected in minority-rights movements around the world, along with movements for indigenous peoples' rights, Black rights, women's rights, gay rights, and so on. On the other hand, majority groups emphasize duties, broadly the duty to obey laws that

support the status quo. However, when a minority gains power and manages to become the majority, then there tends to be a shift of emphasis by that newly empowered group from rights to duties. This in part explains the so-called *paradox of revolution* (Middlebrook, 1995): prior to revolutions, minority groups emphasize rights (e.g., “The people must be free to speak and say what they want;” “The people have a right to a higher standard of living.”), but if a revolution succeeds and a former minority group takes over the government, then the “new majority” shifts focus to duties (e.g., “That is not free speech, that is anarchy—we must have limits;” “The people have a duty to work hard.”). The first author witnessed this firsthand during the 1978–1979 revolution in Iran: when in opposition to the Shah, Ayatollah Khomeini and his group demanded all kinds of freedoms and rights for the people, but when they became the government themselves, they clamped down on rights and used an iron fist to demand that people “do their Islamic duties.”

Although the minority-majority cycle of rights and duties seems to be pervasive in actual political processes, there have also been attempts, on paper at least, to reinterpret and use duties to serve the interests of all humankind, including minorities, and to argue that duties are a precondition for rights. Two examples of this are the *Universal Declaration of Human Responsibilities*, proposed by the InterAction Council of Former Heads of State and Government (preamble, *Universal Declaration of Human Responsibilities*, 1996), and the *American Declaration of the Rights and Duties of Man*, proposed by the International Council of American States in Bogotá, Colombia in 1948.

## Summary and Future Directions: In Search of Universals

We see the exploration of duties and rights to be part of a response to the urgent need for cultural psychology to address “The question of relationship between societies ...” (Valsiner, 2009, p. xi). Rights and duties are foundational to worldviews, and shared understandings of rights and duties can serve as a basis for organizing relationships between and within societies.

The functional argument we have proposed begins with certain behaviors, termed *primitive social relations* (Moghaddam & Riley, 2004), that prove to be advantageous for the survival of groups and become pervasive across groups in the course of evolution. An example is turn-taking, a behavior

that is manifested very soon after birth (Collis, 1985) and is essential for key aspects of social life, such as communications (Duncan, 1972). Without turn-taking, communication quickly breaks down. After the emergence of primitive social relations, there evolve cultural practices for labeling the behavior. For example, depending on cultural conditions, “having a turn to speak” can be interpreted as a right or a duty. In democratic societies, “the right to free speech” is given considerable importance, whereas in dictatorships this right is limited to certain power groups and leaders.

Irrespective of the political and family systems of societies, certain rights and duties are necessarily assigned and adopted as a requirement for using certain modern technologies. In these cases, the requirements of technology override local cultural variations. For example, Iran is a dictatorship in which women are treated as second-class citizens, whereas women enjoy equal rights in Western democracies. However, a woman driving a car in Iran participates in turn-taking in traffic with equal rights to other drivers, just as is the case in Western societies. This is because modern roads and cars require standardized rights and duties for all drivers. Of course, it is possible to deprive a group of the right to drive in the first place (for example, it is illegal for women to drive automobiles in Saudi Arabia).

Working bottom-up, we can identify almost countless cross-cultural variations in duties and rights, including supererogatory acts, reflecting the enormous plasticity of human behavior. However, our conceptual orientation allows us to also work top-down and to identify a small but important number of possible universals in the domain of duties and rights, an example being the minority-majority cycle of rights and duties. Of course, even in the case of this possible “universal,” there are cultural variations in how it is manifested. For example, although parents in both the United States and Afghanistan emphasize the duties rather than the rights of their children in the home as they attempt to socialize them to behave “correctly,” there will be differences in the nature of the duties emphasized, the communications used, rewards and punishments practiced, and so on. Consequently, we need to tread carefully in how we interpret “universals” in rights and duties. This is an area for further research: to test the universality of the rights-duties cycle, and to explore the different duties and rights emphasized in this cycle in different cultures.

Similarly, care is necessary when searching for and interpreting other universals in duties and rights. Although some attention has been given to the psychology of rights and possible universals there, little has been done by way of exploring universal human duties. For a right to be justified, theorists contend that it has to represent a justified *claim-to* (a person's justified claim to, say, clean drinking water) and a justified *claim-against* (a justified claim against some addressee to make water unavailable by polluting a water source) (Feinberg, 1973). Thus, any justified right—such as universal human rights—must be accompanied by a duty (claim-against), as the InterAction Council and others have argued. However, little empirical work has been done to investigate these underlying duties, and whether there is cross-cultural agreement on them. For example, we can imagine different societies agreeing that something is a justified claim-to, but disagreeing about the justification of claim-against. Or perhaps arrive at the same conclusion about a justified right, but disagree on what claim-against was necessary to get there.

Duties underpin and complement rights, as has been previously suggested, and as our examples affirm. Thus, duties are a part of even the most individualistic cultures. It is important to note also that these prevailing cultural norms can be suspended temporarily, as is often the case during emergencies such as natural disasters or terrorist attacks. During this time, *triage*, the prioritization of patients based on severity of injuries and chances of survival, becomes the principle motivation for most medical actors and public managers. By necessity then, everyday notions of individual rights are often temporarily put on hold. Future research should focus on how these rights and duties are understood, maintaining an eye out for whether government recommendations to citizens should be couched as either rights or duties.

Future research should also attend to the implications of the different evolutionary paths through which duties and rights have come to take their contemporary shapes. For most of human history, societies have been organized as dictatorships, with people being trained to give highest priority to their duties to obey authority figures, such as emperors and popes. Rights, particularly individual rights, evolved out of revolutionary struggles of the relatively powerless against the powerful, as reflected in various conflicts, from the French Revolution to clashes involving Black Power, women's liberation, and various other

more recent minority movements. Whereas individual rights are a relatively recent focus, individual and collective duties have been a historical focus. Research is needed to explore the implications of these different paths of development for the behavior of citizens responding to government programs.

# The Interface between the Sociology of Practice and the Analysis of Talk in the Study of Change in Educational Settings

Harry Daniels

## Abstract

The point of departure for this chapter is the long-running methodological debate concerning the separability or inseparability of person and context in the analysis of human functioning. The intention is to discuss one means of bringing together the psychology that has developed in the wake of Vygotsky's early twentieth-century writing with the sociology of pedagogy developed by Basil Bernstein. The chapter also draws on methodological developments emanating from a 4-year study of professional learning in multi-agency services. The analysis provides a way of examining the sequential and contingent emergence of new forms of understanding in specific institutional settings. This provides one approach to research engagement with the processes of mutual shaping that occur between persons acting and the institutional settings in which they act.

**Keywords:** methodology, separability, Bernstein, Vygotsky, institutional modality

There is a long-running tension, within the so-called macro-micro debate (*e.g.*, Huber, 1991), between those, such as Giddens, who hold that individual and group cannot be analytically separated because “the notions of action and structure *presuppose one another*” (Giddens, 1979, p. 53) and those, such as Archer (1995, p. 88), who propose various forms of analytical dualism as a counter to the notion of inseparability. This same tension is witnessed in recent developments of post-Vygotskian theory where writers such as Rogoff (1998, pp. 2, 7) espouse a thesis of inseparability and others such as Valsiner (1998, p. 1) advance the case for analytic dualisms (Sawyer, 2002). As I have noted elsewhere, much of the sociocultural or Activity Theory research that claims a Vygotskian root fails to fully articulate an appropriate theory of social structure and an account of how it directs and deflects the attention of the individuals it constrains

and enables (Daniels, 2008, p. 1). Sawyer (2002) argues that even the socioculturalists who do make a theoretical claim for inseparability witness certain forms of dualism in their empirical work. His resolution of the central tension is to reject the “strong” forms of both inseparability and dualism and calls for an approach to analytic dualism that:

... must include postulates about the two-way causal relationship between individual and social properties, including the internalization processes associated with development and the externalization processes whereby individuals affect social structure.

(Sawyer, 2002, p. 300)

In this way he rejects the individualism that is the hallmark of much cognitive psychology and the deterministic internalization that Bernstein suggests is to be found in some approaches to macro-sociology.

A crucial problem of theoretical Marxism is the inability of the theory to provide descriptions of micro level processes, except by projecting macro level concepts on to the micro level unmediated by intervening concepts through which the micro can be both uniquely described and related to the macro level. (Bernstein, 1993, p. xv)

In this chapter, I will develop an account of institutional structures as cultural/historical products (artifacts) that play a part in implicit (Wertsch, 2007) or invisible (Bernstein, 2000) mediation of human functioning and that are in turn transformed through human action. In so doing, I will draw on recent developments in post-Vygotskian theory and Bernstein's sociology of education. That is, I will seek to avoid the trap of projecting unmediated macro-level concepts onto the micro-level. The aim is to provide a means by which the mutual shaping of the macro and micro can be seen through and explorations in the development of understanding.

### Approaches to the Macro-Micro Problem

Mäkitalo and Säljö (2002) outline the recent history of the engagement of social science in the development of understandings of the ways in which institutions exert a formative effect on the production and maintenance of social order. Their particular interest is on the relationship between the structural and enduring features of institutions and interactional dynamics (p. 58). The attempt to unravel what is institutional about talk, and the ways in which talk shapes institutions, brings together macro-micro debates with concerns about the relations of the present to the past. Makitalo and Säljö contrast aspects of *structuralist*, *ethnomethodological*, and *sociocultural* approaches. That is, between the determination of individual social action by social structures, as in structuralist accounts, the generation of social structures and institutions through communicative action, as in some ethnomethodological positions (e.g., Garfinkel, 1967), and sociocultural accounts in which the primary culturally and historically generated mediational means, speech itself shapes and is shaped by the situation in which it takes place. In this chapter, I wish to pursue the notion that the construction of social and organizational reality involves the production of oral, written, and even gestural texts, which participate in the *constitution* of organizations (Searle, 1969). In other words, the texts we produce and exchange not only represent a world, but also have the property of constituting it (Putnam & Cooren,

2004). However texts and/or utterances need not be accorded primacy, as Archer (2000) argues that it is our practice in the world that gives rise to our self-consciousness,

This is not simply a matter of [practice] coming before anything else, though temporally it does just that; it is also a question of viewing language itself as a practical activity, which means taking seriously that our words are quite literally deeds, and ones which do not enjoy hegemony over our other doings in the emergence of our sense of self.

(p. 121)

Practices and the institutions in which they arise are also transformed over time. Zandee and Bilimoria (2007) focus on the historical making and unmaking of institutions. That is, they move from a focus on the "process by which institutions are produced and reproduced" (Phillips et al., 2004, p. 638) to the processes through which existing institutions "weaken and disappear" (Scott, 2001, p. 182).

### Mediation: From Vygotsky to Bernstein

The mediational process is one that neither denies individual or collective agency nor social, cultural, or historical influence. At the very heart of Vygotsky's (1987) thesis is the argument that the introduction of new tools into human activity does more than improve a specific form of functioning, it transforms it. Tools, such as language, are cultural, historical products that mediate thinking and feeling and are in turn shaped and transformed through their use in human activity. It is through tool use that individual/psychological and cultural/historical processes become interwoven and co-create each other. Vygotsky links the development of consciousness to semiosis, and specifically to linguistic semiosis, and thus links the specifically human aspects of our practical and mental life to socio-historical contexts (Hasan, 2005, pp. 135, 136).

It is important to note that Vygotsky's thoughts on the nature of mediation changed during the course of his writing. Wertsch (2007) distinguishes between the accounts of, what he terms *explicit and implicit mediation*. The former is explicit in that an individual or another person who is directing this individual overtly and intentionally introduces a "stimulus means" into an ongoing stream of activity and the materiality of the stimulus means, or signs, involved tends to be obvious and nontransitory (p. 180). He contrasts this with implicit mediation, which he sees as a feature of the later cultural/historical phase of Vygotsky's work.

... implicit mediation typically does not need to be artificially and intentionally introduced into ongoing action (*as in explicit mediation*). Instead, it is part of an already ongoing communicative stream that is brought into contact with other forms of action. Indeed, one of the properties that characterizes implicit mediation is that it involves signs, especially natural language, whose primary function is communication. In contrast to the case for explicit mediation, these signs are not purposefully introduced into human action and they do not initially emerge for the purpose of organizing it. Instead, they are part of a pre-existing, independent stream of communicative action that becomes integrated with other forms of goal-directed behavior. (Wertsch, 2007, p. 183)

Similarly for Hasan (2002) and Bernstein (2000), visible semiotic mediation mediates a specific category of reasoning, a certain range of technical concepts, and a particular relation to the physical phenomena of the world whereby the world is classified and categorized in a certain way (Hasan, 2002, p. 152). Whereas invisible semiotic mediation is concerned with the ways in which unself-conscious everyday discourse mediates mental dispositions, tendencies to respond to situations in certain ways and how it puts in place beliefs about the world one lives in, including both about phenomena that are supposedly in nature and those that are said to be in our culture (Hasan, 2002).

### ***Invisible Mediation***

Invisible semiotic mediation occurs in discourse embedded in everyday ordinary activities of a social subject's life. Bernstein (1990) argues that while the context for mediation is always the social practices of discourse, an important qualification is that in such practices individuals take up specific social positions and are positioned. The same context offers different possibilities for socially positioned actors.

Participation in social practices, including participation in discourse, is the biggest bootstrapping enterprise that human beings engage in: speaking is necessary for learning to speak; engaging with contexts is necessary for recognising and dealing with contexts. This means, of course, that the contexts that one learns about are the contexts that one lives, which in turn means that the contexts one lives are those which are specialised to one's social position. (Hasan, 2005, p. 153)

I will bring the analysis of the sequential and contingent development of innovation into a Bernsteinian

framework in order to open up the possibility of studying the ways in which such action transforms institutional structures while also being shaped by them. In this way, I will seek to outline an approach to the mutual shaping and transformation of individuals and institutions.

### **MEDIATED ACTION IN INSTITUTIONAL SETTINGS**

Wertsch (1998) has advanced the case for the use of mediated action as a unit of analysis in social-cultural research because, in his view, it provides a kind of natural link between action, including mental action, and the cultural, institutional, and historical context in which such action occurs. This is so because the *mediational means*, or cultural tools, are inherently situated culturally, institutionally, and historically. However, as he had recognized earlier, the relationship between cultural tools and power and authority is still under-theorized and in need of empirical study (Wertsch & Rupert, 1993). This recognition is an important step forward from the original Vygotskian thesis, which as Ratner (1997) notes, did not consider the ways in which concrete social systems bear on psychological functions. He discussed the general importance of language and schooling for psychological functioning; however he failed to examine the real social systems in which these activities occur. The social analysis is thus reduced to a semiotic analysis that overlooks the real world of social praxis (Ratner, 1997).

Wertsch's statement that cultural tools are in themselves powerless and only have impact when agents use them (Wertsch 1998, p. 30), when presented starkly in this way could appear platitudinous. Nevertheless, the statement carries an important reminder about the focus and methods for research on learning resources. With his concern for the materiality of means (including speech), he underlines the way in which the material properties of tools can illuminate "how internal processes can come into existence and operate" (Wertsch, 1998, p. 31). He suggests that goals arise as part of the "background framework" or context within which action is carried out and that there may be conflict between the goals of the agent and the embedded goals of the tools. He is interested also in how new forms of mediated action result from emergence of new means and "unanticipated spin-offs." Here he notes that tools can emerge in unpredictable ways through misuse or borrowing from different contexts or through use for different purposes than designers intended.

Wertsch also considers issues of power and authority with respect to cultural tools and their use. He describes mediational means as “differentially imbued with power and authority,” “privileging” and citing Goodnow, imbued with “cognitive values” (Wertsch, 1998). The notion of cognitive values includes “why it is that certain knowledge is publicly available and openly taught while other forms or knowledge are not” and why certain types of solutions are more highly regarded than others (Wertsch, 1998, p. 66). He suggests that the “emergence of new cultural tools transforms power and authority” (Wertsch, 1998, p. 65) and that “forces that go into the production of a cultural tool often play a major role in determining how it will be used” (Wertsch, 1998, p. 142). He raises questions about how tools are manipulated by users and what tactics are used for employing others’ tools. This is an important departure from approaches to socio-cultural studies of the formation of mind, which neglect the wider situation in which people act. The analysis of relations of power and control as they impact on the production of cultural tools and their use is a vital feature of research that seeks to understand an enriched, embedded view of human functioning in the situation in which it develops.

#### **BERNSTEIN AND THE NEED FOR A LANGUAGE OF DESCRIPTION**

Bernstein (1993) argued that the enrichment of Vygotskian theory calls for the development of languages of description, which will facilitate a *multi-level* understanding of discourse, the varieties of its practice, and the contexts of its realization and production. There is a need to connect the theory of social formation of mind with the descriptions that constitute part of the methodological apparatus of empirical research. This should provide a means of relating the social/cultural/historical context to the form of the artifact. If processes of social formation are posited, then research requires a theoretical description of the possibilities for social products in terms of the principles that regulate the social relations in which they are produced. We need to understand the principles of communication in terms derived from a study of principles of social regulation.

Different social structures give rise to different modalities of language, which have specialized mediational properties. They have arisen, have been shaped by, the social, cultural, and historical circumstances in which interpersonal exchanges arise and

they in turn shape the thoughts and feelings, the identities and aspirations for action of those engaged in interpersonal exchange in those contexts. Hence the relations of power and control, which regulate social interchange, give rise to specialized principles of communication. These mediate social relations.

In order to understand social mediation it is necessary to take into account ways in which the practices of a community, such as school and the family, are structured by their institutional context (Abreu & Elbers, 2005). There is a need to connect the theory of social formation of mind with the descriptions that are used in research. This should provide a means of relating the social/cultural/historical context to the form of the artifact—in the present case the patterns of talk understood and analyzed as communicative action. We need to understand the principles of communication in terms derived from a study of principles of social regulation at the institutional or organizational level.

#### **The Regulation of Action in Institutions**

It is not just a matter of the structuring of interactions between the participants and other cultural tools, rather it is that the institutional structures themselves are cultural products that serve as mediators. When we talk, as Makitalo and Säljö (2002) argue, we enter the flow of communication in a stream of both history and the future (p. 63). When we talk in institutions, history enters the flow of communication through the invisible or implicit mediation of the institutional structures.

My suggestion is that there is need to analyze and codify the mediational structures, as they deflect and direct attention of participants. In this sense I am advocating the development of cultural/historical analysis of the invisible or implicit mediational properties of institutional structures, which themselves are transformed through the actions of those whose interactions are influenced by them. This move would serve to both expand the gaze of Vygotskian theory and at the same time bring sociologies of cultural transmission, such as that developed by Bernstein (2000), into a framework in which institutional structures are analyzed as historical products, which themselves are subject to dynamic transformation and change.

Bernstein’s (2000) model is one that is designed to relate macro-institutional forms to micro-interactional levels and the underlying rules of communicative competence. He focuses upon two levels: a structural level and an interactional level. The

structural level is analyzed in terms of the social division of labor it creates (e.g., the degree of specialization, and thus strength of boundary between professional groupings). The interactional level is analyzed in terms of the form of social relation it creates (e.g., the degree of control that a manager may exert over a team member's work plan). Thus the key concept at the structural level is the concept of boundary, and structures are distinguished in terms of their relations between categories. The interactional level emerges as the regulation of the transmission/acquisition relation between teacher and taught (or the manager and the managed), that is, the interactional level comes to refer to the pedagogic context and the social relations of the workplace, classroom, or its equivalent.

Power is spoken of in terms of classification, which is manifested in category relations which themselves generate recognition rules. Possession of these category relations allows the acquirer to be recognized by a difference that is marked by a category as would be the case of the rules that allow a professional to be recognized as belonging to particular professional group. This is not simply a matter of finding out which service someone belongs to, it also refers to the ways forms of talk and other actions may be seen as belonging to a particular professional category or grouping. When there is strong insulation between categories (i.e., subject, teachers), each category is sharply distinguished, explicitly bounded, and has its own distinctive specialization; then classification is said to be strong. When there is weak insulation, then the categories are less specialized and their distinctiveness is reduced; then classification is said to be weak.

Different institutional modalities may be described in terms of the relationship between power and control, which gives rise to distinctive discursive artifacts. For example with respect to schooling, where the theory of instruction gives rise to a strong classification and strong framing of the pedagogic practice, it is expected that there will be a separation of discourses (school subjects), an emphasis upon acquisition of specialized skills, the teacher will be dominant in the formulation of intended learning and the pupils are constrained by the teacher's practice. The relatively strong control on the pupils' learning, itself, acts as a means of maintaining order in the context in which the learning takes place. This form of the instructional discourse contains regulative functions. With strong classification and framing, the social relations between teachers and

pupils will be more asymmetrical, that is, more clearly hierarchical. In this example the regulative discourse and its practice is more explicit and distinguishable from the instructional discourse. Where the theory of instruction gives rise to a weak classification and weak framing of the practice, then children will be encouraged to be active in the classroom, to undertake inquiries and perhaps to work in groups at their own pace. Here the relations between teacher and pupils will have the appearance of being more symmetrical. In these circumstances it is difficult to separate instructional discourse from regulative discourse, as these are mutually embedded. The formulation of pedagogic discourse as an embedded discourse comprised of instructional and regulative components allows for the analysis of the production of such embedded discourses in activities structured through specifiable relations of power and control within institutions.

The language that Bernstein has developed, uniquely, allows researchers to take measures of *institutional modality*. That is, to describe and position the discursive, organizational, and interactional practice of the institution. Bernstein's work has not placed particular emphasis on the study of change (see Bernstein, 2000) and thus, as it stands, has not been applied to the study of the cultural/historical formation of specific forms of activity. In the next section I will discuss some of the methods of data collection and analysis that were developed in a study of professional learning in rapidly changing contexts.

### ***The Learning in and for Interagency Work Project***

The Learning in and for Interagency Working project (LIW) was a UK research council (TLRP-ESRC) study that was co-directed by Harry Daniels and Anne Edwards. It was concerned with the learning of professionals in the creation of new forms of practice that require "joined-up" solutions to meet complex and diverse client needs. We studied professional learning in children's services that aim to promote social inclusion through interagency working. Working with other professionals involves engaging with many configurations of diverse social practices. It also requires the development of new forms of hybrid practice. This called for joined-up responses from professionals and stressed the need for new, qualitatively different forms of multi-agency practice, in which providers operate across traditional service and team boundaries.

Vygotsky was concerned to study human functioning as it developed rather than considering functions that had developed. The essence of his “dual stimulation” approach is that subjects are placed in a situation in which a problem is identified and they are also provided with tools with which to solve the problem or means by which they can construct tools to solve the problem. When applied to the study of professional learning, it directs attention to the ways in which professionals solve problems with the aid of tools that may be provided by researchers. We studied professional learning in workshops that were broadly derived from the “Change Laboratory” intervention sessions, developed by Yrjö Engeström and his colleagues in Helsinki (Engeström, 2007, *see* Chapter X this volume), which incorporates a dual stimulation method.

In laboratory sessions the participants were helped to envision and draft proposals for concrete changes to be embarked upon. They discussed and designed interventions, which were intended to bring about changes in day-to-day practices and, at times, in the social structures of the workplace. These actions were prompted by reflections on the tensions and dilemmas raised by data. Prior to the workshops, interview and observational data were used as a base from which to select data that mirror embodied tensions, dilemmas, and structural contradictions in the practices of each site. In this way, critical incidents and examples from the ethnographic material are brought into Change Laboratory sessions to stimulate analysis and negotiation between the participants. The crucial element in a Vygotskian dual stimulation event is the co-occurrence of both the problem and the tools with which to engage that problem.

Vygotsky’s cultural/historical psychology created demands for methods that could not be met by the existing resources that early twentieth-century psychology offered him. He instigated the development of methods that were commensurate to the challenges that his theoretical program required.

The search for [the] method becomes one of the most important problems of the entire enterprise of understanding the uniquely human forms of psychological activity. In this case, the method is simultaneously prerequisite and product, the tool and result of study. (Vygotsky, 1978, p. 65)

Vygotsky (1978) consistently argued the case for a historically based psychology. By this he meant a psychology that is concerned with the process

of change. He announced that “behaviour can be understood only as the history of behaviour” (p. 65). He was pursuing a method that allowed for a developmental analysis of process that explained human functioning in terms of dynamic causal relations. The dual stimulation method is important in that “it creates the conditions under which a subject’s course of action toward an experimentally given goal makes explicit the psychological processes involved in that action” (Valsiner, 1990, p. 66). His central concern was to study human functioning as it developed rather than considering functions that had developed. The essence of this approach is that subjects are placed in a situation in which a problem is identified and they are also provided with tools with which to solve the problem or a means by which they can construct tools to solve the problem.

The task facing the child in the experimental context is, as a rule, beyond his present capabilities and cannot be solved by existing skills. In such cases a neutral object is placed near the child, and frequently we are able to observe how the neutral stimulus is drawn into the situation and takes on the function of a sign. Thus, the child actively incorporates these neutral objects into the task of problem solving. We might say that when difficulties arise, neutral stimuli take on the function of a sign and from that point on the operation’s structure assumes an essentially different character.

(Vygotsky, 1978, p. 74, italics added)

The essence of this approach, when it is applied to examining professional learning, is that it directs attention to the ways in which professionals solve problems with the aid of tools that are provided by researchers and become modified in the course of expansive learning. In the Learning in and for Interagency Work Project, the focus of our research was on the operational work of education, social-care and health professionals working within children’s services.

In each local authority our research methodology was organized around series of “developmental work research” workshops involving operational staff. Prior to (and in between) the workshops the research team collected interview and observational data that was then scrutinized in workshop settings by researchers and children’s services professionals from each local authority. We worked in three multi-agency settings:

(a) *Nortonville*, a school whose remit has been extended to act as base for other agencies,

(b) *Wildside*, a children-in-public-care team, and

(c) *Seaside*, a multi-professional team that originally was comprised of education professionals but expanded to incorporate social-care and health practitioners.

We organized six Developmental Work Research (DWR) workshops at each site. The aim was to build upon professionals' "everyday" understandings of multi-agency working, juxtaposing these with reflective, systemic analyses of the ways in which current working practices either enable or constrain the development of innovative multi-agency working. The stated aim of the workshops was to address the challenges of multi-agency professional learning by:

- encouraging the *recognition* of areas in which there is a need for change in working practices, and
- suggesting possibilities for change through *reconceptualizing* the "objects" that professionals are working on, the "tools" that professionals use in their multi-agency work and the "rules" in which professional practices are embedded.

#### ANALYZING AND DESCRIBING THE SITES

There was a need to refine a language of description, which would allow the research to "see" institutions as they did their tacit psychological work through the discursive practices that they shape. A way of describing what were essentially the pedagogic modalities of the settings in which we were intervening was required. That is, the most likely forms of institutional practice that would be sustained in those settings needed to be described. A crucial element in the description was to be an attempt to try to identify points at which communicative action will engage with the transformation of the institution. We recognised the importance of developing an approach to the analysis and description of our research sites that could be used to monitor changes that took place over the course of our intervention. All the more so because we were minded by the understanding that different social structures give rise to different modalities of language that have specialized mediational properties. This was part of the development of an account of institutional structures as cultural/historical products (artifacts) that play a part in implicit (Wertsch, 2007) or invisible (Bernstein, 2000) mediation.

From a Bernsteinian standpoint, the relations of power and control, which regulate social interchange, give rise to specialized principles of communication. These mediate social relations and shape both thinking and feeling: the "what" and "how" as well the "why" and "where to" of practice. We were concerned with the ways in which wider social structures impact on the interactions between the participants and their patterns of communicative action.

#### A MODEL OF DESCRIPTION

A model of the setting in which the development of such multi-agency functioning develops must refer to the group of professionals who were involved in the workshops, the wider local authority and the clients who were to be served by emergent multi-agency practices.

#### *Classification and Framing*

Bernstein's (2000) concepts of boundary strength (classification) and control (framing) can be applied to many aspects of such a model. Here we use the terms *instrumental* or *instructional practice* to refer to the pragmatic actions within practice. Within the workshop group, the strength of classification (horizontal division of labor) in the practices of professional agencies and control (framing) over the membership of these groups was examined. The strength of distinctions in the vertical division of labor, the strength of the marking of hierarchy, and the associated relations of control within this hierarchy were also seen to be central facets of the structuring of the workshop groups. The strength of control over the regulative practice (matters of order, identity, and relation) was also noted. In many respects this shows similarities with Engeström's (1992) discussion of the "why and where to" aspects of activity in that the reference is to the values and beliefs that underpin practice. The features of the practices within the DWR group were modeled as follows in Table 39.1.

**Table 39.1 The DWR group: Model features**

Instrumental or instructional practice	Classification	Framing
Horizontal	yes	yes
Vertical	yes	yes
Regulative Practice		yes

**Table 39.2 The local authority: Model features**

	Classification	Framing
Horizontal	yes	
Vertical	yes	yes
Boundary with DWR group	yes	

In the local authority the vertical division of labor between members of the workshop and their colleagues in the wider authority was also taken as a key feature of the research sites as was the extent to which boundaries were maintained between the professions in the local authority. The control over the boundary relations between the workshop groups and the local authority was analysed and described, somewhat awkwardly, as the framing of those relations where strong framing was taken as a boundary maintained by the authority, weak framing as a boundary relation in which the workshop group maintained control and an intermediary position in which a relatively fluid two-way flow of communication was maintained. The features of the practices within the local authority were modeled as follows in Table 39.2.

The extent to which clients were classified as belonging to a particular category of need (strong classification) or as the “whole child” (weak classification) was also noted. This was taken as the division of labor within the client community.

Each aspect of this model was described for each site through data gathered through extensive observations and interviews. A coding grid was developed for each aspect. The codings were independently validated by two researchers. An example is given in Figure 39.1.

The codings were agreed upon for the full model for each site, as shown in Figure 39.2.

We also noted the means by which attempts were made to coordinate services in the wider local authority, as well as the form of any recent disruption in the order of the local authority. These features are given in Figure 39.3.

A crude typification of these sites in terms of a general application of Bernstein’s model of the embedded features of pedagogic practice in which instructional Practice (I) and regulative practice (R) are mutually embedded, but in which one may predominate (see Fig. 39.4).

In this way we arrived at condensed codings of what may be seen as the historical legacy presented at the moment when we sought to engage with groups of professionals at each site.

*Analyzing Communicative Action at Each Site*

David Middleton proposed an approach to analysis that focused on the forms of social action that are accomplished in talk and text and the sorts of communicative devices that are used (Middleton et al., 2008)<sup>1</sup>. This was designed to focus the analytic attention of the research team on emergent distinctions that were argued by participants. This involved the examination of the shift from the “given” to the “to-be-established.” “What it is to do” or “to learn” was not to be assumed as an analytic a priori (Middleton, 2004). Rather, such issues are approached as participants’ concerns or “members categories” (Sacks, 1992; Edwards & Stokoe, 2004; Stokoe, 2006). This analytic shift aimed to move from framing communication as descriptions corresponding to states in and of the world, to the performative organization of communicative action. In other words, what we do with talk and text can be analyzed in terms of what it accomplishes (Potter &

**Figure 39.2** Agreed codings for the full model

Wetherell, 1987; Edwards & Potter, 1992; Edwards, 1992). We emphasized that addressing such issues required a focus on the sequential and contingent organization of session-communicative action. That is, how people's contributions to the sessions are contingently related to each other in terms of the sequential organization of their talk (Middleton et al., 2008).

Its cyclical application enabled: reading, reviewing, interrogating, collating, and comparing all the audio-visual evidence from the intervention sessions in order to identify the emergent strands of learning and proposals for change. The approach was developed as a means of identifying strands of communicative action, which witnessed the sequential and contingent development of concepts over the course

of the year in which the six DWR workshops were organized at each site. In drawing analytical attention to the significance of claims to experience, we were also able to highlight the temporal organization of communicative action. We also used forms of discursive analysis to trace the emergence of what can be taken as the collective and distributed knowledge of people who are charged with the task of working together. We aimed to track the emergent practical epistemologies (*cf.* Wickman & Ostman, 2002; Wickman, 2004) that come and need to be taken as given in order to take account of hitherto unaddressed gaps in the realization of multi-agency practice. Such gaps were identified and worked on through participation in the DWR sessions at each research site.

	Seaside	Wildside	Nortonville
Coordination of agencies and agents	Perceived lack of response to operational staff views (at several levels)	Strong strategy	No strategy which impacted on case study site. Strategy developing within rest of LA
Disruptions	Several major re-organisations Radical localisation of services		Recent leadership changes and reconfigured systems

- Nortonville I/R The instructional / instrumental aspect is predominant
- Wildside I/R An intermediary / balanced position

**Figure 39.4** Representation of the structure of pedagogic practices at each study site

Initially we approached the data with what could be termed a minimal operationalisation of “what it is to learn” from a participant’s perspective. We examined the data for ways participants signaled some forms of awareness that theirs’ or others’ knowledge state is at issue. Such “noticings” provide the resource that engages the participants in their definition/delineation and deliberation of the nature of the practices that make up their multi-disciplinary work. In the data we could identify many such strands of noting and noticing such distinctions that make the difference. Indeed this sort of analysis provided us with a basis for defining a protocol for guiding interrogation and analysis of the data in terms of the sequential organization of such strands. The analysis was therefore initially guided in terms of the following protocol:

**Deixis:** identify when there is some nomination or “pointing” to a particular issue in terms of drawing attention to a distinction that is then worked up to make a difference in subsequent turns.

**Definition and delineation:** look for how that issue is elaborated in the uptake of others in terms of how the following are warranted and made relevant through: (i) qualifications identifying further distinctions; (ii) orderabilities in the organization and delivery of past, present, and future practice; (iii) expansive elaborations of the problematics of practice.

**Deliberation:** identify how some working consensus on what is the case emerges in terms of evoking both particularities and generalities of marking distinctive features of past, present, or future practice.

The analysis then turned to examining in what ways such sequences mattered. If we identified strands of deixis, definition/delineation, and deliberation, what were their contingent consequences for participants? Did they make visible distinctions that made the difference in ways that participants could be identified as attending to what was necessary to

attend to in order to learn to do multi-agency working? In other words, did they lead to some form of departure or development in claims concerning the practice of the participants? This step enabled us to complete the definition of the protocol with:

**Departure:** identify shifts toward qualitatively different positions in practices in terms of the formulation of emergent distinctions.

**Development:** identify when participants specify new ways of working that provide the basis for becoming part of, or having become part of, what they take to be and warrant as a significant reformulation of their practices.

Sequences of communicative action were analyzed in the transcripts of the workshops. Some sequences progressed to departures, others remained at other stages within the model. Related sequences were identified and these were grouped into strands of talk that wove their way through the progress of the each series of workshops. These strands (comprised of different types of sequences) witnessed the progression of learning through and with talk in the workshops. The themes that these strands addressed and the contradictions that gave rise to their emergence were analyzed in activity theoretic terms. At the end of the project, participants were interviewed about what they gained from the experience and subsequent analysis revealed the traces of each site’s strands in the interviews at each site. In this way we developed an approach to the analysis of communicative action in the workshops themselves, along with a rudimentary approach to validation. The next move was to consider the relation between the communicative action that took place and the historically given structures that shaped the practices of participants.

The overall challenge of the project was to show how institutionally established categories and ways of arguing could be reformulated and transformed

into new strategies and activities as part of learning what it is to become engaged with and in multi-agency work. However, without the comprehensive analysis of the communicative action within the sessions across all the research sites we would not have been able to progress to the final analysis of those transformations (Daniels, 2006).

### ***Communicative Action and Structural Change***

The notion that guided the further development of the analysis was that the institutional arrangements at a particular site would direct and deflect the possibilities for action by participants. This suggestion was witnessed in the findings.

The data suggest that at a very general level there were stronger values of classification and framing of the instructional practice in Nortonville and progressively weaker values in Seaside and Wildside. In addition, a consideration of the nature of the regulative practice in each site suggests strong framing in Seaside, weak framing in Nortonville, with Wildside occupying an intermediary position. Thus, in Nortonville the instructional practice (which was strongly classified and highly framed) predominates over the weak regulative discourse. Whereas in Seaside the relatively weak boundaries witnessed in the weaker values of classification of the instructional practice were embedded in the regulative practice through which common values and meanings have been the object of much of the early work of the team. In Wildside an intermediary position was witnessed in the embedding of the instruction and regulation.

Over the period of interventions in the workshops, many structural transformations were witnessed. The Bernsteinian analysis revealed the boundaries where communicative action in each site was most engaged and how that action was regulated. Analysis revealed how a focus on institutional boundaries and relations of control provided important tools for understanding the shaping of transformative learning in specific settings.

For example, by the end of the intervention it was the weaker regulative practice of Nortonville that was the object of intervention from an external agent. The historical legacy of the strongly bounded extended school site within which professional practices were highly controlled. These remained distinct from each other provided a setting in which a move to multi-agency working and thus weaken-

ing of boundaries was most likely to be achieved through external influence on the values and beliefs within the DWR group (the regulative practice). This was confirmed through the analysis of communicative action within the workshops. An educational psychologist acted in this way.

In Seaside the focus of communicative action was on the rules and practices of communication within the instructional practice. Participants became frustrated by the contradiction between legacy rules (maintained by the local authority) and the new emergent objects of multi-agency work. They had already established a strong regulative practice before the DWR intervention was initiated. On the basis of this legacy they sought to examine the contradictions in the instrumental aspects of their practice and began to bend (or even break) the legacy rules. The strong boundary between the workshop group and the local authority was maintained through practices of communication in which instructions (rules) were formulated and transmitted by local authority strategists who were unresponsive to replies or ideas formulated by operational professionals within the workshop group. This approach which we termed 'd-analysis' confirmed that the boundary between the workshop group and the local authority was the focus of the communicative action in the workshops.

In Wildside the relation with clients became the predominant concern. There were no strong barriers between the group and the authority, and although the categories of professional agencies within the authority remained strong, the learning focused on ways in which multi-agency work could be coordinated through strategic tools. These tools were the focus of much of the communicative action in the Wildside workshops.

The strong boundaries around the professional categories and the strong control over professional behavior in Nortonville maintained the practices of individual specialists. In what was, in essence, a contract culture in which specialist labor was purchased in order to meet needs that were stipulated by one agency, there was no debate or development of the regulative discourse, the "why and where-to" features of the practice. Here the formation of a collection of specialists was mediated by explicit means. Whereas at Wildside there were weak boundaries around the professional categories in which professionals were situated in the workshop and they were more in control than their peers in Nortonville. However their operational professional practice witnessed strong

boundaries between services and their professional peers. In Seaside the weakened professional boundaries and relations of control that had been weakened through rule breaking and bending gave rise to a collection of workers who drew on the primary strengths of their colleagues when they recognized the need for their expertise. Values coordinated by strategy resulted in a coordinated collection of specialists in the field. The implicit meditational effect of the boundary between the operational and strategic aspects of the work resulted in transformations, in the form of rule bending, that were not open to articulation by practitioners. It was only when their changes in practice were represented to them that they realized the nature of the changes they had made in their work.

## Conclusion

This approach gives some insight into the shaping effect of institutions as well as the ways in which they are transformed through the agency of participants. We modeled the structural relations of power and control in institutional settings, theorized as cultural/historical artifacts, which invisibly or implicitly mediate the relations of participants in practices in which communicative action takes place. This communicative action was then analyzed in terms of the strands of evidence of learning in and for new ways of working. This provided empirical evidence of the mutual shaping of communicative action by organizational structures and relations and the formation of new professional identities.

This approach extends the application of Bernstein's work to the study of the transformation of institutional modalities over time. The analysis of communicative action provides an approach to the consideration of the sequential and contingent development of concepts over time in specific institutional settings.

This approach to modeling the structural relations of power and control in institutional settings were theorized as cultural/historical artifacts, which invisibly or implicitly mediate the relations of participants in practices. Their communicative action may be analyzed in terms of the strands of evidence of learning in and for new ways of working, giving some insight into the shaping effect of institutions, as well the ways in which they are transformed through the agency of participants. It opens up the possibility of developing increasingly delicate descriptions of the rules and division of labor that are obtained within and between settings.

At the same time it carries with it the possibility of rethinking notions of agency and reconceptualizing subject position in terms of the relations between possibilities afforded within the division of labor and the rules that constrain possibility and direct and deflect the attention of participants.

## Future Directions

There are many challenges ahead for the development of this approach. Given that the delicacy of the model of description may be adjusted to the demands of the research question:

1. How do we ensure that we are asking the right questions about the potential institutional contributing factors, which exert a formative effect on inter- and intrapersonal functioning, and
2. How do we ensure that we are observing the relevant forms of inter- and intrapersonal functioning when we come to consider the shaping of institutional change?

These are questions about what might be called *lens adjustment* in research.

There is a related question concerning the considerable challenge inherent in the search for methodologies that allow us to uncover the range and extent of invisible or implicit meditational means in different situations.

## Notes

1. I am grateful to David Middleton for permission to draw on project notes for this section.

## The Work of Schooling

Giuseppina Marsico and Antonio Iannaccone<sup>1</sup>**Abstract**

The communication process between the school and home is a universal relation that is crucial for cultural organization of human development. Through the *balcony metaphor*, the chapter outlines how the school is a *place in between*, a border constantly interfaced with both internal aspects (practices, discourses and different actors) and the wider sociocultural climate. The school balcony, as a border zone, is an area of contact with other relevant educational settings. By standing on the balcony and by adopting a binocular-type vision focused inside and outside school, this contribution explores the many processes implied in the work of schooling, moving from the role played by the socio-economic and cultural dimensions, passing through the analysis of intersectional points with other educational contexts (such as family-school meetings), arriving at the definition of identity in the school (the suggested *Educational Self notion*). The choice to “be” on the school balcony, even if it’s an uncomfortable position, allows one to assume a perspective where one is able to grasp the inherent dynamism of the boundary phenomena.

**Keywords:** balcony, boundary process, inside and outside the school, school-family intersection, Educational Self notion

When you think about the school, the most common image that comes to your mind is likely a large, multi-storied building with a spacious entrance and several rooms, more or less of the same size.

This image, that you probably draw from biographic memory and experience as a student, comes in clearly and seems ordinary to your eyes. Besides negligible details, the school seems a place connoted by some features—including architectural features—concurring to build a prototypical and shareable image. When we think about the work of schooling, something similar happens. Suddenly the image comes to mind of a classroom furnished in a standard way, with students and teachers carrying out some activities. The visual and virtual tour of the school, slowly winding before your eyes, seems to follow a specific pathway: you enter the building through the nearly empty entrance hall,

All conversational sequences we present in the following pages were fully transcribed according to the Jeffersonian conventions (Jefferson, 1985). See the appendix for symbol definitions that are used in the excerpts.

walk through the corridors,

enter a classroom where something is going on between teacher and students, following a format (front lesson, discussion, assessment).

But is that really all there is? Do not you think that something is missing? What's missing? Something does not actually appear in this journey—something that the schools do not have—a balcony.

Why a balcony? Why would a school need a balcony? Can you visualize a balcony? Obviously, a school does not need a balcony—but the school can be considered to be a metaphoric balcony of the society itself.

### The School as a Balcony

Schools all over the world hardly ever have balconies<sup>2</sup>. In this imaginary topology, we want to look at the work of schooling from the viewpoint of a metaphoric balcony. In our view, the school is just comparable to a balcony because it is exactly a *place in between*. It is part of the whole—an establishment of learning—but also a frontier, bordering on the outside. In fact, the balcony is a *place that is a non-place*. It is an extension of the house where various events of daily life and many relevant social interactions take place. But the balcony is also a space outstretched toward the outside, suspended in space. It brings the intimacies of the inside to the public visibility on the border with the outside—without abandoning the inside.

School as balcony must constantly face the internal and external world in terms of culture—sociopolitical climate, social change, systems of beliefs and values, conceptions of education or, in other words, the *Weltanschauung* and *Bildung* shared at given time. It also faces challenges in terms of social norms (for example, how the relations between adults and children in different social settings are regulated) and of relations with other institutions (such as families, religious organizations, local authorities, etc.).

The metaphor evoked—like every metaphor—is not a strategic and simple way to summarize concepts. It is an evocative modality to talk about the work of schooling because it contains the way to immediately grasp the multifaceted and concrete state of this specific topic (Lakoff & Johnson, 1980; Dooremalen & Borsboom, 2010). Looking at the work of school from the balcony is certainly an uncommon and maybe uncomfortable position. On the balcony you are actually exposed to unexpected events such as the change of weather conditions. However, from the balcony you can observe both inside and outside the building. From this position you can grasp both internal elements coming out—like the good smell of coffee or an Italian kitchen, people laughing or quarrelling—and external elements coming in—for example, fresh air, light, smog, and noise. Many other things happen

in the narrow and hanging space of a balcony. The balcony actually exposes you to world outside. It is a physical space distinct from the house's interior, which is instead made of well-known objects with their usual place. It is a distinct social space where some forms of interaction with neighbors take place. From the balcony, you can observe life going on and be observed in return, you can look at the changing landscape, the world in movement, the succession of the seasons. On the balcony, you can grow plants or keep the dustbin.

### ***Inside and Outside: The Balcony as a Border Zone***

Applying this metaphor to the work of schooling, we may say that choosing to be on the balcony transcends the idea of school as a closed territory, characterized by its own culture of education (Bruner, 1996), estranged and far away from the real world. This choice rather assumes a perspective able to grasp the dynamism and movement between different social settings, connections and implications between school and broader culture characterized by some ideas about education, some specific form of social organization, beliefs, and shared models of behavior, as well as sociopolitical and economic change. In the metaphor, the balcony is the point of contact between the school—with its own practices and discourses (laughing and quarrelling), its old and new cultural artifacts (coffee, Italian kitchen, material and symbolic objects that are available and familiar)—and the outside world, where different social changes take place (succession of the seasons and change of landscape), and in which different educational models and belief systems coexist, sometimes opposing and disorienting (fresh air, light, smog, and noise). Like every boundary zone (Lewin, 1936; Tüomi-Gröhn, 2007; Tüomi-Gröhn & Engeström, 2003; Konkola, 2001), the school balcony is a place of social interaction with other actors (neighbors) and of intersection with other educational contexts, relevant for a child's development. In order to manage the encounter with the "Other" (for example, families, other education agencies, community), a school has at its disposal more or less adequate tools (plants or dustbin) that can make it fruitful or difficult meeting the world outside.

In this contribution we will attempt to better direct the look, focusing not only on what happens inside and outside school, but especially what happens on the border. The construct of "border"

seems to be heuristically relevant, from the point of view of psycho-social processes, to explore some psychological dynamics and exchanges between life contexts where development events take place. The use of boundary notion is, obviously, not new in psychology. Sufficient is to refer to Kurt Lewin's perspective focused on boundaries (Lewin, 1936).

### **BOUNDARY PROCESSES AND PSYCHOLOGICAL MEMBRANES**

It is the boundary conditions—structured and dynamic as a "membranes" in biological systems (Belousov, 1998)—that we need to explore. The inherent open-ended nature of sociocultural phenomena requires a new theoretical framework that enables us to grasp the fluidity of the relations between different parts of the dynamic system (Tavory, Jablonka, & Ginsburg, 2012). Recent advances in modern biology seem to provide a set of heuristic concepts useful to investigate the complexity and fluidity of the relationship between different contexts. One of these is the notion of plasticity derived from Waddington's epigenetic approach (1940, 1957). *Plasticity* is related to the different possible responses (more or less adaptive, active, predictable, or reversible) of one organism to the various environmental conditions. Such fluid and opened-ended plasticity is a relevant feature of the boundary conditions. The interest for the boundary process is strictly connected with the "crossing boundaries" phenomena. It calls for focusing on what happened on the border or, following our metaphor, what happens on the balcony. We will adopt binocular-typevision, enabling us to constantly focus on both aspects—what happens to actors inside and outside school in the broader cultural context—because we are aware that school walls, as argued, are much more permeable than previously theorized by psychological research.

Even though constantly paying attention to the whole of field forces (Lewin, 1951) inside and outside school, we will attempt to "zoom in," from the analysis of some elements of sociocultural context significantly affecting education, to the way school gets in contact with other education agencies, to explore how the history of one's educational experience affects the definition of Self.

### **A View through the Balcony**

Our privileged position on *the balcony* enables us to clearly observe the twofold function of school, referring to both individual and interpersonal

processes and contextual and cultural aspects with their interconnection. This position enables us to see the unity of differences operating within the same whole (Valsiner, 2009). School holds a prominent position in most societies—as well as in psychological research—because of its crucial role in both individual and social life. In the school context, the individual reaches a series of cognitive, social, and affective achievements that are fundamental in development to become able to appropriate of the culture he/she belongs to (Rogoff, 2003; Lopez, Najafi, Rogoff, & Arauz, 2012) and it happens through more and more active participation in shared social practices. Within the sociocultural context of a given society, school is also the catalyst element—sometimes propulsive, sometimes inhibitory—of specific social processes (Toomela & Valsiner, 2010; Cabell, 2010; Steininger, 2008). On the other hand, school plays more frequently a homeostatic function, devoted to preserving the *status-quo* of society.

### **Context as a Ground of a Figure**

The key element allowing the creation of the relationship inside and outside the school is the idea of a link between context and culture with the *figure* itself (Kindermann & Valsiner, 1995). In this sense, context is the *background* of a *figure*, and cannot exist separately, according to Herbs't's co-genetic logic (1995). When a phenomenon comes into being, context is necessarily there. This idea is in contrast with the cross-cultural and “traditional” psychological concept of context, understood as something into which a person is placed. Following this perspective, school should be a context into which a child is placed. Instead, we argue that when a child enters the school, this context becomes part of the child just because he is in the school. A relationship between the child and the school is thus established, rather than a unilateral effect of school, family, or society on the child. This could be an example of the view we would not follow—context, and its cultural features, as separated from individual processes taking place in school. In some sense, even Bronfenbrenner's model (1979) *de facto* accepts that view. He would probably oppose this claim, but the way he presents the context at multi-level essences of different systems actually separates the context from actors. Undoubtedly, the ecological theory of human development is one of the most interesting scientific perspectives to have emerged during the twentieth century to study the development processes. It

assumes that development can be understood only considering it as a process integrated with social and environmental conditions.

Since its first comparison in the 1970s, Bronfenbrenner's model has had a great impact on the psychological field. Unlike other models, although sophisticated, it offers conceptual tools essential to understand the relationship between certain specific elements of development and the role played by the characteristic of the environment. As stressed by the ecological systems perspective, family and school are the fundamental contexts in which social development takes place. This assumption, widely shared, is the basis of many researches that, at different levels, have examined how things work in these two micro-systems. Few studies, instead, have investigated their intersection. How and where do family and school contexts intersect? Which is the representations' systems produced by the actors in one context toward the other micro-system? Which are the regulatory dynamics taking place during the encounters of the two micro-systems? These questions require defining the nature of this intersection and the way in which the person becomes person-in-the-context. Valsiner's notion of context (1987) is closer to the concept of the functional relationship between person and environment, in which the organism creates the context and the context creates the organism in return, even if they are not melted into one entity. This differs from Rogoff's perspective (2003), in which the two aspects are considered similar and connected, rather than unified but separated. The idea of *inclusive separation* (Valsiner, 1987) is a more heuristic look at the relationships than the idea of *exclusive separation*, in which person and context are just separated—or *fusion*, in which they cannot be distinguished at all. A phenomenon cannot be theoretically analyzed “in relation” without having parts that relate. In order to understand the dynamic nature of the relationship between person, context, and culture, it is worthwhile to theoretically keep person and environment together, like separate entities always related as a whole.

### **THE MUTUAL FEED-FORWARD LOOP**

The theoretical perspective—sensitive to the connections and mutual definition between different elements within the same whole and to the *mutual feed-forward loop* between person and context—seems to support the methodological choice of “positioning on the balcony,” constantly directing the look inside and outside school. In this way, is thus

possible to examine how, during everyday activities inside school—on an intrapsychic and interpsychic level of analysis (Doise, 1982)—the extraordinary endeavour of the formation of higher mental processes (such as formal language, reasoning, problem solving, etc.) takes place. In addition, is it also possible to explore how the personality construction is consolidated through the relationship with others and significant adults. Within this dimension the construct of *Educational Self* is grafted. As we will argue more fully below, it is a specific part of Self emerging from the individual's experiences in the educational contexts. It takes place during the school age, but goes on throughout life, playing a role every time people are involved in educational activities or have to deal with educational contexts.

On a more general level of analysis, school is instead the institution “formally” charged with human development. It is a social organization that, in theory, takes care of—or should take care of (conditional mood is required especially in relation to depressed or developing areas)—an entire generation of children and youths in a given historic and cultural moment. The fundamental construction of human beings as members of society is thus at stake in school and, as a consequence, the construction of collective future directions, the opportunities for positive or negative change, is also at stake. Also in jeopardy is the fundamental play for present and future models of collective life, as well as social rights—for example, the opposition between democratization and privatization affecting the right to access school, a debate taking place in different rich and developing countries. These remarks impose to examine what surrounds the metaphorical balcony from which we are analyzing the work of schooling. Through the balcony, these elements reach school, becoming a fundamental element in constructing school's everyday life and its systems of activity (Engeström, 1987). The first element to be taken into account is the socio-economic dimension of cultural context in which school acts. In this perspective, a historical review of the processes, leading to specific concepts of school and to some outcomes of teaching and learning processes, can be very useful.

### **Homeostatic Functions of the School**

Since the 1960s, extensive scientific literature in development and education psychology stressed the dramatic effects of families' socio-economic conditions on children's school experience. This

scientific production is based on a series of studies in sociology and economics leading to the scathing and common conclusion that—despite an almost universal diffusion of alphabetization and basic education—it is quite impossible, as a matter of fact, to significantly “democratize” the effects of education. It is not possible to provide every student, independently from his own socio-economic origins, actual opportunities of redemption from the original status through education. This is an evidence-based conclusion stressing the critical state of democratic foundations with respect to school. As a matter of fact, despite evident differences in accessing educational resources and cultural capital (Bourdieu & Passeron, 1970), many people would claim that these differences are not actually relevant at school. Every student, provided with good will and enough perseverance, will be able to achieve every aspiration. Democratic systems are based on the reassuring claim that, at least in principle, it is actually possible to remove the obstacles causing “socio-economic diversity” in a large number of the population. Education is charged with the fundamental responsibility to put citizens in a position of equal rights and opportunities, by actually supporting those who move from disadvantaged social and economic positions. Unfortunately, although more people can access education, school seems still unable to narrow the socio-economic gap, even in rich countries. Employment statistics still show a clear and direct relationship between type of job and a family's socio-economic resources. In other words, social class of origin, choice of the course of study, and school achievements are so tightly linked that school seems to be an instrument to maintain social stratification (Dei, 2000).

Besides a student's actual starting condition, related to his or her family's social and cultural capital, there is a second level of influence playing a relevant part in enhancing or balancing the effects of social differences in the classroom. The forms of organization established in the classroom lead to different arrangements in teachers' formal power conduct and in students' group informal power relationships (Fele & Paoletti, 2003). These complex processes originate from socio-economic differences—as well as any other difference of age, gender, disability, etc.—anchoring to group dynamics. These dynamics can minimize or, more frequently, radicalize the perception of differences, affecting group inclusion and exclusion processes. Many studies in social psychology (*see* Speltini &

Palmonari, 2007 *for an overview*) stress how this dichotomy—being inside or outside the group—clearly affects the perception of specific individual characteristics. The group tends to “assimilate” members emphasizing common traits and underestimating differences. On the other hand, differences with nonmembers or conflicting out-group members are overestimated (Tajfel, 1981).

Through psycho-social studies, we can more systematically stress common sense extension and depth of socio-economic differences affecting people life, also in so-called welfare societies. Several sharp studies incontestably show the basic privileges provided by some socio-economic conditions, dramatically highlighting inequalities between students in choosing courses of study, achieving educational goals, and accessing jobs. Although for different reasons, teachers also often underestimate the effects of socio-economic conditions on students. For example, the belief that students’ success or failure is mainly related to endogenous and motivational factors is still commonly held (Iannaccone & Marsico, 2007). It is not unusual to say: “He is a child with scarce motivation to learn,” or “He is not inclined for school,” as if learning processes would totally rely on a sort of magical energy someone has and someone else does not have. In this case, researchers argue that people use this *gift theory* (Mugny & Carugati, 1985) to account for the extraordinary variability of individuals in achieving educational goals. The impossibility to unequivocally attribute success—or failure—to clear and identifiable causes, would lead people to identify elements of individual conduct (e.g., will, specific flairs), or, at worst, of familiar behaviour (“with that family, he can’t get far!”). Teachers instead seem to turn to the gift theory for different reasons, as far as they have a specific experience of learning processes. They use this argument in defense of their own professional identity.

The teacher’s profession is actually directed toward mass alphabetization and education of future citizens, despite challenges related to socio-economic and cultural origin. In everyday life, he must instead cope with an obvious sequence of failures. It does not frequently happen, as it can be argued, that students with low socio-economic origins totally recover the initial gap. Thus, teachers must cope with the rigidity and immobility of social reality much more than they would expect with respect to their job. This dramatically questions professional principles (especially for novice teachers and those worn out by difficult experiences),

activating (according to some social psychologists of development) a sort of “defensive” representation, realized in the “individualistic” gift theory. The attribution of failure to a student’s specific characteristics becomes a teacher’s vindication.

Fortunately, a large part of modern education psychology provides alternative explanations to failure, by contextualizing it and restoring the complex of human experience as a whole (Carugati & Selleri, 2005). Some just point out the relationship between failure and socio-economic variables, while others stress how learning is an interpersonal process by nature. In the latter category of studies, failure is identified with specific social skills, especially argumentative ones (Muller Mirza, Perret-Clermont, Tartas, & Iannaccone, 2009). Thus, the problem shifts from the student’s cognitive and motivational fund to the ability of establishing relationships with others—in situations in which confronting ideas and points of view leads him or her to become aware of the necessary operations to solve problems—enhancing a cognitive progress (Iannaccone, 2010). In the same socio-constructivist direction, there are other interesting perspectives referring to the so-called “Brunerian culturalist.” view Bruner (1990, 1996) outlines an idea of cognitive and learning processes as a construction of meaning with respect to their social and cultural frameworks. Common sense, on one hand, and “contextualist” researchers, on the other hand, are a good example—even if not exhaustive—of the numerous ideas of school circulating within society. These ideas can significantly affect educational policy and practices, on a national and local level. These different visions lead to conflicting and incompatible conclusions also concerning the problem of the actual democratization of educational action. As already mentioned, among the more diffused representations, a naïve vision of school certainly exists, which overestimates positive effects making unclear the latent socio-economic variables. This perspective considers school a pathway to individual and social redemption without manifest rifts. A sort of relationship between students’ “will” and success in study is thus established. This idea has been fully shared in both the scientific community and everyday discourses. It is however undeniable that education has actually improved life conditions of large populations.

### *Maintaining Status-Quo of Society*

Sociology and psychology have shown the less simplistic and reassuring side of the functioning

of educational institutions. Even before psychology of education stressed the social and contextual dimension of learning and failure (Daniels, 2012; Perret-Clermont, 1979; Carugati & Selleri, 2005), sociology already described a school slightly differing from common sense's idealized and stereotyped image. Pierre Bourdieu and Jean-Claude Passeron (1970) shook school's traditional image. School is not just a place in which knowledge is transmitted, but also a context in which social inequalities are reproduced. According to these French scholars, the fundamental element of social distinction concerns a sort of circularity of socio-economic characteristics. Inequalities in parents' economic and cultural resources and the different place they occupy in social division of labor originate nursing practices and interaction modalities that will provide children a sort of educational legacy with which they participate to the educational experiences. These instruments will vary according to the social and economic context of origin. Without generalizing, these differences will "tend" to foster students' behaviors and learning styles that do not always fit with the aims and activities of school. This will inevitably lead students to different forms of integration and assessment outcomes related to their "suitability" with respect to the educational context's features. The following step can be easily argued: a not very brilliant student will probably be directed toward vocational training and will have more limited access to job markets. It is understood that these forms of social distinction do not deal very much with the actual potentialities of students. The educational context, in this type of analysis, is considered as a filter definitely based upon psychosocial characteristics of students that are, more or less implicitly, directed to predetermined careers. Through these clear remarks, sociological analysis provides valuable elements to fully clarify the educational institutions' role—beyond proclamations and theoretical goals—in "validating" socio-economic differences. However, on this level of analysis, sociological perspective runs the risk of providing a fatalistic and unmodifiable picture, if not supplemented by further analysis of real social dynamics taking place in educational contexts.

Actually, there is a potential margin of action also on the level of classroom activities. Preliminarily, it is worthwhile to observe that every form of social distinction has correspondence in students' communicative interactions. As a matter of fact, the classroom actually is a social system supported by both formal

and informal relationships (Daniels, 1995, 2004; Fele & Paoletti, 2003). In this context, different types of communicative interactions are regulatory elements par excellence. They define and maintain order—not necessarily that expected by the institution—but also to foster potential change in social organization. Communicative interactions—as argued by contemporary communication theories—just marginally correspond to the typical metaphor of information transmission. Communicating is, first of all, to share meaning and to establish a common ground in order to cooperate or to conflict, to establish social borders between two or more individuals. From this point of view, language can be actually considered an activity that is not limited to information transmission. Power relationships, personal and professional identities, etc. are equally at stake. Language plays a crucial role in classroom life. Because of its malleability and sensitivity to the contexts of use—especially social and professional—it is often indicated as the key factor to account for disadvantage and socio-economic differences. From this starting point, pioneering sociolinguistics study the relationship between social belonging and linguistic competence. Basil Bernstein's approach (1971) to socio-linguistic disadvantage is one of the best-known and most-criticized ones. He attempts to analyze the mechanisms of reproduction, maintenance, and change of social order through language and symbolic systems used in families and schools. Bernstein's fundamental point is that language and symbolic systems in the family can dramatically diverge from those in the school. He believes that every social context establishes which meaning must be linguistically actualized, also determining which syntactic and lexical choice can be made. Individuals trained in specific contexts find themselves in a brand new situation at school—from the sociolinguistic point of view—probably facing difficulties of adaptation affecting performance. This can trigger a process of marginalization or even exclusion by the institution. Although Bernstein's ideas remarkably contributed to the debate about the role played by so-called socio-linguistic codes in integrating students into classroom social life and discourses, they present several critical aspects. The socio-linguistic code's idea itself has been widely criticized because it is difficult to be defined and operationalized. Actually, research demonstrated inadequacy of some aspects of Bernstein's theory. For instance, the relationship between socio-linguistic codes and abstract references has been widely

falsified. Dialects—widely used by lower classes—against Bernstein’s expectations, are very elaborate at the linguistic level and fully usable in describing and manipulating abstract meanings. After observation studies in the classroom (Edwards, 1990), findings demonstrate that the problem of communicative disadvantage—and probably other forms of marginalization—is not related to the availability of socio-linguistic codes, rather to the acceptance of a new system of rules—also linguistic ones—characterizing classroom context and diverging, sometimes dramatically, from everyday life.

Focus thus shifts from the idea of inadequate socio-linguistic competence to the idea—much more complex and probably able to account for many forms of disadvantage—of specificity in processes of meaning attribution to activity. As Iannaccone (2010) reports, if cognitive activity cannot be separated by the meaning that individuals attribute to situations in which they act, it is convincing that some students’ marginalization and exclusion processes are rather triggered by how they interpret learning situations and the social system below.

### ***Some “Practical” Implications***

Planning every educational activity in this specific area of interest starts from a preliminary remark: evaluating the impact of students’ socio-economic origin on class life and analyzing how it is perceived by the different actors of the learning community.

A first important element is the so-called teachers’ folk psychology (Bruner, 1996). Bruner’s statement makes clear, beyond any doubt, how much educational and professional activity is directed by adults’ representations, namely by teachers. If some of these systems of beliefs can hide the effects of socio-economic differences or tend to transfer the problem through individualistic and de-contextualized explanations, it is quite evident that educational acting will be ineffective, despite the best intentions. In order to actually cope with potentially negative effects of socio-economic differences in the classroom, it is required to start by fostering teachers to become aware of the real problem, causes, and consequences. Teachers’ systems of representations play a fundamental role in constructing and reinforcing teachers’ professional identities (Iannaccone, Tateo, Mollo, & Marsico, 2008). They are “constituent” elements of what can be defined as the teacher’s *Educational Self* (Iannaccone & Marsico, 2007).

For this reason they can seem like “proof” against change. Rather, in presence of a threat to professional situations—like those challenging teachers on the level of social reputation and salary—these elements can get even more radical.

If teachers’ system of representations is the first element to be taken into account when planning effective educational strategies, the second element should necessarily concern teachers’ and students’ “perception” of classroom social life. It is quite clear, on this point, that the different socio-economic origins are easily perceivable in the classroom. Despite schools’ attempts to minimize the display of socio-economic differences, all the actors of the learning community are in some way aware of the distribution of economic and social resources among peers. Beyond external cues, linguistic marks and interaction styles in the classroom constantly recall students’ social and cultural origins. Besides, in the case of immigrant children, these indicators are further emphasized by the cultural framework they refer to in everyday rituals and relating to the educational system. Social psychology has clearly demonstrated that perceptive availability of such similarities and differences generates social categorization. Groups of students will then be formed with respect to these social indicators. Even the groups’ “entry rituals” will be based on the ability of the single student to show behaviors and lifestyles fulfilling a group’s expectations. Thus, it is useful for teachers to monitor spontaneous social groups’ architecture in the classroom. It can be useful to recall Sherif and Sherif’s experiment (1953, 1961)—veritable milestones of social psychology—clearly showing how it is possible to act upon group dynamics, establishing conditions for competitive and cooperative climates to emerge. Although this experiment is just one of numerous possibilities to tune group climate, at the same time it represents a clear example of group management in education. It also makes clear how negatively emphasizing class differences is always a problem that must not be underestimated. Conflict is a “natural” modality human beings use also to assert their identity. The “negative” radicalization of social fabric can make this process extremely dangerous and able to interfere with every educational initiative, if not bearing in mind its nature.

It is quite evident that an in-depth knowledge of the wider social phenomena such as in-group/out-group processes or socio-economic characteristics of individuals is absolutely essential. These dimensions regulate everyday life in different social contexts in

which the actors are involved. They are reflected in the work of schooling, showing a clear overlap between inside and outside the school.

### **What Happens on the Balcony: Looking at Crossing Boundaries**

As we have argued in the previous pages, a number of elements belonging to the wider social and cultural contexts are not alien to the way the school works in practice; on the contrary they act as catalyzers, providing contextual support, which leads to certain form of schooling rather than others. These sociocultural dimensions (socio-economic levels, ingenious or expert theories on education, the school's representations, etc.) pass metaphorically through the balcony and enter the territory of the school.

Studying what happens on the border between inside and outside the school means first paying attention to the intersections it has with other life contexts relevant to the development and education, first and foremost the family. The relevance of "crossing boundaries" and of intercontextual dynamics between family and school are presented in this section.

The crossing boundaries phenomenon (Marsico, Komatsu, & Iannaccone, in press) became evident when we consider the contact's points with school and family. In fact, it is possible to consider boundary encounters, such as meetings and conversations, and events that provide connections between systems. That was precisely the focus of a research project carried out by the present authors that tried to describe what happens when the family goes to the school to receive the evaluation of their child during the school-family meetings<sup>3</sup> (Iannaccone & Marsico, 2007).

The aim of this research was to explore the social space emerging from the interaction between family and school. In the situations under examination, we try to understand how *school culture* comes into contact with *family culture* via a dynamic of delimitation of competences over the key issue of children's education. At this level of analysis, we were particularly interested in the interactional activities and in the conversational strategies that schools and families adopt during the "school report cards delivery" event. This kind of encounter, as in any social space, causes an adjustment between the participants, who will eventually converge or diverge in their evaluation of the child. Metaphorically speaking, meetings take place just on the balcony. School invites family into its own "territory," creating a

temporary shared space (functional, not structural, balcony) that is a prominent extension of the institutional wall. It can be assumed that school, in this way, intends to promote a satisfactory home-school interaction, that is, surely, an essential component of effective education (Huntsinger & Jose, 2009; Henderson & Berla, 1994). The reason for this occurring in a specific space and time, decided by the school, is a different question. What would happen if the school communicated the child's evaluation by formal letter, e-mail, press release on local TV, or via the Internet (allowing, in such a way, the comparison of student's performances all over the world)?

If school intends to support parents' involvement in children's education and fruitful family-school relationships, why not organising meetings with parents at home? What would parent-teacher meetings be like at home? After all, this is not uncommon for other professionals like doctors or social workers. Why not for teachers? How would teachers be received at home? Which forms of social interaction would take place and with what effect on the relationship between the teacher, parents, and child? Would teachers keep the same institutional function even in a different social structure?

School instead decides to invite parents, emulating a certain kind of informality. This informality, however, is only partial (a formal informality). Encounters are placed into an official context, organized according to specific institutional rules. Even though it is a balcony, a border zone, it is still the school's balcony, that parents can enter tip-toeing, feeling uneasy, or on the contrary with confidence, arrogance, and self-assurance. What social rules, instead, would modulate the school-family encounters if they happened in an informal place such as the bar on the corner where parents and teacher, drinking a coffee and discussing the child's school performance (an informal formality)? The articulation between "formality/informality" and "openness/closedness" is also evident in another school event that occurs at the end of the school year, when students' assessments are put up on the wall of the school's entrance-hall. It is an open space, but institutionally characterized, yet another of the school's border zones. Why are some ways of communicating adopted, while others are avoided or judged not admissible? What are the effects on school-family communication and on social regulation of meetings? Although we are aware of the several possible alternatives to

communicate, in the study hereafter presented, we focus on a particular point of intersection between family and school.

### *The Family Goes to School*

The school and family cultures, in the meeting situation constituted by the presentation of the school report, will necessarily have to come into contact in a micro-systemic space. If in daily life family and school communicate almost exclusively via the child/pupil, in this case the meeting is face-to-face, and the respective representations of the child/pupil enter into direct contact in a conversational space. From an ecological and cultural viewpoint, we could say that the “report delivery” event represents an occasion in which the family micro-system and the school micro-system meet/clash, highlighting the meso-systemic connections (both the successful and fruitful ones and the unsuccessful or fruitless ones) between two life contexts of key importance in one’s upbringing (Bronfenbrenner, 1979). During this appointment, two cultural worlds come into contact, each one with its specific sets of beliefs and organization, specific social climates and viewpoints (which can sometimes differ greatly, such as on the educational processes, the child/pupil’s growth and the management of the adult-child relationship). The school-family meeting is thus a critical event, not only for the reasons mentioned above, but also for the meanings it acquires in the experience of the actors involved. Suffice it to consider how the school’s evaluation of their child may be perceived by the parents as an evaluation of their own educational skills, or how the process of the definition of a pupil’s identity is strictly connected with his/her school experience, and the value that school success or failure acquires in relation to a positive or negative definition of the Self (as discussed in the next pages).

In the school-family meeting, the main conversational topic should be, at least in theory, the student. Again in theory, teachers meet parents to present them the results of their child’s learning in school. The meeting may end (as it sometimes does) with a few laconic exchanges from which the parents are supposed to grasp all the necessary information to understand whether their children are “good” or “bad” students. The few laconic exchanges should also allow parents to “justify,” when required, their children’s inadequacies at school. What really happens, albeit within a relatively short time span, is much more complicated than it may seem (Iannaccone & Marsico, 2007).

First of all, during the meeting two or more adults, both of whom are responsible in different ways for a child’s education, are compared, together with their different perspectives on education that somehow compete for the privilege of “having their say” about a human being at a critical stage of his/her life. In this one-to-one match, the school should represent a public institution and as such it is a sort of an “official voice.” The family, in the least problematic cases, will spontaneously agree with this representation; in the most difficult cases (for instance, when the child does not embody the good student prototype and his/her parents accuse the teachers of being the main reason for this), it will defend its own conflicting positions.

The idea of the school’s “official voice” is certainly an unsuitable generalization of concrete observed conversational dynamics. Indeed, teachers follow an enormous variety of educational models, which are only partially in line with syllabus indications and social, cultural, and scientific expectations. As studies on professional identities and sociocultural dimensions in working organizations have clearly highlighted, what the teacher does is the result of a process of adaptation with unforeseeable outcomes (Iannaccone et al., 2008). What makes this process difficult to foresee is the co-participation of elements of the teachers’ human and professional biographies with the sociocultural conditions of the working contexts. From a more strictly scientific viewpoint, this plurality of “voices” is identified as the expression of the various social representations co-existing in professional contexts as in any other social context. This obviously increases the complexity of defining the “success/failure at school” (Monteil, 1989) category when the issue at stake is the outcome of a school-family meeting.

In the school context, with its institutionally “ratified” rules, the definitions of “good pupil” and “bad pupil” will in any case be placed within specific traditions (in this school, children have always studied hard and obtained good results when they went on to high school), specific conducts, and adjustments. Although “modulated” by their belonging to the institutions, the categories of people involved in the issue of success at school represent the result of a complex social process, influenced by a number of key elements (Ligorio & Pontecorvo, 2010).

On a broader level of analysis, when looking at a school’s organizational features and cultural traditions, some elements contributing to the students’ success/failure can be identified. Every school, as a

social and cultural context, is a space where representations are elaborated. It could be considered as a social place in which different actors, with different roles and different life experiences, live together, albeit often unwillingly. As in any other community, also at school these actors produce shared narratives, use gossip to maintain the social order, give credit to various “legends” about what apparently happened at that school in the past, about its pupils’ (positively or negatively) sealed fate, about this or that teacher being good or bad. In other words, a school is also a set of narratives (Bruner, 1996) that in turn generate expectations and modulate the behavior of the actors who carry out their daily activities there. Teachers themselves have specific representations of their work in the different school contexts. Families also often choose the school for their child according to its potential to fulfill their expectations about what the child is capable of and what, in their opinion, he/she should do when he/she “grows up.” This crossfire of teachers’ professional identities and parents’ representations of success heavily contributes to creating very different expectations concerning schools. This will influence, and not negligibly, the students’ success/failure parameters and the nature of their education. In this way, school as a social, complex context will represent a significant framework for a punctual definition of the notion of academic success/failure. For instance, when a teacher defines his/her students as a “bad” or a “good” class, he/she is probably using a Lewinian-type category. Besides, how could he/she otherwise say that, on a given day or moment of the school year, his/her class seems particularly “bright” or extraordinarily “dull”? By adopting Lewin’s notion of group, every student in his/her daily class life, beyond his/her individual distinctive features (which no psychology would completely deny), is also an element of some more complex interdependence. To use a metaphor frequently employed by cultural psychologists, we could consider him/her “a thread in a complex web.” Being “interwoven” with the other actors in the educational context, he/she necessarily lives inside a sort of social polyphony, where the sense of his/her acting will depend on the interactions between his/her individuality and the social contexts in which he/she experiences his/her daily interactions. The research focuses on the articulation between the participants’ representations and interactional activities. This methodological choice allowed us to explain several consistencies between school/family meeting management (by parents),

the family’s perceptions of the school’s success/failure and the family’s socio-economic origins.

#### **TYPES OF INTERACTIONS, FAMILY’S SOCIO-ECONOMIC STATUS, AND SCHOOL RESULTS**

Using an ethnographic approach, several meetings between family and school were observed and audio/video-recorded. More precisely, 22 families were involved (and 26 pupils, since some of the families observed had more than one child at the school). To conduct this study, the parents, with their child, went to school by appointment to meet the teacher who presented them with the child’s school report. The meeting was also attended (though at this time on a basically “nonparticipating” role) by a researcher, who audio-taped and took note of any potentially significant events occurring during the specific meeting. Besides the recording of meetings between family members and the teacher in charge of presenting the report card, the research comprised a second phase, featuring a semi-structured interview. The interview’s general aim is to analyze the voice of the family immediately after the report card delivery ritual. What is the parents’ evaluation of their child’s school report? Was it what they expected? And what do they hold responsible for success in school? And for failure? And, in turn, what explanations can the child/pupil provide for the marks received? The interview, which was entirely filmed, was conducted by a researcher who had a conversation with the family.

The analysis of the transcripts and the field notes show three main modalities of interactional activities. We will see that these activities are related to family’s socio-economic level and to the student’s school results. In fact, during the first analysis of the school-family meetings, in 42.3% of cases the management of the meeting involved parents and teachers converging toward consensual modalities (*alliances*). However, in 34.6% of cases, the family seems to comply with the image of the pupil proposed by the teacher (*acquiescences*). Finally, conflicts, in a more or less latent way, affected 23.1% of the meetings (*oppositions*). By comparing the frequency of these modalities with the socio-economic level of the family, we obtain an interesting result. Alliances, for instance, were never observed during meetings with families of low socio-economic level. They did, however appear in 50% of all meetings with medium-level families and in the 60% of families with a high socio-economic level. In a similar way,

opposition was more frequent for the higher socio-economic levels (from the 17% of low-level families to the 30% of high-level families). Conversely, the interaction modalities of acquiescence are very frequent on a low socio-economic level (83%) and are almost negligible at high levels. It would seem reasonable to explain these differences with at least two types of factors. The first factor could be related to a type of “cultural capital” (Bourdieu & Passeron, 1970). Considering that high socio-economic levels generally correspond to a thicker and better-constructed educational experience, it is possible that the medium- and high-level families feel more “akin” to the school discourse and are better able to cope with the teachers. These families are more familiar with the typical communication tools of the school context, and they have a greater proximity to the sociocultural origin of the teachers. The second factor that could explain the different modalities of meeting management is related to a sort of self-perception of the social asymmetry in that relationship. Acquiescence, a passive relationship modality, indicates a clear acceptance of the teachers’ comments by the families of a lower socio-economic level.

Predictably, the dynamics of school-family meetings is also related to the student’s success/failure. In particular, the alliance is more typical of the discussions about successful situations (75%). Acquiescence, on the other hand, is more frequent during the discussion of students’ failures (57%). Typically, a “good” student facilitates the agreement of the evaluation between the family and the school. Instead, a problematic student could be the “stake” of conflictual dynamics (29%), or alternatively (and this is the more frequent case) of forms of passive acceptance of the evaluation (57%) by the parents. In fact, opposition and acquiescence, taking into account the data mentioned above, seem to be the modalities used to cope with the student’s failure related to the socio-economic origin of the family. In this sense, since failure goes along with oppositional and acquiescent forms of interaction, it is probable that the different frequency of these modalities can be traced back to the social level of the families. In particular, we saw that opposition and acquiescence tend to be respectively associated with medium-high and low socio-economic levels. To better contextualize the discourse, it is appropriate to clarify the relationship, which is also reported in literature (Schizzerotto, 1988; Ballarino & Cecchi, 2006), between the academic performance of students and the socio-economic level of their families. Actually, the highest

percentage of the students with good results at school comes from medium and high socio-economic levels (60%). Conversely, the percentage of failures is higher among students of a low socio-economic level (about 83%). Taking into account the broader category of “troubled experiences at school” (that include every type of socio-relational and cognitive deficit), this relationship is even more pronounced. All the students from families with a low socio-economic level have some kind of trouble at school, compared with half of the students from medium-level families and the 60% of students from high-level families.

### ***Opposition, Alliance, and Acquiescence in the Family-School Interactions***

The following are some examples of meetings between families and the teacher, who was appointed by the class board to deliver the school report; the examples concern three kinds of interaction events: opposition, alliance, and acquiescence.

In particular, the meetings developed in the form of oppositions, alliances, and acquiescences depending on the goals’ orientation. In other words, this kind of encounter assumes different social configurations depending on the convergent or divergent participants’ evaluation of the student’s results. When school and family agreed on the child’s evaluation, they easily shared viewpoints. On the contrary, when the academic assessment represented, for instance, a threat to the educational choices that a specific family considered necessary, more dynamic and conflictual communications emerged. Therefore, the divergent goals’ orientation, mainly observed in the opposition in family-school interaction, stressed the communication breakdown between teachers and parents and allowed us to understand the details of such events and the arguments evoked by participants with respect to, for example, how the problem is presented, who is responsible for it, what has to be done in order to solve it and by whom.

#### **OPPOSITION**

##### *Meeting #1*

Participants: Teacher, Father, (boy) Pupil

The school-family meeting involved the teacher, the 13-year-old student (attending the third year of Italian middle school<sup>4</sup>) and his 46-year-old father, an employee in a private company.

The student’s family is made up of his father, mother, and an elder (18-year-old) sister.

The student's school performance, according to his teachers, is just around the pass mark, and he is weak in technical subjects. The teacher thinks that the student needs to concentrate better and that his parents should monitor him more closely. His father seems to take this statement as a criticism and answers back, stating that, in order to grow up well, a person needs to have the time "to do everything" (e.g., school, fun, sports, etc.) and that school must guarantee students the chance to express their potential in many different fields.

In the opening part of the conversation, the teacher highlights the boy's weakness in technical subjects, which he considers a "serious thing," with a generally positive attitude. At the same time, he underlines (confirming his implicit "opinion" of the student) how his physical education performance is "good," while his behavior

does not exactly fit "our orientation" (the teachers' ideas). The teacher's opening approach and his choice of points to highlight primarily result from his general opinion that the student is distracted by his after-school sports activities. In this opening part, the father seems to accept the teacher's explanations.

In a subsequent phase, which constitutes a turning point in the conversation, the teacher, while trying to identify the reasons for the student's bad performance in certain subjects, specifically addresses his family (I think there is also a problem with being regularly followed at home). The conversation's main topic then becomes that of time management: from the time management of class activities, the conversation, partly because of the parent's reply, will gradually move on to time management in the boy's overall education.
